Hong Kong, a former British colony, did not flourish into a multi-million city until after the Second World War and the setting up of the People s Republic of China and the consequent transf industrialization (Ng, 1995). Figure 2 shows the growth of Hong Kong over the years and it can be seen that reclamation plays a large role in accommodating urban growth. However, since the 1990s, rising concerns for natural and heritage conservation and people s rights to pla development decision making have led to the birth of the Protection of the Harbour Ordinance as well as many protests against demolition of heritage sites and historical communities (Ku, 2012; Ng, 2008; 2011 and 2014). On the other hand, population growth has slowed down in recent decades and instead of developing new towns, the Planning Department and the Territorial Development Department jointly commissioned the Planning and Development Studies on North East and North West New Territories (henceforth NENT and NWNT Studies) in 1998 to identify new development areas to accommodate the then estimated population growth from about 6.8 million to 8.3 million by the year 2011 (LegCo, 1999).

The selection criteria for the new development areas were as follows (LegCo, 1999, p.2):

easy access to existing and planned railway networks;
should avoid as far as possible areas of high ecological and landscape value;
should be of a sufficient size, preferably with a capacity of at least 50,000 persons, for optimization and efficient provision of infrastructure;
should preferably be undivided by physical obstacles to enable the development of a coherent urban area;
should contain as few constraints on development and implementation (including capital, environmental and social costs and programming requirements) as possible; and
should preferably tap into the dynamics of the increasing cross-boundary interactions between Shenzhen and Hong Kong.

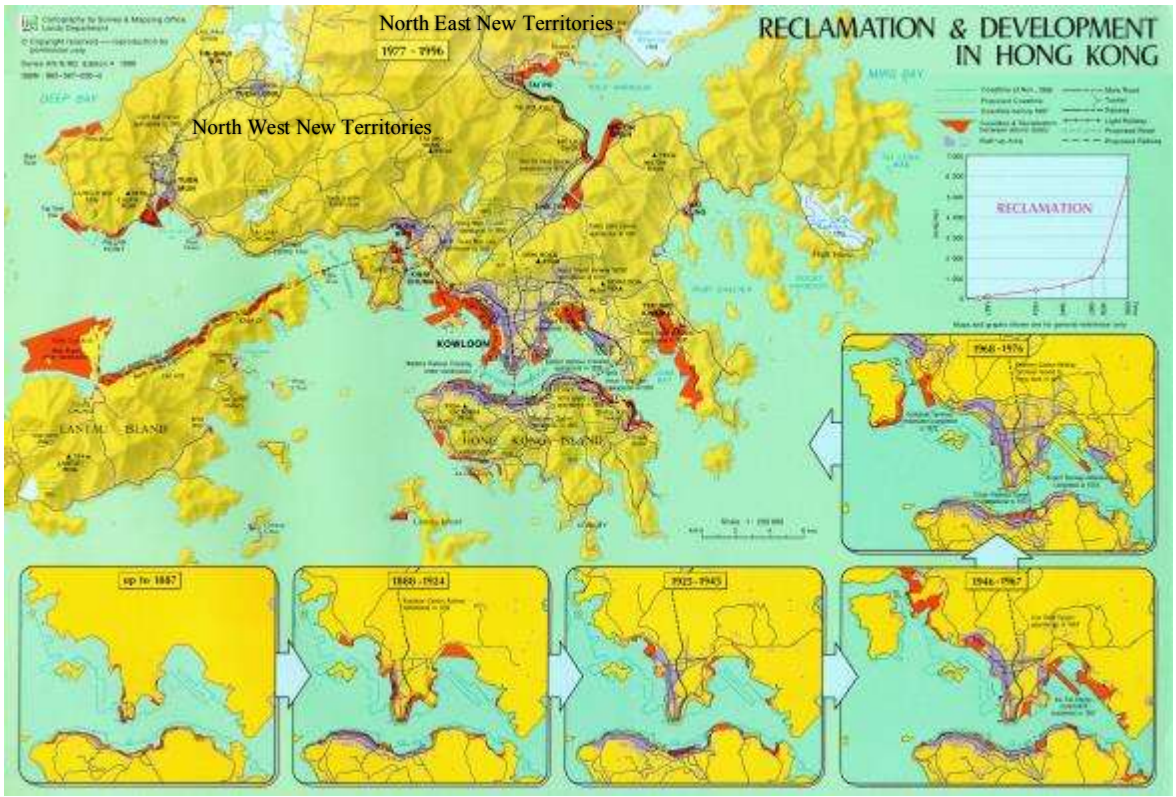

Figure 2. Growth of Hong Kong through Reclamation
(source: http://www.urbanphoto.net/blog/wp-content/uploads/2011/10/landreclamation.jpg)

And the recommended new development areas include three sites, two in Northeast New Territories and one in Northwest New Territories (op cit., 1999, p.3) (Figure 2), basically because they are next to existing new town development, with access to mass transit or strategic road networks, close to China and possess substantial development areas. It is interesting to take note of the selection criteria and the outcomes because as argued by Lefebvre (1991), time has been murdered by society (p.96) and there was no concern about the lived space or use valu alone the people living there. In other words, the whole process had been done technically, devoid of a thorough understanding of the history, heritage and culture of the place. Its use values accumulated over the years by generations of residents, the real wealth , has been neglected and ignored in this site identification process (Lefebvre, 1999, p.341).

The situation in these rural new development areas is complicated by the fact that there are two different types of villagers in rural Hong Kong. New Territories villagers are considered indigenous if their settlement existed before 1898, the year when the Second Convention of Peking was signed and the New Territories was leased to the British colonial government for 99 years. However, those villages formed after that year are called non-indigenous villagers or simply squatters and they have no right to the government land they illegally occupied even though their existence might have been tolerated for decades. The difference between these two groups of village marked material implications when the Government introduced the small house policy in 1972 entitling indigenous male villager from a recognised village who is 18 years old to build a small house (3 storeys not exceeding 8.23m in height and 65m$^2$ in area, by no means small by Hong Kong standard) in his life time. The original objective was to improve the housing conditions of rural dwellers in the New Territories but then it became a very convenient policy during the 1970s and 1980s when the Government implemented the 10-year Housing Strategy through the development of new towns after the riots in 1966 and 1967[2]. In the course of developing new towns in rural Hong Kong, new villages consisting of small houses were developed for the male descendants of the displaced indigenous villages. This privilege, however, is not extended to the non-indigenous villagers. This administratively defined right for male indigenous villagers to build a small house has been written into the Basic Law, a mini-constitution of the Hong Kong Special Administrative Region when China resumed sovereign rights over the city in 1997. Until recent years, few people have attempted to challenge this differentiation and some even mistakes this administrative policy as one that respects indigenous rights.

So, when one of the planning principles for the new development areas stated that all exi villages, burial grounds and buildings and features of historical and/or cultural significance are retained as far as possible (LegCo, 1999, p.5), the Government was actually ref indigenous villages. Other planning principles include: rail-based development, maximization of development potential, balanced community, network of open space and pedestrian walkways and provision of cross-boundary supporting facilities (op cit., 1999, pp.4-6). Put otherwise, nonindigenous farmers were invisible in the eyes of the planners when the NDAs were identified.

Table 2. Planned development scale of Kwu Tung North and Fanling North

| Land Use Zone | Kwu Tung North | | Fanling North | |
|---|---|---|---|---|
| | Area (ha) | | Area (ha) | |
| Land area | 498.5 | | 202.7 | |
| Population capacity | 100,000 | | 80,000 | |
| Employment | 17,000 | | 1,600 | |
| ***Land use budget*** | ***ha*** | ***%*** | ***ha*** | ***%*** |
| Residential | 55.0 | 11.0% | 42.2 | 20.8% |
| Village type | 14.5 | 2.9% | 6.4 | 3.2% |

[2] Because of the Cultural Revolution that started in China in 1966, there had been riots in Hong Kong too. To pacify the grudging public, the colonial government launched a 10-year housing programme. Given the shortage of land in the old urban areas, the Government had no easy choice but to have reclamation in the New Territories to build new towns to provide necessary housing sites.

| Land Use Zone | Kwu Tung North Area (ha) | | Fanling North Area (ha) | |
|---|---|---|---|---|
| development | | | | |
| GIC | 36.2 | 7.3% | 17.0 | 8.4% |

## 4. NENT NDAs

***Representation of Space (Conceived Spaces the Evolving Plans)***

In 2003, the NENT NDAs proposal was shelved pending a comprehensive review of H overall planning under the Study on Hong Kong 2030: Planning Vision and Strategy (the HK2030 Study) (Development Bureau, 2012a, p.1). The HK2030 Study aimed to formulate a broad land use planning framework to guide the development of Hong Kong up to 2030 and it eventually followed the recommendations of the NENT and NWNT Studies. NDAs then were defined as small-scale new towns to provide housing, to meet other land use requirements and to offer an a living through the development of lower-density buildings in quality living environment, with convenient access to mass transportation and community facilities (Development Bureau, 2007, p.2). In the Chief Executive s 2007-2008 Policy Address, the planning for NDAs was identified as one of the ten major infrastructure projects for economic growth (LegCo, 2009, p.1). As can be seen from the planning principles, the existing communities and their lived space were again neglected (Table 3) though the same paper outlined the Development Bureau s promise to carry out comprehensive pub engagement programmes to consult relevant parties including the LegCo, the District Councils, local communities, environmental groups and other stakeholders.

Table 3: Planning Principles of the NDAs (2007)

| NENT and NWNT Studies | HK2030 |
|---|---|
| • Rail-based development | • Sustainable development |
| • Maximization of development potential | • Rail-based development |
| • Balanced community | • Effective and efficient provision of infrastructure and facilities |
| • Networks of open space and pedestrian walkways | • Environmentally friendly planning and urban design |
| • Existing villages and burial grounds | • Environmentally friendly transport measures such as building major roads at the periphery of the NDAs and providing sunken roads and environmentally friendly modes of transport |
| • Provision of cross-boundary supporting facilities | • Energy efficient measures such as encouraging non-fossil-fuel-based transportation and facilitating the use of renewable energy and recycled water for new developments |

Source: LegCo, 1999 and Development Bureau, 2007.

A new NENT NDAs Study began in June 2008 to formulate a planning and development framework for the NDAs through a three-stage public engagement programme to facilitate public discussions and consensus building (Development Bureau, 2012a, p.2). In the Stage One Public Engagement Digest (2008), only two short pages provide a sketchy picture of the existing population and land uses of the

NENT NDAs. Less than 10,000 people currently live in the three NDAs identified where mixed land users exist: small scale residential developments, scattered village settlements, a wetlands, open storages and rural industries (ARUP, 2008, p.2) (Figure 3). There is no information on how many of them are indigenous and how many of them are non-indigenous population. It is interesting to note that in one of the PowerPoints shown in the engagement process, aspirations of major stakeholders were listed and the aspiration of the non-indigenous villages was not even mentioned (Figure 4).

This NDA was taken out in the final stage of the Study. So this paper only focuses on the other two NDAs.

Figure 3. NENT NDAs (Source: ARUP, 2013, p.9)

Figure 4. Aspirations of Major Stakeholders (Source: ARUP, 2008b)

Nevertheless, as the engagement process advanced and with the mobilization of non-indigenous farmers and social activists, their voices were eventually heard. However, as can be seen in the following section, this does not mean that their right to farming is guaranteed. Instead, they face a two-front battle: they are constantly under the threat of being driven away by big developers who have

bought land from the indigenous population and accumulated land banks in the New Territories; and the farmers are often described as selfish individuals who are squatters and barriers to satisfying dire housing needs of the urbanites. Yet, as reflected in the changes of the planning principles and the planning parameters (Tables 4 and 5), social activism had indeed produced some impacts:

- While the public and private housing split was originally favourable towards the private sector, the portion of public housing has increased dramatically in the final Report.
- While the farmers and the non-indigenous population were invisible when the Study their concerns and needs were at least rhetorically addressed towards the completion of the Study.
- However, the implementation operation remains controversial as the Government continues to be seen as privileging the big developers in the development process.

Let us further examine these twists and turns of events.

Table 4. Planning Principles of the NDAs (2007)

| Stage 1 Public Engagement (2008) | Stage 2 Public Engagement (2009) | Stage 3 Public Engagement (2012) | FINAL (2013) |
|---|---|---|---|
| ***Regional*** | | | |
| Capturing cross-boundary opportunities | Coordinate with regional development and capitalise on the opportunities provided by border development | Industries that support regional development and integration with the Pearl River Delta | |
| | | | Form part of Fanling/Sheung Shui/Kwu Tung New Town |
| ***Economic*** | | | |
| | Reserve land for special industries etc. | Reserve land for special industries | |
| | A mix of land uses to provide diversified employment opportunities | Diversified employment opportunities | Meeting Hong Kong s economic needs and generate employment |
| Implementing infrastructure and development projects in a timely manner | | Adopt appropriate development approach to ensure timely provision of infrastructure | |
| | Explore arrangements for resumption, compensation and rehousing | Explore appropriate arrangements to rehouse the affected residents | A special ex-gratia compensation package for affected qualified households & one site in each of the NDAs is reserved for public housing for local rehousing purpose |
| | Feasibility of introducing private sector participation | Adopt appropriate development approach to ensure timely completion of development | Modification of land lease and in-situ land exchange |
| ***Social*** | | | |
| Promoting sustainable development by giving due regard to social, economic and environmental needs of the community | Review the boundary and coverage of the NDAs to accommodate existing indigenous villages & burial grounds | Respect existing and surrounding communities | |
| Ensuring balanced and integrated community by means of mixed and coordinated land use | New community facilities to benefit new and existing residents | Timely provision of community facilities | |
| Engaging the community in an open, continuous, inclusive and participatory fashion | Listen to and consider public views | | |
| | The overall ratio of public and private housing: 35-45% to 55-65% | A balanced mix of public and private housing | Meeting medium- to long-term housing demand |

| Stage 1 Public Engagement (2008) | Stage 2 Public Engagement (2009) | Stage 3 Public Engagement (2012) | FINAL (2013) |
|---|---|---|---|
| ***Environmental (natural and built)*** | | | |
| | | | Compact city form: mixed uses around railway station and public transport nodes |
| | Reduce reliance on road transport by introducing cycling tracks and comfortable pedestrian walkways | | Environmentally friendly transport network, main roads on the periphery and car free living environment |
| Providing quality living environment and ample open space with high quality public amenities | Restrict development density with plot ratio: 0.75 to 5; building height: not more than 35 storeys<br>Protect ridgelines, green and wind corridors | | Quality urban design: ridgelines & watercourses, stepped building height, open space network and greening |
| Creating an environmentally friendly and people-oriented community to meet territorial development needs | Green buildings, district cooling systems, water-saving strategies and re-use of treated effluent | Green and energy-saving initiatives | Green building design, planning and design to minimise changes to micro-climate<br>Renewable energy, effluent reuse, waste reduction, efficient use of water resources |
| Respecting, conserving and embracing existing natural and cultural heritage resources | Preserve existing villages, Fung Shui woodland and cultural heritage | Respect, preserve and optimise the use of the existing natural and cultural resources | Integrating old and new areas |
| | Conserve Long Valley with high ecological value, integrating ecological environment through private sector participation | | Designating Long Valley as Nature Park (about 37ha) |
| | | | Two pieces of land (about 45ha) north and south of the Nature Park and a piece of land in FLN NDA (about 12 ha) are designated as Agriculture zone to accommodate the needs of the affected farmers |

***Striving for Spatial Justice and the Right to Differences***

The final stage of the planning of the NDAs coincided with perceived tightening of the Central Government s policy on Hong Kong and one indication was the election of a new Ch seen as having very close relationship with China. And China has been identified as the strong underlying force that privileges the developers and capitalists in Hong Kong after the political handover in 1997. Developers have been seen as the ruling class (Poon, 2005) and they land bank in the city. In NENT NDAs, farmers, many are non-indigenous villagers, were forced to leave their land and fertile farmland was then fenced off, left vacant and declared private property (Figure 5). While many mainlanders invested in Hong Kong s property market thus inflating an already ultra-expensive sector, the multiple entry permits for non-residents in Shenzhen have led to the booming of parallel goods trading, worsening the over-saturated use of the railway-related infrastructure between the two cities. Against all these background, the NENT NDAs were therefore seen as a plan to facilitate Hong Kong-Shenzhen Unification , a tool to sell o 2012, p.4), a plan to further fatten the hegemonic development sector.

Figure 5. Private Land, No Trespass
land bank of the developer
(Source: author)

One of the justifications for the Government in developing the NDAs is to satisfy rising housing needs in the public as well as the private sectors, due to escalating housing prices. According to the Housing Authority, as at end of March 2015, there were about 137,000 general applications for public rental housing and about 140,600 non-elderly one-person applications[3]. However, as can be seen from Table 5, the ratio of public housing was relatively small when compared to private housing and developing 760 ha of land to satisfy only 8% of the waiting list demand was totally not acceptable to the general public. As reflected in their comments in the Public Engagement process, many worried that the NENT NDAs will become the back garden of rich Mainlanders. To ensure that the new development will benefit local Hong Kongers, many suggested boosting the provision of public rental housing and urged the government to re-introduce the then suspended Home Ownership Schemes and move forward the policy of Hong Kong property for Hong Kong residents (op cit., 201 would be affected considered the Administration had not proposed an acceptable compensation and rehousing/reprovisioning package (op cit., 2012, p.9). These concerns perhaps explained the dramatic change of the ratio between public and private housing in especially the Fanling NDA from 39:61 to 64:36 (Table 5). This will meet at least 13% of the waiting list demand.

With the launching of many protests and varieties of activities (Figure 6), the voices of the farmer-squatters were finally heard in the third Public Engagement exercise though th be described as unlawful (op. cit., p.9). The concerns about existing agricultural activities and t adverse impacts on the livelihood of existing farmers as well as the lack of effective policy for sustaining and promoting local agriculture were also summarized in the engagement reports. And for a change, agricultural land was identified and reserved as Agricultural zone to farming practice (op cit., 2012, p.10). However while this seem to have addressed the concerns of existing farmers, there are at least two problems. On one hand, zoning land for agricultural use means very little. In fact, one identified agricultural zone consists of fish ponds and squatter huts and would not be useful for agricultural activities. Also the so called agricultural rehabilitation policy exists only in name because farmers have to talk to landowners to either buy or rent land and take care of all the related infrastructure needs, not to mention the expenses involved in developing a new farm and rebuilding their squatters , even when a short term waiver for building would (Development Bureau, 2012b, p.2). Hence, although the struggles by the farmers to fight for their rights to farm have yielded some results, the results are far from satisfactory.

Figure 6. Withdraw the Plan; We Want Our Farms and Fields (Source: https://hklawblog.files.wordpress.com/2012/10/blog-photo-cheung-oi-nei-21.jpg)

[3] Information obtained from: Hong Kong Housing Authority website: http://www.housingauthority.gov.hk/en/about-us/publications-and-statistics/prh-applications-average-waiting-time/.

While public housing supply and farmlands represent the genuine needs of many urban households who are living in substandard or subdivided flats and squatter-farmers respectively, the conceived plans, to many, continue to be a plan that attempts to privilege the developers. The Real Estate Developers Association, Heung Yee Kuk (the most powerful body representing the indigenous population in the New Territories) and some developers objected to the Conventional New Town Approach (CNTA) proposed by the Government, that is, government would resume, clear, form all private land planned for public works and private developments before releasing it to the market. On the other hand, the public and some Legislative Councillors had expressed concern that the implementation of the NDAs under a Public-private Partnership approach led by developers would compromise fairness and transparency in the implementation process (LegCo, 2012). The Development Bureau seemed to first concur:

> Upon careful consideration of the public comments received from the previous two PE exercises and balancing all relevant considerations, we consider the CNTA more desirable as it will enable synchronisation of various developments with provision of supporting infrastructure and public facilities. The CNTA will also ensure balanced development with appropriate mix of public and private housing, commercial and business uses, open spaces and G/IC facilities. We therefore proposed to implement the NDAs proposal by the CNTA during the PE3 exercise (LegCo, 2012, p.8).

However it is interesting to note that according to the news media, the Government, since early 2013, had decided to give up comprehensive implementation of CNTA and allow conditional participation of land owners in the development of NENT NDAs. One such policy is for those who owned 4,000m$^2$ or more of land in areas zoned for residential uses could negotiate for land exchange and it was reported that this would shorten the development period by one to two years (Apple Daily, 2013). Figures 7 and 8 and Table 6 list where and how much such land the big developers own in NENT NDAs. Figure 9 shows the worsening trade of housing affordability in Hong Kong. As the housing market has been monopolised by the big developers (Poon, 2005), this planning exercise is seen by many as another proof of the Government s biased policy towards the interests of the landed clas sector.

## 5. Conclusions

There are a number of lessons that we can learn as the Government wants to urbanise rural Hong Kong. The most obvious one is the limitation of top-down technically oriented urban planning that ignores the lived experiences of people who inhabit real places over time. It is surprisi how the various generations of the conceived NDA plans turned a blind eye to the multi-generation squatter-farmers, simply because they do not own the land that they and their family members have tilled for decades. This is the situation that Lefebvre has severely criticised that the representation of space aims to endow every piece of land with exchange value while destroying long-term relationships that have been built through time. To the planners, the history, culture and heritage in place are not important. Indeed not even one planning document focuses on the people and the communities that will be affected by the plan. Fortunately, unlike the silent space users in the past, some of the squatter-farmers, together with social activists, have become much more vocal in defending their spatial interests. If not because of all the protests and social activist movements speaking for the interests of the farmers, the squatter-farmers might be invisible throughout the planning exercise. However, this does not mean that spatial justice is done. Instead of ignoring them in the planning process, planners have tried to rezone some land for their continued farming practice. Yet, land use zoning without proper policies and assistance mean very little for farmers to re-establish their trade. In other words, their struggle to spatial justice and the right to farm (difference) still have a long way to go.

While the invisible squatter-farmers have tried to make themselves visible and their voices noticeable throughout the planning process, the other powerful stakeholder has kept a very low profile as an invisible hand to wait for profit-maximisation opportunities. Buying up land, out farmers and perhaps even negotiation with the Government behind closed doors, the developers and their aides have led to the disintegration of the farming communities in places such as Fanling North. They have eventually also succeeded in reversing the Government s decisio conventional new town development approach and allow them to apply for land exchange and participate directly in the development process. For a market economy, one cannot blame the shrewd developers to buy up rural land in anticipation of urban development. The question is for the Government of Hong Kong to have a more comprehensive development strategy in rural Hong Kong, the New Territories. While the ownership of the land may belong to the indigenous population, land, as a natural resource, should be considered as our society s natural commons. As we are in the 21st century facing many global challenges, it is no longer adequate for us to pursue economic development without considering social and environmental sustainability. How can we replan our New Territories, our new development areas as our future commons is a very important issue to be considered. Hence the current approach by the Government is considered to be not desirable. Indeed, the Government should at least start to consider involving the indigenous population themselves to co-develop the land, rather than always involving developers as a third party.

Hence, we can conclude that the NDA plans have not done full justice to the farmers nor those who have real housing needs because if not for the protests, objections and voluminous comments made by the squatter-farmers, social activists and the general public (over 10,000 comments were received by the planners when the NDA plan was turned in to a draft statutory plan), the needs of the squatter-farmers would not be recognised, the land would be used primarily for private housing and the number of public housing units will be a lot less than the current one (the difference amounts to 13,685 units). The unfolding of the planning process, the hoarding of land by the developers and the Government s apparent U-turn to facilitate their privileged participation in developing the NDAs all seem to prove that the NDA plans are just smokescreens to turn use-value saturated land into spaces for exchange value. If this is not the intended purposes of the Government, then it has a very important task to do in the future to exonerate itself from being seen as a state that perpetuates land hegemony in Hong Kong.

# HOW TO PUT ENVIRONMENTAL INJUSTICE ON THE PLANNER S RADICAL AGENDA. LEARNING FROM THE LAND OF FIRES ITALY

Maria Federica Palestino, University Federico II of Naples, palestin@unina.it

Keywords: Land of Fires, Environmental Justice, socio-ecological resilience

Known from ancient Rome as Campania Felix due to the fertility of its lands, the between the Provinces of Napoli and Caserta southern Italy has been lately national and international mass-media as Land of Fires. The phenomenon of fires iceberg that lies on illicit waste trade by the organized crime. Depicted as a b the consequences on human health and local economy, the case of the Land of Fire incapability of authorities in charge to cope with the new urban question that pose.
If we look at the Land of Fires as an unbalanced ecosystem in the face of socio- connected to the metabolism of waste, the insurgency of movements fighting for t the environmental damages sounds as a fair reaction to the lack of regulation.
Among activism, street science and creative ways to defend the right to health behaving as Environmental Justice Organizations by using the mix of struggles, w discourse of dissent that are usually associated to the marginalized communities
After analysing the kind of injustices local communities are living, the paper i looking at socio-ecological resilience of the Land of Fires in a radical plannin a strategy to help the urban region to bounce back.

## 1. Introduction

In present-day Italy, at the intersection of space and society, fueled by the cu financial crisis, unprecedented forms of conflict and cohabitation are emerging, the rise of a new urban question (Castells, 1972). The change in the relations labor, in the passage from known systems of production to uncertain scenarios, r questions about the demand for fairness in environmental management, calling upo address the social inequities it produces (Secchi, 2011, 2013). In the shift fro (Lefebvre, 1968) to the right to urban environments (Kaika & Swyngedouw, 2011) institutions are visibly hard put to adequately deal with the issues at hand bec regard are still too sectorial, and often merely symbolic.
Because of the universal values that the multiple demands for a healthy environm these new urban issues are at once tragically local, as regards damages, and rad ethical implications. Demands for public health and safety are arising ever more one hand, they influence the perceptions and behaviors of stakeholders living ne on the other they migrate across the web into the radical agendas of national, i mobilization.
According to the described trend, analysts and students of Political Ecology emp forms of elitist environmentalism promoting a cult of wilderness are gradually b the south of the world to the heart of a Europe debilitated by the crisis by t environmentalism of the poor (Martinez-Alier, 2002)[1], a phenomenon, due to an increasing awareness of the connections between nature[2], and human beings, the intersection of

[1] For further discussion, in the light of the classification of environmentalist approaches propose Guha, I refer the reader to Armiero (2014).

surroundings, and was later extended southward to include the Phlegraean Fields and the Vesuvian a

[6] To understand the origin of the designation Land of Fires, we have to retrace the history of th
Campania, which went through the following stages: first, between 2000 to 2006, the Domizio-Agro Aversano
Province of Caserta, was singled out by the Ministry of Environment as a Site of National Interest
degradation (perimeter: 77 town administrations). In 2013 The Land of Fires was the object of a P

In the destruens stage the web of dynamics which, by interacting with the sregu[7] of the urban region in question, have eventually led to its branding as Land of Fires will construens stage, instead, the forms of community resilience that could provide reterritorialization of Campania Felix will be emphasized.
In the conclusions the paper suggests some preliminary actions a planner could t together with the collectivity, to the new demands for environmental justice.

## 2. The key facts

The Land of Fires phenomenon is the tip of an iceberg which Legambiente[8] in the 1990s labeled ecomafia. According to the results of over twenty judicial investigations, the province of Caserta during the 1980s. It was the result, on the one hand, of the entrepreneurialism which today has spread throughout the country thriving on special waste, on the other, of the failure of the strategies whereby public institu since 1994, to manage the treatment and disposal of urban solid waste through th authoritarian regime that took the name of Commissariato per l emergenza rifiut (Commissariat for the Waste Emergency in Campania) (Iacuelli, 2008; Corona & For 2013). In spite of its local origins, the illegal traffic of waste particularl over time, a web of connections with the metabolism of the whole Italian penin
The waste emergency, which endured from 1994 to 2009, was addressed by setting u organization which not only failed to deal with the technical problem still uns had a further negative effect, namely, that of fueling the resentment of local p them from decisional processes.
This exclusion, while it failed its intent of preventing criminal infiltration, participation of the uncorrupted part of the population. The people remained tra militarization of their area by the national government and the spread of crimin engaged in the illegal quarrying of building materials, which later proved extre their quarries as unauthorized waste dumps.
The combined effect of governmental inability to manage the area, collusions bet professional world, and organized crime, and the worsening of the global financi Campania Felix became a dump of toxic waste for North, Central and South Italian for low-cost illegal solutions for their waste problems (Ausiello & Del Gaudio, Trocchia, 2010).
The imposition of an authoritarian decisional regime set off a long period of co communities and state authorities. These conflicts went through several forms an peaking in 2007 and 2008, they have left behind a situation of permanent tension
In parallel with the conflicts, and in a way as an unexpected side-effect of the network of associations and movements has arisen in the course of time. This net

---

rule of law signed by 57 town administrations (33 in the Province of Naples, 24 in the Province of Caserta). This incohere group of areas (about 1076 Kmq) with a population of over 3,000,000 is what, up to present, ha designated as Land of Fires. Depending on contingent events, its limits oscillate following the media campaigns or symbolic policies by local or national authorities. Finally, by effect of Act 6/2/2014, originally iss manage the Land of Fire emergency, 31 more townships (22 in the province of Naples and 9 in that among the agricultural areas whose state of health needed to be assessed. Now including 88 towns, the pe of the Fires eventually ended up becoming connoted in the media as a vast Non-Place.

[7] The term is used here to translate the Italian sregolazione, a neologism introduced by the sociol to describe the degenerative effects that a lack of governmental control and inadequate rules and opinion, on the Italian landscape and society, generating forms of exploitation and abuse that oft private interests and illicit businesses.

[8] This is the most deeply-rooted and popular Italian environmental association, which has a nationa network of local circles.

heterogeneous and hard-to-interpret social capital (Petrillo, 2009), about which unless to portray it, too simplistically, as an ally of the Camorra. This oversi often used by state institutions to defend themselves from the attacks of a real more complex and multifaceted although its infiltration by Camorra groups inte conflicts cannot be ruled out (Iacuelli, 2008). This is one of the many lies, pr that have contributed to casting mud on the uncorrupted and participative part o Twenty years of conflicts, as the environmental historian Marco Armiero argues, vain. A significant part of these groups have developed new knowledge, competenc strategies (Armiero 2008; 2014c; Armiero & D Alisa 2012; D Alisa et al., 2010). Leaving the complex deconstruction of the crimes of the ecomafia to scholars in reassessing the object of our study in the light of this unexpected side-effect. In 2012, in Caivano, a town in the northern hinterland of Naples, the Coordiname was formed, by initiative of Don Maurizio Patriciello and with the support of hi and disowned population combined a grim cocktail of poverty, ignorance and crimi intelligence and competence in the management of their land.

At the peak of the rebellion – i.e., during the great demonstration called Ragi paraded in the streets of Naples on 16 November 2013 against the ravaging of Cam Coordinamento gathered almost a hundred movements and associations, which, in sp backgrounds and histories, felt the need to form a cartel, choosing Don Maurizio collectivity.

Many lay associations, even including some historically left-wing ones, found a platform in Patriciello s cry of grief for the wave of cancer and illness which, had struck the affected area.

Biocidio, the murdering of life" a neologism coined by a Neapolitan activist, epidemologists investigating the presumed weakening of the DNA of Land of Fires have been living in contact with toxic waste[9] (Cicatiello & Giordano, 2015) has become a catc in the common struggle undertaken by part of the local movements and association coming from distant cultures, such as Catholicism and Marxism. It is indeed a po evoking both the ravaging of the harmony of creation and the aberrant effects of capitalism (De Rosa, 2014).

In the course of time the process of slow violence (Nixon, 2011) inflicted on Caserta and Naples has heaped a heavy load of injustice and sorrow on common peo undermining the lifestyles of the communities involved and their relationship wi Fortunately, the mechanisms of local control and defense activated by local subj the nature of the disaster and react against it have been determining a social a significant part of the community (Armiero, 2014b).

## 3. The infrastructure, concealment, and stigmatization of waste

Struggles such as that of Warren County in North Carolina at the end of the 1970 the rise of environmental justice movements reacting against the contamination o enclaves, were triggered by political decisions based on the path of least resi activities with noxious effects on human health were located next to areas inhab were discriminated by race or class.

Leaving aside racial factors, which play a minor role in Italian society, simila

[9] The controversial sources about the oncological and degenerative illnesses allegedly proliferatin been made public especially by the doctors and pediatricians of the ISDE association of Naples and have been engaged in the dissemination of epidemiological studies commissioned by public institutions super-national research institutes. On the basis on the scarce available data, the most viable int Campania s morbidity rate is comparable to that of other Italian metropolitan areas, its mortality

to have inspired the decisions that led to the processes of abandonment, decline
things, lands and lives, the dark side of change (Lynch, 1990), bringing on th
disaster.[10]
Although the Land of Fires is an extreme case of marginalization, its story invi
permeability of forms of environmental injustice, which, by penetrating in the i
peninsula, could place the national metabolism at risk through the absorption
socio-ecological sregulation in other marginal areas.
The fabric of the waste-disposal infrastructure dotting the stretches of land be
towns offers services that, while less noble than those traditionally provided
themselves, are certainly no less indispensable for the vital balance of urban e
schools, parks and theaters, they house incinerators, landfills, waste-recycling
processing plants, etc. Along with former industrial areas awaiting reclamation,[11] the future
spatial ordering of Italian urban regions will depend on the organization of the
In Campania, public institutions inadequate regulation of waste treatment and d
followed by a concatenation of forms of criminality, poverty, and fragility of t
acting as a driver for improper land use. It is hardly surprising that the resul
mechanism that favored the concealing of waste or its stocking in open spaces, i
industrial, commercial, or, in any case, non-residential areas.[12]
Acting as an amplifier, media stigmatization has also played a role in the deter
land maintenance and control forms, triggering a proliferation of forms of unfai
social actors that has caused further deterritorialization.[13]
Not only in the case at hand, but also in other cases stigmas seem to be so powe
influence the decisions of institutional actors and bring further damage, creati[14]

---

[10] The 2001 and 2011 Istat censuses have reported one of the highest unemployment in Italy in the u
Caserta and Naples, along with widespread poverty and low schooling. We are thus dealing with a ma
of both social class and income. As to the historical rooting of contamination processes with harm
in the area, least resistance considerations clearly apply here. To give an idea of the seriousn
cite the example of the town of Giugliano. Here a paradoxical situation has occurred, depending on
hand, a disproportionate quantity of still undisposed-of solid urban waste legally stocked on the
commissarial management of waste disposal, on the other, 10 million tons of prevalently special wa
disposed of and buried by the Camorra over the last 23 years (Legambiente, 2015).

[11] Between 2006 and 2012, by effect of Act 3/4/2006 n. 152, 57 Sites of National Interest (Siti di
were singled out for restoration. 18 of these were subsequently declassed to Sites of Regional Int
Regionale, SIR). The restoration of SINs falls to the Ministry of Environment, that of SIRs to the
and complexity of the administrative procedures involved, very little has been done to date to res

[12] For example, the landscape plan of the Province of Caserta approved in 2013 documents and maps f
land, described and measured as follows: critical urban areas (1617 ha), critical infrastructure
space areas (1502 ha), quarries (1345 ha), areas with accumulations of waste (153 ha), Chap. 9. Re
accompagnamento al PTCP, Il territorio dell illegalit , pp. 222-233 (ftp:// ftp. Provincia.caser
Apart from spaces and surfaces where polluting waste and other dangerous materials are illegally stored a
temporarily or persistently, in the Land of Fires there are different patterns of waste and wasted
stretches of agricultural land housing illegal dumps; porticoes of abandoned mass; private homes
national (Sni) or regional interest (Sri); housing or productive facilities confiscated by the sta
partially condoned unauthorized buildings that, being unregistered by the tax authorities, are class
buildings abandoned or soon to be abandoned shopping malls; urban waste treatment, disposal and recy
surfaces, areas and infrastructures designed to host marginal lives.

[13] As regards forms of unfair competition exploiting the Land of Fires stigma, we have been observi
effectiveness of forms of media discredit which are capable of ousting from the market whole categ
agro-food sector. This phenomenon has sparked a media war against the products of Campania, inaugu
low-cost marketing strategy that consists of discrediting the products of competitors rather than
Palestino, 2014).

[14] The ways in which national institutions are reacting to socio-environmental sregulation by pron
symbolic policies are currently being investigated by a research project funded by the national Ministr
Research, in the frame of the PRIN program Post-metropolitan territories as emergent forms of urb
sustainability, habitability and governance (coordinator professor A. Balducci).

It is hence possible to deconstruct the tangle of narrations produced and circula
the last few years, highlighting how, from 2012 to the present day, issues of he
security are being addressed by discourses which – depending on their targets –
scientific, legal, economic and market, populist rhetorics, taking a more or les
one of outright struggle against institutional planning models. Narrations and i
manipulated public opinion,[15] destabilized decisional processes, and even influenced inst
policies.
Each of these discourses often contains a part of truth, but none contains all th
their degree of truthfulness is not measurable, because there are no data, the a
insufficient for complex diagnoses, or the data are scattered among actors who a
them.
In the battle between hidden interests and collective values, the only opportuni
back appears to lie in the social dimension of community resilience, which provi
chance to convey images, however fragile, of a recovery of the area.

## 4. Ecological metaphors as a lever for new local geographies

As complex and adaptive socio-ecological systems, towns, cities and urban re
fundamental characteristics. The first is that, like natural ecosystems, of
artificial outgrowth (Whiston Spirn, 1984), they are endowed with resilience,
a system to absorb disturbance and reorganize while undergoing change so as to s
the same function, structure and feedbacks, and therefore identity (Folke et al., 2010, p. 20). The
second characteristic, consequent on the first, is that they feed on human actions,
abilities proper to communities, organizations and institutions, and convert
memories, emotions and competences into creative resources.
Within such a horizon of meanings, the ability of a local land system to maintai
build a new one, through synergies generated by investing on the local ecologica
organizational capital (Walker et al., 2004) can be reactivated starting from th
the genetic heritage of the system.
In this perspective, an analysis of the factors that have led to the deteriorati
opens a window on the new geographies of socio-ecological resilience that are fo
crossroads between the stigmatization of the area and the activation of organize
or informal reaction to this stigmatization.
The case study of the Land of Fires indicates that the viscosity of areas betwee
communities much more than cities themselves, which are increasingly relegated t
like romantic ruins. The explosion of fragments of cities like Naples, or towns
Afragola in their urban areas sets in motion new aggregation processes based on
sometimes temporary ones, that are as recognizable as those that once used to be
administrative boundaries, art-historical heritage, or natural features.
The urban region discussed here is made up of places inhabited by populations wh
and mobilize ever since the 1990s around issues of environmental justice raised
management of the Regional Plan for urban solid waste. Starting from an individu
private property, these movements have gradually become increasingly sensitive t
such as health, security, and democratic participation. From a Not in My Backy
Not in Anyone s Backyard one, these struggles and conflicts have reverberated
Acerra and Salerno areas, and to the northern suburbs of Naples. They have put t

[15] On the use of images as a strategy to manipulate and distort the public opinion, see the metapho
by Soja: ( ) a subtle form of social and spatial regulation ( ) that ( ) plays with the mind manip
consciuosness and popular images of city space and urban life to mantain order (Soja, 2000, p. 324

of aggregation, at once local and global, national and transnational, which are
apical powers and bottom-up movements (Castells, 2012).
Beyond a growing weakness of institutions, inversely proportional to the vitalit
entrepreneurs, colluded politicians and administrators, the outcome to emphasize
local communities which, in the transition from stakeholders to careholders, are
defend commons such as water, land, air and energy, or promote alternative ways
This situation highlights the demand for new profiles of local administration an
experiments in governance.
By regarding the Land of Fires as a complex mosaic of out-of-balance ecosystems,
apply the ecological metaphor of panarchy (Holling & Gunderson, 2002) to surveys
capturing new equilibria and alternative stable configurations. This means inter
of the Land of Fires as an opportunity to activate new life cycles, sharing the
which spatial orderings are based (Di Martino, 2013; Gasparrini, 2013).
In this perspective, once again, embedded forms of self-organized response and g
constitute the potential allowing the Land of Fires fragile ecosystems to bou
surviving antibodies to readapt.

## 5. For a co-evolutionary approach to the[16] Land of Fires

The Land of Fires has been the object of growing media manipulation of informati
disinformation. This phenomenon, compounded with the current economic and moral
helps to determine how to manage the area. If we look at the evolution of the ma
information and data, all the arguments put forward by politicians, technicians,
individual inhabitants appear, in one way or another, partially convincing (Merl
The media describe unspeakable and intractable situations, where everyone is in
everyone is right, in a paroxysm that pushes things beyond the edge of sustainab
possibility to make democratic decisions about the future.
Analysts especially oncologists, epidemiologists and agronomists are incredi
catastrophism and a wish to shed light on the situation and look[17] for some opportuniti
scholars in the latter camp are even being accused of negationism (Di Gennaro,
meantime, between 2013 and 2014, governments have sued national newspapers[18],
of transparent communication, entrusted the President of the Republic with merel
declarations and actions, promised effective solutions, and issued equally symbo
6/2/2014 to appease public opinion (Piccirillo, 2014).
At this point, we wonder what kind of planning is possible when environmental po
the attending conflicts) arise from an attempt to address the concatenation of d
environmental stress, capable of extending their deteriorative effects from the
sphere.

[16] In the last Aesop Conference, by introducing the Land of Fires as a paradigmatic case of plannin
that undertaking the environmental restoration of this area may require planners to accelerate the
evolution by interfacing with local society and cultures (see Palestino, 2014).
[17] As Laura Centemeri has effectively shown, these are cultural attitudes that are deeply rooted in
traced to ways of dealing with environmental controversies that have been to the fore ever since t
(Centemeri, 2005).
[18] In 2013, the weekly magazine L Espresso flashed the title Drink Naples and then Die (De Feo &
article reported, not without ambiguities, the results of test carried out by American investigato
forces stationed in the Naples area. The data mainly regarded the contamination of water in milita
Caserta, and only marginally the periphery of Naples and its surroundings. The title s artful forc
that Neapolitans were drinking polluted water caused a reaction by local authorities. The mayor of
decided to oppose the stigmatization campaign launched by the newspaper by suing it for libel.

When public health is threatened, as it is in Campania, it is the family and int
are at stake, and it is very difficult for institutions and the communities them
them. The reason for this difficulty is the irreducible, intrinsic incommensurab
connected to life (Boltansky &Thevenot, 2006).
Even in a lay perspective, the situation requires us to take account of the soci
done to local populations, in the awareness that it is the authorities task to
to immaterial values into the public arena.
A way, albeit an indirect one, to begin to construct forms of interaction and de
communities could be, for example, to combine the planning of new spatial orderi
disposal infrastructure with appropriate processes of democratic deliberation. T
39 Sites of National Interest is on the agenda of our Ministry of the Environmen
governments are to restore the 17 Sites of Regional Interest. This action, if un
strategic surplus value, because it would allow the testing of forms of socio-cu
through the active participation of local communities.
Implementing restoration projects within the dimension of participation in decis
least, beginning to offer those who have suffered the illness or death of loved
who have grown in the shadow of conflicts, the opportunity to participate in the
that has been their home for generations (Centemeri, 2015).
It is clear that this is very difficult to achieve, and even a scary perspective
we cannot always look for easy solutions, at least not for wicked problems such a
here (Kaika & Swyngendouw, 2011).

## 6. Resilience as a radical agenda

We are faced with the paradox that the government commissioner has declared a re
Giugliano area impossible (Ausiello & Treccagnoli, 2013). Judicial investigators
are warning against the risk of Camorra infiltrations in the land restoration bu
local producers in the agro-alimentary sector are staging protests (Sardo, 2013;
The population is, understandably, reacting emotionally (Limatola 2013). Politic
exploiting the media stage of the Land of Fires to construct unprecedented forms
leadership. The national government is undecided, and has repeatedly gone back o
without explanation. In the face of all this, what is the sense of appealing to
recovery?
The case study discussed here shows that, in the passage from the natural world
when using the concept of resilience we needs to take into account issues of equ
Herein lies the centrality of planning and, accordingly, the need to define the
In my opinion, the social dimension of resilience reveals how urgent it is to de
strategies to combine technically relevant arguments and knowledge with testimon
know how sedimented in local material culture, promoting cultures and narrations
collective sense of collaborative planning (Healey, 2007).
Increasing and making the most of the knowledge and desiderata (the software )
communities helps to interact with the peculiarities that individual contexts co
professional with, in terms of hardware as well as software. The daily scena
Fires is one of conflicts and covert particular interests, structural shortcomin
in managing economic resources, opacity and fragmentation of available data, gap
knowledge, and widespread manipulation. For the demand for regeneration to gathe
seeking leverage in a direct participation of social actors, based on an interpr
ecological resilience as a radical agenda (Shaw, 2012), may be decisive.
This hypothesis finds confirmation in the fact that, zooming in with the lens of
forms of resistance in the Land of Fires, we discover that the scholars in the ca

activists have pointed out, in some detail, the emerging of increasingly sophist
organization of environmental movements (Armiero, 2014a, 2008 cit.; Armiero & D
combining activism, street science (Corburn, 05), and creative ways of defendir
(De Rosa, 2014), social movements from the Campania Region are behaving as envir
organizations (Martinez-Alier et al., 2014). They are doing so by providing thei
the combination of struggle, ways of learning and discourse of dissent that lite
Environmentalism of the Poor (Martinez-Alier, 2002) usually associates with ma
communities inside or outside the globalized West.
These organizations have managed to keep together the cries of the Mamme vulcani
a country parson (Patriciello 2013), and the creativity of networks that have be
expertise. Their Nimby approach of the 1990s has given way to advanced knowledge
and innovative abilities (Armiero, 2014b). They are no longer merely struggling;
striving to take care of the places they are fighting for (De Rosa, 2014).

## 7. Conclusions

In addressing the catastrophe of the Land of Fires, we need to take account of t
the process of socioecological deterioration that has been going on in the area
and carefully time our reaction.
This paper emphasizes that the first lever for the recovery of the area is the a
uncorrupted components of local communities. In the short term, a first goal sho
of community resilience, i.e., the promotion of a local planning which, however
should be regarded as a resource for the recovery of this violated land.
In this regard, one of the priorities is to restore the image of the area to bre
its stigmatization. We need to counter the deterritorialization of the urban are
Caserta by granting recognition to, and reinforcing, the forms of active resista
actors oppose the libelous equation Campania Felix=Land of Fires in informal, se
quasi-structured ways.
This resistance, staged by temporary communities that aggregate to denounce, pro
their land, should be guided through a detailed assessment of competences and ab
rich and diversified offers of local forms of bottom-up reaction. This means res
of narrations and images of Campania Felix coming from the communities themselve

# HIGH-SPEED RAIL IMPACTS ON SHANGHAI S URBAN FRINGE COMMUNITIES: AN INTEGRATED APPRAISAL FROM SOCIAL SUSTAINABILITY AND ENVIRONMENTAL JUSTICE PERSPECTIVES

Shuping Zhang[1] and Zhu Qian[2]

[1]University of Waterloo, s289zhan@uwaterloo.ca
[2]University of Waterloo, z3qian@uwaterloo.ca

Keywords (maximum 3): high-speed rail impacts, social sustainability, environment

## 1 Introduction

High-speed rail (HSR), the advanced rail system normally operates at a speed of new tracks or 200km/hour on conventional tracks, is advocated as an effective tr with dwindling energy supplies, severe air pollution, and increasing traffic con of this transit system includes: increasing traffic efficiency; improving spatia logistics connections; promoting regional equity and economic coordination; and alternative to air transportation in regions where geography allows competitive railway (GutiØrrez, J. 2001 Givoni, 2006; Albalate and Bel, 2012). For China, H essential considering the country s massive population that needs efficient trav regions demanding for equal connection, and the state goal of city-region integr by rail upgrade (Takagi, 2011).

On July 1st, 2004, China s Ministry of Railway developed a Middle- and Long-term Plan and announced investment targets through 2020 (Fridley, Zheng, and Aden, 20 components include:

- Total operational railway track of 120,000 km with a 50% share of rail elect double-tracking;
- 12,000 km of dedicated high-speed passenger railway tracks with speeds of 20 above;
- Four north-south and four east-west high-speed passenger rail networks to li hubs; and
- Three regional intercity rail networks.

China s interest in HSR construction is rooted in the desire to improve the connection and economic productivity. Although there are sound economic incent development, given its very recent implementation and controversial impacts, fur the quality and problems with HSR development should be undertaken. Different fr lens of spatial-economic impacts and accessibility analysis (Kim, 2000; Chen Chen, 2012; Chen, 2013; Jiao et al., 2014; Shaw et al., 2014), this study sheds perspectives of HSR impacts at a local community territorial scale by inves excluded, marginalized, and disadvantaged groups of population (i.e. farmers, el who live with HSR s daily operation in Shanghai s urban fringe. The research un everyday life has been affected by the HSR projects, utilizing an integrated co linking social sustainability and environmental justice. Guided by this integra research will answer three major research questions: (1) What are the major communities in Shanghai s urban fringe? (2) Who are the main recipients of th and how has their every day life been affected? (3) What political institution procedure have led to the current situation?

The rest of the paper is organized as follows: first, a literature review of ar framework will be provided to lay the theoretical foundation for analysing HSR

and social impacts on surrounding neighbourhoods. The next section will introduc
area and present our research methodology. Then the research findings and ar
presented in three sub-themes: (1) the unfair distribution of environmental bur
inequity in compensation arrangements; (2) procedural concerns for environmenta
social inequity in relation to public consultation inadequacy and social exclusi
institution manifested by local pro-growth governance. Finally, a conclusion
research findings and offer policy implications.

## 2 An Integrated Conceptual Framework

Since the Brundtland Report of Our Common Future (WCED, 1987), there has been a
literature devoted to the general topic of sustainability. The 1992 Rio Decla
suggests that sustainable development keep the balance and achieve certain trad
pillars of sustainability, namely ecological, economic, and social sustainab
considerable academic and political attention has been paid to the discussio
development, social dimension of sustainability is the least conceptually exp
practically under-implemented among the three pillars (Littig and Grie ler, 200
Dillard, 2009; Cuthill, 2010). In addition, comparatively insufficient studies
theoretical connections and interplay among the three pillars of sustainable dev
Grie ler, 2005; Bostr m, 2012).

Just sustainability proposed by Agyeman and his colleagues (Agyeman, Bullard,
2002 and 2003; Agyeman and Evans, T., 2003; Agyeman and Evans, B., 2004) con
further exploring the social dimension of sustainability and advocates an int
framework that link environmental analysis with anthropocentric concepts. They
recent years, environmental justice campaigns globally are being reformulate
sustainability, and vice versa (Agyeman and Evans, B., 2004, pp.160). Para
egalitarian conception of sustainability (1999), their definition of just sustai
common ground between human rights and environmental issues and highlights fo
concerns on: quality of life, present and future generations, justice and
allocation, and living within ecological limits (Agyeman, Bullard, and Evans, B.

Based on the just sustainability discourse, we aim to structure an integrated co
connecting social sustainability and environmental justice in assessing HSR in
communities. There exists an area of theoretical and practical compatibility bet
an integrated conceptual framework can provide a more inclusive approach to as
changing built-environment affects people s daily life.

### 2.1 Conceptual Origins and Definitions

Social sustainability is an open and contested concept (Bostr m, 2012) that a
develop schemes to define it. Based on an experimental research in Australia
identified an interdependent and self-reinforcing relationship between four k
social sustainability: (1) social capital that provides a theoretical start
infrastructure that provides an operational perspective; (3) social justice and
ethical imperative; and (4) engaged governance that provides a methodology
together . Littig and Grie ler (2005) extended the fairly vague notion of needs
report to a linkage of political pragmatism and social theory. According to the
sustainability is about a quality of societies , and it signifies the nature
mediated by work, as well as by relationships within the society (p.72).

Similar to social sustainability, environmental justice has multiple definitions
Environmental Protection Agency (2008), Environmental justice is the fair
meaningful involvement of all people regardless of race, colour, national orig

respect to the development, implementation, and enforcement of environmental la
and policies . Bryant (1995, p.6) referred to environmental justice as the cul
rules, regulations, behaviours, policies and decisions to support sustainable
people can interact with confidence that their environment is safe, nurturing
Looking beyond time and space, Stephens et al. (2001) maintained that to guarant
justice is to ensure a healthy environment for future generations and to ensure
one region will not cause negative externalities for other people s health. Fo
the responsibility of carrying on this value requires us to transcend individu
vision (Beckerman and Pasek, 2001; Beckman and Page, 2008).

## 2.2 Conceptual Common Ground

Among the definitions provided by governmental officials, grassroots associatio
scholarships, we can find common ground between social sustainability and enviro
The overlaps indicate an opportunity for incorporating the two concepts in acces
on local communities.

Anthropocentric Perspectives: both social sustainability and environmental jus
anthropocentric perspective. Until recently, eco-centric models have dominated
sustainable development and environmental issues. Heavily influenced by e
movements, these models highlight the negative impacts of human interventio
environment and emphasize the need for more efficient use of resources. The ad
centric models reflects people s anxieties about environmental collapse, limite
and threats to biodiversity. In contrast to an eco-centric model, an anthropoce
more on impacts of natural or built environments on human beings. Caring for h
relationships, life quality issues, as well as environmental impacts on huma
sustainability analysis often takes an anthropocentric perspective (Littig and G
Lloyd-Jones, and Allen, 2010). Different from ecological justice, environmental
mainly focus on the justice concerns of people, regardless of their social, e
background (Low and Gleeson, 1998; Agyeman and Evans, T., 2003; Schlosberg, 2007

Substantive and Procedural Characteristics: Both social sustainability and e
justice concepts include substantive (what) (i.e., equal right, justice, and
procedural (how) (i.e., meaningful involvement, social inclusion; citizen
characteristics. Bell (2004) held that environmental justice has both procedur
components. A substantive component of environmental justice underscores a fair
sharing of environmental burdens (e.g. harm and risk) and benefits (e.g. resourc
To achieve that, three questions need to be answered: (1) Who are the recipients
distributed? and (3) What is the principle of distribution? Procedural perspecti
justice includes the pursuit of justice for all people regardless of their back
meaningful involvement of these people in decision-making process (U.S. En
Protection Agency, 1998; Bell, 2004; Schlosberg, 2004). As a concept with pri
social equity, as well as equal access to resources, participation and soc
sustainability has both substantive and procedural characteristics. (Manzi, Lloy
2010). A critical aspect of social sustainability is social justice and equity
This substantive perspective provides an ethical foundation when formulating so
policy or strategy, and when implementing operational initiatives (Cuthill, 201
substantive characteristic of social sustainability cannot be guaranteed without
enforcement. Additionally, Bostr m (2012) pointed out how procedural aspect
sustainability affect its substantive aspects ought to be pondered through a lon
which is also true for environmental justice.

Two Inter-related Political Dimensions: The major actors involved in the two co
both perceived in two inter-related political dimensions (Littig and Grie ler,
Jones, and Allen, 2010; Bostr m, 2012). On the activist level, individuals a

capitalize on social sustainability and environmental justice to pursue politic
mobilization, and rightful resistance. On the government level, these concepts a
policy guidelines to ensure that no public action would disproportionately
specific social group (Agyeman and Evans, B., 2004). Social sustainability is
tackle the relationships between individual actions and the created environment
between individual life-chances and institutional structures (Jarvis et a
Environmental justice exists along with intense interaction between political au
root forces.

## 2.3 Conceptual Significances for the Chinese Context

In recent years, the Chinese leadership has made sustainable development an impo
recent Five Year Plans. The central governments strong promotion of sustainab
policies and environmental protection is buttressed by a renewed public
consciousness, a newly formed domestic environmental civil society, and ar
international aid (Lam, 2006, pp. 362). Witnessing frequent natural disasters a
outcomes, Chinese are increasingly concerned about the environmental conditions
places. However, concepts such as environmental justice and social sustainabili
ordinary Chinese people, and grass-roots social mobilization has not included
their campaigns.

In China s planning system, economic growth enjoys priority. The concerns for s
justice have not been explicitly raised and addressed in planning implementatio
makers believe that sustainability and justice could be achieved later (Wu,
pointed out that Chinese scholars have been conspicuously absent in addressing
of social and environmental justice. For example, the existing discussions o
impacts in China mainly focus on the spatial and economic aspects. Few of them
the scope to include work that critically analyses social and environmental in
surrounding neighbourhoods and further explores how the growth-centred in
construction has affected the socially excluded, marginalized, and disadvanta
integrated conceptual framework that connects social sustainability and enviro
imperative for assessing China s growth-oriented urban transition driven by
projects such as high-speed rails.

In Shanghai s particular social, economic, and political context, the empirica
examine the applicability and power of integrating social sustainability and en
in analysing HSR impacts on nearby neighbourhoods. In particular, it examines
socially excluded, marginalized, and disadvantaged who live with HSR s daily
Shanghai s urban fringe.

## 3 Case Study and Methodology

Informed by an integrated conceptual framework of social sustainability and envi
employ a case study in Shanghai s urban fringe. The reason we focus on urban
because this particular geographical setting is the most contentious location
where competition for land has been intensified and social conflicts have fre
2009; Hsing, 2010). In urban fringe, low land acquisition compensation rates ar
scale infrastructure development (Dai et. al., 2013). In the case of Shanghai,
HSR stations are located in central city and two of them are sited in the city
(Figure 1).

The case study fieldwork was conducted from June to August in 2012 in two v
Shanghai-Hangzhou HSR line. The data collection method included participant obse
surveys, and in-depth interviews. As residents perception of HSR might vary
socioeconomic circumstances, we chose two villages for comparison. With about 8

in an area of 2.88 square kilometres, Xuejia Village is located in Songjian
undergoes the fastest economic development among all the suburban districts i
2013). The majority of young people have left the village for better job opport
centres, and the remaining elders take care of their household plots. During th
industrial parks have been developed near the village, attracting an influx of
rent rooms from the villagers. The other case study site Weixing Village
approximately 600 households in an area of 3.27 square kilometres. Almost all
local residents with rural household registration status (hukou) (Jinshan Arc
village shares some similarities with Xuejia Village such as the out-migration c
However, the economic development of Weixing village is slower than that of X
Jinshan district, where Weixing Village belongs to, is one of the three district
subway connection. The Weixing villagers think their village might be the poores

The structured questionnaires were completed through face-to-face interviews. Th
were designed to identify what social groups form the recipients of the HSR s environ
social impacts. The surveyed households were asked to provide each family member
education attainment, household registration status (hukou), residency time,
monthly household income. This was followed by more detailed household intervie
village members perceptions of and reactions to the HSR operation from the pers
sustainability and environmental justice. In total, we collected 30 valid qu
which 10 local households were from Weixing Village, 10 local households from X
and 10 migrant households from Xuejia Village. The selected households are locat
areas closest to the rail tracks, with the assumption that the closer the resi
tracks, the more visible and remarkable the HSR s perceived impacts might be.

Figure 1. Research Sites in Shanghai s Southwest Urban Fringe (Source: Authors

# 4 Findings and Analyses

## 4.1 The unfair distribution of environmental burdens and the social inequ arrangements

We found the co-existence of the unfair distribution of environmental burdens a in compensation arrangements after the HSR construction. This is certainly not s rapid urbanization always prioritizes economic pursuit, compromising its social influences (Ma, 2007; Wu, 2015). The Shanghai–Hangzhou HSR service runs 177 tr (including 128 trains from Shanghai to Hangzhou and 49 trains from Hangzhou to the beginning of the HSR operation, residents in Xuejia and Weixing Villages h from various sources of disturbance including noise caused by passing trains, v electro-magnetic interference, flashing-headlight pollution, and increasing ai Among those negative externalities brought by the HSR, noise is the most sever dwellers. The sound waves produces a sound pressure level (SPL) that is gene decibel A-weighting (dBA). The rapid approaching of a high-speed train is accom increase in noise. Commonly, sounds of approaching vehicles carry a sense of co greater annoyance than receding sounds (US Federal Railroad Administration, 19 Japanese Ministry of Environment promulgated regulations to control HSR nois surrounding areas. Tested from the nearest residential areas, the maximum SPL o be no more than 70 dBA. In China, the relocation red line for HSR construction households whose residence units are within 30 meters from the rail centrel relocation to avoid severe noise disturbance. In our cases, the majority of hou lines still have to endure the noise because the distance of their housing unit over 30 meters. Table 1 is a sample of SPL results obtained in Xuejia Village meters from the rail centreline. When an HSR train is passing by without slowi over 80 dBA, which is not safe for human beings according to the Japanese standa

Two social groups shoulder the environmental burdens, especially the noise caus local elders and the young migrants. They both have limited social and economic difference between the two social groups is that the local elders have lived years while the average residency length for migrant household heads is about Without convenient transportation and adequate urban facilities, most local you and Xuejia Villages prefer to move to city centres. As the economic situation better than Weixing Village s (in terms of average monthly household income per the elder population situation is more remarkable in Xuejia Village. The other s from HSR disturbance is migrant workers and their families. Different from the l 70 per cent of the migrants are young or middle-aged adults. Many choose to live because rent is much cheaper than that in urban centres, landlords are friendly, industrial parks are close by.

Education levels of the surveyed adults over 18 years old are lower than those
Half of the local dwellers have only obtained primary education or even lo
interviewed migrants have obtained higher education such as a university degree
typically farmers and workers in nearby factories. Male migrants are usually
physically demanding or dangerous lines of work, most notably in construction. F
either in factory production lines or in service industry. The per capita month
urban residents in Shanghai is 3,349 yuan (around $536), and the per capita
income of rural residents in Shanghai is 1,450 yuan (around $232) in 2012 (S
Yearbook, 2013). The average of the surveyed households (rural in our cases)
abovementioned rate, which indicates that the recipients of environmental injus
sties comprise an economically marginalized social group.

urbanization, has resulted in unequal and unfair societal consequences.

## 4.2 Procedural concerns for environmental injustice and social inequity i consultation inadequacy and social exclusion

As discussed in the section 2.2, besides substantive meaning, both social
environmental justice concepts are closely related to procedural analyses. In ou
the environmental injustice has been reinforced by the social exclusion, signif
sustainability. Faber (1998, p. 14) emphasized, the struggle for environmental
distributing risks equally but about preventing them from being produced in
remarkable fact of limited procedural justice lies in the public consultation i
are involved in the decision making process, they are more likely to be support
and implementation (Potapchuk, 1996). Wu et al. (2010) revealed that Chines
reluctant to arrange negotiation that involves various stakeholders because t
negotiation slow down urban development. The state dominance in mega urban pro
public consultation is more at the stage of policy implementation rather than p
2015). Lack of community participation prevented the HSR project in those villag
being endorsed by the local residents. Ms Zhang mentioned that she had never he
project until one day when she saw large trucks carrying construction materials
while for Mr Xun to understand what was going on, No one ever asked our feeli
uncertain about the potential HSR impacts at its early construction stage. It w
the whole process of HSR construction, there was no meaningful and transpa
participation. Mr Zhu concluded three points regarding the decision making
construction was conducted without any hearing process in the communities; (2)
arrangements and negotiations were not open to the public; and (3) the final com
not released to the affected communities.

Manzi et al. (2010, pp. 10) maintained, The general idea of social exclusion i
social, political and economic processes erect barriers that prevent specifi
participating fully in the society in which they live. The effects of these ba
conjunction of material poverty and the processes that define particular group
barriers also prevent people from improving their circumstances through their ow
protests, as a response to social exclusion, are not tolerable in China. From t

sense of social exclusion. When asked to make choice between leaving the place
HSR s daily disturbance, most of them intended to stay.

### 4.3 Political institution manifested by local pro-growth governance

Local pro-growth governance has driven the discussed social unsustainability
injustice. The devolution of state power to lower-level governments and the in
from fiscal decentralization have combined to push local authorities to advoca
economic activities with high revenue returns. Local officials play an entrepr
making activities. Eaton and Kostka (2014) argued that Chinese local government
growth-centred administrative manner without long-term vision is similar to t

# TRACK 18

# Complexity, Planning and Fuzzy Responsibilities

## Track description

Co-chairs: **Peter Ache**, Maro Finka

Cities and regions are facing increased complexity and fuzziness of their spatial and functional structures. Their institutional and managerial systems, including planning, are expected to manage it, but their capacities are limited. Moreover, additional new structures have appeared, which may rather contribute to the complexity on the management side, many of them making responsibilities becoming even fuzzier than before. Perhaps, we perceive such a situation more intensive with the recent economic and political disturbances being confronted with the question: Can planning respond to both, the challenges of complex issues and of ties?

The track invites academic and practice referring papers reflecting current concepts and practices in urban regions, like metropolitan or city regions, both inside and outside Europe. Specifically, the papers are expected to address the following questions:

- Which new forms of governance are evolving in functionally closely related urban regions? How can they be described and understood in their operation? What are our theoretical or conceptual tools to support our understanding and maybe also our attempts to improve their management capacities?
- The attempts to manage complex urban regions on the basis of distributed responsibilities and resources are mostly understood as expert realm. How can a cit tive or the proto-professional world help create the necessary innovations in our management approaches?
- Planning and its organisational structures are just one player in the management of complex urban regions. How can we understand the interconnected system of policy making and implementation that shapes the framework conditions for the operation and the planning challenge of complex urban regions?

While focusing on above topics, the papers should also make sure that the audience/readers have a good understanding of the region under consideration, relevant historical and actual development trends, and relevant politico-administrative aspects of national and urban planning systems.

# Re-scaling of the state in Turkey: The case of villages

Zeynep Ceren Aky z

K r kkale University, Political Science and Public Administration Department, Environmental Issues Division, Research Assistant

Ankara University,Urban and Environmental Sciences Department, PhD Candidate, zeynepcerenakyuz@gmail.com

## The Abstract

This paper uncovers the main economic, political and social drivers of state rescaling in Turkey through historical and comparative comprehension. It touches upon the transformation of the state and its development trajectories to examine in what ways the triad of local, national, global scopes, along with their main actors, roles and policies evolve. The discussions will provide hints of the evolution of local government structure of Turkey while particularly depicting the position of village administration during the heyday period of metropolitan municipalities and regional formations. For the Turkish case, it is possible to classify the drivers and motivations of rescaling under certain themes which are promotion of democracy, tackling identity issues, fighting corruption, generating economies of scale. More importantly, rescaling notably takes place for its professed close local units to confront uneven development (Smith, 1986) which could be defined as contradiction of capital (O'Connor, 1981).

**Keywords**: state rescaling, Turkish local administration, village

## Introduction

The re-conceptualization of the state space stands for the rescaling processes multi-scalar hierarchies of state institutional organization, political authority and regulatory conflict are being generated. (Brenner and references therein, 2004, p.71).The idea of dispersing urban populations and economic activities across the territories of the country has taken its source from diverse and mutant legitimising or compulsive factors. In reference to Poulantzas comprehension this derives from the nature of ephemeral capitalist spatial formations, which are both the precondition and the reification of social relations. (Poulantzas, 1978) Soja stated this is the material form of social relations. This perpetual course of social production of space is highly e ideological and political stances. ( Soja, 1985).

Although rescaling as a processual response, either in proactive or reactive ways, is orie political and social matters, its vigour is substantially affected by the dynamics of economy. The states also experience difficulty in terms of their technological competence, informational proficiency and adjustment capacity. (Eisenschitz and Gough, references therein, 1998) Therefore, the states appeal to internal spatial realignments. These re-formations include federalist readjustments, administrative amendments, gerrymandering practices, metropolitan jurisdictional fragmentations together with dissolution or incorporation of the legal entities of local units (Brenner, 2004, references therein). By employing these novel formations, the states target to arbitrate, propagate and entrench when desired the everyday power relations of a particular locality (Brenner, 2004).

In this context, this study ultimately aims to uncover rescaling process of Turkish state with its new geographical scales and territorial contours, giving particular emphasis to the case of villages during the post Law no. 6360 era. It is credible to point out the existence of a tendency towards larger units metropolitan and regional within states. (Soja, 1985; Brenner, 2004; Swyngedouw, 2004;

2006) To this point, Swyngedouw highlights the contingent threat for the groups with less negotiating capacity as the technocratic-managerial-entrepreneurial state grows up at the citizen's state (Swygedeouw,1996).

## The state rescaling in Turkey

During the 1950 election, Turkey took a step into the democracy scene (Rustow, 1991; Szyliowicz, 1963). With the transition to a multi-party system, the Democrat party became competent to represent the discontent groups comprised of landlords (whom were severely affected by the Land Reform Bill of 1945), the merchants and also rural groups whom felt estranged by the secul policies (Aydin, 2004). Despite the fact that Turkey initiated a multi-party regime, the relationship between local units and the central state continued to carry the traces of the single party period (Tekeli, 2009; Bayraktar, 2007). Regarding the question of central state`s position in Turkish nascent democracy, it should also be noted that the elections of 1950 strengthened the hands of bourgeoisie to tackle and confront the autonomy of the state . While this emergent tension h for anti-elitist bourgeoisie segments to gain seats in the political scene, w obliged to hover in an unorganized complexion with no other option than depending on a patro client affiliation (Ayd n, 2004 and references therein). Concerning the state spatial tenets of the 1961 Constitution widely preserved the constructed administrative organization, though with certain amendments. Alluding to a regional pattern, a new spatial unit was Article No.115. According to this article, the adhesion of multiple provinces with the purpose of fulfilling certain public services is permitted. ( Bayraktar, 2007).

Beginning from the first Five Year Development Plan, designed for the years of 1963-1967, the emphasis on and the expectations from small and medium sized enterprises gained a momentum in development plans and programmes of Turkey. Later, this inclination was revitalized once again with the notions of the Washington Consensus and also by the European Union agenda ( zar, 200 year of 1963 is also important as Turkey put its signature to the first contractual agreement, an Association Agreement known as the Ankara Agreement with the European Economic Community (EEC). The path from 1960s towards 1980s was shaped both by internal occurrences and international developments. Until 1980, Turkey adopted the capital accumulation model of import-substitution under auspices of national developmental state. This model is based on the assumption that the regulatory role of the state is necessary to promote industrial bourgeoisie and to ensure their international engagements. The Turkish state also took the principal role of allocating credits and foreign exchange through its administrative structure and instruments. To illustrate this by means of the Iller Bank since 1945, the state played an active role not only through the transference of resources but also through handling the construction and industrial sectors at local levels (Tocci, 2012; nar, 2009 and references therein).

In this regard, the maturity of the Turkish bourgeoisie was also determina towards 1980 coup d Øtat, which marks a breaking point in the social, politica of Turkey due to its definite repercussions on Turkish state`s spatial reorganization. It is not possible to point out the specific stage or time to which Turkish state rescaling dates back to due to the process nature of state rescaling. Still it could be stated that, especially in the aftern coup d Øtat, Turkish state has begun to devise rescaling to handle, alleviate the existing obstacles and disputes while tackling the derailed political and economic situation, by paving the way for integrating Turkey in the global capitalist economy ( ni , 1994) The urban places, in terms of their form and composition, were not immune to prevalent transformations. One of the striking outcomes of this period is the conviction that the real estate sector set out to winning a seat at the core of Turkish economy.( Erman, 2012; Bu ra , 2014)

According to Article no. 127 of the 1982 Constitution, provinces, municipal districts and villages are considered as units of local administration. It is noteworthy that the Constitution regulates for the first time that special administrative arrangements may be introduced by law for large which forms legal basis for metropolitan administrations. Besides, Article no. envisagement by stating that central administrative organizations comprising several p be established to ensure efficiency and coordination of public services . This served to envision larger urban units, which turned over a new leaf in Turkish state spatial organization.

The ascendance of the Motherland Party to power in 1983 carried the agenda of market economy and decentralization with itself. With respect to decentralization, it should be highlighted that this agenda was not exclusively but substantially covered with *metropolitan* content. The rescaling policies and regulations of this period were undertaken for the sake of promoting democratization and economic efficiency. At this point, it is pertinent to slightly touch upon a vast and growing literature regarding the relationship between early and late capitalist countries in terms of implementations with their administrative and economic facets. Concerning the extent and nature of rescaling, the mainstream tendency is to put emphasis sheerly on the over-accumulation crisis of the former group of countries and their inclination towards other/new geographies. In the case of Turkey, being content with such focus could neglect the ascendant propulsion from maturing national capital groups for internationalization. This limited approach also amounts to neglect the decisive capacity of these propulsive forces in terms of rescaling (Ercan and O uz, 2006). Thus, Er state that the scale issue in Turkey can be traced through the intersections of these two groups: the international-advanced and the national-emergent (Ercan and O uz, 2006). In order to dep internal economic dimension of this discussion, attention is due to the emergent small and medium enterprises (SMEs) which focus mainly on labour intensive manufacturing businesses. Their fame as Anatolian Tigers proceeds from their success on transnational and retail ch expansion of their demands and increase of their negotiation capacities both contributed to the state rescaling process as they were configured as the soaring hubs of industrial gr the issue of rescaling and the positions and positionalities of the actors of these emergent cities, Jessop puts forward the concept of scalar forms of representation as an alternative political representation, namely parliamentarism, corporatism and clientelism (Jessop, 1990, pp. 119-121). In this sense, Brenner's statement is also illuminative: the prolifer approaches to urban governance represents a key expression and outcome of the place- and scale-specific types of state spatial projects and state spatial strategies that have been mobilized by post-Keynesian competition states. As such, entrepreneurial urban policies have been closely intertwined with contemporary processes of state rescaling. (Brenner, 2004, p. 177).

In that respect, the heading of Motherland Party towards decentralization could be interpreted as a complementary mechanism to its gravitation towards market economy. In the year of 1984, two-tiered metropolitan municipal structures were launched in Istanbul, Ankara, Izmir and district municipalities were initiated under their roofs in accordance with Law no. 3030 (Heper, 1987). By means of this law, the room of district municipalities to manoeuvre was restricted in extent, as they were put under the tutelage of Metropolitan Municipalities. Thus, the decentralization appeal became short of a board implementation and could only stretch out territorially and functionally from the centre to th Metropolitan level by disregarding the district level. Metropolitan municipalities and metropolitan mayors were turned into new-fangled formidable fortresses. They formed the novel *central configurations within locality* through their intimidating tutelage power and impressive revenue generation capacity by productive and unproductive methods. In other words, this decentralization attempt was a cautious one (Heper, 1987). As Erg der mentions, the state still governments on the scene with the intention of controlling the periphery rather than service delivery and democratization ( Erg der, 1987). This period also marks the begging of th

mayors equipped with ad-hoc duties and areas of action (Heper, 1987,p.55). Despite this, the monopoly of Ankara in terms of authority and resources remained as a prevalent and Danielson, 1985). In last instance, as municipal debts intensified, debt payments have almost gained a character of direct resource transfer to financial capital ( nal, 20 therein). This is critical to indicate the expansion of financial capital`s embeddedness to the municipal system and to show their prevalent mutual interdependencies. ( nal, 2009)

In the meantime, on January 1st 1996, the Customs Union Agreement with the European Union came into effect in Turkey. This marks a milestone not only for big business groups but also had a profound effect on small and medium sized enterprises of Anatolia. It includes provisions that elimination of tariffs on manufactured imports originated in the EU, the adopti policy toward third countries and the elimination of many of Turkey s exiti programs ( zar, 2009). These provisions have all served the purpose of inte markets with enormous reflections on state rescaling and the prominence of urban places. In December 1999, Turkey`s candidacy to the European Union was recognized by the European Council, while in October 2005, negotiations commenced (Tocci,2013).

The amendments merged under the title of the Turkish Public Administration Reform (2004), which remained on the top of the agenda from 2003 to 2006, can be considered as milestones in the Turkish rescaling process and are worth to take note. The Greater Municipality Law no. 5216 in 2004, the Municipality Law no. 5393 and the Provincial Administration Law no. 5302 in 2005 as well as the legislation enacted regulating the foundation of Regional Development Agencies in the NUTS-II areas in 2006 all fall under this reform package (Ata v and Erayd n, 2011; Y lmaz an

With this scenario in the background, and a couple of decades after the initial law on Metropolitan Munipalities, Law no. 5216 was enacted in 2004 concerning metropolitan municipalities. Under this law, the issue of district municipalities and their confined role and underprivileged position in terms of income-sharing remained (O uz and S nmez, 2014). Four years later, in 2008, by no. 5747, changes were issued regarding first-level municipalities under metropolitan municipality boundaries. Additionally, the scale of Metropolitan municipalities was amended. Leaving functionality out of the scope of required conditions and relying on the 750.000 inhabitants to form a metropolitan municipality under Law no. 5216 also faced criticisms. Furthermore, this law was still destitute of the tenets and norms regulating the means of public participation. The non-existence of arrangements on public participation is in contradiction with its initial purpose, which originally set forth to be closer to the public. (O uz and S nmez, 2014). Certain allegations and reservations exist regarding the award of the metropolitan title to the municipal units whom voted for the political party at power in previous elections. Besides, it also led to criticisms by allegations of gerrymandering. Also, reform initiatives altered the population criteria for municipalities and reduced the threshold from 5000 to 2000 inhabitants. In the sequel of this regulation, municipalities with a population below 2000 were disincorporated in 2008. Yet again, this exemplifies the motivation subservient to generating economies of scale in delivering services. (Y lmaz and G ner, 2013)

## The Evaluation of State Rescaling in Relation to the Law No. 6360: The Case of Villages

Turkey`s current rescaling report takes up a new position with its proposed severances from well-established and historic settings. One striking example is the disincorporation of the village entities under all Metropolitan Municipalities, including both the former and recent Metropolitan epithet entitled ones. It alters not only the political and economic structure but also the social and physiological mould of citizens. Even considering the fact that Turkey is urban-biased in terms of countless measures and perceptions, the metaphor of village still remains adamantine in national

psyche. That is to say that the village unit is still weighty as a founding component of identity ( zt 2012).

In his interview for the Marxism and The Question of Scale issue of the Tur concerning the fading prominence of neighbourhood and village/countryside formations and patterns within developed countries, Jamie Gough clearly states that under current conditions, just a limited extent of daily social, political and economic interactions and socializations occur within such small-scale settlements. Gough relates this issue with the decisiveness of qualitative distances which could contain interdependencies and enable forms of societal cooperation for generating the reproduction of labour and capital. This enabling congruent size also forms the required scalar-level through which the state could intervene (Gough, 2006). Turkey, with its endeavour to become a developed country, has also been adopting similar legal, administrative and economic initiations which are worth to elaborate on.

There are numerous motivations behind the ceasing of village s legal entity where agricultural a concentrates and rural populations dwell. In the aftermath of 1980s, heading towards export-oriented strategies with the integration of low technology and labour intensive production exposed the need for low waged or clandestine workers (B l kba ,2012 and references therin). In the mea population of rural areas begun to face decline due to both dissolution of the agricultural sector and\or internal displacement due to security reasons. Thus, without much option, rural/village communities became suited to this worker role with minimum salaries and informal employment. Meanwhile, the gradual entry of companies to the agricultural sector has also generated a change in rural reality by contracting of agricultural labour (B l kba , 2012) In that respect, it pertinent to mention about gradual and on-going process of de-agrarianization in conjuncti de-peasantization in Turkey. It is not wrong to claim that rescaling as a too boosting these two interpenetrated processes. To be more precise, de-agrarianization as a process stands for a gradual occupational (re)orientation, income source modification, estrangement from the agricultural mode of livelihood as a dominant way of making a living and drifting apart from the rural places (Bryceson et al.2000, Ayd n, 2009). Ultimately, this dwindling demographic trend, due to a waning economic capacity, caused the de-peasanization as a derivative of the de-agrarianization process (Ayd n, 2009). The former and the latter processes rescaling by causal and correlational relationships.

A critical reading certain articles of Law 6360, issued on 12 November 2012, with its concurrent and deep-seated fallouts in political, social and economic spheres is a must. scholars, the amendments made to the constitutionally guaranteed legal entity status of the village are problematic and can even be considered as unconstitutional. G zler states t amendment is compulsory to readjust the status of villages. (G zler, 2013,) Within the borders metropolitan cities, newly designated or not, Law 6360 envisages the termination of the legal entity of villages by converting them into neighbourhoods with no legal entity Under the constitution, villages are public corporate bodies established to meet the common local needs o (Constitutional Article No.127). Thus, one needs to bear in mind that the needs of village inhabitants differ from the needs of neighbourhood, district and metropolitan municipality inhabitants. In the cases where necessary measures are not taken, casting the responsibility towards upper level units would be unfeasible under current circumstances. More importantly, ceasing the legal entity of villages forces them to desist from the right of litigation for claiming their rights in case of discontent with the policies and decisions regarding their civic life At the same time, it puts village communities into a relatively passive position as they can no longer lean on their own capability to respond for their needs and necessities, meaning they might have to wait for the services rendered by the municipality.( G zler, 2013)

On the other hand, the law states that erstwhile granted rights on meadows, quarters to the villages are transferred to the neighbourhoods which they evolve into Article:16),This is problematic in the sense that transferring rights is not enough to make village/rural people avail of these rights as the inhabitants lost their right to sue due villages legal status. It is also important to note that the status of police and gendarmerie forces is estimated to undergo a change within villages. According to Law No: 2803, Article: 10 (Gendarmerie Organization, Duties and Authorities), the areas within provincial and district borders fall into the responsibility of police forces whereas in the areas falling outside these jurisdictions, the gendarmerie is entitled as responsible. However, Law 6360 leaves no area out ; as municipal borders overlap wi provincial borders, it could be interpreted that police forces will be incumbent on all areas within the jurisdiction of the Metropolitan territory. This might create a need for rearranging the tools, organizational capacity and structure of police forces while a change might also be necessitated in the areal deployment of the gendarmerie forces. Considering the Turkish rescaling experience solely through this aspect of village rearrangements is sufficient to indicate that it is hard to naively underestimate the state s role within rescaling process. (G zler, 2013)In tha perspective is explanatory: the state has the monopoly of the legitimate u enforcement of its order (Weber, 1918). Thus, the state is the only entity capable to adjust the guardian forces of the reorganized sub-state units.

Another issue is that the dissolution of the legal entities of villages would be disputable in terms of ecological concerns and identity politics. Duru states that although the enforcement of Law 6360 granted the groups who have been internally dislocated due to security concerns (namely Kurdish communities) a right to return to their earlier abandoned villages, it beca fact that their villages were disincorporated. Even though the Village Law of early Republican times - still in effect - is equipped with pioneering tenets, those were sacrificed for the sake of unity and integrity reflexes during Republican times with certain exceptional periods. For instance, during the legislation process of the Village Law No. 442 (the year of 1924), the deputy o is crucial to decentralize beyond the province level; only if further decentralization is realized could it be possible to prove the intimate intention of founding a regime on behalf of t Although this is a quotation from early Republican discussions, decentralizing *beyond the province* still maintains its importance in the Turkish political and administrative scene considering the fact that metropolitan administrations have become the symbols of centralization within 2012)

From an economic perspective, the motivations behind the alteration of villages legal status can be elaborately explained in reference to the theories, discourses and debates commons , primitive accumulation and accumulation by dispossession .(Harvey current situation, meadows, pastures, winter quarters, grasslands and rivers within urban areas have already been depleted under utilization, whereas in rural areas, there are still common areas and fields allotted by laws to villages or municipalities that have remained quite untouched. Even though the orthodox Marxist discourse claims that the dispossession of commons as a phenomenon precedes the capitalist development, Massimmo De Angelis asserts that the processual implementation of both the separation of people from their means of production and the enclosure of commons are embedded in all stages of capitalism, including today s form. Thus, rather than being a periodically-c phenomenon or a precondition for capitalist development, the new enclosures as the encroachment of land, water resources and rural livelihoods for the sake of industries, energy infrastructures, real estate developments and for other development projects and purposes. In case counter measures are not designated, it is not far-fetched to claim that these processes could have conduced to poverty, migration and criminalization and therefore bear risks for the future. (De Angelis and Stavrides, e-flux)The states legitimize these processes by putting forward their developmental stance or by relying on the concept of the tragedy of the commons . The latter conce

Gerrit Hardin in 1968, is based on the belief that to make common resources sustainable, either privatization or direct state inclusion is necessary.

From his point of view, it could be assumed that Turkish villages are experiencing the compound of enclosure of commons; the enforcement of disincorporation of villages legal en the *magnum opus* of this process. The motivation behind rescaling towards larger units at the expense of small and historical components can be understood by employing the primitive accumulation practices studied by Harvey. As briefly stated above, these practices may include commodification and privatization of natural resources in their entirety; the land, streams and labour power are at bull`s eye. The amendments made to property rights by converting common and collective ownerships into exclusive private property rights , the elimination of indigenous methods by schemes and the transcription of debt and credit systems fall under this conception. There is no doubt that Turkey is not an exception, but a representative element of the set of applications (Harvey, 2009).

To ponder upon the notion of dispossession, MacPherson points out the acclaimed indissoluble bound between the individual and possession: there is no possession of property if (MacPherson, 1962). Hence the presence and absence of a person binds upon the condition of being a man of property . In this sense, Butler presents the essence of dispossessed ensuing derivative condition of enforced deprivation of land, rights, likeliho belonging (Butler, 2013, p. 5). Butler takes one step further to crystallize the functionality of dispossession which is critical for interpreting post-dispossession beneficiaries and losers/payers. In her words, *dispossession works as an authoritative often paternalistic apparatus of controlling, appropriating the spatiality, mobility, affectivity, potentiality and relationalitly of (neo)colonized subjects* (Butler, 2013, p. 5) Moreover, Butler states that the political fibre is converted into technocratic, corporate and post-political governance at the expense of hist components (Butler, 2013, p.40).

In parallel, 10th Development Plan of Turkey for the years of 2014-2018, under Article 898 envisages that metropolitan areas will henceforth be entitled as responsible for the rural areas. This rearrangement is believed to have the potential to contribute to the development of Turkey, generating high commitments and expectations. Official documents pledge that the spread of urbanization could bring solutions to problems of technical and humane capacities, quality standards and productivity (10th Development Plan 2014-2018). On that note, Article:914 of 10th Development Plan predicts that in the year 2018, the urbanization rate might reach 76.4 per cent in Turkey. Putting the rural-urban dichotomy and urban limits discussions aside, it should be noted that if this rate is reached, it will not be as a result of free-will nor of an evolutive trend.

Within this context, Turkey is experiencing two confounding situations at the same time. On the one hand envisaging the one single blueprint for all metropolitan municipalities by solely relying on the population criteria neglects the complex and locally variable nature of the development issue. On the other hand, disincorporation of villages under Metropolitan Municipalities while leaving villages under other cities as they are has caused duality and discord across the coun have the potential to cause problems for the status of villages and equality before the law.(Duru, 2012)

There exist widely-accepted assumptions and certain reported facts that, more fragmented local units could hamper service delivery and foment troubles for reaching collective decisions. Besides, more fragmented formations are also not favoured due to claims that their structure is relatively higher cost-generating than the systems composed of large-scale sub-state units with no further sub-level ramifications (Pagano, 2013, pp. 37, 114). However, it is neglected that transformations in this direction bear the high risk of serving the sake of built-environment`s suppression on natural

environment. Thus, ceasing the legal entity of villages under a Metropolitan municipality could be comprehended as an *outcome* of preceding resolutions rather than being a *motive* for future contemplations to succeed development. As Duru proposes, this could be perceived as the outcome of the pursuance of lands and natural resources` commodification for further construction, infrastructure and development purposes (Duru, 2013). Additionally, there is also apparent anxiety regarding how villagers might respond to estate taxes in the sequel of the five years of legal exception granted to them (G zler, 2013). Backing up village communities in socio-economic terms appears a order not to sacrifice them by adding new burdens onto their shoulders.

The current condition is not the debut of urbanization without cities (Duru, in Turkey. Quite the contrary, urbanization in Turkey has had a long-established history of urbanization without industrialization , as Erman defines, which indicates th the urbanization experience of Europe and Turkey. The former came along as a derivative of industrialization whereas the latter ensued that the intervention of the agricultural sector, which rendered the vast number of communities in rural places redundant. Yet again, the imposition of the (metropolitan) *model* to cities and the recognition of urban places and local entrepreneurs as able to generate production capacities and economic boom proves that the tradition of effect relationship concerning urbanization and industrialization prevails in the Turkish experience (Erman, 2012).

Still, it is not surprising that the cities converted into metropolitan municipalities pretty much greeted their new status with happiness. In this regard, the image of metropolis in determinant, given the fact that particularly Ankara, Istanbul and Izmir are considered the Turkish equivalent to the land of opportunity (Erman, 2012). Nevertheless, this could a na ve imposed and/or self-persuasion at least in the short term prospect. It is also worth to note that a townsman has always been considered as being inventive and contributing to the wellbeing of the country while the metaphor of living in a metropolis has been enough to be gratified (Erman, 2012 and references therein).

It is significant to note that, as the legal status of 29 provincial local governments, 1.591 municipalities and 16.082 villages were altered, it would be pertinent to consult the local public consent by means of a referendum. This would fall in line with Turkey`s commitments to the European Charter of Local Self Governance, under which Article. 5 articulates on the protection of loca that changes in local authority boundaries shall not be made without prior co communities concerned, possibly by means of a referendum where this is permitted by statute. pursuance of such approach would also comply with Turkey`s recent undertakings for further democratization and its prospective democratization agenda. Besides, if Turkey is committed to green development in line with the European Union candidacy prospectus, one of the fulcrums is engendering participation and self-determination, which requires taking all measures to guarantee the participatory approach. As Adams (1992) stated greenness of development is to concern with ecology or environment per se, but in its concern with control, power and self-determination (Adams, 1992, p. xiii; Arsel and Adaman, 2012, p. 317).

## Conclusion

Turkey, in its official rhetoric, puts forward diverse political and economic motives for its course of action to explicate and contextualize its rescaling venture. In that sense, it is pertinent to touch upon the achieved and failed fields. It should be noted that rescaling applications have been undertaken to tackle corruption. However in February 2014, Transparency International called attention to the issue of the accountability of politicians and the transparency of their relations w in times when lucrative construction contracts are brought to the table. Strengthening th

mayors in consequence of the rescaling process and failing to care for the necessary precautions properly to prevent corruption might lead detrimental results. (Transperancy International, 2014)

In 2010, nder and zy ld r m put forth a paradoxical display of the state regional development. According to their findings, state-owned banks make more positive contributions to developed regions through the means of credits when compared to less developed ones while private bank credits have equal contribution to GDP (Gross Domestic Product) of both developed and the less developed regions. In the last instance, their study su their purpose of existence state-owned banks did not reduce economic disparity among Turkish provinces ( nder and zy ld r m, 2010, p. 975). Taking the findings of this role of efficient allocation of financial capital, it could be estimated that reconsidering the priorities and conditions for credit extension in the banking sector could have a constructive effect on less developed regions.

On the other hand, pushing for alternative proposals should also be promoted. Brenner, in his commentary on Lefebvre's autogestion , reveals how dissenting and confrontin parties, civil society members and communities all sing the same hymn sheet concerning rescaling and decentralization. (Brenner, 2001, p.789 and references therein). In that sense, being incapable to propose any alternative options causes deadlock in the social, political and economic spheres which could be summed up as the perils of consensus .( Rodrik, 2014)

Within the context of rescaling, it is also critical to discuss how the participation is presented as a heroic recipe not only for development and democratization but also to boost investme other hand, giving credence to the myth of a single, indivisible local community acting in concert is na ve (Cleaver, 2001, p. 44). The recurrently stated expectations from partic the procedural and technical means (as only these means deemed appropriate) for civic engagement to the process while precluding the ways of radical or critical engagement. In that sense, participation is limited within proposed and permitted methods which are mostly individualized and depoliticized. As an example, public availability sessions for hydroelectric power plants projects are allowed while other patterns of participation are mostly condemned to be underwhelmed (Cleaver, 2001).

It is also critical to lay the way open for local actors and their actions to address *non-local* subjects, affairs, situations and the concepts. Local actors should be promoted to address the issues transcending their respective localities. Only in the cases where local appeals go beyond the range and limits of locality by overarching issues such as feminism, anti-capitalism and anti-imperialism can the signs of upturn and progress in social, political and economic spheres. (Kothari, 2001, p. 166). Concerning the social movements, and much like with a compass, it is essential to keep one foot with a strong support foothold on locality while allowing the other to draw across the upper-tiers. Thus, it is important to note that social movements strategically and discursively construct and refra Sandberg and Gilbert, 2009 p. 249) This illustrates that even for peasant movements success, having claims transcend to the spheres of the states and elites is fundamental. (O Brien and Li, 2006, p.2; Borras, 2008, pp. 282-283)However, it is crucial to remember that in order to make use of the latter strategy it is necessary to preserve the competence of the local socio-political core, which in the Turkish example corresponds to villages. Finally, it is cardinal to note that although the narratives of hyper-mobility, globalization, and multi-level governance command the various spheres of life, people still live in localized contexts and with predominantly local-scale sets of re interactions (De Filippis, 2001, p. 368).

The rescaling process has become a potent symbol that entitles power to certain groups and classes while concurrently incapacitating the others, ultimately generating winners and losers (Miller, 2009; Y lmaz 2006). This process mostly results in a greater size and degree of control on human ca

other potentialities attached to a particular locality for the winning group sense, Lefebvre's notion of autogestion, which proposes the affirmation of gr an on-going limitless project at all geographical scales and within all sectors of social and political life including state institutions themselves , could be put forward (Brenner, 200 embracing tenet could be enriching for any country as such an approach is not limited in duration, as in the case of development plans or reform packages, and is not confined by a deadline, as encountered in accession schemes.

# EXPLORING ALTERNATIVE METHODOLOGIES OF SPATIAL PLANING IN WESTERN BALKANS

The case of Albania 2030 National Strategic Visioning

By: Prof.Dr. Besnik Aliaj[1], Doc. Sotir Dhamo[2], MSc. Eranda Janku[3]

## ABSTRACT

*One of the biggest challenges of our country still remains the consideration of urban planning as a management tool for controlling the development, in order to achieve territorial, social and economic cohesions. The transition from a centrally planned economy, where everything was controlled by the government, towards decentralization and market economy caused many consequences, among which uncontrolled and fragmented urban development, loss of agricultural land due to urbanization, concentration of population and dense urbanization in the major cities, abandonment of western lowland and eastern parts of the country etc.*

*This research work tries to build against the vacuum that is created in Albania by the lack of tradition of national spatial development policies and plans, on the conditions of market economy and freedom. Previous elements of national visioning have not been sustainable in the long run, due to the fact that they have been imposed by authoritarian means and not understood as a real need of the country and society, facing growing competition among nations at global scale, and the need for creative solution, facing economic recession and waste of national resources. Therefore this work is a modest practical and theoretical contribution for Albania with a hope that could be useful also for the Albanian authorities, while undertaking action at such level. In return the Albanian case of national spatial visioning might serve as an interesting learning laboratory for the new science of spatial planning in Europe and beyond.*

## INTRODUCTION:

### Albania: Urban Development Models 1945-1990:

From the beginning of the 90s Albania was one of the most centralized planned economies, where government practically owned everything and controlled all forms of territorial developments. Two main criteria characterized the urban development and the whole process and structure of urbanization in the country: the combination of concentration and centrality (Aliaj, 2003, Making Cities Wor
The main planning instrument during this period was the so-called Regulatory Plan for living urban areas, which was very rigid and did nothing more than showing where and what was the use of each building, with very poor appliance of architectural standards. Even though an official national spatial plan was still not to be mentioned, the interventions and policies taken by the authorities of the time were somehow the first steps toward a national spatial planning conception. Although, this was done on the basis of top-down principles and centralizing objectives. This was represented by the government s aims on the economy of the country, which were directly related with territoria and development. The government s top aims were to set-up and prioritize the development

industries. Based on this economic policy, the main principle for taking the decisions in relation with the industrial allocation, were by setting up these industries nearby raw-material and thermo-energy sources, as well as near the consumption centers, which in most of the cases was followed with the foundation of new industrial cities. On this context the main priorities of the government of the time were to ensure the harmonious development of industry and agriculture, in favor of the general progress of the countryside, and the support of the intensification of agricultural production. Related to this last intervention, the government aimed to use it as a barrier for preventing urbanization. Authorities neither wanted, neither could afford quick urbanization and its consequences. But this accumulated and exploded after the 80s. Meanwhile before this period the go improve the living conditions in less-favored agricultural areas, and to concentrate the resources in well-suited regions of high productivity, in order to keep the population there and occupied with the agricultural activities. But during the 80s the sustainability of such centralized spatia system collapsed totally.

Figure 1: Urban Development models 1945-1990

**Albania: Transition of Planing System 1991-2014**

From the beginning of the 90s Albania became a more open and a democratic country, so on the following years the Albanian Parliament approved two planning laws, namely Laws of Urbanism No. 7693 (1993) and No. 8405 (1998), which changed many times on the later years. Both these laws presented the general regulations for the development, location and architecture of the structures, based on the land use. Even though the second law made some new changes and improvements compared to the first one, it still didn t succeed on recognizing the recent changes of the territory informal developments and the ownership transference, from the state to the private sector, otherwise known as the privatization process . Therefore, yet, failing to set national spatial planning an development objectives. However it must be specified that until 2006 territorial planning in Albania

was mainly based on the tradition of the so called Urbanism, with culture of authoritarian planning, mainly with physical objectives. In 2006 the government decided to reform legislation and move towards more abstract rules and principles of decision making related with spatial planning, regional planning and national policies, influenced by two main forces: (i) the bottom up pressure coming from the local initiatives, mainly represented by Co-Plan, Institute for Habitat Development, a local NGO inspired by the Dutch Planning Schools; (ii) and political influence of the international partners/donors in Albania, mainly represented by the development assistance programs like World Bank, UNDP and USAID, and the Dutch and Austrian Technical Assistance in Albania. The 2006 Legalization Reform, for the first time articulated the term Spatial Planning, but despite the recognition of such need, no Spatial Plan was draf policy document was drafted, but never turned into a legal document and a spatial plan. Furthermore, capacity building programs did not associate the initiative, in order to prepare the un-experienced local/regional governments, which were not yet able and trained to cope with the new spatial concepts (Toto, 2012).

However, despite the new reform law, which was approved by the parliament, in 2007 a law for the formalization and integration of the informal settlements in Albania was approved, also associated by a process of self-declaration of the informal constructions. In addition, a national aerial survey, and the respective GIS applications developed into a national system, including a national registry of planning initiatives and development permits. In 2009 the parliament approved the new Territ Planning law, which was a framework law for emerging spatial planning concepts and developm processes, but it was still very detailed on some other aspects, and its implementation was totally depended by the relevant bylaws and specific regulations, which were yet not fully completed. It s also important to recognize that the present Territorial Planning Law is a legal instrument, which brought new spatial development concepts and practices in comparison to the previous laws. These new concepts amongst other include the introduction of new compulsory development instruments such as the detailed local instrument/ plan (Albanian: PDV/ IDV); in order to avoid the plot based development and allow for the transference of development rights; etc. Few changes were made to this law for electoral purposes during 2013, but there still remain the same concepts for territorial planning law for Albania (Toto, 2010). On 2014 the new government has initiated the reform for the administrative and territorial reorganization of the country, which started with proposals to consolidate existing local governments and reorganize regions. So far the government has been on favor of the proposal with the 35-47 LGU and there is still no decision made regarding the reorganization of the country in regions, although several proposals have been taken in consideration. However it is very important to mention the three main priorities that the government has: (1) drafting the National Plan of Albania; (2) drafting the Integrated Coastal Zones, (3) drafting the Durrana Plan.

As a conclusion, after the changes of early 90s till now-days, Albania practically shifted to an extreme. It has been one of the most liberal economies of the former Eastern Europe, with practically no spatial planning policies and no control of authorities over the territory. Despite several attempts to reform the planning legislation, almost nothing has been working on the ground level, especially at national scale. In spite of efforts made over the last decades, territorial development and administration still remain misunderstood by professionals and mishandled by politicians. (Aliaj, Dhamo, Shutina, 2010). The planning system will continue to go into further changes, because of

regular political changes and economic recession. Therefore its instability will remain a main issue for the coming years, until a balance is reached from inertial pressures of transitional developments. However the big urbanization and construction boom, as well as consequences of informality are becoming at ease, thanks to the relatively small size of the country and completion of urbanization as well.

**Planning Problems and Consequences:**

During the last 20 years the so considered traditional urbanism , in the sense of strict ap the principles of codes and distances , has become more a kind of administrative corruptive over-exploitation and densification of land, rather than an urban management tool. People have taken matters into their own hands, undertaking extreme individualistic solutions, and aiming to avoid inflated prices and often corrupt procedures of public administration (Aliaj, Dhamo, Shutina, 2010). So in the overall, this led to chaotic initiatives and informality, which spread all over the country. Practically 90% of businesses and 80% of properties are considered to have at least certain degree of informality (Albanian Government, ILD Peru/UNDP, 2007). This resulted in serious environmental concerns, development of an arbitrary property system, over-densification of the main living centers, and loss of agricultural land. Therefore, efforts of spatial planning, especially at the urban scale have been failing, among others, because of the lack of planning instruments and lack of national/regional visioning, as well as confusion among different ministries over such competency. Such a radical process of changes has been promoting further urbanization and displacements/changes of economic structures, while threatening irreplaceable spatial and natural potentials of the country.

**New Territorial Realities and Challenges**

On these conditions, Albania met with a new reality over its territory at the brink of EU accession. According to the latest INSTAT, Population and Housing Census of 2011, peripheral regions in the north and south of Albania have been nearly abandoned, while the central and western ones, although have been more dynamic on the urban growth perspective, they still have not kept apace with population growth. Whereas the population has tripled in the capital region, and developed land has doubled without proper physical and social infrastructure, thereby creating a problematic urban model (Aliaj, Dhamo, Shutina, 2010). This in return harms future development of the country, especially high expectations on tourism, agriculture and energy developments (Aliaj, 2008). On top of that, more than 2 decades after the social-political changes of early 90-s, Albanian administration has not been able yet to develop and approve a spatial vision at the national scale, not mentioning the total lack of professional capacities on the way this vision must develop and be visually represented. This consequently harms economic growth and prosperity and is worsened by the failure of authorities in establishing a stable property registration system, and fair property restitution inherited by the past. Authorities need to also learn how to formulate understandable policies and translate them properly into policy and cartographic representations, in order to ease their implementation and easily address them to their aimed institutions and audience. So far no one has been contributing to these aspects, so it s crucial to work on both directions: the instruments of visioning and techniques of visualizing. includes the use of statistical basis, with a constructive dose of creativity , in order to synthesize and reach to aimed trend-scenarios and proposals regarding the national economic, environmental and spatial development.

In conclusion, despite the fact that Albania has entered a radical and quick process of change, and that there has been a combination of a set of inherited problems, it must be emphasized that the lack of national spatial development policies and plans has been seriously harming the sustainable growth of the country. This is a result of both, lack of understanding at political/ decision-making levels, as well as poor professional capacities at specialized institutions. Therefore the sustainability of future growth and the solution of the accumulated problems need now a qualitative jump at strategic level. The drafting and implementation of a national spatial development plan is considered as the next strategic step to be undertaken by Albania, to adapt to the standards of the EU family.

**Research Proposal & Aims:**

National governments in some countries, take the lead in creating a proactive and integrative spatial planning system that can encourage investment and facilitate more sustainable development *(Alterman, 2001; European Commission, 1997).* Indeed it is a common fact for most of the Southeastern European countries (including Albania) that lack of such initiative, results nowadays in sufferings from chaotic growth and informal developments manifested in sprawl of urbanization. Inspired by the Albanian context and its need for future sustainable development, this thesis project aims to help on drafting a series of national spatial concepts, which will be used to formulate an overall national spatial development vision for the territorial development. Since there is a lack of understanding of planning policies regarding the poor communication and poor cartographic language, which also affects their implementation, the product of this research paper will be followed also by some guidelines on how to make a proper and understandable translation, through the presentation of a set of recommendations and principles, the introduction of a spatial development vision and the visualization all of these documents with respective cartographic material.

**Methodology**

So far, there has been no research work done to address or support the creation of a spatial development vision for Albania, so it was quite essential to first start the work with the observation of other cases, where spatial development policies have been implemented. In order to collect this information, the work was based on two types of research methods:

- Field study (interviews, group discussions, meetings, conferences, etc. also considered as primary data);
- Reading and reviewing of local/international reports and literature (secondary data);

The revision of the specialized literature on the applied spatial policies in the EU countries and other cases, which are leading on this aspect, gave input on learning how spatial planning works, and how to apply it on our context. At this point, evidencing the progress of such debate on the national scale, by interviewing key-stakeholders, professionals and decision makers was very crucial. An integral part of this phase was also the participation in conferences, workshops and meetings organized in Albania on this subject, or related issues, on the framework of EU integration of the country, and national spatial development policy related. The reading and reviewing of local/international reports and literature, was particularly important for identifying the international efforts made on this subject. Regarding the Albanian situation related with this topic, despite the published written materials, there were also two main local sources that provided the necessary information: (i) *Statistical instruments*

from the official data since the 1990 s; especially the 2001 and 2011 popul censuses; (ii) *Maps and areal images* before the 90s and up to date, especially the maps of during late 80-s of the *National Institute of Military Topography* ; and the national areal surve during legalization process undertaken by ALUIZNI (albinfo.al).

**A NATIONAL SPATIAL DEVELOPMENT VISION FOR ALBANIA**

Developing a national spatial vision and formulating spatial concepts in a context like Albania, on which no previous attempts have been made, and planning has not been working, makes it challenging. It s very important to take into the account the fact that during the economy, territorial policies aimed mainly at agricultural purposes, while anti-urban policies were regular practices in the country. On top of such tradition, during the last 2 decades Albania was also pushed by the international partners towards an assistance, which aimed the use of agricultural potentials and natural resources (like energy and mining). Practically at this moment are considered only development issues of agriculture, forestry and tourism, but they have not been fully addressed and considered, as a complete set of potentials. Let alone they were never seen interrelated with the urbanization process. At this point, the national spatial development vision should address specifically such issues, formulating policies and related spatial concepts for protecting and using them properly, in order to provide territorial, social, economic and sustainable development. At this point working on the basis of ecological planning concepts, which offer practical blueprint for relationship between the built environment and nature, is quite essential *(Ian McHarg, 1969).* On the other hand, having put to practice the comparative planning theory (Faludi, 19 and helpful.

**Issues to address on a national scale -** In order to establish a national spatial vision one might address several critical issues:

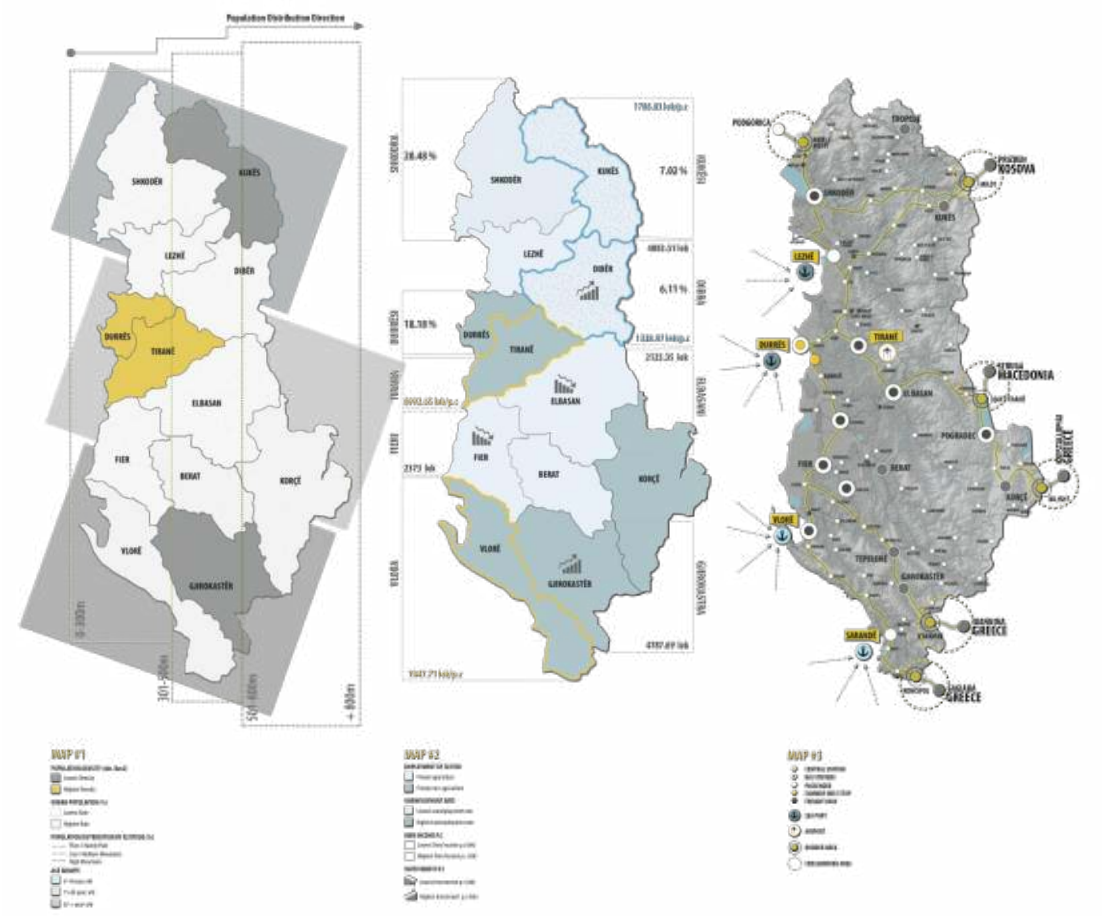
- The need to establish a good system of statistical database, based on the same indicators, which can allow professionals and decision makers to make research and on that basis to take the right decisions to address existing problems;
- In order to establish a long term spatial system is necessary to establish also good geographical information systems, which allows drawing different graphical outcomes, which are helping better management of territorial and spatial potentials.
- The national planning legislation and procedures must encourage and enforce the design and implementation of national visions, which serve as an instrument for central, regional and local governments for good spatial governance.
- Therefore the planning practice needs also to have a school and tradition on how to draft, design a national spatial plan, on basis of well accepted technical and graphical tools. This is important because professionals at national scale and decision makers must establish a common language and understanding of such instrument.
- Last but not least the spatial plan at national scale must be associated with sub plans of spatial importance for the country, which treat in details sectorial issues like: national trunk infrastructure plans, land use plans, environmental and sustainable development plans, social economic development plans etc. However it does not mean that the importance of spatial national plan can overshadow the importance of planning at other levels of planning (regional and local), because a

combination and complementation of planning tools at three levels, can be the only solution for a long term sustainable development and positive social economic growth.

**Context analysis -** In order to start setting up a set of principles and then visioning, is very important to understand the context in Albania, regarding the social-economic-and territorial components. The research work took in consideration several main indicators for each interest field, and for each group of analysis there was made a synthesis with conclusions (more detailed information on part 1 of the annexes).

- The Social Development
- The population density is higher on the central parts of the country, mainly in the metropolitan area;
- Based on the altitude, the population distribution increases from the low plain areas (0-300m) towards the low and medium mountainous (301-800), and the high mountains of over 800m;
- The urban population is higher mainly on the central and southern parts of the country;
- According to the age groups, the group of 15-64 years old dominates in the whole country, but however the higher rate of 0-14 years is more accurate on the northern regions, while the higher rate of 15-64 years on the central parts, and the last group of over 64 years old has a higher rate on the southern regions.

- The Economic Development
- The population of the south-west and the metropolitan area works mainly on the non-agricultural activities;
- These areas have also the highest rates of own income;
- Meanwhile the highest rate of investments p.c is mainly on the north-east and south-east areas (which are poorer, but with touristic, landscape and cross border cooperation potentials);
- Unemployment is higher on the north-west (agricultural and touristic values), and lower on the northeast areas.
-
- The Territorial Development
- Sea ports play a crucial role on the import/export of goods and also on the touristic flows;
- From these focal points the main national roads distribute the flows (of goods or/and people) towards the other parts of the country, where the metropolitan area, the seaside west and south and the mountainous north and south are the most famous ones; the central inlands of the country are more abandoned, less developed and not well integrated with the rest of the country;
- The railway system could play a crucial role on connecting the less developed areas, but this infrastructural system is outdated and old, and does not play its role properly;
- The cross border areas are very important, because of the activity they generate and the opportunities they present for both parts of the territory, Albanian and/or not.



Map 1: Social, Economic and Territorial Development Profiles of Albania

**Set of Principles -** The formulation of a spatial vision for Albania needs to be supported by a set of principles, which build on existing potentials and ensure sustainable development. These principles will be then explained and translated through a series of spatial concepts.

1. Regionalism

Based on the foundation of regions of different importance within a country, which consists on the creation and implementation of institutions that express a particular identity and shape collective action within a geographic region, and also as a political ideology that focuses on the interests of a particular region or group of regions, whether traditional or formal.

2. Polycentrism and Growth Poles:

- Polycentrism, based on the theory of Palmiro Togliatti refers to the organization of a region around several political, social or financial centers. A county is said to be polycentric if its population is distributed almost evenly among several centers in different parts of the county.
- The central idea of the growth poles theory is that economic development, or growth, is not uniform over an entire region, but instead takes place around a specific pole, or cluster (Rodrigue, Comtois, Slack, 2013).

3. Development Corridors and Free Economic Areas:

- Development Corridors provide connections between different nodes or hubs of urbanized and economic agents along a defined geography, and they work as a system, or in terms of the network effects, that they include.
- Free Economic Areas refers to designate areas, well equipped with infrastructure and services, in which companies are taxed very lightly, or not at all in order to encourage economic activity.

4. Sustainable Development through the consideration of Natural Potentials and Green Corridors

- Sustainable Development stands for a good balance between the three components economy-environment- society, and promotes the preservation of natural and cultural heritage on long terms.
- On the other hand green corridors represent areas of habitat, which connect wildlife populations separated as a result of urban development and human activities.
- On this last principle is very important to also consider the ecological component that stands for those planning concepts, which will ensure a healthier relationship between the built environment and nature (McHarg, 1969).

**Albania 2030, a Spatial Vision for the Country -** Albania 2030 describes the development policies for the coming 15 years, based on the growth scenario of the four main economic pillars: tourism, agriculture, energy and mining. This is achieved by taking in consideration several spatial instruments, including:

- Controlling the growth of urban centers against sprawl and informality, by consolidating urbanized areas, metropolitan regions and complementary urban centers;
- Identification of industrial and economic priority areas to support employment and economic growth;
- Increasing the regional competitiveness of the country by strengthening the international hub, national and regional networks and regional gateways;
- Identification and completion of national and regional importance infrastructure of roads, sea ports, airports and energy;
- Identification of 6 main regions of the country which are specialized based on their social-economic resources;
- Identification and strengthening of polycentric and cross border regions, growth poles and free economic areas, aiming to establish a new economic model which is based on a better regional balance and corrects the effects of radical urbanization, disparities and segregation;
- A special focus on environmental issues and sustainable development by identifying projects of hotspots rehabilitation, protection of forestry and green space, extension and consolidat Albania ;
- Recognition and cultivation of the big potentials of the country as regarding landscaping, historical and natural routes, eco-tourism etc.;
- Achieving national development goals by considering with special importance the neighboring Albanian speaking territories as well as coordinating with western Balkans and Adriatic sea region, not forgetting the process of EU integration;
- Improving the social-economic efficiency and effectiveness by providing integrated and equal access between the center and periphery based on a ring radial system. Therefore achieving an important

objective, transforming Albania from an isolated economy, on a regional and European actor of economy.

## CONCLUSIONS AND RECOMMENDATIONS

**Conclusions -** This research has been dealing with spatial planning and its role to boost social-economic growth of the country. The problem is that Albania so far has not been able to develop a document that has the full meaning and role of a national spatial development plan. On the other hand EU, which is the political objective of Albania, has not imposed a law on territorial issues and a directive, because this is considered an exclusive function of the national authorities of each country. But EU has introduced its own perspective (ESDP) on this subject and has established a network like ESPON, which is trying to use the statistical data produced by each country and by the EU institutions to analyze, research and draw conclusions that help policy making and decision makers take the appropriate decision for the best use of national territory and resources in accordance to national and European interests. At the end a spatial development plan must be an instrument for better governance and better quality of life for people and communities.

- As a first conclusion we can say that nowadays, when European integration is a national priority for Albania, spatial development also becomes a priority issue. And when we talk about spatial planning we mean a key instrument for establishing long-term, sustainable frameworks for ***social***, ***territorial*** and ***economic*** development, both within and between countries (UNECE, 2008).
- A second conclusion is that spatial planning although highly praised, it s rela very few countries implemented it in the real meaning that it has.
- A third conclusion is understating what are the visualization techniques and graphical instruments of representation to prepare the cartographic data of the national spatial plan. Since many countries have features of national spatial planning policies, but there is no common ground for the their translation into cartographic documents for the broader public, building a common reference system of visualization manners is quite essential.
- The fourth conclusion is that in order to develop a national spatial development vision for the country is necessary to refer to several scientific arguments. Throughout the context analysis and case studies four main principles were considered as crucial for the national spatial visioning. Each principle was then explained through a series of analysis and spatial concepts. The four main principles list as below:

Map 2: Connectivity before 90s; Connectivity according to Albania 2030 Vision.

COMPLEMENTARY URBAN CENTERS

- Regionalism - There was made an adaptation of the proposal of Co-plan 2014 for the re-organization of the country on 6 regions. This concept supports the efficiency and the effectiveness of the economic growth of the country, considers environmental sensibilities by considering the concept of river basins, and brings central government near local communities and authorities without extra costs in terms of infrastructure and services. The further analyses of this research work have evidenced the cultural historic identities and economic specializations of each of these regions, as an instrument for promoting regional development balance, for fighting regional disparities and promoting balance.
- Polycentrism and Growth Poles - On this aspect there were identified 6 main growth poles, which have two patterns of polycentric development each. Within the country they are interrelated on a radial system because of the existing patterns of infrastructure and services, with the exception of Tirana, which is interrelated on an annular system. The second pattern of polycentric interrelations has to do with the cross border perspective and in this case all the growth poles interrelate on an annular system, again with the exception of Tirana, which has a radial interrelation with the European and global markets.
- Development Corridors and Free Economic Areas - The development corridors are strongly related with the infrastructural and services corridors. Most of the Albanian economic corridors are located on the western plain of the country and few of them in the peripheral growth poles. There were identified the economic specializations of each corridor, promoting the concept of clustering areas and recommending strengthening of such specialization, in order to avoid competition and promote complementarity. The economic corridors are strongly related to the free economic areas, airports and seaports. Therefore there were identified 5 types of development corridors, 7 free economic areas, 3 strategic airports and 4 sea ports, trying to explore also the geo strategic position of the country.
- Natural Potentials and Green Corridors. - Albania is rich on natural potentials. There were outlined several green, historic and landscaping corridors, which can promote a national identity, environmental education and boosting of tourism industry. These corridors are part of a networking strategy that was added to the existing agricultural land and protected areas. On the first step is planned an increase of the existing surface of protected and green areas, and then the consolidation of this network through several linking green corridors. This goes in line not only with the conservation needs, but also with the rehabilitation of the environmental hotspots in the country, which are mainly concentrated on the western plain of the country. This green framework corrects also the negative impact on environment, because of rapid infrastructure development.

**Recommendations -** Albania should move from the inherited spatial framework of centralized economy that was promoting self-isolation culture towards a new society, which is open and competitive towards regional and global markets. Therefore from an enclosed 8-shaped concept of the main national infrastructure, the spatial development vision on this research paper promotes shifting towards a ring radial system, starting from the capital region towards peripheral growth poles and cross border areas of interests. All infrastructure and services should be oriented towards such concept, where radials improve national and international connectivity, and rings increase national economic efficiency and courage prosperity of the Albanian speaking territories in the neighboring countries. Another recommendation is the enforcement of the creation of 6 regions with clear social economic patterns and specialized identities. Therefore the Metropolitan Region and Voskopoja Region will be focused on the regional and international strategic infrastructure and services, the

Northern and Southern Regions will be focused on the sea and mountainous tourism, while two other remaining regions will focus on the main economic activities like agriculture, mining and energy. The final recommendation is that Albania 2030 spatial vision for the country must foresee a development perspective for at least 15 coming years, and it should promote a sustainable economy, based on the four economic pillars.

# COLLABORATIVE INNOVATION AND INSTITUTIONAL CAPACITY IN NORWEGIAN PUBLIC SECTOR

**Abstract**

Norway experiences that the administrative public sector structure with municipalities, counties and regions are not suited to handle the problems in the more functional territorial structure rising from urbanization and zooning of industry, services and housing areas etc. Problems with infrastructure, housing, industry, public health, commuting etc. are related to each other and interact in a functional process and structure across the administrative boarders. These problems are often complex and sometimes as even wicked, and there is a growing understanding on national level that the existing administrative structure must be changed and adapted to the functional territorial structure. The preferred political solution at national level is to amalgamate municipalities, counties and regions and make them bigger unites and more territorial similar to the functional activities and structures. This national policy implicates great changes, and is met with reluctance and opposition at the local level. However, there seem to be an agreement across the governing levels that collaborative innovation is needed in order to handle the complex problems, but the existing mismatch between the administrative and the functional spatial structure, and the influences of New Public Management seem to create a blurred responsibility, an institutional egoism and make collaborative planning and innovation very demanding. To have a local and regional institutional capacity becomes a decisive demand. In this paper, I will present several cases trying to cope with the complex problems and fuzzy responsibilities, and I will discuss their planning activity and their institutional capacity and legitimacy as political actors.

## 1 Introduction

Successful innovation in the public sector means creating and implementing new processes, goods and services, and implementing new delivery methods that lead to appreciably improvement in productivity, efficiency and quality (Mulgana and Albury, 2003:3). In this paper, we discuss seven public sector development cases against this theoretical concept of innovation. We distinguish between the linear and interactive understanding of the concept, which also can be found in planning theory as instrumental and communicative planning, and learning theory as instrumental and communicative learning. The discussion of these notions reveals that the main challenge in both

theory and practice is to combine them. This is no new knowledge, and it is discussed in many fields of science, not least in planning theory (Allmendinger, 2009; Healey, 1979; Healey, 2005; Sager, 1992 etc.). By using the concepts instrumental and communicative rationality, we tie the different understanding of innovation to planning theory and learning theory. In the planning discipline there seem to be a growing understanding that planning, reporting and learning should be tied together in a management system with institutional, strategic, tactical and operative levels, and that such a systematically and continually management work can promote innovation (Amdam, 2014).

There are similarities between systematic innovation in the private and public sector. It is expected of both sectors that they are innovative in own organization and showing social responsibility by contributing to innovation in society otherwise. For the public sector, this responsibility for promoting innovation in society is far more pronounced than what it is for the private sector. Moreover, there is still no reason to exaggerate the difference between the private and the public sector when it comes to innovation as a process. The typical innovation processes and the driving forces in the processes seem to be much the same, and much of the innovation research today is about how to stimulate collaborative innovation where both private, public and voluntary actors participate (Sørensen and Torfing, 2011a and 2011b).

Only one of the cases in this paper, the Forus Business Park, can be said to represent collaborative innovation across the public and private sectors. The other cases are also collaborative, but mainly between public actors. The selection of cases is based on available master thesis from over planning and leadership master program, and represent development work in width and insight, and the different levels in the planning and management system. The purpose is to show examples of how innovation is conducted in the public sector**.** The strength of this approach is that the reader can see the width of the innovation effort in the public sector, and that the cases to some extent discuss the decoupling between levels, for example between wished development at the strategic level and implement actions at the operative level. This phenomenon is referred to in the organizational theory (DiMaggio and Powell, 1983; Meyer and Rowan, 1991; Røvik, 2007). The phenomenon is also featured in the planning theory by Kleven (1990) which uses the concepts Sunday theory and Everyday theory to characterize the decoupling of goals and practices in result oriented planning in a municipality.

**2 Summary of the cases**

*Communicative school development.* In this case, Moltudal (2012) discusses the collaboration between different actors and levels at a Secondary school during implementation of the national reform Knowledge Promotion (Kunnskapsløftet). The case is an example of change work at institutional level and illustrates how the context in the form of a national reform affects a school, and promotes both process and organizational innovation. In this case, there are implicit and latent tensions between

instrumental and communicative rationality. This is a polarization which the author uses pervasive in the study, both to position the theoretical perspectives, but also as theoretical terms to shed light on both theoretical and empirical approaches to problems. The cases show how the instrumental and communicative rationality collide in schools as an arena when reforms are implemented, and show the essential role teachers have to fill in the space between the top down and bottom up forces. The author summarizes the empirical data writing that the teacher section, through its cultural, geographical and academic "outsider position" in relation to the rest of the organization, largely had to take responsibility for implementing the reform using a communicative process. This deliberative process put critical light on existing practices, and the process uncovered, to a greater extent than before, that every teacher had individual knowledge, qualifications and values. The process led to a distinct culture in the teacher section where experiential learning and planning stand strong, and that takes care of both the individual and collective autonomy that is rooted in the overarching reform guidelines from the Ministry.

*Shared values in municipal management and leadership.* In this case, Vikhagen (2012) presents how a municipality worked systematically to develop common values. The case represents process innovation at a strategic management level and shows how the value debates may support the municipal planning and the goal and results based reporting. The author writes that the reason for developing core values can be related to a number of organizational issues. She stresses that a characteristic of a municipal organization is that the employees ultimately receive its mandate from the municipality inhabitants. Leadership processes can therefore not be independent of the municipality as the basic political organization. The political rationality is an important part of the context. She points out that it is in a value debate important to clarify the purpose of a municipality. It is expected that a municipality shall realize human, academic and economic values. Users expect to be treated with respect, care, justice and equality. Structures and systems for feedback and a broad willingness in the organization to participate in these processes are therefore necessary. To open up for debate of values, let inhabitants and users take part in the debate through surveys or other dialogue is a way to reconcile identity and reputation. The author shows that in a value based leadership, the leaders are important in the change work, but the author found that her informants deduced the decided common values differently, and interpreted their role in influencing the municipality identity and reputation differently. In conclusion, she writes that in an increasingly more complex society, interaction skills and ability to handle disagreement are crucial competence needed for an organization in order to create belonging to a community.

*Municipal economic four-year plan as an innovation promoter*. In this case, Haraldseide discusses to what extant this economic plan promotes innovation. This case is an example of planning at the tactical management level, and is about process, organizational and product innovations. The author writes that the economic plan shows that the municipality uses more resources on schools than

average, and less than average on health care available for older, and that her informants not were willing to reduce the school budget, but rather cut the health care budget "to the bone" if necessary. This political willingness when it comes to schools seems to be guided by values that are tied to the term "living communities". The informants argued that schools through centuries have been cultural lighthouses in the villages and made small communities livable. Her informants say that they see that the teaching and learning at the small schools need to be improved, and that the costs of special education heightens, something that may indicate that the schools are in a "vicious circle", but still they do not want close down the small schools. Haraldseide concludes that value standpoint related to the education sector in a municipality obstructs needed changes and innovations. Health and care in the community is not marked by such conserved values, and here the change and innovation rate is far higher.

*Interactive patient care in cancer care*. Lindseth (2012) has interviewed different people with cancer about how they experience the everyday live after attending a rehabilitation residence. The case stands as an example of process and product innovation at operational level. Capacity and capacity building are central concepts in the study. The author writes that new treatment methods have increased the number of cancer patients that survive the diagnosis and can be cancer free or live with the illness. However, late effects after cancer treatment, such as fatigue, affect the quality of life and thus the opportunities to self-mobilization, and are perhaps the biggest factor that prevents capacity building. He finds that rehabilitation leads to a self-mobilization, but that there is a great need for individual adapted support afterwards. The great majority has learned useful lessons, or has become aware of possibilities, especially physical possibilities. However, it is revealed a need for maintenance of knowledge and sustained motivation after coming home. He writes that experiences from cancer survivors are varied and contrasting, and that the degree of capacity building for participants after rehabilitation depends on an individual approach and follow-up in the home environment and the municipality. The case shows that there is a need for rehabilitation long after ended treatment at a residence. The new national cancer strategy outlines a linear "cancer proceeding", but the author argues for a more continues and interactive proceeding where private, voluntary and public actors are engaged in collaboration and reflection on social practice. He argues that the actors must cooperate more and they must see patient care as an interactive and not a linearized process. If so, the potential for successful individual and institutional capacity building certainly is true.

*Planning, reporting and learning in hospitals*. In this case Sandersen (2011) discusses how planning and the reporting function in a clinic at Oslo University Hospital, and how leaders use processes to promote learning and innovation. The case is an example of both process, organizational and product innovation and emphasis the relationship between institutional, strategic, tactical and operative planning and management levels. Major changes and restructuring has occurred through the past 20 years in Norwegian hospitals and health care in general. Last, but not least, is the merge between

hospitals in Oslo; Rikshospitalet, The Norwegian Radium Hospital, Ullevål University Hospital and Aker University Hospital, which came into force 01.01.10 under the name Oslo University Hospital, also called OUS. She writes that her informants feel that changes and restructurings have become an common part of the hospital everyday life, and that it is therefore crucial that leaders at all levels have a reflective and conscious relationship to processes of change. Simultaneously with restructuring or precisely because of the restructuring, leaders are in a cross-pressure between the requirement for financial savings and satisfactory quality services provided to the patients. She finds that the strategic plans to a small degree contribute to learning and change at section level, because section leaders who will organize and implement changes do not feel that they have had the opportunity to participate in the strategic planning. Only one-half of section leaders at the Woman and Child Clinic regard visions and strategies as usable objectives in their daily work. The other half believes that the strategic plans are only fine words on paper and even hinder daily operations. Inadequate connections between vision, strategy, organization and operations, seem to have significance for learning and thus for opportunities to implement changes. On tactical and operational level where the planning of the organization and implementation of changes shall be done, the informants experience limited rooms of action. They have observed that different forms of reporting is useful and that they learn much that is important for further planning, organization and implementation at the tactical and operational level, but that this is not learning in a broad sense. They feel that the reporting largely requests numbers and measurable data. The section leaders say that these data are important, but that they only describe parts of the reality. They experience that they receive little response when they report the quality of services for those patient groups they serve. Sandersen concludes that more dialogue and participation in the processes can legitimize the plans and reports and stimulate innovation.

*What kind of learning happens in planned change processes at three university colleges?* In this case, Furnes (2012) focuses on what kind of learning, or more correctly, on which learning level one can register learning in a planned learning processes. The case is an example of the link between planning and learning in management, and is about process, organization and product innovation. With a qualitative approach, she wishes to elevate the voices of the participants in such processes. Informants are both leaders and teachers. She finds that the participants have learned that external pressure was what was needed to get started and implement the organizational change processes. In two colleges, there were a real threat to the existence of the nurse education program. The outer pressure gave the leadership the opportunity to amalgamate the two programs. A general trend towards larger unites within the graduate education seems to have reinforced this external pressure. The informants learned that processes of change create commitment and that this commitment is a driving force in change processes. Informants have otherwise learned that traditions are important into processes of change, and that the process creates an increased need for information. However, at the same time the capacity to absorb the information seem to be reduced. Both leaders and employees learned about increased

expectations regarding firm leadership of the process, but they have also learned how difficult it can be to meet these expectations. The local leaders learned that they could calculate with good but general support from their leader, and that the employees expected a great degree of participation in the process. When Furnes with a few words sums up what in general can be learned from this planned organizational change processes, it becomes apparent how complex and demanding change processes are. This complexity implies that most aspects of the organization are involved, in particular the values and cultural aspects, but also the regulating and practical aspects. She stresses the that participants have learned that these various aspects of the organization go into each other, affects each other and must be seen in context. Furthermore, they learned both what plans are needed, but also what kind of value-based planning processes that are needed in such processes of change.

*Forus Business Park - a force for democracy or a loose cannon for regional planning?* In this case, Bjelde (2014) discusses the historical battle about the locations for Statoil Head Office and the development of Forus as an industrial site, and later on, the Forus Business Park as a company and regional development actor. This collaboration between private and public parties, and the unity between the actors over time, has become crucial for the region s ability to meet challenges and find solutions for the benefit of the region. Perhaps especially within the industrial development, but also within transportation and infrastructure, and not least the University of Stavanger can be deemed as the product of this strong partnership. The aim of her study is to get more insight into the interaction between the involved actors, the legitimacy of this intermunicipal collaboration, and to gain knowledge about how power and status of the various actors affect democratic processes. Starting with (Scott, 2013) she operationalizes legitimacy in three institutional mechanisms; regulative, normative and cognitive which constitute the institutional environment. In addition comes the pragmatic legitimacy representing the technical environment. Bjelde concludes that the company's success is tied to the pragmatic legitimacy; the company works and is regarded as useful. The company has managed to implement activities and cerate output legitimacy and has a strong regulative support from its owners (the municipalities). There is now a strong legitimacy based on regulative and pragmatic legitimacy, while there are weaknesses in the cognitive and normative legitimacy. It appears that the company's activities and strategies are not adequately anchored, or have achieved sufficient legitimacy in the region. This causes that the company might not take out the legitimacy potential that can be found among other actors in the region. When it comes to regional planning, the business park is regarded as a private company, and is expected to influence the planning from the outside, as an ordinary actor that can react on the official plans. It may nevertheless by mentioned that the company has a strong political power from the outside, through agenda control and influence on democratic decision-making processes, through relationships, networking and the status of key players in the company. There are indications in the data material suggesting that this power, because it takes place outside the ordinary democratic processes, may lead to a reduction of input legitimacy, because some

actors may perceive the process as illegitimate lobbying, or some actors may experience not to be included in the processes.

**3 Increased need for acceptance and legitimacy**

Innovation is not a goal being directly mentioned by the actors in the cases, but all cases have potential innovations in themselves through implementing new processes, services and delivery methods. However, in order to be defined as innovations, the changes need to make improvements in productivity, efficiency and quality **(**Mulgana and Albury, 2003:3). What we can say, is that the cases represent public sector change work, and that more thorough systematic evaluations are need in order to say to what extent the cases can be deemed as successful innovations. It may not be desirable that this evaluation only is conducted as an instrumental research missions, because the assessment of the results in the public sector may vary from person to person. In order to have a good mix of quantitative and qualitative data, a collaborative evaluation and learning with an open a transparent discussion of how the data can be interpreted, need to supplement the instrumental evaluation and learning.

We will say that these cases have in common that innovation in the public sector aims to safeguard theese public sector unites' existence by increasing their acceptance and legitimacy. Thus expressing that the welfare state is currently facing major challenges, something that has led to an extensive change wave in the public sector (Kettle, 2000). However there are few evaluations trying to measure the effect of these changes in the public sector (Pollitt, 2002), and the evaluations conducted show a complex pattern of both positive and negative effects (Pollitt and Bouckaert, 2000).

Public sector existence is not just based on law, regulations, decisions and allocated money (input), but is also based on assessments of how the public sector actually delivers in relation to objectives and expectations (output and outcome). In the actual situation the solution is not automatically more input when the society asks for better output and outcome. The increased focus on acceptance and legitimacy is a logical consequence of the introduction of goal and performance management in the public sector (Veggeland, 2004 and 2009).

If we take the public schools as an example, it is now much talk about rebuilding the status of the teachers by among other efforts, to give them a longer education (masters). This is what we can call the input legitimacy. Nevertheless, how the government system works today, this is not sufficient. The teachers must deliver outputs and outcomes that meet the production target and expectations. Low scores on national and Pisa tests as well as many school leavers lowers the general acceptance and legitimacy of the teachers and the public schools. Here we use schools as examples, but the situation is equivalent in many other parts of the public sector, which the cases above show.

Thus change work and innovation becomes an important tool. Low output and outcome legitimacy can be caused of lack of resources and expertise, lack of appropriate structures and processes, and not

least, lack of change culture and change stimulating management. Something that cases in this paper show may be the case. We also notice that these change works are marked by incrementalism and small steps forwards. However, the municipal reformer with new large municipalities can become a radical change. Larger regions and municipalities imply that regions and municipalities must organize themselves otherwise. If so happens, the reform without doubt can be called destructive construction in the term of Schumpeter (1949).

Furthermore, it is important that legitimacy can be based on both instrumental and communicative rationality and logic (Weber, 1971). Instrumental rationality can justify the public sector by technical and economically efficient production of goods and services (output legitimacy). For the public sector, this is not enough (Eriksen, 1993). Legitimacy must also be based on communicative rationality. This means that the process through communicative logic must make the public sector more democratic, transparent, fair and humane (outcome legitimacy).

In the modern society the instrumental logic dominates the communicative, but Habermas (1995) and many with him (for example Dryzek, 1990; Friedmann, 1992; Forester, 1993; Healey, 1997 and 2005) believe that in a political legitimating process, the communicative rationality must override the instrumental rationality. It is the better balance between the two logics that Habermas (1995) argues when he writes about several different discourses, which together form his process model for political legitimating. The combination is also clearly seen in Scott's contribution to new institutional theory when he distinguishes between technical and institutional environments. The institutional environment is threefold: regulative, normative and cognitive mechanisms, and coexist with the technical environment, which in sum give organization their legitimacy (Scott, 1998: 134).

1. Regulative mechanisms. These requirements in societies have a legal basis that is decided by the politicians. Here we find the laws and regulations that the organizations have to follow for not being judicial punished. This is also called legal and regulative legitimacy and can be promoted with Habermas' legal discourses.

2. Normative mechanisms. This is rules for what is expected of organizations and what organizations can do, that is to say the norms and values that convey what is right and wrong and what is ethically and morally accepted behavior. This are called normative legitimacy and can be promote with normative discourses.

3. Cognitive mechanisms. This is thought constructions in terms of models that conveys what an organization is and how it should behave. This also includes the image the organization gives of one's self. This is also called cognitive legitimacy and can according to Habermas, be promoted with ethical-political discourses.

4. Technical Environment is where the organization's production of goods and services takes place, where goods and services are paid for, and where productivity and efficiency are evaluated. This involves assessment of benefit and the calculation of benefit versus cost. The activity is all about pragmatic legitimacy and coincides with Habermas' pragmatic discourses.

Suchman (1995) discusses the different approaches to how an institution can create, maintain and develop its legitimacy. Suchman distinguishes between pragmatic, cognitive and moral legitimacy. The regulative legitimacy is in his model a part of the context. What is useful for us to take further is what he writes about strategies to achieve and to maintain legitimacy. He regards legitimacy construction as a proactive process where leaders are important (Suchman, 1995: 587). His strategies constitute a continuum from relatively passive conformity to active change. The logic of this approach is that changes can be interpreted as measures to adapt to expectations in the environment, and thus help to increase the acceptance and legitimacy. Several other authors have contributed to the development of this perspective. DiMaggio and Powell (1983) emphasis that changes may be the result of desire or pressure to achieve conformity in relation to the environment. Meyer and Rowan (1991) emphasis symbolic and ceremonial changes, and a Norwegian contribution by Røvik (2007) emphasis that changes are expressions of dominating ideas and trends that are tradable and moved between contexts. These contributions convey that there are two ways an organization can assert its existence: (1) either through the creation of technical, rational and effective or (2) by satisfying the expectations that are in the environment about how the organization shall perform.

**4 What make a change an innovation?**

What do these cases tell us that may be useful to take with them further in the public sector innovation? Firstly, we highlight the fact that the knowledge and experiences that we have from planning and development studies of communities and organizations are relevant and may be used in the innovation processes. Changes and improvements do happen continuous and more or less random or planned based on new insights and knowledge. Concepts and models developed to understand, explain and improve planning and learning process can be used to understand, explain and improve innovation. According to (Mulgana and Albury, 2003: 3) public sector changes can be called innovation, when changes in processes, goods, services and delivery methods satisfy one or more of these four requirements:

1. *The change should lead to increased productivity.* Innovation in the public sector must have users and providers who consider the services as helpful for them, which simplify their work or save time and resources that they can use on others tasks. Furthermore, all new products and services that involve costs of developing and operating them must be regarded as cost

efficient. This means that productivity must be good, and preferably better than before the innovation. Increased productivity will contribute to increased pragmatic legitimacy.

2. *The change should result in increased efficiency*. Good productivity is to produce without unnecessary waste of resources, and good efficiency is to produce the right in relation to specific objectives. Objectives can be called mental models of what is accepted pattern of behavior, organizational structures, culture, and processes. If the objectives are unclear, the mental models also will be unclear, and allow for interpretations and adaptations that can foster conflicts. Anyway, increased efficiency can lead to increased cognitive legitimacy.
3. *The change should result in increased quality.* The term quality is unclear and is used differently in many contexts. We use an understanding of the concept that defines quality as the totality of features and characteristics of a product or service that on its ability to satisfy given needs (Evens, 2011: 5-6). Quality has both an objective and subjective component. It make sense to measure quality objectively using indicators such as for example inhabitants per doctor, survival five years after an operation, drop out from schools, etc. These quantitative indicators need to be supplement with the service recipient s subjective perceptions of quality and thus how their needs and expectations are being satisfied. Real quality assessments need arenas where one discusses both how the situation is perceived and how the situation should be. Only a process that combines indicators and discussions can decide if changes are innovations in the way that they have resulted in increased measured and perceived quality. Good quality can increase the normative legitimacy of the provider.
4. *The change should be within the contextual framework.* All innovations are contextual, and laws, regulations, plans, programs, projects etc. are regulative elements in this context. Changes cannot normally be in conflict with the context in order to be considered as innovation. Changes in the law and regulations can be an innovation. Changes and reforms in the public sector often require changes in laws and regulations. Thus, changes in laws and regulations may be the result of an innovation and become the start of other innovations.

Finally, we will add that when Lundvall and Johnson (1994) discusses the concept of *learning region* , he emphasis that knowledge is the fundamental resource and learning the most important process in the global commercial competition that no exist. I see no reason why this argument not also applies in the public sector. The interactive learning process should contribute to learning at the operational, tactical, strategic and institutional levels and should contain pragmatic, ethical-political, moral and legal discourse. Several of the cases presented in this paper show that changes at one level is almost impossible because they depend on changes at the level above. For instance, the strategic value of small local schools overrun the well-documented and needed change at tactical and operative levels. In that case, we will say the organization lacks innovative capacity. This conclusion leads us into a discussion of the necessary conditions and preconditions for successful innovation.

**5 Structural powers and innovative leadership**

How well the involved actors are able to do collaborate in planning, acting and learning, are crucial for the organization s capacity to innovate. Based on research and our cases we believe that the way we manage public sector makes a structural force on the actors, and therefore it becomes an important leadership task to promote innovation given the actual structural forces. Hartley (2005: 28 and 29) identifies three competing paradigmatical concepts for public management and leadership that are structural forces that influence public sector s ability to innovate:

1. *Traditional Public Administration* organized as Weberiansk bureaucracy with a hierarchical and commanding leadership function that implies a separation between expert and client.
2. *New Public Management* based on an order and provider model, a result oriented leadership function and a separation between provider and customer.
3. *Network Governance* based on organized networks of interdependent and equal actors. Here citizen participation is emphasized and the important leadership function is to create good and inclusive processes of reflection and learning.

Public sector is large and the regimes exist side by side, and they partly overlap in each other. This is both functional and desirable since the three regimes have different characters and thus have different options to function optimally in various organizations and environments. Hartley (2005: 33) stresses that actors are important in innovation, but that are also groups, teams and critical mass of support. Therefore, it is important to supplement the traditional hierarchical model of innovation (Traditional Public Administration) with a clear understanding of what constitutes innovation and how public leaders can work together with others to promote innovation (Network Governance).

Sørensen and Torfing (2014: 2) write that insight into innovation calls for reflection about public management and administration, and a change of the total public management system. They argue that a stronger emphasis on New Public Governance, or what Hartley calls Network Governance is needed because New Public Management to some extent have failed to stimulate innovation.

All the cases we have analyzed above have collaborative processes, and the cases seem to imply that New Public Governance is a prerequisite for improving productivity, efficiency and quality through innovation. Sørensen and Torfing (2014: 9) argue this view based on Nyhan (2006) who have found that trust based leadership based on collaboration, mutual evaluation and empowerment, motivate public employees to solve problems and encourage collaboration and innovation. Furthermore and based on Wart (2013) they write, that collaborative leadership emphasizing creation of good, constructive and purposeful processes can counteract organizational and sectoral boundaries, and can stimulate transparent planning and transformative learning. They further refer to one's self and write

that collaborations unlike competition will promote the exchange of knowledge, ideas and resources and generate support for new and innovative strategies (Sørensen and Torfing, 2011c).

## 6 Conclusion

Successful innovation, learning and planning need systematic work over time and combination of instrumental and communicative logic. Innovation in public sector requires interactions that include critical acknowledgment and new practices. Leaders can stimulated innovation, but innovation needs processes that manage to combine quantitative calculations and qualitative stories. Such processes have the planning profession been studying for many years and we know a lot of how such processes successfully can be organized in the public sector. If such planning shall serve collaborative innovation, public sector must be organized more by ideals for New Public Governance. The emergence of this network administration can be deemed as a reply to the weaknesses of the Traditional Public Administration and the New Public Management. In contrast to New Public Management, the New Public Governance consider complexity, fragmentation, silo thinking and selfishness entities that are part of the problem. This entails that the interacting actors must acknowledge that they are mutually dependent on each other and trust each other, in order to solve wicked problems and satisfy the needs. This has to a certain extent occurred in the public sector, but the challenge, or more correct the paradox, is that actors working in public sector organizations dominated by the Traditional Public Administration and the New Public Management regimes, are so structured by these regimes that they find participation in network governance very demanding. Therefore it is important that public leaders contributes to design and implement governance structures, planning and learning processes, and create cultures with values, attitudes and actions that promote collaboration and more public sector innovations.

# AMBIGUOUS RISKS, FIXED RESPONSIBILITIES: URBAN PLANNING IN JERUSALEM

Roni Bar[1]

**Keywords**
urban planning urban design risk ethics resilience

**Abstract**

*Urban resilience has been widely adopted by planning scholars and practitioners as a framework for managing complexity and contingency. However, the term is not only over-ambiguous, but is also frequently adopted a-critically into planning policies. Therefore, the paper uses the concept of risk (rather than resilience) in order to investigate the way planners define, prioritize and respond to risks. This is explored as a normative decision (and action) with ethical implications, rather than a purely professional one. Acknowledging the need to investigate both the planning process and the physical* environment, the paper focuses on the prioritization of risks, planners res *concretization of risk perceptions in the urban environment through urban planning and design.*

*These issues* are investigated in Jerusalem s city center, an area that has witnesse *attacks and has been going through a process of densification and renewal. Findings reveal that planners assume a fixed responsibility and distinguish between two types of risk: (a) economic-demographic risks, which are seen as central, and (b) security risks, which are disregarded as irrelevant and were not considered in the plan. Despite this distinction, the analysis reveals correlations between economic and security interests, demonstrating the connection between security practices and neo-liberal urban regeneration. The last section of the paper acknowledges the importance to resist the fortification of urban spaces, yet warn that ignoring certain risks in a conflictual arena may reflect a dismissal of the* conflict itself, as well as urban planning s role in perpetuating unjust circumsta

## A. Scope

During the last decade, the preparedness for unexpected risks has become a central theme in planning literature and practice. In this "period of crisis" (Larner, 2011), planners have been searching for theoretical frameworks that hold a promise for understanding and managing complex systems (Welsh, 2014). This is especially apparent in cities, which are viewed as the most pressing (and promising) sites for addressing the uncertain future (Wakefield and Braun, 2014). In light of this search, the idea of "urban resilience" has emerged as the main framework for dealing with unexpected disasters and events (Vale and Campanella, 2005; Coaffee, 2013). The resilient city is often expected not only to "bounce back" after a disturbance but also to bounce forwards (Shaw, 2012), in a process that is described disaster betterment (Olshansky, 2006). These expectations reflect the frequent non-critical and passive reception of the term (O hare and White, 2013), evident mainly in policy papers (e.g. UNISDR, 2012; City of New York, 2013). Thus, an a-political epistemology is being used in order to deal wi political of questions [ ] the causes, distribution and effects of differentiate (Welsh, 2014, pp. 21). Acknowledging this paradox, scholars have been recently emphasizing that resilience is a normative concept (Vale, 2014), and therefore needs to be investigated and employed from a critical perspective, taking into account questions of definition, power, politics, jus (Davoudi, 2013, pp. 5).

Indeed, the preparation for future risks is far from neutral; rather, it reflects a normative decision regarding the way risks should be defined and confronted. For instance, current preparedness strategies stress the importance of individual accountability (Joseph, 2013), arguing that communities and individuals should self-organize in order to deal with risks, while the state s role mediation and support (Rose, 2000; Wakefield and Braun, 2014; Welsh, 2014). However, despite this responsibilisation of risks, the public is not an active participant in deciding *which* risks should be confronted and ho*w* (Coaffee and Rogers, 2008). Thus, planning for future risks may prevent democratic access to public spaces (through physical barriers) and to decision-making processes (by promoting a discourse of experts). Moreover, since planning translates risk perceptions into a physical space using public resources and spatial tools, it concretizes certain risk perceptions that may not be shared by all.

In light of this debate, the paper suggests using the concept of "risk" rather than "resilience", which is not only over-ambiguous and in danger of becoming an empty signifier (Davoudi, 2012) but also already holds an inherently a-political character. While the debate around resilience explores ways of dealing with unexpected risks, the debate around risk investigates the way certain events are framed (Stanley, 2013) and acted upon. This is based on the premise that when confronted with a state of uncertainty, i.e. lack of knowledge about an unwanted outcome (Ericson and Doyle, 2004), different groups not only prioritize different risks, but also set different modes of action in response to the perceived risks. Therefore, the paper uses the idea of Risk Cultures for describing planners attitudes and actior Risk Cultures is used here not only to indicate that risk perceptions are socially constructed and

embedded in cultural values (Douglas and Wildavsky, 1982) but also to explore the way in which planners actively (and often deliberately) prioritize and respond to certain risks.

Furthermore, since major events such as the 9/11 attacks, Hurricane Katrina, Superstorm Sandy and the Fukushima nuclear disaster were catalysts of the discourse revolving risk and resilience, empirical studies tend to focus on major events (for example: Campanella, 2006; Gotham and Greenberg 2014; ULI 2013; Zhang and Peacock, 2009). However, the focus on major catastrophes may ignore many other cases that are not shaped by a single occurrence but rather by multiple events and chronic crises. This research, then, responds to the need to prepare for sudden emergencies as well as for more gradual changes (Vale, 2014). Therefore, it expands the notion of risk by defining it not only as an anticipation of a potential catastrophic event, bounded in space and time, but also as an anticipation of a more gradual crisis, without a clear beginning or an end.

Using these definitions as a point of departure, the paper is comprised of five sections, proceeding from an empirical case to a theoretical discussion. The first section describes the conceptual-methodological framework that is used to understand the relationship between the prioritizati responsibility and the urban environment. The second section introduces the case study: the urban regeneration of Jerusalem s city center, an area that has witnessed numerous terror attacks an going through a process of densification and renewal. The third section analyzes the case study in relation to two types of risk: (a) economic-demographic risks, which are seen as central, and (b) security risks, which are considered by planners as irrelevant, although present in the everyday reality during the time of planning. The subsequent section summarizes the findings and identifies correlations between seemingly different risks. The last section of the paper is organized around three core questions: Why do planners perceive their responsibility as limited and address only certain risks while disregarding others? Why is it possible to identify correlations between different risks? What are the ethical implications of planning for future risks while disregarding others?

## B. Goal and research framework

The goal of the paper is to understand the way risks are defined and confronted when facing a chronic and prolonged state of risk and uncertainty. It explores the way planners define and respond to risks as a normative decision (and action) with ethical implications, rather than a purely professional one.

In order to investigate the relationship between planning, risk and ethics, the paper addresses a key theme in ethical debates the distinction between teleological and deontological approaches; the former is concerned with whether the outcome by itself is good or bad, while the latter focuses on the rightness of the action (Campbell and Marshal, 1999). Acknowledging the need to investigate simultaneously the action (i.e. the planning process) and its outcome (i.e. the physical environment), the paper is based on two-stage research framework (see figure 1):

i. **The planning process** is analyzed with an emphasis on prioritization (i.e. which risks are being confronted and which are being ignored and why?) and responsibility (i.e. how do planners perceive their role and responsibility regarding these risks, the city and the public?). These aspects are explored using in-depth interviews with planners in the public and private sectors, observations in relevant meetings and roundtables, as well as a survey of plans, reports documents and transcripts.

ii. **The physical environment** is analyzed with an emphasis on resources and tools (i.e. how are these perceptions of risk concretized in the urban environment, through urban planning and design?). This is explored through a spatial analysis of plans and the built environment, using three spatial parameters that reflect questions of power, politics, control, equality and representation:

The built form, including land uses, anchor institutions, typologies and regulation, which reflect issues such as the distribution of municipal resources and the promotion of certain target audiences, activities and goals.

The urban language, including the urban design of public spaces and street furniture, which reflect issues such as place making, branding, creating a desired image, memory and history.

Connectivity, including motorized and pedestrian traffic, public transportation, the relationship between different areas and the movement through space, which reflect issues such as accessibility, freedom of movement, boundaries, restrictions, mix and separation, security and control.

This framework is employed in order to investigate the urban regeneration of Jerusal

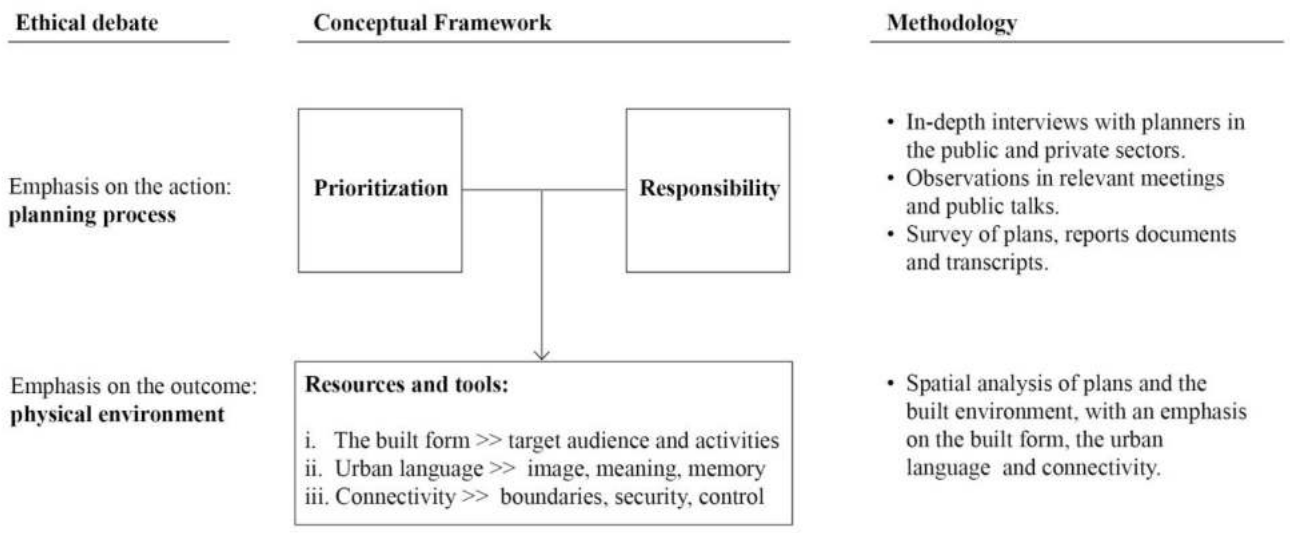

**Figure 1.** conceptual-methodological framework

## C. Case study

Jerusalem is Israel s largest city, with a population that exceeds 800,000 (appro 36% Palestinians).[2] The city has grown substantially since the annexation of East Jerusalem in 1967. During the annexation, 28 Palestinian villages and towns were incorporated as neighborhoods in Jerusalem (B Tselem, 1995). They have expanded significantly in the last five decades, and at the s time, Jewish neighborhoods were constructed in East Jerusalem as a way to modulate this growth and to prevent an urban continuum of a future Palestinian city (Braier, 2013).[3]

Jerusalem was selected as a case study for two main reasons. First, as a city under dispute, Jerusalem is not shaped by a single major event but rather by multiple risks and uncertainties. Second, as a contested urban environment in an asymmetrical power balance, Jerusalem does not only represent a case of uneven vulnerability but also a case in which one man s risk may be another man's desire

The paper focuses on the changes that were planned and implemented in the city center in the last fifteen years. Attempts to reinforce the geographic center of Jerusalem were made since the annexation of east Jerusalem in 1967, in an effort to construct a "united city" (Ramon, 2011). However, these were unable to stop the deterioration of the area. The deterioration reached a pinnacle point in the late 1990s and early 2000s, when dozens of people were killed and hundreds were wounded in over ten suicide bombings.[4]

At the same time, two consecutive plans for the urban regeneration of the city center were submitted, the first in 2000 and the second in 2003. The plans were integrated into the Jerusalem 2 (2009) and its introductory reports (2002, 2004). These plans attempted to *"inject new life to the streets of the city center"* (Urban Regeneration Plan, 2003, pp.15) and focused on densification and diversification of land uses in the city center, improving transportation and accessibility, creating employment opportunities, construction of anchor institutions and upgrading the public space. In 2001, the Jerusalem Center Development Company ("Eden") was established as a sub-company of the Jerusalem Development Authority, with the purpose of initiating and implementing both physical projects and economic initiatives. During these years, the city erected a light rail along Jaffa Street, the city's main commercial axis that connects the city entrance with the Old City. Apart from connecting the city center to remote (mostly Jewish) neighborhoods, the light rail project re-shaped the city center itself: The main section of Jaffa Street was completely renovated, vehicular traffic was banned, the street was re-paved, light rail stations were constructed and new street furniture was installed.

---

[2] The majority of the Palestinian population in Jerusalem holds a permanent residency status and not a full citizenship. This status entitles them to vote in the municipal elections but not in the national ones. Furthermore, their status is dependent on their place of residency and may be revoked if they move out of the city (Braier, 2013).

[3] The Jewish urban growth is characterized by the construction of new neighborhoods, which are usually autonomous and spatially isolated. Palestinian urban growth, on the other hand, is characterized by the expansion of existing neighborhoods.

[4] From 1989 to 2003, Jerusalem has witnessed 73 terror attacks, which killed 283 people and injured 2067 more than in any other city in Israel (Savitch, 2005). In the second half of the 1990 s suicide bombings have become threat in the city. Suicide attacks mainly targeted the city s central areas, such as Jaffa Street as ( Yehuda pedestrian mall (09/04/1997, 5 deaths), Mahane Yehuda market (07/30/1997, 16 deaths) and the Central Bus Station (25/02/1996, 26 deaths).

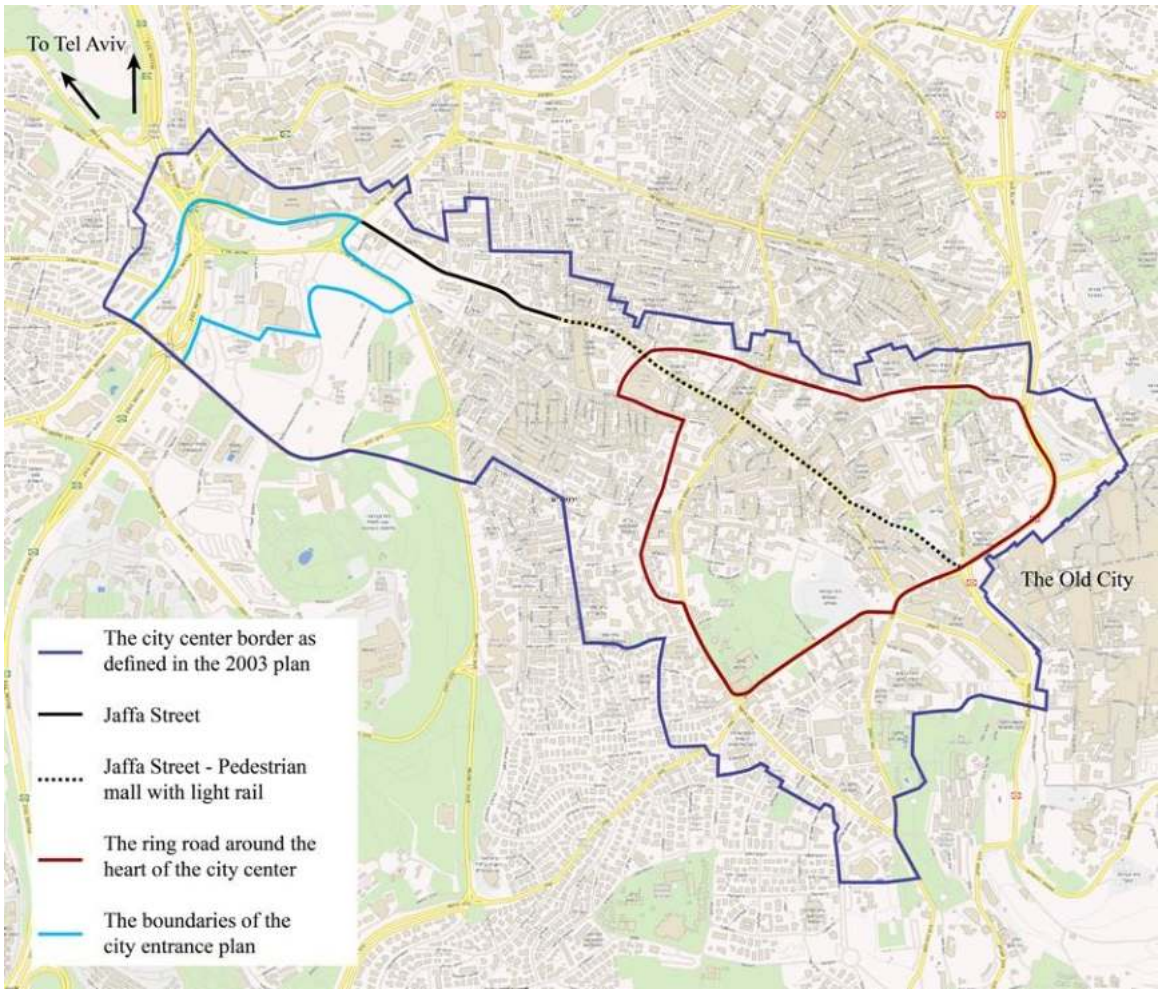

**Figure 2.** Jerusalem s city center as defined in the 2003 plan

The trigger for the urban regeneration of the city center may be traced back to a double paradigmatic shift. The first shift occurred in the planning paradigm. Following decades of suburbanization, planners and decision makers re-discovered the city center as the main anchor of the city. While a senior planner stated that this decision is purely professional (interview, March 2014), it is also tied to a change in the political paradigm. The suburbanization of the 1970s and 1980s was characterized by a construction of new Jewish neighborhoods in East Jerusalem. Today, the municipality's ability to sprawl to the east is limited for political reasons. While planners insist the policy did not change officially, they often also state that the decision to build (or to sustain from building) new projects in East Jerusalem is determined by national and international dynamics and is ex-territorial to the planning establishment and to the municipality itself (interviews, March and May, 2014). In light of these limitations, the city promotes urban regeneration and densification of the inner city, as stated by the city s c *towards urban regeneration. [If] anyone thinks that we will continue to go for another hill and another hill and another hil*l, it will not happen (Israeli Planners Association annual conference, February 2014).

Given the violent history of the area and the unstable political climate in Jerusalem, the urban regeneration of the city center raises several questions: Were security risks considered in the plans? Were other risks taken under consideration? How do planners perceive their responsibility towards different risks and how do these risks influence the urban environment? The next section will respond to these questions and analyze the Risk Culture that emerges out of the city center regeneration plans.

## D. Findings: between security and economic-demographic risks

In accordance with the conceptual framework that was presented above, the findings are presented in two stages: the first stage analyzes the way planners prioritize risks and perceive their professional responsibility. The second stage analyzes the concretization of these risks in the urban environment, based on three spatial parameters.

### Planners priorities and responsibilities

The planners that were interviewed were asked to name the most significant risks that pose a threat to the city s future. At the same time, based on the definition of risk as an anticipatio crisis, further perceived risks were extracted from interviews, reports, transcripts and plans. These accounts do not use the term risk directly yet they do express a state of em upcoming disaster or crisis. Findings do not portray one unified image but rather uncover multiple risks that can be divided into two groups: (a) security risks, namely terror attacks and violent eruptions; (b) economic-demographic risks, namely the escalation of social conflicts and loss of balance between different social groups, and in particular, the out-migration of economic activities and Jewish secular residents. As this section shows, although both risks are perceived as important, planner's responsibility towards them differs significantly.

*Economic-demographic risk: high responsibility*

In general, the Jewish Ultra-Orthodox and Palestinian populations are often described as unproductive in terms of labor and subsequently as one of the main causes for Jerusalem s low socio-economic status. Therefore, planners view the growth of these populations and the out-migration of the Jewish secular population as an economic risk to the city's future.[5] While for the Palestinian population the Master Plan does acknowledge some growth (from 30% to 40%), the Ultra-Orthodox Jews are seen a real threat for the city's economic independence, with Jerusalem facing a destruction *in twenty years this could be a backward frontier town supported by the state"* (interview, March 2014). The secular Jewish population is described as feeling threatened (interview, May 2014) and as a minority group on decline (Master Plan

[5] According to the Israeli Central Bureau of Statistics, the percentage of orthodox Jews in Jerusa grown from 26.5 in the years 2002-2007 to 31.2 in the years 2008-2014. The percentage of secular Jews has dropped from 22.5 to 19.4 in the same period of time (CBS, 2014).

Report 4, 2004: 223). While the language in the official documents is neutral, in interviews and talks planners use blunt language to describe the Ultra-Orthodox population, for instance: *"entire neighborhoods are falling", "they are most likely to spread south and conquer Jaffa Street"* (interview, March 2014) and *"the sprawl of the Ultra-Orthodox population is shredding the city"* (high ranking former public official, "The Challenge of Jerusalem" conference, March 2014). [6]

The head of the 2003 urban regeneration planning team confirmed that these issues were on the agenda *all the time. The intention was to revive the city center* for everyone there was a sort of feeling *emergency, that if the city center continues to deteriorate it will become an Ultra-Orthodox residential* neighborhood and will cease to be a place for everyone (interview, December 2014). An Ultra-O majority in the city center is expected to change the situation in Jerusalem, by allowing one *group to transfer the center* from the hands of the public to the hand of a community ( Report 4, 2004: 223). Demographic and economic issues are constantly intertwined. For instance, the 2003 regeneration plan lists a set of problems, the first of which states that Jerusalem is a relatively poor *city (economically), its population is polarized, and out-migration is carried out. These problems are reflected also in the state of the city center"* (Urban Regeneration Plan, 2003, pp. 13).

This type of risk is seen as integral to planning. One senior planner states that environmental or economic risks are risks that *"planning can completely control. Moreover, I think that these things are a result of planning, I mean that if you allow the city to be built in a non-*balanced way this is something that i *completely in the hands of the planners, in my opinion. Of course it is also influenced by other things, but 80-90% of it is in the hands of planners and planning can change it"* (interview, May 2014).

*Security risk: low responsibility*

The terror attacks are described in interviews and publications as the heaviest burden on the city center and a significant factor in its deterioration (interview, December 2014; Vitman, 2011), transforming it into a ghost town, devoid of people (interview, July 2014). Yet, although security instability peaked when they drafted the plans (in the early 2000's), planners assert that they did not address any security risks in the planning process. As a senior planner explains: It wasn t a consideration at any moment. It wa *reality, painful, bitter, an everyday reality during those weeks. [You] go to the city center, sit in a café,* and one week later, this cafØ explodes it was the center of the conflict [7] (intervie This understanding of security risks as irrelevant or to planning has not changed in recent years, although the discourse revolving urban resilience has become more prominent in planning literature and practice (interview, July 2014).

[6] A demographic-driven policy is not new to Israel. Criticized as "demographobia", these types of policies often see the Arab population as a threat to Jewish existence (Khamaisi, 2011). The discourse in Jerusalem exposes an additional economic-religious demographobia targeting Orthodox residents, as part of a neo-liberal agenda that promotes "productive" populations.

[7] It is important to note that the plan occasionally addresses the need to create a sense of comfort and personal safety (Regeneration Plan, 2003, pp. 15).

Findings reveal two possible explanations for this disregard: first, planning is not considered to be an effective measure to treat security risks, as a senior planner explains: *"some things you can deal with, some things you can't, for instance a security threat to tell you that this is responsible for or to greatly influence? no"* (interview, May 2014). Similarly, the city architect expressed skepticism regarding urban design's ability to eliminate terrorist threats, since erecting fences and protective measures might only transfer the risk from one place to another (interview, July 2014). This reflects an understanding of security risks as constant, while planning actions merely relocate it and not abolish it altogether.

Second, since these were long-term plans, planners describe looking into the distant future from an optimistic point of view, *"as if this cloud will lift from over our heads"* (interview, March 2014). All planners interviewed in the research state that they are optimistic, and the planning profession is characterized *as "optimistic by definition"* (interview, December 2014). Being optimistic is described as a mission (interview, December 2014), without which "we don t have a right to exist as plann (interview, July 2014).

**Resources and tools**

The previous section illustrated the different attitudes towards economic-demographic and security risks. The current section analyzes the concretization of these risks in the urban environment by analyzing the spatial changes that were planned and implemented in the city center. It will show that although the security risks were officially disregarded, some of the changes can be understood as addressing security issues, either indirectly or in retrospect. Based on the conceptual framework presented above, the changes are analyzed using three spatial parameters: built form, urban language and connectivity.

*Economic-demographic risk: "creating a modern city for a liberal population"*

As mentioned, the urban regeneration of the city center is part of an attempt to stop the area's economic deterioration, which was feared to be followed and accelerated by the further sprawl of the Ultra-Orthodox population. The first component, the built form, is the most significant tool in modifying these trends. An emphasis is put on encouraging commercial activities, employment and tourism, while housing remains a relatively minor land use. This is evident in the plan for the city entrance, which was not yet implemented and is expected to consist of 12 high-rise buildings containing offices, hotels, congress halls, entertainment and commercial activities (see figure 3). The area will not contain any residential units (district planning committee meeting, 29/07/2008;). The suggested plan is expected to encourage economic activities and to change the overall orientation of the city center towards the west, i.e. towards Tel Aviv, Israel's financial center (see figure 2). Furthermore, based on the assumption that *"in an urban area there is no void"* (Report 4, 2003, pp. 223), the lack of residential units would prevent Ultra-Orthodox residents from moving into the area. Since this is a sensitive subject, this is often only implied rather than stated explicitly. For instance, in a district planning committee meeting (29/07/2008), one of the participants implied that adding residential units in this area would create a continuum between two

neighborhoods, Romema and Giv'at Shaul (both characterized by mainly Ultra-Orthodox and religious residents, R.B.).

Nevertheless, the plan does recommend increasing the number of residential units in other areas of the city center. Although the plan s official goal is to attract a variety of populations, it recommer enhance the following housing mix: small apartment for students and young families; unique units in historic neighborhoods, and luxury apartments for an affluent population (Regeneration Plan, 2003: 70-71) all of which do not address the needs of the Ultra-Orthodox population, which is characterized by large families and relatively low income.

These attempts were surfaced more directly in interviews, in which planners describe high-rises and luxury apartments as unsuitable for Ultra-Orthodox populations. The head of the Master Plan planning team summarizes these attempts:

> *"We tried to build a plan that would create a modern city fit for a liberal* population We wanted high construction throughout Jaffa Street, why? *Because we said that high construction is the barrier preventing the Ultra-Orthodox population from penetrating into the area. We said that if the city loses its center, then there would be a problem. And we said that since they have reached Hanevi'im Street they are likely to continue to spread south and conquer Jaffa Street as well. That is why we said that Jaffa Street needs to be mainly offices, commerce and employment, not housing, and high construction" (interview, March 2014).*

Not all of the densification plans have been implemented, yet recent projects in the city center follow these lines. Several luxury apartment buildings and boutique hotels were (and still are) constructed just north of Jaffa Street and south of Hanevi'im Street. The momentum in the city, said one planner, *"has created a sort of market that is also and this needs to be said carefully but yes, it is definitely a market that appeals to a higher economic status than the one in the heart of the Ultra-Orthodox city"* (interview, December 2014).

The second component, the urban language, is used in order to create an attractive commercial street that will be conceptualized and managed as a shopping mall (Urban Regeneration Plan, 2003, pp. 70). In addition to the joint management, the "mallification" of the street is supported by a cohesive high-quality urban design, which is meant to re-brand the street in a new image (see figure 4). The beautification of the public realm is an explicit part of the plan s aim to compete with the suburbs an attract young families and visitors and to increase the property value of adjacent properties (Urban Regeneration Plan, 2003, pp. 71, 81). As part of this goal, the main section of Jaffa Street and additional 20 streets were completely renovated, and transformed from an urban space that *"looked like garbage ten years ago"* (interview, May 2014) to *"the most attractive and beautiful street in the country"* (the city chief architect, round table, May 2015).

These planning actions are tied to the third component, connectivity. The renewed public sphere in the heart of the city is pedestrian-friendly (see figure 4). It is encircled by a ring road, with multiple parking lots spread along the perimeter. The light rail connects the city center to residential neighborhoods (Jewish and Palestinian) and improves accessibility to the area. These changes can be analyzed from two points of view. On one hand, these actions have re-created the city center as a shared space for diverse populations. On the other hand, the same Jaffa Street or the planned city entrance are mentioned and constructed as a barrier, preventing the Ultra-Orthodox population from sprawling any further.

**Figure 3. (left)** a rendering of the planned entrance to the city (Farhi Zafrir Architects)

**Figure 4. (right)** the renovated Jaffa Street

*Security risk: "it's in everyone's interest to keep the peace"*

As elaborated above, although they admitted that the terror attacks do indeed constitute a significant factor in the city center's deterioration, planners stated that these security risks were not a consideration during the planning process. Yet, it is possible to identify three different ways in which security risks influence the urban environment: compensation (via the built form), negation (via the urban language), and regulated movement (via the connectivity).

The first component, the built form, was used as tool to compensate investors and encourage new construction in times of high security instability. In order to do so, potential investors were offered increased building rights, for instance when contracting or renovating hotels. Two senior planners from the district planning committee have spoken of these practices:

*Planner A: "When we see [in] approved plans, suddenly a huge building that does not fit, we say: 'oh, it was during the Intifada*

*Researcher: Why?*

*Planner B: "To compensate the people"*

*Planner A: "It was a terrible period, all the cafés closed down, people were scared to walk in the street, and every investor that came, they caught him and begged: 'build whatever you want'."*

(Interview, May 2014)

This wish to increase the tourist activity is tied to another form of economic compensation, as planners view the increased tourist activity as creating a shared economic interest and thus reducing security risks: *"This is also connected to the economic resilience, because it's a place of employment that provides income to low-income populations as well, Arabs and so forth... It's in everyone's interest to keep the peace, because they make a living"* (interview, May 2014).

The second component, the urban language, reflects a different approach towards security risks, one of negation and intentional disregard. The new urban language of Jaffa Street and the surrounding area is not based on security measures. On the contrary it opts for an open, barrier-free urban design. For instance, the light rail stations are completely open to the street, without any fences, despite earlier suggestions to construct them as enclosed structures with a security perimeter (interview, July 2014; see figures 5 and 6). As a design philosophy, the urban design of the public sphere is based on what the city chief architects describes as "universal urban design" (interview, July 2014), which is based on accessibility, coherence and cohesiveness of the public space. The universal nature of the urban design is also manifested in numerous references to Europe and the United States as precedents and as justifications for planning decisions (Urban Regeneration Plan, 2003). Creating a completely new image (and a universal one) may also have helped to disassociate the city center from its recent violent history, dimming old memories and images of the place. *"When the city changes its appearance, I'm sure it has an effect"*, argues the city architect, "*they forget it was dirty and that things were terrible here"* (interview, July 2014).

The creation of a well-ordered and cohesive urban space is further supported by the third dimension, connectivity, which has a potential to regulate the movement through space, especially within the ring road, due to the moderate vehicular traffic within its perimeter and the absolute ban on cars along Jaffa Street. Furthermore, the light rail line is the only form of public transportation along the street, replacing the buses that passed there in the past. Its stations are under constant surveillance, using CCTV, security guards and public announcement systems. It is important to note that while this regulated movement can potentially be used for policing and security purposes, it was achieved unintentionally.

In addition, planners and public officials from the municipality's emergency management department describe the increased accessibility to the city center, the shared infrastructure and the subsequent social

mix as potentially diminishing security risks.[8] They offer two explanations to this argument. The first, more optimistic, views the city s heterogeneity as contributing to its resilienc Similarly, the city center is described as *"the place to meet, the place for dialog, the place for tolerance"* (interview, December 2014). The second, more pragmatic, is based on the premise that that if Jews and Palestinians share the same space they also share the same risk: *"if the train explodes they need to understand that everyone explodes*. Fatma and Shoshanna explode together. (interview, May 2014).

**Figure 6, 7.** light rail stations along Jaffa Street, completely open to the street.

[8] In this respect, it is important to note that only two Palestinian neighborhoods, Shuafat and Beit Hanina, are connected to the light rail line. Both are considered to be of relatively high socio-economic status in comparison to other Palestinian neighborhoods in East Jerusalem.

**Figure 7.** summary of findings

### E. Summary of findings: fixed responsibilities, overlapping interests

What is the Risk Culture that emerges from the urban regeneration of Jerusalem s risks perceived, defined and confronted by planners? At a first glance, it seems that the risk culture clearly distinguishes between economic-demographic and security risks. Furthermore, planners assume responsibility towards the former and disassociate themselves from the latter. However, when analyzing their temporal and spatial characteristics, the distinction between the two risks becomes more ambiguous.

The temporal characteristics of these two risks share some similarities. The economic-demographic risk is a gradual process, without a clear beginning or an end. Likewise, planners also view the security situation in Jerusalem as a chain of events; a state of constant risk that cannot be completely neutralized. This challenges the distinction between event and crisis as distinct concepts. Here, the event does not represent a critical rupture or a sudden break from the status quo (Gotham and Greenberg, 2014), but an extreme occurrence in an already erratic sequence. This view of risk as constant has some common grounds with the idea that it is best to accommodate natural risks, i.e. to go along with rather than to try to defeat ecological processes (Fainstein, 2015). Here, however, the attitude of acceptance is extended from natural to man-made risks, and in particular to security ones.

The spatial analysis uncovers further points of conjunction between security and economic interests. First, in order to address the economic-demographic risk, planners aimed to create a social mix and encourage economic activities. Yet, these are also seen by planners as a means to diminish security risks, since they create a shared space with shared risks, shared opportunities and shared (economic) interests. The economic growth and increased tourist activity are hoped to prevent violent eruptions. Furthermore, the renovation, "mallification" and re-branding of the public sphere were done in order to increase the street's competiveness and attractiveness. However, these actions may also have helped to create a well-organized, regulated and potentially delineated space, as well as to disassociate the area from its previous image, which was tied to disorder, violence and terror.

Another correlation between the two risks emerges from the attempt to frame Jerusalem as a "normal" city, with "normal" population (liberal, secular), "normal" goals (economic growth), and without extreme risks (terror attacks). Planners insistence on normality is demonstrated by their emphasis o and the multiple references to cities in Europe and the United States. By doing so, they challenge the idea of Jerusalem as a particular event in space. This echoes their perception of risk as constant, which can be understood as a way to challenge the idea of "risk" as a particular event in time.

## F. Debate

The last section of the paper is organized around three core questions. First, why do planners perceive their responsibility as fixed, addressing certain risks while disregarding others? One apparent explanation is that security risks are much more controversial than the allegedly neutral goal of economic prosperity. While a terror attack targets one population (either Palestinian or Jewish), an economic crisis threatens to harm the city as a whole. Another possible explanation can read this insistence on normality as a resistance to the centrality of risks in Israeli political discourse and daily lives, as well as in current planning literature. According to this thesis, urban planners are trying to create shared infrastructures and to enable normal routines, assuming that the political and security risks will be resolved on the national-political level. As opposed to the first explanation, which sees planners as passive and avoiding confrontation, the second type of explanation assigns them a much more active role. Their desire to create a normal and global city, which is regenerated as an economic and tourist center, surpasses the frequent tendency to fortify the urban space and to erect defensive cordons around strategic sites (Coaffee and Rogers, 2008). This is a significant statement especially in light of persisting security threats in Jerusalem, and although terrorism tends to target places with strategic or symbolic value such as city centers (Savitch, 2005).

This dismissal of security risks leads to the next question: if security risks were not officially considered in the plans, why some spatial changes can be understood retroactively as addressing them? In other words, why is there a correlation between economic and security risks? The plan to create a mall-like urban space in the middle of Jerusalem was initially meant to attract capital and economic investments. Yet, it shares a common logic with security interests. The mallification" of the urban environment as a controlled and well-ordered space, demonstrating the connection between policing practices and entrepreneurial urbanism, with security and order being a necessary precondition for neo-liberal urban regeneration (Samara, 2010). Thus, the regeneration of the city center can be understood as "post-crisis re-branding" (Gotham and Greenberg, 2014), which creates a pleasant and unintimidating urban environment as a means to suppress the harsh reality and to avoid the root causes of the problem for as long as possible (Ellin, 1997).

What are the ethical implications of planning for certain future risks while disregarding others? On one hand, it can be argued that ignoring certain risks has its benefits. It can allow planners to overcome the obsession with imagining the worst-case scenario (Neocleous, 2013), in which crisis is ubi the disaster-to-come is inevitable (Wakefield and Braun, 2014: 5). The fixation on risk may be then replaced with a positive vision and a conflict of principles can be reinstated as a conflict of interests, as a way to facilitate compromise (Sanyal, 2002).

On the other hand, while the paper acknowledges the importance to resist the fortification of urban spaces, some words of caution are required. Planners should be aware that the aspiration for normality is legitimate, and perhaps even beneficial, but it is also far from neutral. As Susan Fainstein argues: "normality tends to be what is in the interests of property owners [...] What ap

ontological security for many, even while exacerbating the insecurity of others" (Fainstein, 2015). In Jerusalem, the so-called normal vision of a universal and economically dependent city promotes a certain economic-demographic profile, while ignoring two thirds of the city s population, struggles and political conflicts.

Moreover, planners perception of certain risks as stemming from exterior, complex and uncontroll forces may lead to a denial of existing power relations (Swyngedouw, 2010). In other words, since planners do not see themselves as part of the problem they do not see themselves as part of the solution either. However, ignoring risks in a conflictual arena may reflect a denial of the conflict itself, as well as urban planning s role in perpetuating unjust circumstances. By disassociating from controversial risks and assuming a fixed responsibility, planners are in danger of assuming a professional and neutral fa ade in an extremely political and conflictual arena.

# 25 YEARS AFTER TRANSFORMATION: CHANGES IN SPATIAL DISTRIBUTION OF PRODUCTION ACTIVITIES IN THE CASE STUDY OF WROCLAW, POLAND.

Jan Barski[1], Jacek Barski[2]

Keywords: industry, suburbanisation, spatial distribution of activities

**Abstract**

*In the post-industrial, free-market economy, the ability of spatial planning to truly influence the location choices of business owners is limited, while the vast majority of means of production are in non-public hands. On top of that, coordinating spatial policies and decisions between administrative entities is a major challenge in numerous places in Europe. This paper offers a convenient case study of a medium-sized European city (Wroclaw, Poland) and an analysis of the spatial management complication which has observable consequences for the spatial structure and economic functioning of the city.*
*The paper examines the situation through the lens of production and manufacturing activities (with a cautious approach to the term industry). The case is analysed in two inseparable ways: spatial and economic; parallel to that, the discussion is developed on the issue of the interconnection of policy-*
making in the metropolitan area (the city vs its surrounding rural communes).
*the changes in employment in subsequent sectors of the metropolitan area in the 25 years since the political transformation of Poland while keeping an eye on the physical, spatial changes of the aforementioned metropolitan area.*
*The secondary output of the paper is outlining the suburbanisation processes of large Polish cities, however as seen not from the most frequently presented perspectives (such as housing or transportation), but from a more economy- and spatial responsibility-focused one.*

## 1. Introduction.

Poland, along with all post-communist countries of Central Europe, has been subject to major changes in its spatial structure, and the functioning and growth of it, in the period of the twenty-five years which had passed since the political transformation. Due to the totality of change the switch from planned economy to free market and from fa ade citizen rights to direct democrac space management can hardly be called gradual or well-groomed. This paper examines a very narrow fragment of the otherwise massive topic, as it focuses on only a minute portion of the territory of Poland Wroclaw, the country s fourth largest city, and its agglomeration and just c economic phenomena which has its exemplification in spatial phenomena the industry sector or, in more precise words, production activities (the terminology challenge is discussed shortly later in the paper). This paper is a stub of research conducted at the Department of Spatial Planning, Faculty of Architecture, Wroclaw University of Technology, touching on the issue of spatial behaviour of production activities in middle-sized cities of Central Europe and will include three more cities similar in size and history to Wroclaw: two Polish ones (Poznan and Szczecin), and one Eastern German one (Dresden).

## 2. Background.

In order for an outlook of the very specific case, which is the focus of this paper, to be understandable better, a picture of underlying phenomena is worthy of being painted. This includes observations of extremely general nature as well as ones of more particular, local character.

The fundamentally good and desired value of the ability of societies and communities to make their own decisions collectively, through their representatives, instead of ones made in an arbitrary way by any type of officials, has a trade-off side. The existence of private property means that citizens are free to fully own material goods, among which land, and therefore space, is a prominent feature. In fact, elements of space, as buildings and plots of open land may be dubbed, have throughout the history of human civilisation been considered one of the topmost valuable and tradable goods, in the realm of material ones rivalled perhaps only by food. The free real estate market means that individuals are able and free to make their own, singular decisions concerning the land and buildings they own, which in multitude of owners and decisions builds up to a great challenge in coordinating the transformations of the common space – a difficulty significantly reduced by limitations in private property and commonality of decisions: an obvious feature of any semi-free political system.

A surprisingly unknown realisation is the one that space, in all scales considered together, is the arena for literally all that happens and can be named – outside of the human mind. This lies at the fundament of why the construction of laws and regulations concerning space is an inexplicably complex task: legal provisions dealing with space in fact indirectly touch upon most facets of life. All over the world, spatial regulations are far from perfect, especially if their functioning is relatively young and the ability of the public to influence it hardly has an established nature, which is the case in Poland. Among numerous shortcomings of the Polish spatial law, the following can be named in an attempt to clarify the setting of the spatial changes of the last 25 years:

- soft and imperfectly consistent strategic documents:
    - a regularly-updated national spatial development plan is in force, but its power and efficiency in executing spatial transformations are limited;
    - regional spatial strategies are well-thought-through, but similarly may be accused of containing provisions which are soft and difficult to apply in conformity with the original intent or scope;
    - on the lowest administrative level there is a harmful gap in the power of the general planning document which every commune has in force and updates every several years (the so-called *Study of conditions and directions of spatial development* of a commune) and the specific, smaller-area *local land use plans*;
- all levels of planning have been marked by unimpressive public participation standards. However, currently a new *Act on spatial planning* is being drafted and it is to have public participation mechanisms inscribed in planning processes incomparably more thoroughly.

The Studies of conditions and directions, independent of quality, do not carry executive or punitive power, and are in fact well-informed guidelines which local land use plans are supposed to follow (but not have to); the *local plans* are the only documents in the Polish planning system which have actual executional power. The difficulties, however, do not end here, as *local plans*:

a) do not cover 100% of the surface of all communes (in other words, only a minority of communes is fully covered with *local land use plans*);
b) do not sum up to any regional or sub-regional larger picture;
c) may be changed or originally created in a way which suits short-term or particular goals of local politicians or outside investors (and frequently that is the case, especially in less privileged areas).

This leads to perhaps the most natural explanation of decisions made by local authorities: the economic factors. It is clear that just a minuscule proportion of communes, and not even always, is able to afford choosing and picking its investors. In the vast majority of scenarios, communes race to attract investors and if they succeed, they largely conform to the investors wi to no surprise, taking into account the post-transformation reality of radical, rapid change and the need (or necessity) to secure the economic fundamentals first (such as jobs, tax base, territorial brand), and viewing the quality of space as a desirable, but undoubtedly secondary goal.

An additional argument could be made here concerning the psychology of the post-communist societies. It might be possible to defend a claim that due to being for five decades deprived of such seemingly natural privileges as private property, freedom to travel, move home, or change jobs, citizens of these countries, in collective, are prone to compensate on the ability to consume. If such an assumption is followed, then correlation can be made to the drive to own material goods therefore the preference for private cars over public transportation or for (often suburban) home ownership over (mostly in-city) apartment rental. This, globally, contributes more to *urban sprawl* phenomena than *compact-* or *slow-city* ideas.

Moreover, the reverse from the local scale i.e. the global one has come into play in the last two decades with a challenging effect. First of all, two sides of the economic landscape have opened colossally widely: the competition and the opportunity. The scope of what local authorities may think of achieving has broadened to an extent, and that sometimes puts a serious strain on the communes resourcefulness and imaginativeness. Meanwhile, the very-open and very-free market makes everybody equally eligible for the investment sweepstakes, therefore pushing competition to new levels; this competition, naturally, brings both good results (such as creation of better conditions for investors, which leads to successful investment, which benefits whole regions) and bad ones (lowering the investment conditions too low or stepping away from other standards, thus hurting the regional employment market more than helping it). With all of this in mind, the communes of the region in question Lower Silesia weigh their strengths and weaknesses in their strategies and in negotiations with potential investors. In a generalised description, among strengths of Lower Silesian communes one could name the region s international and interregional location, relatively network and external transportation connections, relatively attractive workforce understood as a product of cost and qualification, and low salary requirements (for Western-world standards). Among weaknesses, one could point to the frequently-reminded time limitation of the low-salary advantage (as it will stop being an advantage along with the gradual overall increase in wealth of the Polish society), and a relatively small internal market.

Finally, the general national policy in the realm of transportation needs to be commented on. In Poland, the whole post-transformation era has been marked by extensive effort to develop vehicular traffic[1], unparalleled in attempts to improve or maintain, as they were operational in the socialist era railways[2] and inland navigation. Undoubtedly, the development and improvement of the road network in Poland, highlighted by the ever-expanding length of motorways, is more than significant for the country s economy and the quality of life; it does, however, benefit spat residential and commercial which favours perimeter locations over downtown ones. The above general description is particularly true in the case of Lower Silesia, which had the luck of being equipped with a long, existing stretch of a pre-war German motorway (A4), which later was among

[1] The number of cars in Poland grew from 5,26 million in 1990 to 17,24 mil. in 2010. (Zdanowski 2012)
[2] The number of passengers of the railway transportation in a year was at 1 billion in 1985, 0,79 bil. in 1990, 0,36 bil. in 2000, and 0,26 bil. in 2010. The average citizen of Switzerland travels by train 43 times in a year (European high); of the Czech Republic (also a post-communist country) 17,5 times; of Poland 7 times. (Zdanowski 2012)

the first to be extended further east and west; that was coupled with a significant decrease in available regional railway connections and a decline in the capabilities of the waterways.

## 3. Resulting situation.

The background described above bears consequences which strongly influence the challenges the Polish planning system faces. Primarily, territorial competition is born, which, although fundamentally healthy, is easy to skew towards chaos. This type of competition naturally leads to *territorial marketing* which is a phenomenon significant enough to be a separate class taught to spatial planning students of Polish universities. Territorial competition and marketing accompanying it do not help the cause of territorial cooperation or cohesion. The higher the level of strategic spatial plan, the easier the cooperation is to envisage and assume; the more local the level in question is, the more neighbouring administrative entities are likely to fight each other instead of cooperating.
Clearly, the lack of truly executable coordination of spatial development results in chaos and conflicts in transportation (a city vs. its suburbs and agglomeration[3]), in taxation (the situation where a majority of residents of areas just outside city limits use numerous services, including these financed from the public [municipal] treasury, in this city, while paying their taxes in the neighbouring commune they live in), in the quality of work and free time (time spent on commuting, increased difficulty in accessing recreation and culture), or image-wise (the arguable visual appeal of 1990s 2000s suburban urbanisation, and the embarrassing reputation of an agglomeratio traffic jams). To make things more challenging, all above is being said with no attention paid to whether the metropolis itself is working well or not.

## 4. Industry[4] and industrial suburbanisation .

In Poland, between only 2004 and 2010, the number of jobs in predominantly urban regions[5] (to which the Wroclaw agglomeration belongs as one of several in Poland) rose by 20% (Adamczyk 2014). Although the direction of change growth is not surprising, the dynamic of it may be. This figure illustrates the fast urbanisation and the power of the largest settlements in the country. Between 1987 and 2007, the industrial and construction sector employment decreased from 36,3% to 29,0%, but on the way it observed a dip (25,2% in 2001), after which it bounced back a couple of percentage points. The figure for the year 2006 (29,6%) has Poland above the EU-27 average (25,0%), but, for instance, at the exact same share of this sector as in Germany (Zajdel 2010). Two main conclusions can be drawn from here: 1) that the sector of industry and construction still provides for a lot of jobs despite the perceived crash resulting from the decomposition of obscure, heavy socialist-era industry; and 2) that the move towards the western-type economy relying strongly on the so-called services and self-employment is fuelled largely by shift from traditional forms of economy, mostly from agriculture-related professions[6]. The relatively large proportion of industrial jobs is a topic for discussion from a few points of view, particularly in the strategic economic aspect (the idea of reindustrialisation of

[3] In this paper, as well as in all discussions about Polish urbanisation, the word agglomeration is used merel in its everyday, semantic sense, and not in any concrete way meaningful for spatial planning. Poland has no legislation which would establish any structure for major cities and their surrounding settlements. For this and other reasons, local attempts to create agglomeration associations are only subject to their internal success or failure, with no help possible from external legal provisions or mechanisms.
[4] The paper focuses on all production activities of the economy and postulates using the word industry in a broader (ironically, post-industrial) sense than its traditional, relatively pejorative one. Moreover, in the current technological and globalised era, the border between the industry and the service sectors is more blurry than ever.
[5] As classified by Eurostat.
[6] This share still was the highest in Europe in 2006, at 15,6%.

Europe; the question of sustainability of industrial economic growth), and the aspects of ecology and image (the good reputation of green industries vs. the bad classical reputatio general). For the 25 post-transformation years of Polish history, however, the number of available industrial jobs seems even too low for the economic needs of the country, keeping in mind the most dire unemployment phases (20,0% in 2002) and the current, moderate unemployment rate (11,6% for April 2015).

In the regional scale, research shows Wroclaw and Lower Silesia being in an average-to-good situation concerning the industrial sector of the economy. Work efficiency research shows the region as one of the leaders in the country (fig. 1) (Rachwa 2010).

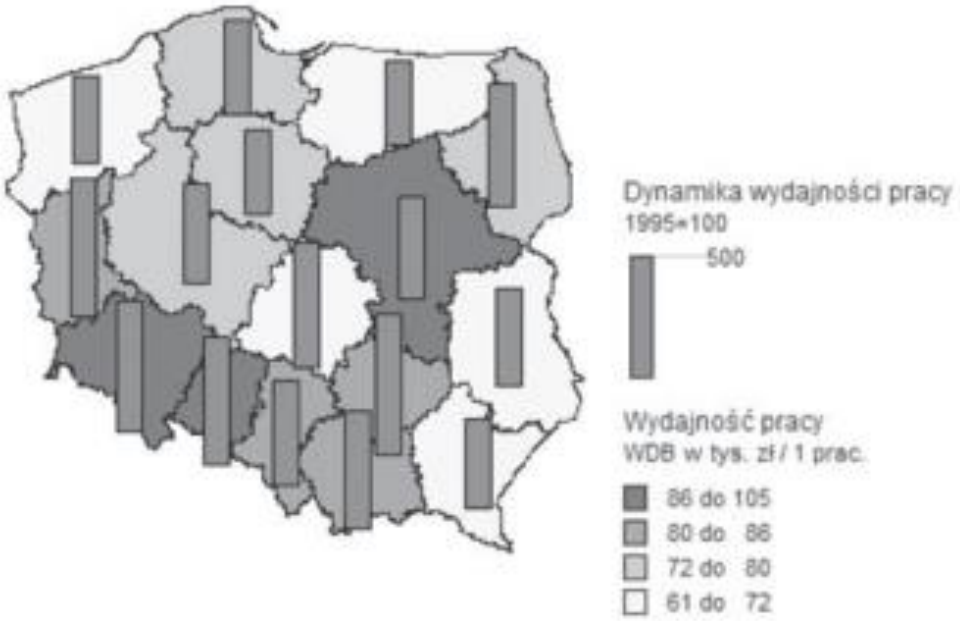

*Figure 1. Work efficiency in Polish regions (2007).* (Rachwa 2010)
*Bar chart: work efficiency dynamics, base value: 1995=100.*
*Colours of regions: work efficiency in thousands of PLN per worker.*

This couples with the region s convenient geographical location in attracting foreign and domestic investment. In a research focusing on innovation potential, Wroclaw was classified as type II: equipped with a well-developed R&D base and weak industrial resources (fig. 2); the referred research points to significant growth of the service sector in this type of cities (Si k

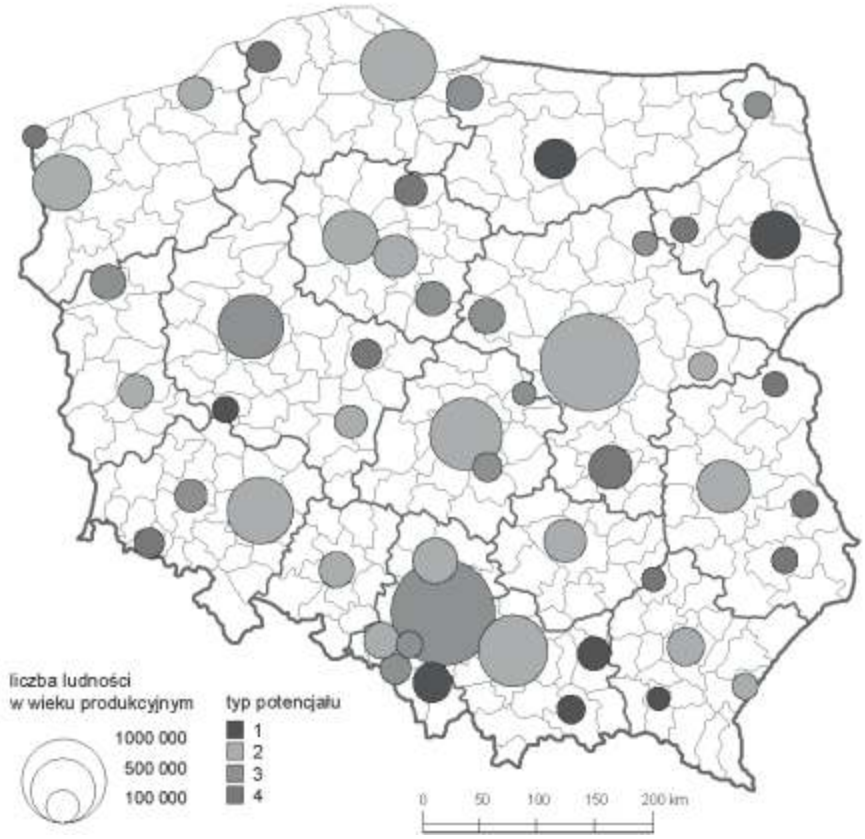

*Figure 2. Classification of Polish cities according to innovation potential type (2008).* (Si ka 2012)
*Circle radius: population in working age.*
*Circle colour: potential type.*

Another reason might be found in the collapse of old, large-scale industries of the previous era and the rise of more modern industries, many of which have geographically settled outside the city limits. With the administrative constraints in mind, in a study of the number of foreign investments attracted by Polish cities between the transformation and 2012, Wroclaw ranks second in the country after Warsaw[7] with 55 of them, and experienced a 6,7% increase in that number between 2008 and 2012 (G bocki 2013). Numbers for all cities would be certain to grow if investment vicinities were taken into account, and in the case of Wroclaw the increase in the count may be significant [future work within this research will explore this topic]. Finally, studies of the economic base of major Polish cities point to Wroclaw as having a solid industrial workforce foundation with some surplus in this sector, despite noticeable industrial job market already in 2008; Przyby a, Gonda-Soroczy ska 2013).

In order to shed some light on industrial suburbanisation , as well as on the difficulties i a cohesive agglomeration spatial policy, and in order to keep the particular focus of the city of Wroclaw in mind, a number of explanations need to be provided. A look on production companies located in downtown areas of cities may serve as a convenient starting point. Primarily, they are subject to their own technological regime, as well as to norms and regulations. When faced with a must to modernise, companies calculate whether it pays them better to invest in modernisation in their

[7] However, the capital drew exponentially more investments than any other city 509 and more than the next 25 cities in the ranking combined. This, again, is an imperfect count due to the seats of multiple companies being located in the capital, which does not necessarily fully represent their geographical business focus.

current location or in construction of new facilities in a new location. Often, the result favours the latter solution, especially since it additionally poses an opportunity to switch to modern, prospective technologies and hopefully make a technological leap. This scenario is particularly more probable in the case of space-consuming industries, which find perimeter locations more comfortable and affordable. The more modern, high-tech ones which frequently means less materially productive ones mostly need less space and can afford staying in more attractive, central locations. This is coupled with the aforementioned efforts of communes in vicinity of large cities to attract investors, which by far does not mean only external ones; luring in a company from inside their own metropolis is just as good, if the final result is as desired.

Most (non-global) companies, even if they decide to move their seat, prefer to stay in their regions. That is the case for example due to the already-established contact network or the well-known market. The move, then, takes them to suburban communes. The regional connotation remains, however, frequently along with an office or a branch in the metropolis. Such a company needs to dispose of the property which it had occupied before the move, and faces the question for what use the property is suitable. Continuation of industrial activity is unlikely, because then the original company might not have moved at all; therefore, such real estate undergoes change according to the fashion of the time, be it petrol stations, residential estates, cheap or regular supermarkets, etc.

As far as efforts to create and maintain a cohesive spatial plan for an agglomeration are concerned, a division line between the main city and its neighbours is clearly visible. The metropolis, naturally, cares for the best possible balance between the number of available jobs, the number of available and affordable homes, transportation capabilities, cultural/entertainment offer, and multiple other factors. In consequence, the city tries to keep any production (industrial) company wanting to move away from it; if that fails, it tries to work towards a scenario in which the replacing business is also from the industrial realm (or from a different but work-related one). This is due to a number of reasons, but primarily due to the need of sustaining the jobs the leaving company vacates, and due to the resulting spatial conflicts (for instance, between a newly-introduced residential use and the pre-existing unfriendly uses, such as industry or a railway line). At this point, the aforemen difference in the power of the two documents the Study of conditions and the local land use plans can be traced: municipalities have incomparably more influence on spatial turnover if they had managed to install a local plan into an area before it underwent change.

All the described spatial struggle, however, is being played out on the stage of single communes; no documents exist which would coordinate a larger number of them. As it has been said earlier, a national spatial plan and regional plans are there, but they mostly include the most serious public initiatives; agglomeration-scale postulates present in them are either not executable or are too so stand the clash with everyday practice. If there even existed a mechanism for creation of such documents, then a new tension would emerge: who would be supposed to draft them (what kind of body), and what would be the roles of the parties (especially of the metropolis) and the division of votes among them. The nature of this tension is clear: the administrative entities surrounding the metropolis would fight tooth and nail for a non-weighted split, and the metropolis would want the opposite.

In general, the difficulty in keeping industrial activity inside large cities is serious. In order to name a handful of particular Wroclaw cases, the following could be brought to attention:

- the massive former rail infrastructure repair facilities (ZNTK) in the north of the city have long been divided into numerous smaller businesses;

- the historic Piast brewery, partly preserved due to conservation protect dismantled, and partly unused, were supposed to be converted into attractive loft apartment complexes, which has not happened;
- the so-called burgher brewery , located in the eastern part of downtown, has transformed into a cultural centre;
- the large former meat production facilities, west of the city centre, have been partly conserved in terms of historic architecture and converted into a large shopping centre;
- the refractory materials production facilities, located in the westernmost district of the city, remain undeveloped until today;
- the PaFaWag railway production plant pose a rather positive case but largely due to the presence of local land use plans; from a major industrial facility, they have first turned into a rental area for all kinds of businesses, then (as part of another market fashion) into a private universities hub, to finally reach the stage of hosting technology parks and some smaller production companies.

Areas which the city has allocated for industry or production activities are als extent under land uses, which only may convert to something else in the future such as allotment garden complexes. Moreover, it should be mentioned that with the acknowledgment of the existing trends and with the use of the available planning tools, many areas in Wroclaw have been secured for production activities. However, these of them located close to the border of the city will stay empty as long as plots a couple of hundred metres away, outside the city limits, are simply cheaper to buy or rent.

## 5. Conclusions. Future work.

A crucial notion needing attention in this discussion is that the challenge lies in the continuous nature of industrial activity. A developer who has completed a residential estate aims at selling the apartments; if this succeeds, the company moves on to another project. An industrial company, in turn, needs to have its operation safe for years, and therefore calculates differently than other businesses.

The described situation is similar in other post-communist countries, but the authors of this paper are unable to offer a comparison with proper scientific responsibility. The opened research will, as mentioned in the introduction, include a case from outside of Poland (Dresden, Germany). The next stages in the research will focus on hard statistical data (numbers describing production activities in the selected cities), and on spatial representation of the changes of the last 25 years (mapping).

Keywords: key urban projects, fragile urban landscapes, urban ecologies

## 1. Introduction

This paper focuses vulnerable local-regional urban situations suffering from neg
regional imbalance, discussed here as fragile urban landscapes. The main aim is to bet
the planning problems of such landscapes, and especially to explore how key urba
developed as an operative planning method to transform such situations.

Urbanisation, urban competition and increased mobility have changed administrati
networks between cities on both global and regional scale (Harvey 1989; Sassen 2
Massey 2007), blurring specific characteristics of, and division between, urban
periphery. New approaches are needed in order to understand how urban systems, f
meaningful coherences amalgamate on local, regional and global scales (Mostafavi
Brugmans and Strein 2014) and to bridge local-regional gaps in planning (SKL 201
It is also necessary to tackle uneven geographical development with increasing d
population, economy etc. between growing and shrinking regions (Massey 2004; Tie

Sweden's strong planning tradition from the 1960s has undergone a shift from 'go
governance' with consensus-driven modes of participatory planning processes pair

ambitions for sustainable development. At the same time, urban concentration, vi
and entrepreneurial tactics drive cities and municipalities to attract dwellers
in order to secure welfare and local services (Tunstr m 2009; Fredriksson 2014).

According to sociologist and geographer Neil Brenner, current urbanisation must
both concentrating and expanding processes, the first being a clustering process
containing diverse socio-spatial changes working across territories and scales a
mechanisms of today's capitalised and industrialised economy. (Brenner 2013, p.
differences in urbanised landscapes must not be understood as a dichotomy betwee
but as an 'explosion' of changing patterns and potentials in a densifying textur
This challenges traditional conceptualisation of towns and cities as defined cen
rural (non-urban) contexts (Brenner 2013, pp. 99-101), and calls for systematic
reinvention of urbanisation from both specific material contexts and the 'contex
structural geopolitical and geo-economical processes of change (Brenner 2013, p.

With outset in Brenner's understanding of urbanisation, we speak here of 'urbani
critically recognising what Harvey (2006) and Massey (2004, 2005) discuss as gro
regional development, which threatens to be socially discriminating and regional
argue, that current planning suffers from stereotyped city models, with focus on
'regional blindness' that disregards the potentials of the regional landscape as
formations (Nielsen 2004; Tietjen 2011). Our research also responds to a recent
land use planning to better meet with societal challenges (Swedish Government 20
need new planning approaches, and an emerging interest within the Swedish planni
proactive design-based research.

Our focus of investigation has been to identify, develop and enhance the key pro
the operative capacity of key urban projects at various stages of urban planning
processes, especially concerning fragile urban landscapes. The work includes: to
theoretical framework for key urban projects; to develop and discuss key urban p
planning tools to handle fragile urban landscapes; and to test these tools in re
processes. The research has oscillated between theoretical studies and collabora
local-regional planning situations, exemplified in this article through two empi
ambition has also been to formulate a conceptual and methodological framework fo
local-regional planning, primarily concerning fragile urban landscapes.

The study is part of a practice-based PhD-project in architecture, conducted by Nils
supervised by Catharina Dyrssen, with the overall aim to enhance local-regional
possibilities in urban development. The paper first presents central concepts an
overview of relevant research and practice approaches to key urban projects. The
methodological framework is outlined followed by a description of two cases refl
landscapes, and in which Bj rling has actively participated as an architect and
student.

## 2. Fragile urban landscapes

The mechanisms of urban competition and its inequality effects may lead to formi
defined as fragile urban landscapes, i.e., local situations that suffer from wea
more important, find themselves locked in their existing circumstances, physical
positions and identity.
Our empirical and theoretical studies have discerned four interdependent conditi
landscapes: (1) The local situation, lack of resources, planning competences and decision mandat
handle local-global change and meet with new demands about sustainable conditions and

to adapt the current situation to new needs and possibilities; (2) the current si
physical structures that are resource-demanding to adjust to new possible use; (
have affected the local position and function within regional and global networks; (
situations are augmented by the use of idealizing and unrealistic future images,
of the successful city classify the fragile urban landscape as problematic or ir

The lack of power and capacity in relation to ideals and expectations for develo
situations vulnerable to the impact of ongoing political, social, cultural, econ
this often hinders them to recognise new meaning and potentials in resources (ma
well as in the physical landscape. Therefore, it is necessary to approach the si
systemic level, as a physical-structural problem, and from a sense-making perspe
understand this as an integrated topographical, topological, systems related and
densification, of importance both to the local and to the regional contexts.

To meet with new demands, fragile urban landscapes need to transform and be prov
accessibility to urban functions and increased collaboration (between municipali
sectors, areas and actors) in order to strengthen the local-regional possibiliti
resilient urbanised local-regional landscapes. It is therefore crucial to study
and meaningful relations can be developed, and how new combinations of existing
bridge the lack of built density.

## 3. Key urban projects

Key urban projects are defined here as projects that can open, lock or change di
transformation processes. This includes to make visible, question, generate and dr
specific, local-regional, relational conditions; to bridge gaps between local an
make operative the transformations by gathering resources, competences and decis
We use the concept of project in regard of its projective capacity, where the ar
tool to assemble relevant knowledge, give it coherent form so that it can be dis
stakeholders, and suggest a direction for a transformation process (Cuff and She
conceptualization of 'project' is always inscribed in continuous transformation
may have far-reaching impact in both space and time. Thus, the single project is
part of systemic urban processes. Key urban projects shall have a projective cap
and design processes and an operative role in the actual urban redevelopment. The cor
indicates that the project needs to have the capacity to either open, lock or ch
transformation, and that it shall be able to meet with existing conditions of ea
'urban' refers to the extended urbanised landscape that humans shape and form in
develop societies.

Thus, key urban projects shall be able to manage step by step transformation of
landscapes and form a fruitful method to handle planning situations. Accordingly
through what they are, but through what they can do; what they can make visible
process, how they operate in decision making, and what processes they open or lo
projects-capacity should include to: (1) handle relations between center and per
contingencies with onset in space as interconnected processes between urban and
make visible driving forces for the development (change) of society; (2) operate
spatial and planning conditions to identify available resources, skills and poss
(3) support dialogue and critical negotiations; (4) develop diverse perspectives
available resources into alternative directions of development; (5) develop and s
making relations, positions and networks; (6) intervene in local-regional situat
and relevant meaning; (7) make possible alternative strategies for regional and
where Key Urban Projects provide concrete steps to strengthen fragile urban land

Investigating key urban projects sets focus on the possibilities to rather densi
co-productive relations than urban space as such, that is, to reveal conditions
densify relational networks, i.e. increase connectivity in scattered urban forma
realistic and resilient visions of the future urbanised landscape. It is assumed
qualities and values can be improved as conditions for transformation, and used
different scales and qualities of the urbanised landscape.

## 4. Urban acupuncture and projective prototypes

During the last thirty years several efforts have been undertaken to develop the
that can initiate urban transformation at different scales. Early examples are t
Sol –Morales, with Urban Acupuncture where specific small scale interventions
coordinated strategy to trigger urban transformation (de Sol –Morales 2008, 24).
through a detailed understanding of spatial formations, possibilities can be rev
making relations in apparently meaningless and abstract urban landscapes.

Correspondingly, Raoul Bunschoten demonstrates how Projective Prototypes can b
operative mapping-tool to reveal hidden potentials and possibilities in urban la
2001). Through interactions between the documentation of existing conditions and
alternatives, a number of options are created, in turn identifying liminal bodi
actions that are needed to transform the current situation in new directions. Af
critical negotiations, alternative changes are tested through the prototypes wit
flows and reveal both the material conditions of urban formations and the underly
sustain them.

On a regional scale, Emscher Park in the Ruhr region (Sieverts 2003; Waldheim 20
strategic plan for Flanders (Stalenhoef and Geldof 2007) are examples of how sma
coordinated through overall frameworks to step by step transform regional landsc
formed a flexible structure that connected and facilitated new regional networks
existing potentials through a large number of individual projects. Flanders focu
economic driving forces in a national perspective. Both cases contributed to giv
landscape new meaning from available resources, skills and mandates.

Relating to these examples, we argue that there is a need to see key urban proje
mapping tool and a mode to establish collaboration and critical negotiations, wh
be identified and obviated, and existing qualities combined in order to build me
productive networks for lasting strength.

## 5. Theoretical-methodological framework

The knowledge production in our studies moves forward by continuously shifting b
theoretical framing, comparisons to relevant reference projects, and development
Theoretical models have been tested and remodeled in actual planning situations
mapping processes that oscillate between defining problems and outlining concept
spiraling process gradually forms strategies for negotiation and implementation
situations, with the intent to assemble resources, skills and mandate in adequat

To support the systemic and operative logics of key urban projects it was necess
correspondingly flexible, multi-faceted theoretical-methodological framework, of
components are: (a) design based, proformative strategies (Corner 2006; Cuff and
constructed around (b) an understanding of the urban landscape as layers of urba

2001 (1971); Guattari 1989; Reed & Lister 2014), (c) diagrammatic layers (Deleuz
1987; Deleuze 2006) of urban form, (d) a discussion on space as absolute, relati
(Massey 2005; Harvey 2006), and (e) assemblage (Deleuze amd Guattari 1987; DeLan
Dyrssen 2010) as design-based tools to elaborate sense-making relations.

a. Design-based, proformative strategies
Dana Cuff argues for proformative methods, i.e. future-oriented approaches opera
complexities rather than abstract models (Cuff and Sherman 2011, pp. 24-31). The
approach can be understood as a type of action-oriented, design-based research,
an investigative methodology with concrete steps and close feed-back loops betwe
mapping, construction of problem settings and theoretical reflection (Dyrssen 20

b. Urban ecologies
In 1971 Reyner Banham characterised Los Angeles as based on four ecologies ( Sur
Foothills , The Plains of Id and Autopia ), deriving from the city as layered
aspects of climate, topography, water-supply and infrastructure etc., which incl
cultural systems forming the premises and intricate mechanism for development (B
pp. 117-121). Movement and mobility in all scales and with all kinds of infrastr
preconditions for urban life in a double process of what can be made possible (B
Combining space with time and speed, Banham questions traditional notions of den
structures and urban identity, arguing that the concept of urban ecologies can b
definitions of what composes the urban landscape, and to indicate new relations
and social life (Banham 2001, p. 218f).

As a conceptual basis for our work, Banham's material ecologies need to be suppl
dynamic interplay between mental, social and environmental ecologies, as introdu
Guattari in The Three Ecologies (1989) and which, he argues, constitute a contin
process for individuals and their habitats through a logic of intensities rather
(Guattari 1989, pp. 134-136). However, as biopolitical processes, ecologies need
producing and forming concept of power, shifting between producing and being pro
and being controlled, distributing and being distributed, thereby articulating c
and normative processes (Foucault 1998, p. 15, p. 33).

Hence, production of space is always related to a power perspective concerning w
produces spatial norms and meaning, at the same time as space in its material co
subjects and produces societal frames. Spatial design with its capacity to deal with ph
meaningful structures and historical layers is one of the most useful tools we h
change of society (Reed and Lister 2014, p. 98). Urban ecologies can bridge the
urban and rural, culture and nature etc., and are therefore crucial for a sustai
understand and handle the interplay between systems to position the social condi
centre of discussions on urban transformation.

c. Diagrammatic layers
With onset in the biopolitics of Michel Foucault, the spatial configurations o
seen not only as the result of advanced capitalism, urbanisation, the welfare society
essential tools for producing and ordering modern society (Wallenstein 2009, p.
Deleuze's reading of Foucault, normative identities, hierarchies and relations o
through the spatial context where the layered relations that constitute power fo
discloses the mechanisms producing order and control embedded within all institu
all physical typologies (schools, supermarkets, highways, intersections, apartme
coding and un-coding mechanisms of the diagram, society can be changed (Deleuze
Diagrammatic layers are in constant modulations and can thereby be seen as relat

compose and assemble sense-making networks (Deleuze 2006, p. 69) in an ongoing c
process of control of and control by, production of and production by etc. Hence
diagrammatic layers key urban projects can trigger, accelerate, block or break t
processes and open up for new productive combinations.

d. Absolute, relative and relational space
The notion of urbanised landscapes as overlaid and combined ecologies can explai
transformation can be triggered by apparently small changes. The potential of th
connected and transformed through both physical and narrative changes. In order
foundations of, and trigger points for, qualities of a certain urban ecology, we
spatial aspects presented by geographer David Harvey (2006, 2009): absolute spa
material, topographical, Euclidian spaces), relative space (topological relati
as well as individual interpretations and abilities), and relational space' as
sense-making relations of space. According to Harvey there is no such thing as
of the processes that define them , and these processes do not occur in space b
spatial frame (Harvey 2006, p.123).

Both Harvey and Cuff argue that planning using predefined understandings of what
should be produces static spatial solutions to planning problems (Harvey 2006; C
2011) and has resulted in urban landscapes of typologies, specialised for progra
have difficulties to handle diversity and change over time. In order to grasp th
urban landscape, architects and urban planners need tools that work through all
relational) notions of space. The consequences otherwise are urban landscapes un
shifting processes coursing through and across the urban field: terra fluxus . T
be space as process rather than space as form (Corner 2006, pp. 28-30).

e. Assemblage
The concept of assemblage is important in order to structure and handle the spat
operative and flexible way. Manuel DeLanda, transferring the theory of assemblag
and FØlix Guattari towards a design theory, stresses that a relevant assemblage
linkages between components as well as mechanisms of change, interaction between
interior-exterior contingencies in which one may discover triggers and catalysts
p.20, p.32). The assemblage is a flexible composition of content and expressi
ongoing processes of territorialisation and deterritorialisation through cod
condition and develop the assemblage (DeLanda 2006, pp.12-21, pp.28-31).

To deal with the complexity of the urbanised landscape, we need to replace the t
cause and effect by the assemblage as a sense making, relational, evolving and t
composition (DeLanda 2006, p.20). This can be regarded as a design approach to k
evolving mappings of key points, links and qualities of relations in specific si
With urban ecologies, connecting also to diagrammatic layers and space as absolu
relational, assemblages can be constructed as evolving models of thought that op
both to transform the urbanised landscape and to change normative identities of
or large scale operations. Essential here is the design competence to handle and
temporal-material complexities, and the recognition of evolving, non-linear processe
with ecologies, assemblage is also useful to map active processes that constitut
situations.

## 6. Empirical contexts

In this section we will describe two projects and how their capacity to transfor
landscape can be used as key urban projects. It is discussed how they may addres

continuities rather than hierarchies, how they develop as sense-making rather th
and how they may have the capacity not only to produce solutions in a local situ
trigger change of relative and relational qualities and networks. The projects c
fieldwork included in the doctoral studies, and have promoted the understandings
capacity and the construction of the framework (also see Bj rling 2014).

Project 1: Beneath the pavement is a beach , Mariestad
The town of Mariestad in Sweden used to be an important local center as capital
inland port for regional and national transportation of grain and oil. The main
Mariestad as a fragile urban landscape are the topological changes in trade-flow
being the county capital to a position in the geographic periphery of V stra G t
region in Sweden), which affects the notion of what Mariestad is and can be in t
structure is also locked into reproducing existing spatial relations between its
therefore has problems to adapt to new needs.

In 2004 the architect office AIM Architecture Is Made won a competition about th
brief was to find a strategy for how to transform the area into a residential an
town and thereby add a considerable number of new housing and activities in the
Mariestad. The motto was Beneath the pavement is a beach . With the aim to esta
transformation process that could evolve over a long period of time, the proposa

outlined relational and topological principles for future change that would impr
That far it was a process-oriented urban design project. Later, as part of pract
studies, it also initiated a methodological framework for key urban projects fro
perspectives:

a) A changed narrative: First, the project suggested a new beach. The future saga
created has been very important both for the waterfront project to evolve around
new position of Mariestad as the town by the lake in a regional context. It ha
administration, politicians and the public in order to move forward with the pro
waterfront. The beach illustrates the relational perspective and the impact of t
creates a common future narrative that changes relational space and plays a powe
transform local identity and spatial sense making.

b) Temporary projects: Mariestad struggles with the backside effects of global e
stagnated population and a small annual investment budget, changes of absolute s
pace. It has therefore been important to identify projects that focus on change
aspects. Art projects, small commercial booths and a new playground have been te
in the harbour area to activate the boardwalk and make it a strong public space.
along the river now evolves as an additional recontextualisation project. The te
two main focuses; first to show immediate change and, second, to involve people
are seen as laboratories that through additions, like Bunschoten's projective p
existing potentials, include a diversity of individual initiatives and relative unde
future relational memories of the waterfront and the town.

c) A future context: Also (more) permanent projects need to be dealt with as too
possibilities. During and through the design process the existing situation is c
future context that in return generates guidelines for how to further develop th
architectural projects. In this way the planning process takes its onset from bo
historical context and a modelled projective future situation.

These three perspectives relate to alternative and interlinked ecologies, from w

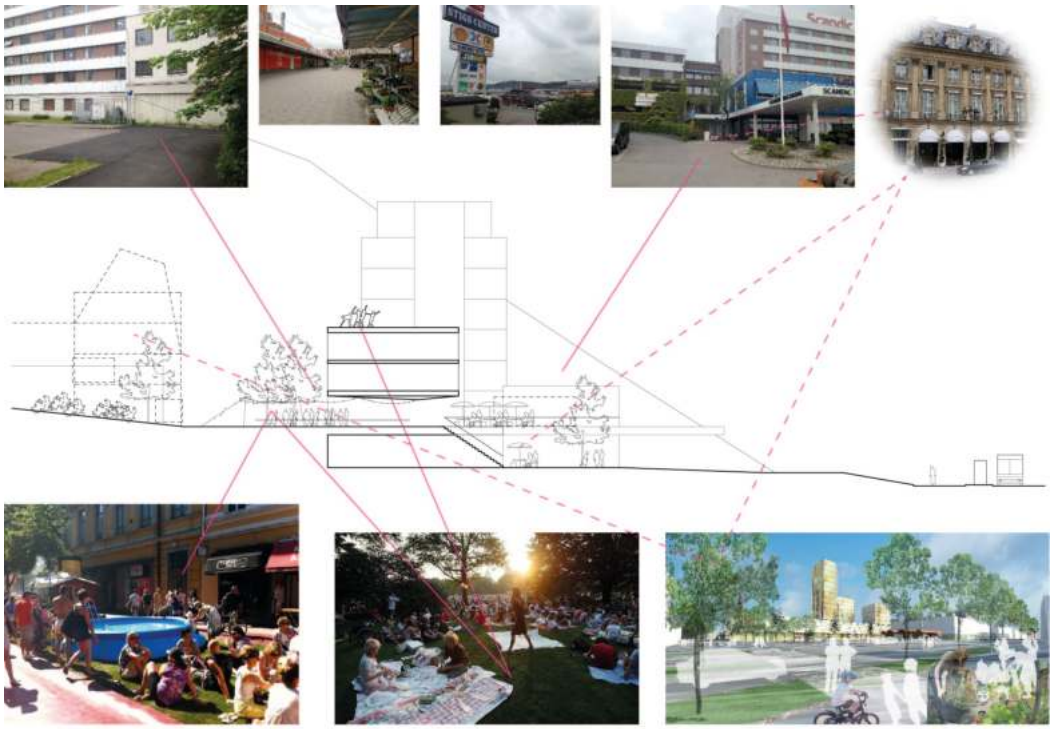
connections between people.

Project 2: Selma, G teborg
Another example of a fragile urban landscape is the transformation of Selma Lage
the G ta ˜lv river valley in Gothenburg. The valley can be described as both par
interconnected systems of different urban ecologies. In collaboration with Noema
Mapping, AIM made an invited competition in 2011 about how to regenerate the are
square. The competition program presented the square as a problem area that coul
diverse mix-used urbanised landscape. This makes the area s current values, prog
fragile for future development. The proposal by AIM and Noema was presented as a
with its point of departure in the existing social situation, qualities and pote
tried to start processes of transformation and densification from local conditio
approach was to combine potentials from different urban ecologies into new possi
development by adding new functions and at the same time sustaining existing pro
ambition was to work with a stepwise densification of both buildings and new rel
feed into the overall revitalization process for the area.

Selma Lagerl f square is a local square surrounded by residential areas about 7 k
centre of Gothenburg. From a traditional perspective it relates to the city peri
the main motorway entrance from the north to Gothenburg (road E6), and thus the
places today, relates to double and complex center-periphery conditions. The highway
Stig Center, close to the square has a characteristic program with gas stations,
and workshops. So depending on scale, issue and perspective, the square and the
can be seen as nodes, either central or peripheral, as part of the local ecology
structure from the central city or as part of the regional ecology that connects
the regional network of Gothenburg. It is important to recognise this flexible i
understand the specific site conditions and potentials; depending on perspective
ecologies change the articulation and qualities of the topographic and topologic

These ecologies are in several ways interconnected but at the same time they are s
physical design of the urban landscape, a relationship in which Scandic Hotell
point (Figure 2). The hotel was built in 1971 as a motel including restaurant, b
station. Even if the building mainly served travelers from the motorway, it turn
entrance-zone towards both the regional and local ecology. However, since the se
been extended with rooms and parking and the entrance-zone has been redirected o
motorway, turning its backside to the residential areas with weak connections to
the same time the main entrance towards the motorway does not have a satisfactor

appearance of functions and programs connected to the regional ecology. With a s
wintergreen plants and a large cherry-tree it rather communicates an ambition to
metropolitan surrounding. By reworking the hotel area, its entrances and connect
link could be formed between local and regional, old and new structures.



**Future memories**
The regeneration process of Selma Lagerlöfs torg is important for creating a future saga about the local situation and create a will to reopen the closed fasade.

The narrow green space around the main entrance can then be delevop as a passage where a part of the parking-space is rebuild as a small workshop or office-space. maybe a barber? or a gym.

On the west side a small "silent" park can be a part of the open air café.

**Temporary projects**
As a project to create common memories the garage can be used for a street-dance festival to connect the hotel to the local dance-school.

**Future context**
When the area around Selma Lagerlöfs torg is regenerated new buildings will be added and old buildings replaced. New housing will give more people to the area and bring more activitities. But it is important that new additions are seen in relation to the two ecologies and that new buildings contain programs that support the relation between The square and the intersection, between Selma and Stig.

Figure 2: The passage from the local to the regional scale is re-open

This split situation has been the context for elaborating ideas about how the ec
different programs and functions can be connected in new ways in order to use th
potentials to deal with related urban issues. What we want to stress here is tha
transformation needs to build on different perspectives of centrality, grow as i
find key solutions, sometimes small interventions, that can unlock the conflictin

Several other projects have been conducted, also coordinated within the ongoing, Structural Image for the Skaraborg Region, conducted in collaboration with fifte municipalities and West Sweden at large, and for which Nils Bj rling is the proj means both an opportunity to upgrade the methodology development to a larger com challenge more extreme polarities between perspectives on centre and periphery ( West Sweden's major city), and to test possibilities of local-regional effects o their potential capacities.

## 7. Results

Our results so far show that the capacities for key urban projects as an operativ fragile urban landscapes need to develop in coherent, flexible, adaptable, inven refined in accordance with urban ecologies, assemblages and multiple spatial und where design based thinking-making forms the basis for knowledge production. Mor planning processes, the key projects' capacity includes to:

(i) operate mappings processes (topographic, topologic and relational) to invest contemporary urbanised landscape as overlaid systems, model alternatives and inc diversity of perspectives on needs and opportunities; (ii) identify, analyse and processes that maintain, open or block conditions for urban formation; (iii) mak specific interventions that change the local position and function in networks, of meaning, and establish spatial relations between the urbanised landscape and Establish platforms for critical negotiations and set up dialogue to discuss dif long-term sustainable development; (v) Form co-operations that gather a diversity relevant actors, and combine available resourses, skills and mandates to secure

## 8. Discussion

To qualify as key urban projects, planned interventions need to trigger or open transformation process. This capacity depends on situation-specific qualities an but adapted to various contexts.

As described through the projects in Mariestad and G teborg, transforming the ph fragile urban landscape is often characterized by slow pace and lack of economic this landscape needs tools able to reveal keys that start or turn the direction qualities can be improved and combined in new ways.

In order to distinguish key urban projects within the planning process, mappings identifying relevant issues and relevant contexts (ecologies) and the constructi part of constituting the framework. To reveal what is relevant it is necessary t models that reach over and interact between scales, with assemblages simultaneou micro and macro-scale. This, in turn, can guide how the concepts of site and pla understood as a combination of all Harvey's spatial aspects. Such mappings can r conditions for, and significance of, a site, with its specific qualities and pos transformation. Further, key urban projects can be used to visualize implementat shown in the Mariestad case. In order to formulate future visions and aims, key been used to trigger critical negotiations and support decision making. So in order t urban projects they need to gain the capacity to transform both relative and rel reconfigure its own typology, question existing normative images of the urban, o Stig, connect urban ecologies challenging preconceived understandings of center

Through assemblage thinking, and with the complex urbanised landscape as articula
urban ecologies in mind, we may turn back to the critique of strategic planning,
introduction, of space as form rather than space as process. It is then clear th
some cases no longer make sense. Short term problem solving needs to be replaced
of normative identity. It is also important to work with the urbanised landscape
own site specific and regional networking capacities in order to develop long-te
resource efficient conditions and to expand the notion of what the urbanised lan

## 9. Concluding remarks

It is through the material reality that relative and relational aspects of space
play. The characteristics of these processes are an ongoing search for the relat
assemblages that reveal significant issues which, in return, may open up new fie
combinatory possibilities to develop. Here key urban projects can wedge in betwe
catalytic and proformative potential to transform urbanised landscapes by connec
revealing relative and relational qualities, visualising strategies and triggeri
mechanisms for implementation. This must always be accompanied by an awareness o
and unstable conditions in the understanding of the urbanised landscape. Deleuze
DeLanda's theories of assemblage and Guattari's and Banham's definitions of ecol
these compositions are never stronger than their relations. New knowledge and ch
always require that the whole assemblage is revalued. The relevant assemblage is
to identify key urban projects and a composition that helps to also reveal and d
the specific key urban project.

We argue that key urban projects, by taking on these active roles, can be used to streng
form strategies for incremental densification of sense-making networks in urbani
lack resources, skills and mandate to meet with current competitive modes of str
key urban projects are also developed as diagrammatic additions to change unde
de-coding of assemblages, they can also increase the capacity to change the me
relational networks and qualities, and to trigger synergy effects and produce ne
Through such understandings, sustainable strategies can be projected as guidelin
transformation and densification of fragile urban landscapes.

**Two decades of urban dispersion in Lisbon Metropolitan Area or the failure of consensus in urban and regional planning**

Luís Carvalho[1]
Jorge Gonçalves[2]

[1] CIAUD, Faculty of Architecture, University of Lisbon, lsc@fa.ulisboa
[2] CESUR, Instituto Superior Técnico, University of Lisbon, jorgemgoncalves@tecnico.ulisboa.pt

## 1. Introduction

### 1.1 The subject and its context

The dispersion became part of the urban lexicon applying a binary understanding: the dispersion is a problem and urban concentration is good; the first is inefficient, the second monetizes; the low density generates weak territorial cohesion, compactness is a sign of life and dynamism. One is always applicable; the other is always to refuse. There are alternatives to these dichotomous keys or gradations that can be applied. There are - apparently - enormous facilities that these binary reading processes provide to urban planners as to politicians or to academics.

And this, apparent clearness, is essentially based on three components:

The urban design where there is the urban form (said rational) that mobilizes technicians, politicians and academics;

The territorial classification, it is the line between urban land and rural land that separates and groups;

The dimension of the application of cost-benefit system where continuous and coherent urban form allows distributing the costs and benefits among a set of well-defined owners.

Otherwise is the diffused and blurred urban form which makes uncertain the demarcation of the urban perimeter and the urban dispersion, generating costs, do not easily allow:

The representation of the urban shape that appoint the evocation of an identifiable and classified city model;

The demarcation of a line establishing the territorial classification;

The distribution of costs and benefits conferred by applying a cost-benefit system which aims a fair distribution of capital gains generated in the territorial transformation process.

Always the shape, the line and the rule as if they were absolute truths emptying any criticism that could be made. Almost never the process, the dynamics, the cultural identity and the strength of multidimensionality. And rarely, the incorporation of chance and unpredictability, of conflict and uncertainty. The work is done with a cut in space and time and it is in this section, which crystallizes the time and suspends the action of agents (natural and anthropogenic) in the territory, that decisions are taken and rules are set out.

### 1.2 The problem(s), the purpose and the concept

The problem of no variety: the consensus, near the single discourse, on the problems of urban dispersion and about the virtues of compactness, which disrupts the (various) evidence arising from the reading of the actual transformation of the use and occupation of land in recent decades in Portugal.

The problem of the concept: the urban dispersion is indisputable evidence and takes in Portugal (as in other countries) very different approaches in time, in formal and dimensional aspects, typological diversity or legal issues (Ulied *et a*l, 2012). This diversity and the difficulty in categorizing the phenomena(s) associated with this dispersion carry, even today, a lack of consensus on their own definition and corresponding impacts. But this vagueness widens mainly to the perplexity on the very occurrence and strength of urban sprawl and the lack of understanding of how to act facing this reality.

> "The urban sprawl in Portugal is not a possible choice. It is, first of all, a territorial reality with social economic and cultural diversified contents. For this reason, it should be the starting point for any territorial organization model for the development of 'new urbanities "and" new residential areas " that do not necessarily have to reproduce standardized and urban pre-determined forms." (Soares, 2002 quoted by Vaz, 2009).

The Objective

This Communication puts forward a double check on urban dispersion: i) its territorial extension; ii) the (in) capacity of power in dealing with the phenomenon. We intend to show between 1990 and 2010 and in a precise spatial horizon, the Lisbon Metropolitan Area (hereinafter LMA) - what is the relationship between the intentionality of technical and legal discourse on urban dispersion and the effective occurrence of this dispersion in the territory[1] [2].

The issues to be addressed to meet the goal:

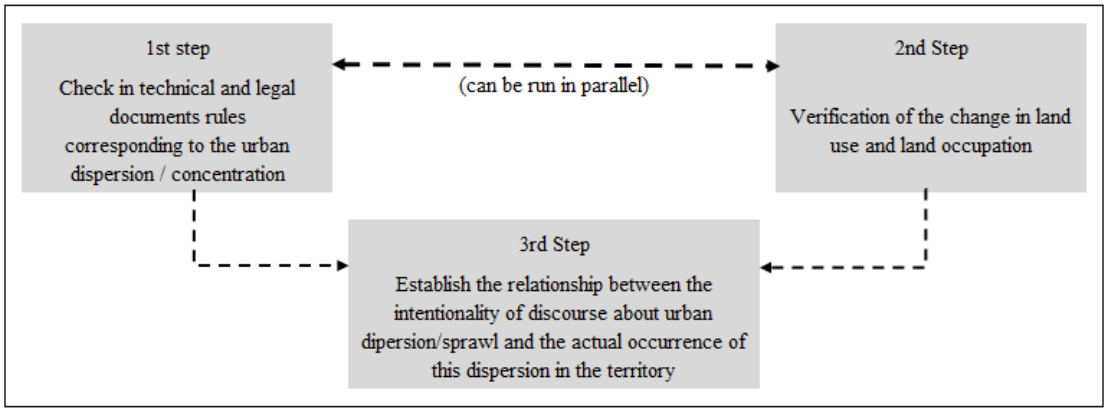
i) Verification of the rules regarding to the dispersion/urban concentration contained in the key documents of urban and regional planning in Portugal and in the territorial management `tools` (the plans) of national / regional level covering LMA;

ii) Verification of the land use and the changes regarding to artificialized territories landscapes and, in these, the territories allocated to the urban fabric (continuous and discontinuous).

## 2. Methodology

The definition of the objective and the statement of the issues to be addressed determine the methodological process of the studies presented in this Communication (Scheme 1)

Scheme 1: Linking the 3 steps of the methodological process



[1] Although the temporal focus is the past two decades some data records to the 80s of XX century .

[2] Space horizon of the study is LMA (always taking into account the municipalities currently covered by metropolitan area) but in some issues will be considered national data.

## 2.1 First step: the reference standard

A set of technical and legal documents focusing on the most decisive specific rules that express the intention about the urban dispersion/concentration was studied.
A first component addressed to the key legal documents of Portuguese urban and regional planning system.

- Land Law, Decreto-Lei n.º 794/76 de 05-11;
- Lei n.º 48/98, de 11-08, sets out the bases of spatial planning and urban and regional planning policy,
- Legal Regime of Urban and Regional planning, Decreto-Lei n.º 380/99 de 22-09;
- Criteria for territorial classification and reclassification, Decreto Regulamentar n.º 11/2009 de 29-05;
- Lei 31/2014 de 30-05, sets out the bases basis of public policy for spatial and urban planning;

A second component to the two land management plans of national and regional level with a focus on the Lisbon Metropolitan Area.

- PNPOT - National Programme for Spatial Planning Policy, Lei n.º 58/2007 de 04-09 e Resolução de Conselho de Ministros n.º 41/2006 de 27-04;
- PROT AML, Regional Plan of the Lisbon Metropolitan Area, Resolução de Conselho de Ministros n.º 68/2002 de 08-04;

## 2.2 Step two: the land use and his transformation

It was found the land use and his transformation in the last two/three decades in the Lisbon Metropolitan Area taking into account three different and successive levels:

First level, taking into account the territory classified as artificialized;

Second level considering the artificialized territory classified as urban fabric and, within this, the land classified as discontinuous urban fabric

Such verification was based in the work developed from the Corine Land Cover[3] and Landyn projects[4] and the Census data[5]. Such records of the land use were weighted with the evolution of the resident population and building stock in the same time period (1990-2010) and in the same space horizon (LMA). For consistent verification a first task would be the correct perception of the lexicon used both in in projects Corine Land Cover and Landyn - for the good understanding of which areas are the so-called Artificialized territories (Table 1).

[3] The Corine program (Co-ordination of Information on the Environment) was created in 1985 by the European Community in order to develop an information system on the state of environment in Europe. The Corine Land Cover 2000 project (CLC2000) in Portugal is developed under the initiative IMAGE and Corine Land Cover 2000 (I & CLC2000) of the European Commission (EC).

[4] This project based in the Direção Geral do Território - focus the analysis of land use and land cover (LULC) in three moments (decades of 1980, 1995 and 2010), which allows to get an original and unique vision of land use and land cover changes (LUCC) on the past and present and preview the future in Continental Portugal. This project has adopted a strategy based on the Eurostat guidelines - Land Use and Cover Area Frame Survey (LUCAS) on sampling to estimate the spatial land use and land cover changes (LUCC).

[5] Censos 1981, 1991, 2001 e 2011; INE Portugal.

### 2.3 Step three: the confrontation between the rule and reality

The results of the previous steps - the study of documents and verification of soil transformations where weighted in order to verify the degree of adherence, or divergence, between the technical-legal intention to regulate the use and transformation of the land and the real expression of this transformation in the last two/three decades in LMA.

## 3. Analysis and discussion of results

### 3.1 The regulatory framework

Since the Land Law (published in 1976) until the recent law review on public land policy, spatial planning and urbanism (Law 31/2014 of 30 May) that all the studied documents, and they are the most relevant for the construction of political, administrative, technical and legal structure of urban and regional planning in Portugal, have rules that, in essence, aimed at (see Table 2):

i) To counter both urban sprawl as the scattered building (though the fight against the latter phenomenon is more marked in the plans than in general laws;

ii) To favor urban concentration being evident that intentionality, although with different strength in two territorial levels: the national level favoring the competitiveness of metropolitan areas in the European context; the regional level favoring the so-called "medium size cities"[6] [7];

iii) Restricting, complexifying (more markedly from 1998/1999) land classified as urban and/or the reclassification of rural land into urban land;

iv) Enforce rules of land classification and occupation that strongly limits the spread of existing urban areas and virtually preclude the occurrence of scattered building;

In short, all the studied documents are revealing a determined intentionality towards containment and combating urban dispersion, urban sprawl and scattered building and, in the other hand, to stimulate urban compaction. The reasoning of that intentionality has several facets: i) the argument of cost, which are higher in urban dispersion/sprawl; ii) the argument of rationality in locating public facilities, absent when it includes urban dispersion/sprawl; iii) the argument of the protection of natural values, which is weaker when considering urban dispersion/sprawl; iv) the argument of the consolidation of the urban network, called into question by urban dispersion.

[6] Term that in Portugal became more consistent in the last decade of the XX century from the PROSIURB program that had, among other its purposes, the consolidation of an urban network of me

[7] In a later part of this process of research on urban dispersion should be studied the contents of the Municipal Master Plans of the 18 municipalities of LMA. In order to understand if the level of municipal plans anti-urban dispersion intentionality is also present. It should be noted however that it is agreed that, in general, taking into account both the national scene as the LMA, these municipal plans (especially the so-called 1st generation run in the 90s of the twentieth century) turned out to be very permissive on urban expansion, urban dispersion and scattered building.

| | | | | IV — Normas orientadoras; 3 — Acções urbanísticas; 3.6 — Área de dispersão urbana a controla | *Os IPT devem:*<br>*a) Definir mecanismos que impeçam a habitação dispersa e concentrem o alojamento, designadamente segundo padrões de habitação de baixa densidade, nas proximidades de núcleos urbanos ou rurais existentes, desencorajando o fraccionamento da propriedade, regulamentando o destaque para construção e definindo a dimensão mínima da parcela edificável por categoria de espaço* |

### 3.2 Land use

Between 1980 and 2010 the artificialized territory in LMA expanded almost 60%, which corresponds to an increase 1.5 times the increased number of housings (about 38%) and 4.5 times greater than the increase of resident population (less than 13%). This divergence (see Table 3):

- It is emphasized in the last two decades (since 1995), during which the expansion of artificialized territory deepened while the increase of population slowed;
- It reflects a general decrease in urban concentrations since both the population density (in 2010 it has become 2/3 of that in 1980) as the dwelling density (which decreased from 29 to 25 houses/ ha in 30 years) decreased markedly;
- It tends to reinforce the urban dispersion as population, building and dwelling density decreases with the consequent increase in the consumption of artificialized land per inhabitant (in 1980 each inhabitant "consumed" 148 m2 of artificialized territory and in 2010, 209 m2);

Note however that in 2010 the artificialized territory of LMA accounts for just 20% of the total territory (throughout the country this value is around 5%), which denounces the Lisbon Metropolis or is too large and/or is too sparse.

Taking into account the specificity of the land uses of artificial territories proceeded to an analysis that allows the perception of the changes observed in the various components of the urban fabric (see Table 4):

- In the last 30 years the territory identified as urban fabric rose nearly 50%, but their share in all the artificialized territories has gradually decrease which indicates a substantial increase in this period of the territories dedicated, among others, to industry, networks of transport and/or spaces associated with these infrastructures;
- Introducing in this context the notion of "net" density it appears that, taking in consideration the the urban fabric, population density and especially the dwelling density decreased strongly since 1980[8];
- The continuous urban fabric as nearly doubled between 1980 and 2010 while the land classified as discontinuous urban fabric had a residual increase in the same period.
- This record, which could indicate a tendency for the containment of urban sprawl, is contradicted by the fact that, since 1995, the discontinuous urban fabric have increased about 30% while the continuous urban fabric have increased 20%. This record suggests, rather, a recent trend (in the last two decades) to the greater weight of discontinuity and urban sprawl in the transformation of rural land into urban land;
- Note also that the designated areas under construction tripled between 1980 and 1995 but between 1995 and 2010 decreased by 10%, which seems to reflect a significant drop in the process of urbanization and construction in Portugal since the beginning of the 21st century[9];
- The discontinuous urban fabric data in LMA are divergent with respect to the data checked for the all country: i) between 1980 and 1995 this tissue type LMA decreases more than 20% while in Portugal increased by 6%; ii) between 1995 and 2010 in the LMA discontinuous urban fabric increased nearly 30% while in Portugal increased by only 2%. These records suggest that in the last two decades allocated to discontinuous urban fabric virtually stagnated in Portugal but in LMA, this kind of urban dispersion is in constantly extension (over 3,390 ha between 1995 and 2010).

[8] Net population density = Total Population in LMA / urban fabric and net dwellinc dwellings in LMA / Urban Fabric.

[9] It includes: construction areas and abandoned areas in artificial surfaces territories.

Projeto LANDYN (DGT, 2013)

Checking the progress on changes in land use and occupation affection to artificialized territories and more specifically the land classified as urban fabric (continuous and discontinuous) now it is important to cross this evolution with other variables. This crossing took into account the artificialized territories in Portugal between 1990 and 2010 (see Chart 1).

Between 1990 and 2000:

i) mortgage loans (both in terms of amount and in terms of the number of beneficiaries) and the number of completed dwellings explode and the number of housing units completed in LMA (in which lies 1 / 4 of the population of Portugal) was substantially 1/10 of the total national which shows a strong reduction of the LMA weight in the particular context in relation to the dynamic building[10];
ii) the national GDP also recorded an exceptional increase but the resident population stagnated whereas in LAM, GDP growth generally followed the national trend but the resident population increased slightly;

In the late twentieth century the overall picture in Portugal suggested: a developmental spurt with significant increases in consumption capacity and access to credit and a strong property market which by a brutal increase in the number of dwellings (increased from just over 4 million in 1990 to about 5 million in 2000) and an increasing expansion of artificialized territories (from 3% to 4% of the national territory).

Between 2000 and 2010:

i) mortgage loans and the number of completed dwellings fell sharply (but only since 2003) and in this period, the number of housing units completed in LMA was significantly quarter of the national total which discloses a recovery weight of the LMA in the particular context in relation to the dynamic building[11];
ii) ii) the national GDP virtually stagnated and the resident population increased slightly and that the LMA GDP growth and resident population generally followed the national trend;

At present the overall picture in Portugal suggests: a prolonged stagnation of economic activity with breaks in access to credit capacity and a strong downturn in the real estate market with a a brutal decrease in the residential building dynamics (in 2013 it is concluded 1/10 of housing units completed in 2002). But despite this, two phenomena deserve attention: the residential market has a dramatic oversupply (about 800,000 empty homes in 2011) and artificialized territories continue its expansion trend (passed in 4% to 5% of the national territory).

[10] In 1991 the number of dwelling slightly exceeded 60,000, in 2001 were completed over 117,000 and in 2002 it recorded the highest value ever when it concluded almost 122,000 dwellings.

[11] In 2010 they were completed just over 30,000 dwellings and depressive trend has strengthened in recent years and in 2013 were completed less than 20,000 dwellings

## 4. Work Limitations and future developments

This oral presentation, by their own limitations in length and thematic range, deals with a fundamental aspect of the research process on urban dispersion: its verification in terms of use and transformation of the land. It is assumed that the questions not to treat in this oral presentation and determinant to have accurate answers to the questions regarding urban dispersion - respond to aspects to be discussed in futures developments:

The question of diversity, about the different types of urban dispersions and the respective characteristics that determine these differences (differences between scattered building and urban dispersion, between urban dispersion and urban sprawl or between suburbanization and urban dispersion);

The question of formality, about the (legitimacy) of land tenure and the (i)legality of the phenomenon(s) associated with urban dispersion;

The question about the process in the transformation of rural land into urban land (private promotion vs. public promotion, systematic building vs. subdivision property, municipal planning vs. sum of urban developments);

The metropolitan uniqueness about the specifics of urban dispersion in a me
the Portuguese s context;

The national uniqueness about the specifics of the Portuguese urban dispersion context.

## 5. Conclusions

In the last two/three decades there is a huge difference between:

a) The dominant policy and technical intent supporting the urban concentration (and regulating the use and transformation of the land to restrict strongly the reclassification of rural land into urban) and fighting the urban expansion, the urban dispersion/sprawl and the scattered building and
b) The real dynamics of land use in which it appears that the urban sprawl not only was not reduced or stagnant as, in some aspects, even strengthened, particularly in LMA in the early twenty-first century.

The entire political, technical and academic powerful consensus regarding the benefits of urban concentration and systematic revision of key laws is driving policies, legal framework and manuals towards a direction that is not being followed by the agents that act in the territory. Understanding this gap is urgent, necessary and possible and the university is central in the search of this knowledge.

In the last decade there is a paradox in LMA:

a) When the crisis reaches Portugal smashing the building dynamics, break credit and locking GDP growth; when the resident population slightly stagnates and 800.000 dwellings are empty
b) The artificialized territories, and specially the discontinuous urban fabric, continue its expansion.

All signals are regarding to a country in a deep crisis specially in all the with building industry (that almost stopped) but in tough times the urban disp the discontinuous urban fabric, goes on its territorial expansion. Again, understanding this apparent contradiction is urgent, necessary and possible.

Then we understand that beliefs , technical certainties and fiery speech shape reality. At this last finding still joins the national trend (cultural? historic?) for a little disciplined land occupation as can be seen in large areas of the portuguese territory, LMA included. Regarding land use transformation in LMA the reality is far away from what the politicians want and proclaim, the urban planners draw or the academics think it´s best.

Faced with these phenomena seem to be necessary to be valued knowledge of the processes and dynamics of land use in order to determine possibilities of using and manipulating sustainably towards deemed the most adjusted in economic and financial but also cultural perspective.

# ZwischenInnovation: Actor-Network Theory through Temporary Use in Bremen

Robin Chang

Technical University of Dortmund, Dortmund, Germany, robin.chang@tu-dortmund.de

Keywords: Actor-Network Theory, Urban Studies, Temporary Use, Performative Planning

**Abstract**

*The Actor-Network Theory (ANT) is born out of a discipline that is far beyond the spatial and theoretical borders typically associated with Planning. Since the theory's inception in the mid-1980s, ANT has been debated and ultimately shared across technical and social disciplines because of its concepts transferability. Despite its origins, it is hailed as a re-definitive, richer, active, transcendental idea and perhaps useful tool for urban studies including planning theory and practice. As a means of exploring how ANT can add value to planning by bridging theory and practice, this paper introduces and deploys ANT in the temporary use case study of Plantage 9 in the German city of Bremen, Hansestadt Br to highlight potential contributions to planning. Practitioners use various forms of temporary strategic and tactical instruments for urban regeneration. Opportunities for affordable and acceptable experimentalism presented by temporary use activate urban regeneration and development. Temporary Use sets a background of shifting stability ideal for Problematisation and sets ANT in action. Research in this area is key to furthering the epistemological development of ANT in urban studies, and rooting the concept in planning theory and practice. As a theory that outlines methodology, ANT is a hybrid concept new to planning that lends itself as a heuristic benefit. The contributions of this research would help question and understand the processes, roles and competencies of an emerging and performative planning addressing urban decline.*

## 1 Introduction: The Planning Exigency

Both scholarly and professional planning experts suggest a need for new approaches to fusing scientific insights with professional practice. As of late, critics question the legitimacy of planning practice due to its weakness as an evidence based discipline, and argue that it should sh stigma (Laplante, 2010; Fecht, 2012). Both academic and popular sources discuss aspects of planning practice that can benefit from more substantiated practise. Writers with both professional and academic backgrounds highlight the convoluted and disjointed processes that facilitate planning, the lack of engagement between practitioners and research, and converse challenges that motivated urban scholars to publish and not participate with their research in practise, or limit practitioners from information sharing. (Laplante, 2010; Taylor and Hurley, 2015). Consequently, meaningful knowledge exchange between scholars and professionals is compromised. In response to the professional and academic concerns introduced above, this article endeavours to explore and illustrate a potential approach that could help support practice-based cases studies with scientific methodology. This potential is the *Actor-Network Theory* (ANT) approach which advocates for a scientific study of how networks emerge by following the actors that construct them (Latour, 1987, 1996, 2005), and also providing a synergistic solution to both academic and professional needs and a better alternative to remedying the weak science in planning.

## 2 Actor-Network Theory in Planning: Theoretical Background

As a technology and science based approach, ANT is gaining ground in planning theory and practice (Selman, 2000, p. 110; Doak and Karadimitriou, 2004, p. 7; Crawford, 2005, p. 3; Wessells, 2007,

p. 351). In a 2010 urban studies collection featuring ANT, Bender details ANT capacity to bring a different level of empirical transparency [to] planning sci diligence, richness and innovation that reveal transforming networks complex Bender, 2010). Other ANT research concludes that it releases planning theorists and practitioners from traditional and rigid means to making sense of complexity and urban change is perpetuated when human actors as opposed to non-human actors are privileged or recognized (Beauregard, R A., 2012). Consequently, ANT provides an alternative approach to exploring and articulating the agency and arrangements within new institutions, procedures, and concepts that con changing world that is hidden when understood through traditional ways of knowledge production (Latour, 2005, p. 11; Rocheleau and Roth, 2007, p. 436; Wessells, 2007, p. 352, 2007, p. 352). On account of ANT s compelling potential as a tool for planning practice, the work pr to answer the research question: *How is knowledge derived from ANT significant to planning practice?*

*2.1 Actor-Network Theory*

ANT is growing a following for its unique approach to articulating current socio-urban development (Selman, 2000, p. 110; Bender, 2010; Beauregard, R. A., 2012). ANT attempts to take advantage of commonalities between science, technology and social studies, by recognizing that it is no longer the natural influencing the technological but a mutual cycle in which both realms influence each other. For instance, Beauregard contextualises ANT in practice by discussing how place, setting and tools legitimize planners arguments, technical positions, formality and general impo development review process (Beauregard, R. A., 2012, pp. 184 185). ANT work encroaches further on planning theory and practices with its presence in studies on architectural practice, brownfield regeneration, wetlands conservation and management, rural political conflicts, real estate and housing development, gelleable space to political ecology, regional economics, and planning reform. (Healey, 1994; Burgess *et al.,* 2000, p. 131; Selman, 2000; Doak and Karadimitriou, 2004, 2007, pp. 72 74; Guggenheim, 2010; Tironi, 2010; Rydin, 2013, p. 26). The vast amounts of research and publications that explore science and urban development through the ANT lens undoubtedly demonstrate that ANT has already made its mark in planning theory. The information provided only partially demonstrates how information derived from ANT is significant to planning.

*2.2 ANT: Relevant Concepts*

ANT is an attractive social theory because of its descriptive and articulate characteristics. These advantages are channeled through the paradigm s key elements and principles that e that both human and non-human actors are equally recognized. The first key concept that is central to this article is that of the *actant*, which Latour introduced and other ANT scholars use to denote all network actors both human and non-human (Latour, 1987, p. 84). Actants can emerge in specific roles as an ***intermediary*** or ***mediator***. *Intermediaries* transport meaning or force without transforma simply by transporting or supporting an original meaning without alteration (Lat Rydin, 2013, p. 26). In comparison, *mediators* create associations and enrol other *actants* but modify the meaning and message that is transported (Avrahampour, 2007, p. 358; Latour, 2005, p. 39). An excellent illustration of *actants*, *intermediaries*, and *mediators* is provided by Beauregard through the description of various planning vignettes within which objects such as site plans, models, and photographs are introduced into discussion (Beauregard, R. A., 2012, p. 184). These tools play communicative roles (as *actants*) in the discussion. These *actants* sometimes provide neutral visuals such as photos and mock-ups (as *intermediaries*) that ensure all participants share the same visualization of the site on which they are working Equally important is the concept of a *translation* which refers to an act or interaction that induces two mediators into coexisting (Latour, 2005, p. 108). A transla

contribution to ANT emerges in two different forms. The first definition of a *translation* is fixed as a material outcome and the second meaning expresses the act of how a *translation* occurs within the ***Translation Process*** (Latour, 1987; Crawford, 2005; Latour, 2005). It is easiest to begin by considering an initial ***claim*** or ***statement*** that sets a series events into place. The new interpretations of the initial interests reiteratively render themselves into adaptations of the first *claim* that is now either simplified, referred, and eventually legitimized. How the interpretations finally appear as a ***fact*** depends on the modalities through which actants receive and further perpetuate the *translations*. To illustrate the progression of a claim towards a *fact*, Latour s *Controversy Ladder* schematic (Figure 1) breaks down conditions and elements that advance and hinder claims from becoming facts. As outcomes of *translations,* ***inscriptions*** are concrete examples of how later statements confirm the status of earlier statements. *Inscriptions* help in the ordering of things and provide durability to actor-networ (Doak and Karadimitriou, 2004). Another important ANT concept with technological origins is a ***black box*** (Latour, 1987; Crawford, 2005; Latour, 2005). A *black box* is a simplification of a concept or arranged network or assemblage where relevant information is reduced to inputs and outputs, or transfer characteristics (Latour, 1987, p. 3). Concepts or entities are *black boxed* o become a *black box* when they achieve of stability or legitimacy, are taken for grante counted as a resource (Latour, 1987; Crawford, 2005, p. 2). *Black boxes* as reductions of complicated information, however, may be reopened (Crawford, 2005, p. 2)

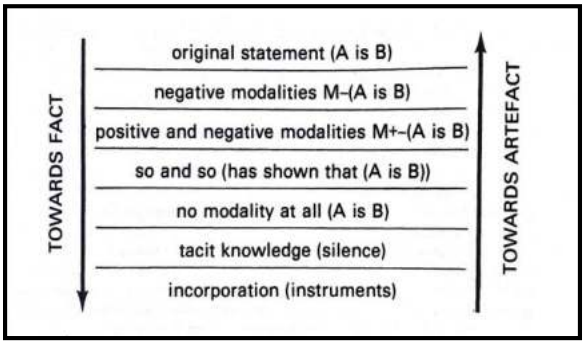

*Figure 1 Latour's Controversy Ladder*

*2.3 ANT: Relevant Principles & the Translation Process*

The ANT approach is interested in human and non-human participants, both of which are equally recognized for the as network participants. Beauregaurd explains this best when describing things as participants of sorts . . . [that] carry with them information, arguments, and commitments that shape talk and action (2012, p. 186). They empower and they disempower . . . [and] in the absence of things, there is silence. And, as things are modified . . . deliberations are transformed (Callon, 1986a, 1986b; Callon, M., Law, J., Rip, A., 1986; Latour, 1987, 1987, 1987, 1996, 2005; Law, 1992; Beauregard, R. A., 2012, p. 186; Rydin, 2013). This constitutes ANTs first principle of ***agnosticism*** *or* ***radical relationality***. Under the aegis of this principle, actants are empowered to define their respective identities, their individual range of actions . . . [and the] choices which are researchers and analysts (Callon, 1986b; Burgess *et al.,* 2000; Rydin, 2013). Following the first principle is the second principle of ***generalized symmetry***. This tenet pleads for the use of a common con repertoire to describe and explain the relations between humans and non-humans in order to understand how change happens (Latour, 2005, Farias and Bender, 2010, p. 3, Rydin, 2013). Simply put, a single set of terms and vocabulary is set to describe the objects and their processes of knowledge construction across social and technical fields. The third and final principle is that of ***free association*** (Callon, 1986a, pp. 3 4; Latour, 1987; Law, 1992; Burgess *et al.,* 2000, p. 123; Crawford, 2005, p. 2). This methodic principle corresponds to the belief that all ***a priori*** distinctions should be discarded before following actants paths.

Guided by the three principles explained above, ANT advances that actor-networks are traced through the *Translation Process*. This process is broken down into the four phases of 1) ***Problematisation,*** 2)

***Interessement***, 3) ***Enrolment***, and 4) ***Mobilisation***. ***Problematisation*** is the initial phase in which researchers frame how to investigate an issue. Callon also notes that in reality, the *Problematisation* phase is not often clear as entities are formulating their [identities] and goals in a totally inde manner (1986a). The next stage of the process is that of ***Interessement*** within which various actions negotiate and develop stability between currently and potentially involved actors (Callon, 1986a; Doak and Karadimitriou, 2004). During this process, the identity of new actors are established and join the identity of the initial alliance formed during the *Problematisation* stage (Callon, 1986a). What is important in this stage are the range of strategies and mechanisms through which new links that interest new actors are formed. Just as relations can be forged, they can also be disrupted. Following is the ***Enrolment*** phase which only happens if all means of stabilizing associations in the *Interessement* phase are successful (Callon, 1986a). At this point various transformations take place. Not only is there a transformation in the modality of the claim from a question into a statement or fact, but the actors have been transformed through the attribution of new or different roles (Callon, 1986a; Doak and Karadimitriou, 2004). The latter usually happens with the help of a mechanism or non-human actant, and results in a consensual resolution (Callon, 1986a; Doak and Karadimitriou, 2004). Lastly, the final stage of ***Mobilisation*** completes the *Translation Process* (Callon, 1986a; Doak and Karadimitriou, 2004). In this stage, a combination of human and non-human actions and materials fulfil the negotiated aim and the network stabilises (Callon, 1986a; Latour, 1987; Doak and Karadimitriou, 2004).

## 3 Temporary Use as a Translation Process

The *Temporary Use* context in planning practice is a suitable ANT backdrop as there is still a gap in knowledge about the ways in which temporary projects should be incorporated into planning, and the relationship that planners should have with various other t 2013, p. 2). The progressively familiar term *Temporary Use* (TU) is a general means of describing the popular method of incremental, and short-term approaches to producing urban interventions (Hollander *et al.,* 2009; LocusLab, 2009; Lydon, 2012; Glick, 2013, p. 5; Pfeifer, 2013). Despite its new-found allure in the urban settings, TU has been a major part of historical urban development, and also continues as it has been in developing cities and countries for a long time (Lydon, 2012, p. 2). TU is a low-risk way for both community members and municipalities to improve neighbourhoods (Pfeifer, 2013, p. 2). Over a decade ago, studies documented how economic changes in the 1990s hastened German cities to find solutions for increasing inner city vacancy and growing number of brownfield sites (Zehner and Hoffmann, 2007). The result of economic and political changes was that the clas instruments developed mainly in the 20th century [were] not only no longer applicable but restrictive to planning innovations necessary for the transition into the 21st century (Altrock, 2012, p. 16). TU emerged as a strategy recognized in mostly German cities to revitalize vacant and dead zones that had become liabilities (Hollander *et al.,* 2009). Short-term, temporary methods, unlike long-term strategies do not require tedious bureaucratic processes, large up-front investment, and . . . little public input, but instead aim for sustainable improvement through non-threatening, affordable, short-term opportunities (Glick, 2013, p. 10; Lydon *et al.,* 2012). More recently, scholars describe TU as a new style of performative planning [that] offers a novel planning perspective that ir planning theory facilitate that both productive and responsive roles for the pra (Altrock, 2012, pp. 21 22). The *temporary use* projects discussed in Altrock s performa interpretation feature the development of a new culture that is distinctly more inclusive with emerging arrangements of non-traditional actors. The participation of a wide range of characters including everyday citizens, artists, and other professionals shifts the planning culture away from its prescriptive roots to a voluntary culture that impels a community (as opposed to a select few) to take onus for the complex change in their urban settings (Altrock, 2012).

TU rallies citizens with emerging planning actants and *problematizes* land use, economic and community challenges that urban settlements face. It is important to examine the participants of

*temporary use* projects not just because of how and why actors and networks emerge, but because urban scholars agree that a majority of *temporary use* projects are successful because of the non-planning participants involved (Altrock, 2012; Lydon *et al.,* 2012). Because of the latter, *temporary use* events not only share similar conceptual emphasis as ANT on modalities and strengths of relations based on action that arises from the forming of (temporarily) stable links [between h actors] within networks (Rydin, 2013, p. 25), but also an awareness of what agency empowered within non-human actants. Since the ANT approach is most suitable for exploring how and why questions, it becomes an appropriate means of considering the actants, characteristics and linkages in TU networks and relationships as a Translation Process that not only identifies an issue but emerges and develops through *interessement*, *enrolment*, and *mobilization*.

As a previously industrial, port city, Bremen experienced post-industrial challenges in the 1980s and 1990s as shipyards, ports, and other industrial areas along the Weser River closed (URBACT Pilot Transfer Network, 2015). Like other German cities facing urban shrinkage and post-industrial challenges, the city of Bremen took advantage of the Stadtumbau or federally funded Urban Renew program supporting urban regeneration and renewal projects (Froessler, 2010; ZZZ Bremen, 2010, Zwischennutzungsagentur Wuppertal [Wuppertal Temporary Use Agency], 2014; Elisei, 2014; Hollander *et al.,* 2009). Since Bremen is featured as a model with the URBACT *Temporary use as a tool for urban regeneration* (TUTUR) program that promotes TU in European cities (URBACT Pilot Transfer Network, 2015), this article will feature the case study narrative of a project facilitated by the city s temporary use agency *ZwischenZeitZentrale Bremen* (ZZZ) as a means to articulate new arrangements embodied in TU through ANT concepts and principles. This particular case study was a part of a research the evaluated TU through ANT in four different case study cities in Germany, Canada and the USA.

## 4 Methodology

The preceding elaboration on theoretical work demonstrates contributions to planning theory. Further work is necessary to evaluate potential contributions to planning practise. Thus a mixed methods approach that allows for flexibility and exploratoration is needed to set up the practical research evaluating ANT in temporary use case studies. To facilitate this, the Case Study approach in combination with Narrative Research guided the research design. ANT objectives encourage the analysis of how networks are constructed. Appropriately, case studies help describe and understand research questions focussing on how and why phenomena take place at individual and detailed le (Yin, 2014; Flyvbjerg, 2011, p. 301). The unit-based design of case studies structured the work to focus on developmental factors, events over time, and also the unit relates to its environment (Flyvbjerg, 2011, p. 301). In addition, Narrative Research is an ethno-methodological technique in social research strengthens the mixed methods approach by making use of stories and accounts as instrument scientific investigation (Cihodariu, 2012, pp. 29 30; Yin 2014). Adding to the descriptive advantages of case studies, narratives provide a general means of framing [the] interpretation and renderi events and things (such as discourse, frame, mental model) used (Lejano *et al.,* 2013, p narratives in the form of accounts, Latour s appeal to trace social connection action is achievable (Latour, 2005, p. 122). Stories that inform narratives not only express the identities of their owners, but help model complex realities around us (Lejano *et al.,* 2013, p particularly relevant to the ANT approach as narratives reflect the concerns, hesitations, and amb of people as they react to, shape and are shaped by their environment (Lejano *et al.*

### *4.1 Research Process: Mixed Methods*

In order to capture the localized detail of Bremen s best-practise TU examples qualitative i facilitated the chance for studying subtle nuance in attitudes and behaviors and for examining social

processes over time (Babbie, 2004) through the narratives that respondents provided. One semi-structure interview that lasted for over two hours was conducted for this research with Oliver Hasemann and Daniel Schnier of ZZZ in Bremen on the 5th of January 2015 after extensive literature and background research. The interview format allowed for the discussion of TU as a general topic and also the freedom to follow up on specific topics raised by the respondent (Babbie, 2004, p. 300) with regards to their best-practise project. The interview intended to capture details such as black boxes, actants, interaction modes and strengths contributing to a final ANT coding and analysis of TU. Narratives provide another means for understanding networks. Agreeing with Mark Granovetter, scholars supporting the use of narratives in environmental network research describe how trust embodied through shared information can be transferred through shared narratives (Lejano *et al.,* 2013). In light of this, narratives are not only instrumental to qualitative interviews but also to the modalities of interactions they describe and consequently key elements that construct a network (Lejano *et* Transcriptions and interview notes contributed to the data-collected and were offered to interviewees both during the meetings and after the meetings so that accuracy and transparency of the information collected was assured. With the information provided through the interview, key human and non-human actors were identified and considered. This process informed the coding of the collected data. Following this, a narrative context was induced to describe the case studies pre- and post-TU projects. Recognizing that narrative can illuminate insights for event-centered and experience-centered accounts (Andrews *et al.,* 2013, p. 5), the combination of Narrative Research and the ANT approach was justified. According to the ANT approach, the act of recording accounts is a form of tracing social connections and agency (Latour,2005, p. 122). By taking the narrative data and identifying the ANT elements (i.e. black boxes, actants, translations, intermediaries, mediators etc.), the network tracing advocated by Latour is codified. Subsequently, the data collected is analytically digestible and easier to organize into tables and other visualizations.

*4.2 Bremen: Awakening Second Hand Space*

In the wake of Bremen s post-industrial development, interest turned to reactivating vacant buildings and sites and supporting entrepreneurial projects as a means of reviving the city. Compared to other post-industrial cities, Bremen s vacancy opportunities lay not in urban neighbourhoods, outskirts (URBACT Pilot Transfer Network, 2015). The city saw the vacant buildings, and brownfields as chances for economic development and revitalization. As the city lacked a specific agency to manage the redevelopment objectives, they created the temporary use agency *ZwischenZeitZentrale* Bremen (ZZZ) in 2009 with funding from the National City Development Policy (*Nat* *Stadtentwicklungspolitik*) (URBACT Pilot Transfer Network, 2015). This event constituted the problematisation of economic degeneration and supported a claim that TU could help with economic regeneration through partnerships and projects specifically supporting local businesses. With further support from local level partners such as the Senate for Building, Environment, and Traffic, the Senate for Financial Affairs, the Senate for Economic Affairs, Labour and Ports, *Immobilien Bremen* (IB), as well as the local economic development agency *Wirtschaftsförderung Bremen* (WfB), Oliver Hasemann and Daniel Schnier from *Autonome Architektur Atelier* (AAA) initiated the agency (Plantage 9, ZZZ Bremen, 2010; URBACT Pilot Transfer Network, 2015).

From the onset, policies such as the new land use plan and municipal programs such as (Soziale Stadt) were enrolled to the networking of people and places (ZZZ Bremen, 2010; Elisei, 2014, pp. 31 32). Furthermore, the soft urban policy represented by the ZZZ crossed all otl policies to build project-based synergies, encourage meaningful urban transformation through bottom-up collaborations through alternatives means of socio-economic and cultural behaviours (Elisei 2014, pp. 31 32). So began the enrolment of administrative actants and the interessement with local actants. Further actants such as a website and a steering committee were organized from the start TU movement to inventory and guide projects and further enroll interest (Elisei, 2014, pp. 31 32).

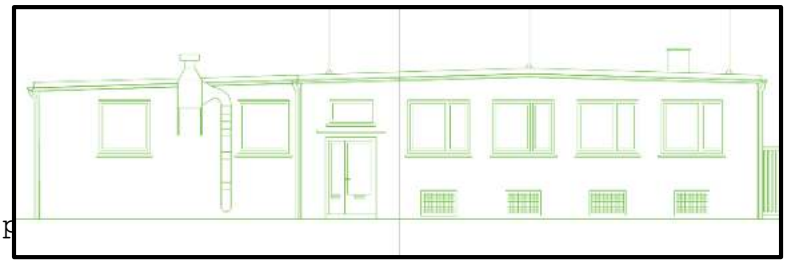

*Figure 2 Building Façade Sketch (Plantage 9)*

Additionally, conference events were organized to help establish and construct a temporary use network and also enrol additional support for TU in Bremen. Oliver Hasemann describes the significance of the first event, 2nd Hand Sp Sustainable Design for Urban Change through Temporary organized in 2010 was vital for the network enrolment and mobilization with other TU projects, and foundational to the success of their initial projects (ZZZ Bremen, 2010). While the website served as an early intermediary for TU in Bremen by providing summaries of potential temporary use spaces for potential owners and users (URBACT Pilot Transfer Network, 2015). The Steering Committee and informational events and relevant materials became mediators in the course of TU in Bremen. By bringing a diverse representation of experiences together and also publishing their own knowledge to share with other municipalities, ZZZ actively participated in the creation and shaping of policy claims that TU is an effective method and solution for economic development through the aforementioned mediators. At the same time, the ZZZ initiated further enrolment and mobilisation of other networks. The majority of initial projects began on publicly owned sites and facilitated TU while incubating many entrepreneurial projects. One of the most successful and earliest example is the *Bricolage Plantage* that would later be renamed *Plantage 9* also the address of the building site (Plantage 9; URBACT Pilot Transfer Network, 2015). *Plantage 9* began as an abandoned store house with a rough area of 1,600 m² originally built in the 1950s for a textile factory that was later home to a fire protection company (ZZZ Bremen, 2012b, pp. 68 69). Once the municipality acquired the building in 2009, zoning and development plans illustrated plans for the building to be demolished despite its good structural quality and a road in its stead to be built (ZZZ Bremen, 2012b, pp. 68 69). According to Hasemann, however, it would not be until meetings on creative centers in Bremen in 2009 that an actant in the form of a photo emerged and mediated the eventual change of the building s use and space for the successful tempor use project. Hasemann details, that a few city officials at a creative centers meeting shared photos of a building space that was intended for demolition due to its vacant status and plans for a new road, members of the ZZZ caught a glimpse of the space and realized the contingency embodied in the space. This realization impelled the temporary use agents to visit the site and confirm that a specific characteristic of the building and its space could facilitate temporary and creative and entrepreneurial development. As a part to the Bremen s temporary use narrative, Hasemann undersco of the spirit and character of this space that was conveyed through the photo without it, there would have been no contingency for their best-practise project.

### *4.3 Plantage 9: Extending* Bremen s *Temporary Use Network*

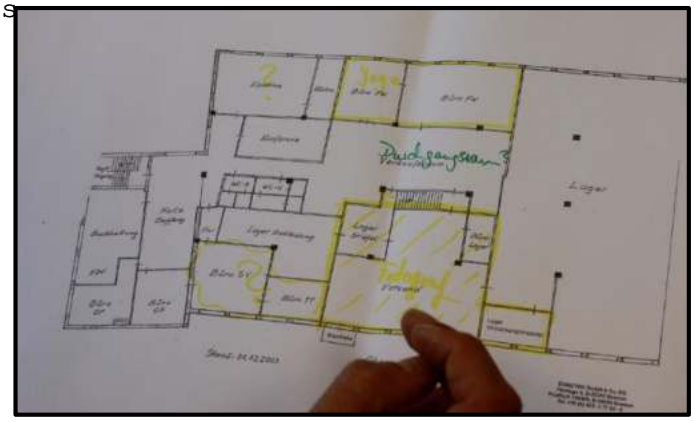

*Figure 3 Workshop Visuals (ZZZ Bremen, 2010)*

As of July 2010, *Plantage 9* became the working home for 30 artists, photographers, university graduates and also teachers enrolled and mobilized by artists interested earlier. Its heterogeneous combination of spaces turned into offices, warehouses, workshops, social space and canteen facilities that responded to the needs of the diverse group of users (ZZZ Bremen, 2012b, p. 68). With the help from the first conference from

2010, feedback as well as a workshop organized before users moved into the building aided in the design and transition of the project from temporary to sustainable community workplace (ZZZ Bremen, 2010, p. 19). The representatives of ZZZ explained that their initial role as a middle manager ended after explaining the rental conditions and passing responsibility of building on to the tenants. Hasemann further explains that once the year was complete, the users formed their own tenants association and initiated the process of transferring the responsibility for building management. In addition to this transfer, the tenants formed their own collective and officially renamed the temporary use project as *Plantage 9*.

By this point, the group of human actants enrolled and mobilized as renters evolved into mediators that further translated TU claims into fact. The act of establishing their own association and taking over the rental agreement with the WfB concluded this process in April of 2012 (ZZZ Bremen, 2012b, p. 68). In addition to the many mediators and intermediaries involved in this successful case study from Bremen, the creation and construction of trust as a part of the temporary use network was pivotal (ZZZ Bremen, 2010, p. 20). Not only did the trust strengthen the relations in the network, but it for exchange and learning that strengthened the group dynamics (URBACT Pilot Tran 2015).

Policies such as building codes and zoning maps presented hurdles to the implementation process of TU. During the interview, Hasemann and Schnier describe the opportunities for TU difficult as has only recently been permitted on various sites due to a tacit acceptance or tolerance despite building code restrictions. Hasemann further explains that the local government managed the project as if the plans for a new road did not exist as officials could not technically make any building improvemer with the zoning plan still in place. As for building improvements to bring the site up to standard, ZZZ contributed 10,000 to improvements while the remaining estimate of 100,000 was new three year-long contract between the new renters association and Bremen City. Not only did the policies and contracts in this best-practice example emerge as actants, but they defined themselves as actants with negative modalities around which other actants had to manoeuvre.

Beyond the key influence of non-human actants, the Bremen case study illustrates a successful process for actants in the form of heterogeneous spaces, documents, visuals and people who collaboratively construct networks. The temporary use agency in Bremen developed a legacy recognizing TU (URBACT Pilot Transfer Network, 2015). Early reactions to TU were also uncertain, but the commitment with which Bremen City and the ZZZ pursued TU as a generator for grassroots economic development resulted in the black boxing of TU as a means for testing potentially sustainable uses for difficult spaces (ZZZ Bremen 2010, 2012b; URBACT Pilot Transfer Network 2015). Moreover, the role of space and place is significant in the Bremen example and appears boldly as an actant that facilitates the cohesion of network extensions. According to the ZZZ and other temporary use academics, the key is to find and select the [spaces and] places to put in the game of the re-use and allow the second hand places to be found again with new opportunities as drivers for business, qualitative features that improve the civic fabric of the city (ZZZ Bremen, 20 Hasemann and Schnier, 2014; Elisei, 2014, pp. 31 32). Through this emerges a clear process of problematisation, interessement, enrolment, and mobilisation through which diverse actants with distinct capacities and competencies, strategically and sustainably address urban decline through tactical interventions.

## 5 Discussion

The process of illustrating ANT through TU concluded that ANT is in fact a useful tool to planning. The theoretical approach s unique interpretations and means of articulating

environment offers an approach that dismantles and investigates networks and the process through which they emerge and extend. Furthermore, the recognition and agency that ANT allows for human and non-human network participants, surfaces truths regarding existing weak planning actants that are impede or hinder planning processes as was the case with building codes and zoning maps with *Plantage 9* in Bremen. Traditional planning and development policies and regulations that are supposed to support urban change suddenly emerges as an outdated inscription that challenges and ultimately hinders planning processes and the actants pursuing TU. Conversely, new potential planning actants also surface such as temporary use agencies, tactical and improvised experimentation (as opposed to strategic policy making), second hand places and new entrepreneurial collectives that regenerate declining spaces. What is innovative is that they do not appear as traditionally planning practices or instruments, but have the potential to be adapted and integrated for planning practise once the identified weaknesses and barriers such as grandfathered policies and instruments are addressed or updated. This innovation illuminates the shifting arrangements and evolving actors that collectively constitute TU from and policy and practice level for urban redevelopment. Thus a moment and space to bring scholars and practitioners together as weaknesses in existing practices and instruments are revealed and the potential and contingency to experiment and adopt new practices and instruments emerge.

*5.1 Challenges*

While ANT is highly useful for understanding the processes in which actants emerge, and enroll others in the extension of a network, it does not provide a certain explanation of the cause and effects of events. This potential area for confusion must be heeded and noted as the ANT approach seeks to describe and explain the relations of the events in the form of actants. In detail, the illustration of ANT through temporary use narratives strives to show this by narrating the situational assemblage of actants that come together, enact each other and create contingency for new situations. This point of note is also highly relevant to critiques of ANT regarding power. ANTs approach is not meant to explain power and domination as structural framework to which most are accustomed society (Murdoch 1994, Farias and Bender 2010). Indeed its inability to explain power in such a way, is in fact as Murdoch states, its strength as it means to interpret power as outcomes ( in potential ), as acts of exertion ( in a (Murdoch, 1994), and also what this study proposes as measures of contingency. In this sense, the research presented here confirms the work of others that use ANT to perceive power as performative flows and effects in networks, and not on a compositional arrangements (Latour, 1987, 2005; Murdoch, 1994; Rocheleau and Roth, 2007; Rydin, 2013, p. 26). Nevertheless, this thesis presents an introduction of how such research can be forwarded in other facets of planning practice and deservers further investigation.

This study initially outlines increasingly popularized and academic interests to substantiate the science in planning. While corresponding possibilities to respond to this call to better ground planning practice in science are endless, the ANT approach presents valid and appropriate philosophy and methodology as a solution to this concern. Its historic roots in technological science present direct methods and procedures that scientifically substantiate findings. Additionally, its applicability to all contexts of network and knowledge creation make it accessible to scholars and practitioners alike. The fact that ANT is adopted in fields of research outside of planning demonstrates an effectiveness for research. The next step is that we learn from the ANT tenets to translate its claims to tr facilitate the access for planning practitioners. The principles and concepts of ANT are veritably radical and innovative, but difficult to adopt without commitment and time. To articulate *agnosticism*, *generalized symmetry*, and *free association* requires that first complete understanding and secondly, discipline to trail both human and non-human actants and record their performative legacies without *a priori* assumptions. Resources such as time, patience and energy to follow through with the process are in most planning practices limited. However, the willingness of planning scholars to collaborate with

practitioners facilitates opportunities for fruitful results if not an altered ontological perspective. The concepts such as *actant*, *black box*, *translation*, *inscription*, and with which ANT communicates its *Translation Process* are also a new vocabulary the non-technological scientist must learn.

Beyond this initial hurdle, ANTs language presents a distinct way of regarding urban environments and portraying the observations in a way that is extremely relevant with the increasingly technological world. Latour s argument to dispel the exclusivity of agency embodied in humans is fair. As desc Avrahampour, Latour s campaign to correct social theory and its anthropocentri indeed an attempt at fixing faulty attitude (Avrahampour, 2007, p. 358). While it may have seemed that the radical extension of agency to all things is silly, the growing interest in ANT demonstrates that is no longer so. It is only a matter of time before such a philosophy is fully embraced by planning practitioners and legitimized. The current status of urban studies scrutinizing ANT in planning theory and furthermore in planning practice is still preliminary. Nevertheless, the opportunities to study ways to improve or adapt ANT for planning theory and practices are many. Specifically, more precise means of distinguishing and characterizing the phases of the translation processes as well as the typology of actants and modalities could improve the robustness of ANT s contributions. generousity of the concept lends itself well to a range of varied interpretations. This, however, undermines the general operationalization of the concept as it exposes vulnerabilities to bias and extreme interpretation. Nevertheless, like many other theoretical concepts, ANT is characterized by theoretical abstraction. The new contingency that is brings is its unique methodic approach that behooves scholars and practitioners to collaboratively refine and polish ANT s potential, planning policy and practice.

## 6 Conclusions

Through the fusion of ANT and planning practise, both scholars and practitioners are provided the opportunity to be humble and acknowledge that humans are not the drivers of change in the world. It is in fact many and all things that affect change (with)in varying degrees of magnitude or separation. The illustrative context of TU is one example presented in this thesis. This, however, does not mean it cannot be transferred to other practice based scenarios. This research has examined and presented ANT through one temporary use case study. The information provided here adds to the range of existing ANT research in urban contexts, and thus highlights the range and adaptability of ANT. The research also presents the strategic and tactical evolution of TU as a response to urban decline.

This article has demonstrated ANT facilitates the examination how TU is developed and implemented. Additionally, ANT facilitates and analysis of the network participants and how they come together as conditions for change. The contingency illustrated here is clearly evident in the presented case study and could also be so for all planning in general. As such, there is still much for ANT to contribute to planning, and conversely much for planning to contribute through ANT. Despite the early stage of progress with research integrating ANT and planning, this article presents a step forward and demonstrates ANT can positively contribute to both planning theory and practice. The work present here is a chance for further problematisation, interessement, enrolment and mobilisation in a greater scheme of ontological and epistemological understanding in the planning. Further testing and improvements on the operationalization of the *Translation Process* and the ANT principles must be further experimented and adapted. And so this work concludes with the expectations that ANT contributions further be debated, falsified, [and] repla himself also finally encouraged (Latour, 1987).

# Self-organization and Spatial Planning

## The foundations, the challenge, the constraints and the consequences

Gert de Roo[i]

**Draft**

### 1. Does self-organization matter to planning?

Spatial Planning and self-organization: A perhaps somewhat unexpected combination of these two themes, one being a collective manifestation of intent , the other representing a spontaneous ph Nevertheless this combination is recently getting serious attention by the planning community. There are a few empirical incentives such as the spontaneous but devastating global housing, mortgage and financial crisis which are a challenge since 2008 to critically assess traditional practices and to develop alternative strategies. The repeating failures of large planning projects are another trigger. These projects cannot be treated as isolated activities, as the planning community is confronted with a highly interconnected world which evolves through unprecedented non-linear chains of causes and effects. There is a growing awareness of a world beyond the planners control, evolving in various This abstract notion of our world developing non-linearly is an incentive to explore further emerging theories addressing complexity, non-linearity, adaptivity, co-evolution, transition and self-organization.

Notwithstanding the recent interest, the world in which planners operate in has always had self-organizing processes. These processes were around in the traditional, coordinative era of command-and-control policy making and in the controlled reality of technical and functional planning. Also in the communicative era of planning and policy making processes of self-organization are very much there. These processes were not seen, were taken for granted, never got much attention and therefore never became part of mainstream planning. They were just there and did not relate much to the planners language of control, regulation and rationality or the planner s drive to reach consensus and a shared responsibility.

Therefore the question is: Does self-organization matter in understanding spatial development processes and will it be in support of the planner to address a world which is progressing beyond our control?

Here we take the stand processes of self-organization do matter and are relevant to planning. We consider the understanding of these processes to be supportive to an understanding of a reality which evolves spontaneously and autonomously from humans intent, their purposeful actions and control and their desire for consensus. At this very moment these processes are hardly understood. In this contribution we aim for a better understanding of self-organization combining planning thought with reasoning within the various disciplines which too relate to self-organizing processes and with theoretical arguments such

as those from the complexity sciences. This is the route we are willing to take, exploring characteristics and mechanisms of self-organization and how these can be seen in relationship to the planners de theory and practice.

## 2. What if assumptions fail?

Quite some planners were showing interest in non-linear processes way before 2008 and the crash of the housing, mortgage and financial market. Nevertheless the crash of the various markets made non-linear processes very explicit and hard to ignore. The credit crisis proved to be a major challenge affecting our political and socio-economic systems fundamentally. A lack of critical assessments, feedbacks and mechanisms of corrections of regulatory governmental and economic systems came into the light. The systems that were there failed completely. With it the idea fell apart of humans being in control. No one at that time had a clue what caused the crisis, what route it would follow, and who or what would be affected. It meant a complete blank about how to adjust, structure and regulate the situation after the crash.

Control and regulation are to the planning discipline what certainty and predictability are to disciplines having a traditional, reductionist and neo-positivist orientation. This orientation is also very much influential within the planning discipline, despite the idea of control and regulation being heavily criticized. And it would be wrong to take these traditional approaches to planning and their technical rational as dated or outdated. But instead of being valid for any kind of situation we argue the traditional approaches are relevant under particular conditions: in stable situations where straightforwardness, stability and certainty reign.

Planning has emerged towards a level of understanding through which the world is seen as differentiated, with approaches and strategies which are not just generic but are situation specific too. And therefore there is more to planning than control and regulation. Alternative, interpretative approaches have been around now for two decades. The unexpected crash of the various markets is supportive to even more alternative and competing approaches, fuelling kinds of reasoning which refer to the idea of a world evolving along in a non-linear, spontaneous and autonomous way.

Planners interest in the non-linear connects with a world that is fluid, fuzzy, and in a continuous process of discontinuous change including those processed we could call self-organization. Self-organization as a mechanism is quickly becoming a popular issue. Is it that self-organization is seen as the cure to all the pain society is confronted with? Self-organization being synonymous to problem solvi and self-regulation ? Of course it isn t. Could it that be self-organization is felt to be an expression hope or promise, comparable to notions like self-made and self-supporting ? Again organization is also not to be mistaken for a political agenda, such as neo-liberalism and its emphasis on the individual taking opportunities by its self .

A danger of fastly appearing popular notions is these being easily claimed by a wider community not willing to invest much in understanding its deeper meaning. This wider community is likely to give meaning to these notions making reference to them with a common, traditional or intuïtive understanding. Remember how such a mechanism made sustainability meaningless. Compactness is anoth

notion, stressing the importance of dense and multifunctional space, and in the past being praised as a route to a sustainable urban future, nowadays having lost its meaning with everyone using it to its own desires. And its assumptions remain by and large unproven. While spatial quality goes back to Vitruvius and his quality concept of functionality (utilitas), sustainability (firmitas) and beauty (venustas) being complementary to each other, it is another notion relevant to planning having lost most of its specificities due to the overarching power of common language and the one-sided attention by experts on functionality. How than to consider the notion self-organization ?

### 3. A semantic exploration

Self-organization is obviously a combination of two words each having specific meanings by themselves, independently from the other. When seen jointly, self and organization do not necessarily have intrinsic fit or meaning together, or logically add up to an integrated or synthesized understanding. There is no common denominator giving a clear meaning to self-organization . Self could my own identity (being my-self and knowing my-self), as in self-reflexive, self-assuring and self-made. According to this line of reasoning self-organization would refer to the organization s own identity, for example a self-made organization. This would have been supportive to Rousseau s philosophy (1712-1778), emphasizing the authenticity or uniqueness being a quality of importance for a self , an entity or an organization. This reasoning of an authentic self considers the organization as such, independent from a context. Some do define self-organization in this way: a process through which the organisation of initiatives, including the rules and responsibilities related to them, enfolds without intervention of an authority (Huygen, Van Marissing en Boutellier, 2012). This however is not how self-organization is being understood as a non-linear phenomenon.

Self could represent how it is , in the sense of being . This sense of b requires an object-orientation which can only work with an observer being present. From t point of view the self is subject to experiencing the world around him by himself t thoughts and ideas. The self is in this respect an observer experiencing his env conscious of him self . Some define self-organization accordingly, for example as a kind of social entrepreneurship with specific characteristics: intrinsic motivation, coherence with the surroundings through connectivity and fine tuning, autonomy and creativity (Wmo Kenniscahier 18, http://www.verwey-jonker.nl/participatie/publicaties/zorg/condities_ voor_zelforganisatie). The observer is also conscious of himself in response to his environment, not as a given but through interpretation. This self-awareness in the sense of being relates to how we consider ourselves and as being organized.

Descartes was among the very first to reason what self-organization could stand for, arguing that universal laws of nature represent the ordered production of organization. And how right he was! Consider a reality not responding to the order dictated by the universal laws of nature, a reality not being perfect, orderly or ideal. It could be an argument to interfere, to re-install the order according to the universal laws. Purposeful adjustments are in such cases meant to create a well-functioning environment.

It would mean a proposed route to reaching an orderly, perfect, ultimate, utopian or ideal outcome. This concept in which reality is supposed to reclaim its original state might seem traditional and out-dated, but surprisingly it isn t as it is currently going through a revival. This revival strongly relates to one particular type of resilience, a notion which gets loads of attention these days. While the idea of adjustment is crucial to self-organization, which we will discus below, the emphasis on being is substantially in contrast with self-organization as a non-linear process.

Self-organization as a non-linear process relates most of all to becoming (Prigogine, 1980; De Roo, 2012; Hillier, 2012). Self could refer to a chain of events which does start somewhe triggering various connected entities, situations or systems, resulting in a sequence of moves, activities and changes, sometimes self-replicating, sometimes triggering ad random effects along the chain of events, and all this seemingly unorganized. In a process of becoming self could be considered as effortless , without any attempt , going smoothly or spontaneous .

The notion organization originates from the concept of organs (and the Greek word or Organs , organized and organization do come up easily when considering the meanings of se such self-organization could be seen as a pleonasm. Organs refer first of all to an environ is biological. An organ has a specific function as part of a wider structure, th considered a metaphor for a system which is well structured in a mutually responsive way with all its parts. Kant (1790) has been arguing such processes are both means and ends. Organs are able to behave as if these have a mind of their own. Organs are not just all essential parts to and connected with a wider whole. They do show to some extend the flexibility to expand with and to adjust to the way the wider whole is developing, and are able to absorb negative impacts to a threshold before giving up. Despite all this, organs are structured a-priori, and show no patterns which are the result of self-organization as a non-linear process.

The notions organized and organization are first of all social constructs. The notion organization stresses an environment which is institutionally structured to allow agents, as parts of the organization, to aim collectively for a collective result based on collective actions. Herbert (1963) considers an organization to be a whole of parts in relatedness, of things and events in a r spatial and temporal relationships , being organized on the basis of a certain structure to end (Herbert, 1963, p. 200). Organization relates therefore to institutionally pre-arranged collective intentions. And that is contradicting with what we consider self-organization to be.

The self in self-organization as a non-linear process is not so much referring to m it is or to being . It relates more to by itself and to spontaneous . The or organization is neither pre-arranged nor intentional. Instead it refers to a pattern being the consequence of an unintended collective result. Cilliers defines self-organization as a property of (complex syste which enables them to develop or change internal structure spontaneously and adapt in order to cope with, or manipulate, their environment (Cilliers, 1998, in McDonalds, 2009: p. 460). Therefore organization is not a process aiming a-priori for a particular goal from within as an organizatio do. Self-organization is above all emphasizing a situation without organization a-priori , without organization , without purposeful behaviour or without intent . Consequently se

to a seemingly non-existing collective of disordered parts being triggered to an effort or move through which patterns emerge as a *collective result*. Self-organization stands for a spontaneous result w seemingly looks organized: A pattern that is becoming visible, which is seen by agents as something to respond to, therefore becoming a trigger for further action, out of which consequences emerge.

An organization has a strong goal orientation, which can be represented by a spectrum of options: It could be the organization is meant to maintain or to be supportive to something outside the organization or is meant to reach a new state of affairs. And in all situations the organization is linked to an external environment. The organization is doing its actions purposefully, intentional, with an internal structure being well informed and being ready to comply with its intended function.

And this is precisely what makes an organization different from self-organization. While an organization is a purposeful entity reaching out to its environment, self-organization is to be seen as an autonomous process triggered by and responsive to its environment. Organizations are prepared for intentional actions. Processes of self-organization are able to enfold without intent if the right conditions are met, allowing structural change to happen. Social systems are organizationally and institutionally conditioned, which doesn t make it easy to recognize processes of self-organization in a environment.

Well known examples of self-organization are the spontaneous emergence of pattern in traffic flows (Kerner, 1998), pedestrian movement (Helbing et al. 2001), bird flocking (Hemelrijk & Hildenbrandt, 2012), school of fishes (Camazine, et al., 2003), and a lot more. To what extent all these spontaneous patterns do emerge without pre-informed behaviour is not always easy to say. Traffic flows and pedestrian movement do have in common culturally informed agents. Also self-organization in trail-tracking and wall-building by ant colonies is not entirely without intent and undetermined, as mechanisms of sustained information are responsible for a kind of swarm intelligence (Bonabeau et al., 1999). As a result mechanisms of swarm behaviour become visible which include positive and negative feedback in the multiple interactions among the individuals leading to an increase of behaviour modification. However in all these examples there is no clear strategy or programme which determines a predefined and organized outcome.

Self-organization represents a situation that is in a state of becoming while balancing through a context of discontinuous change. While self-organization suggests a situation to be without organization, this will not mean a social system is impassive to self-organizing processes. On the contrary, aside from social systems to be organized for the sake of the organization and the goals are set, we argue social systems could or should also be organized in such a way to have the system prepared and ready for change to happen spontaneously. In those cases the social system or the organization is willing to bend along with the dynamic changes of the environment it is part of. This is sometimes more forfilling than opposing these contextual changes, which is often done to assure a misplaced idea of being in control. To organize a system to be ready for change means we have to consider the conditions of a system to allow responding to processes of self-organizations.

The process of self-organization is spontaneously evolving, giving rise to new structures, patterns or organizations within a system or a network as a result of interactions between elements, parts, agents or actors which are not externally controlled, coordinated or regulated (Nicolis and Prigogine, 1977; Bonabeau et al., 1997; Bak, 1999; Heylighen, 2008). In that respect self-organization is a process creating spontaneous order. And the abstract knowledge about how this process of self-organization evolves could be seen as a theory of spontaneous order. We know initial and contextual conditions are important in these processes, as well as the presence of fluctuations, and the existence of positive and negative feedback loops. These characteristics have been identified within physical, chemical, biological, ecological and social systems. Scientifically self-organisation relates to natural selection and other evolutionary mechanisms (Kello et al., 2010, p.223).

## 4. What about the invisible hand?

Being organized is subjective to the observer. It is a criterion we lay upon the world we perceive. Observations made to evaluate a situation which is not anthropocentric (for example morphology, cell structures and flocks of birds and fish) bring into the picture parts which are connected with a seemingly well-structured whole. We assume such a structure is a consequence of universal laws, biological programmes or social conventions. The observer would consider these laws, programmes and conventions as intrinsic intent of the system which determines the system s behaviour and th with mechanisms to connect the parts being predefined and laid down in advance. Intent has metaphorical meaning when referring to non-human parts or to agents, with conscious action and purposeful behaviour being absent. These parts have no intent what so ever to step in line or to act according to any law or programme. From their perspective it just happens. Due to an understanding of universa biological programmes or social conventions the observer is nevertheless capable to understand this happening as part of a determined process of change. The understanding of determined change and the Newtonian reasoning supporting this understanding was for several ages so successful it often pushed observations to the side which did not fit well within the Newtonian frame of reference. Not all of these observations were ignored though

Adam Smith proposed already in 1776 the idea of the invisible hand being a self-organizing mechanism within economic systems. Krugman (1996) illustrates the economic consequence of self-organization, which is is something we observe and try to understand, not necessarily something we want (Krugman 1996: p. 5-6). Economics is about what individuals do, and individuals are self-interested. The societal impact of these individuals (the parts) might be disappointing and might even contribute to a crisis, such as the global credit crisis that came up in 2008. In response to an increasing interest in self-organization Krugman reminds us self-organization is not necessarily a process with a positive outcome. This made Hardin to propose his concept of the tragedy of the commons of a higher order to interfere and to set conditions in case individual actions add up to disastrous and destructive consequences for the group (the commons) as a whole.

In modern times the concept of self-organization has been re-introduced through the works of W. Ross Ashby (1947) in cybernetics. Self-organization has been touched upon implicitly in writings on cybernetics by McCulloch and Pitts (Portugali, 2011). Cybernetics has had a strong effect on systems thinking, and system thinking has had a major impact on planning theory. Despite this chain of interests, self-organization did not get much attention in planning theory if at all. Self-organization gained wider attention through the work of Prigogine and Nicolis (1977), introducing dissipative structures and systems.

Dissipative systems are boundary breaking, and adapt and self-organize through their interactions with their environment (Bor, 1990). Dissipative structures (and synonymous to self-organization) within an open system environment and their irreversible mechanisms allow energy, matter and added to these by Eigen (1971) information being exchanged between the system and its environment, triggering the system itself to change. Dissipative systems exist in situations which are out of equilibrium and are therefore not in a stable state. Instead these systems continuously transform, reposition themselves, seeking for best fits, and are gaining, absorbing and passing on energy, matter and information. Systems exist, stay alive and even progress while being out of equilibrium, in a flow (of multiple agents) through which interactions between systems and within systems result in persistent new patterns and transformative effects. Consequently dissipative systems evolve. And Prigogine made us aware of self-organization having a role in the emergence of these transformative patterns (Keller, 2009).

Prigogine s work opened up a wonderful world of non-linear relations, with surprising examples ranging from self-organized Bénard cells (also known as the Rayleigh Bénard convection: Getling, 1998; Koschmieder, 1993) to fractural structured cities (see simulations made by Batty, 2005; Torrens, 2012). Prigogine s work is supported by additional ideas from Hermann Haken (1977) and his theory of synergetics. Humberto Maturana and Fransisco Varela (1974) and their concept of autopoiesis made a susbstantial contribution as well. It contributed to proposals for self-organizing communities (Luhmann, 1984), infrastructure systems and urban networks (Batty and Longley, 1994). All these ideas and concepts are part of the wider notion of complexity and non-linearity, and contribute to or build on the notion of self-organization.

## 5. From the outside and from within

While Prigonine stresses external interactions, Haken s synergetics (a term he considers more or less synonymous to self-organization, Keller, 2009) explains interactions within the system (Haken, 1977). At system level energy, matter and information is being absorbed, used and transformed, and being passed on, resulting in both stable phases and dynamic phase transitions. Through processes of self-organization among subsystems the system will show an increase of pattern-formation, which we perceive as order .

Maturana and Varela explain how subsystems are capable of reproducing and maintaining themselves introducing their model of autopoiesis. According to Jantsch (1980) autopoietic self-organization would then be the self-maintenance and reproduction of systems, or the inward orientation of social systems that is about self-maintenance, identity forming and stabilization, and reproduction . The focus is on subsystems, which are considered to function more or less autonomously while being

structurally coupled with their contextual environment. Through this process of autopoietic s
organization the system is able to stabilize, to attain an existing structure, to differentiate itself from its environment and maintaining its identiyt in self-referentiality (Luhmann, 1995; Flood, 1999).

It is not that hard to imagine these external, internal and bottom up processes influencing each other and through which the system transforms. These transforming mechanisms are structurally coupling more or less autonomously functioning subsystems and their contextual environment. This gives us a conceptual understanding of our reality existing out of very many layers, with each layer interacting with a higher level, exchanging energy, matter and information, which is digested within the system and it subsequential parts.

Obviously changes in the subsystems, affecting the system as a whole, will have an effect on the system s interactions with higher levels of existence. Perhaps systems at the levels beyond the immediate context of the system within which the process of self-organization was initiated will be triggered. And so on. The idea of the various levels of scale interacting gets evidence across disciplines, and relates to scaling laws . These scaling laws are among the factors conditioning processes This means a system and the processes of self-organization by which the system can be affected, is on all scales sensitive to change. And the mechanisms of self-organization allow systems to progress and to seek best fits with their environment (Kello et al., 2010: 223-224).

The result is a highly connected world of systems which interact with various levels of scale. It is an open world in which structure and function, and in which content and process are not to be seen isolated from their environment. Instead content and process are highly dependent and determined by their context. The world as it is , fixed and stable, can no longer be. How to relate self-organization to all of this?

Self-organization (or dissipative structures, or synergetics) is the product of nonlinear dynamics and stable attractors. In other words, it is the production of stable patterns observed in nonequilibrium systems governed by nonlinear dynamics (Keller, 2009: 17). Self-organiztion is part of and contributes to an alternative, non-linear world view, with processes of emergence and co-evolution, and with adaptive behaviour as a response to external influences. Emergence is crucial in complex adaptive systems not only due to the fact that it links different levels, but also because this creates memory , as the st on a higher level will through feedback loops affect the self-organization of the low level components (McDonalds, 2009). While its contribution is limited to spontaneous pattern formation due to symmetry breaks, self-organization is fundamental in creating spontaneous order and discontinuous change (Kauffman, 1993). Self-organization is a spontaneous creation of some sort of order within a complex adaptive system environment (Heylighen, 2001). And discontinuous change is at the core of non-linearity. A non-linear world view results in a relational understanding of space and time, and all it stands for.

The consequence is we have to consider reality not just as generic or universal, but as situational and specific as well. Such a specific situation is allocated at a particular place on a particular moment in time. And if the conditions are met, at such a particular place on a particular moment in time a spontaneous change might occur, due to a process of self-organization. This view is fundamentally different from a

Cartesian, Newtonian, neo-positivist or modernist perspective. Instead of a one true wor an exciting world, full of options, possibility space and windows of opportunity.

## 6. The fundamental steps of self-organization

Self-organization is a process, and a rather special one. Self-organization is not intentional, it is autonomous and spontaneous. While being a representative of a non-linear world that is becoming , self-organization is producing new states of being. And that is why self-organization matters. Agents and actors being parts of a system do respond to these new states of being. These new states of being emerge as spontaneous patterns, which are visible everywhere, around us, as part of everyday life.

Self-organization can be understood if we are willing to consider our world not to be static, but to be in a continuous state of discontinuous change. Instead of linear development such a world will evolve non-linearly, including sudden changes, jumps and transformations. Such a non-linear world might be far more common than we re used to think it is. Such a non-linear world is also far more out of our co than we perhaps would like it to be. Within such a world the various parts, agents or actors behave more autonomously than we might have imagined as we re used to see our world highly func planned, full of rules and driven purposefully and intentionally. This might indeed seem to be the case, nevertheless we argue that if we re willing to see spontaneous developments we wil often, and we ll see it everywhere. We dare to state that the world and our developments depent on it. Each and everyone of us behave partially autonomous and without intent, nevertheless contributing to pattern formation ang by being attracted to patterns. Self-organization is an autonomous process, resulting in patterns we understand, we relate to, we have confidence in and act upon.

Self-organization is a spontaneous process, and therefore beyond our control. Despite these characteristics, it doesn t mean it s a process we cannot understand. To begin with, sel situation specific. Social scientists are very much aware of situation specific processes resulting in rather unique events. While rather familiar to the social sciences, the phenomenon of unique events attracted attention of some physicists as well. This forced them to follow an approach which might be somewhat unusual within physics, nevertheless with interesting result which also supports social scientists again, in their struggle coping with non-linear processes of self-organization. Instead of doing research confirming laws of physics the specificities being essential to make self-organization happen are taken into consideration.

In the following we will dig deep to identify the various conditions under which self-organization will take place. We will identify *a set of rules* which help explaining how processes of self-organization do contribute to change and transformative processes. We will see the process of self-organization can be understood as a process being built up out of four essential steps:

- The *first step* is the creation of a symmetry break, a mismatch in an existing situation.
- While this symmetry break is increasing it builds up energy, which eventually will lead to the *second step*: reaching criticality.

- *Step three* is what happens beyond this critical point. Various parts, agents and actors respond individually to the symmetry break or mismatch, all in an effort to reach i effort state or a best fit with its environment.

- While there is no agreement or a collective intent in responding to the symmetry break having reached its critical point, it results nevertheless in a spontaneous pattern formation. This pattern formation is the *fourth and final step* in the process of self-organization: an unintended but collective result.

And this pattern formation will function as an attractor for more agents and actors to becoming part of it or to respond to it, which makes the pattern formation a stepping stone towards developments to come.

And that is why self-organization matters. And consequently it is important to understand more of this process of self-organization, about how it functions, under which conditions, and to what kind of consequences this process might lead to. And relevant questions from a planner s perspective: a to make use of these spontaneous, self-organization processes? And are we able to influence such a process at all? So here we go

Self-organization as a non-linear process relates first of all to structural change, through which a (spatial) pattern emerges by itself . Some use the word spontaneous , some refer say coincidental , in all cases it is an undefined becoming (Boelens and De Roo, 2014) this change by itself is a change in a response to something undefined which has layers, in the context and/or in the past. While self-organization relates to an undefined becoming its cause is undefined as well. But probably the best way to pinpoint the undefined cause of self-organization is a symmetry break within an existing structure.

*A symmetry break*

Let s imagine first a non-systemic, isomorph environment. Its basic structure would be a collection of parts being positioned in a least effort state. Bak s piles of grain and BØnard s examples, which we will explore more in depth further on in support of our argument. One would expect an isomorphic environment to be in equilibrium. Nevertheless due to an undefined cause parts become dislocated, having been perturbed from their original location, building up tensions around a symmetry break or single-phase interface. This is the beginning of an increasing tension within the existing structure, which comes with high interfacial energy and relatively weak bonding. The break becomes structural, and the preferred spot for the onset of a slide and for the precipitation of a new pattern.

Any kind of self-organization is being initiated somehow, with a symmetry break being pushed beyond its critical point. It might be unclear what the trigger is to this symmetry break: An unknown, undefined, internal or external initiator. While self-organization is considered to be a bottom up approach the initiating factor for a symmetry break to occur (step 1 of self-organization) might very well be contextual. For example a contextual force more or less evenly spread throughout a contextual plain or field triggering not only one particular system but as well its immediate (and perhaps even its wider)

environment, resulting in a planar movement. Such a movement could trigger systems, subsystems and their environment all at once, resulting in a major shift in interdepencies and in shifting balance between structures and their functional meanings.

Vesterby (2008) makes reference of a collision situation : An external movement and initiating internal movement, which triggers the first stages of self-organization. The Bénard cells experiment shows a contextual change which could trigger parts or agents, having an effect throughout the system s or the agent s contextual environment: a plain field of changing cond (1993) calls this weak turbulence) flows through the system, with triggering effects.

Vesterby (2008) qualifies self-organization to be essentially exceptionally simple at it after which it could develop further going through many stages. He made a serious attempt identifying origins of self-organization . Seemingly taking a paradoxal reductionist, mechani approach analysing a situation with spontaneous change, Vesterby s analysis allows us to get a clear understanding of the very beginning of self-organization. At the very beginning the process of self-organization is rather deterministic. In this process it is essential what comes first and what will follow. Crucial in such a process are space, motion and substance, with substance representing not just form (matter, energy) but information as well (Eigen, 1971). In social environments agents respond in particular to information.

Space, motion and substance are essential for seemingly organized structures and patterns to emerge. Space (made explicit by Rayleigh s contextual conditions (Rc)) allows substance to ongoing motion. This substance in motion is constrained by structural criteria depending on the kind of substance. The motion in space contributes to substance s identity as it is anchor and direction. The continuing motion will result in self-referential interactions, which could result in a new status quo. As such it is getting self organized through spatial patterns be certain point on a time-space continuum. In other words: To any observer this self-organized process in space becomes a pattern formation at a particular moment and place, through which this pattern gets identity and congruent structures and functions.

As it might sound all quite abstract, it is nevertheless visible around us. For example tectonic plates moving along each other or pushing one-another up or down, create tensions and frictions which build up energy until the point criticality. This energy being released every so often usually results in hardly noticeable shakes. It can happen the earthquake has a magnitude which is beyond imagination. These shakes are all the result of a symmetry break reaching criticality, sometimes generating destructive powers. A collective of water drops getting beyond a critical point could be the beginning of a flow of water, progressing into a stream, which after some time could become a river which organises itself a route based on physical conditions. The initial stage of Lorenz story of the butt as a process of self-organizing: The butterfly flapping its wings which triggers at a particular moment a chain of air movements varying in pressure, catching up speed and differences in pressure, eventually building up a tremendous force which is being released with a destructive power after a period of time, whipping away anything that s in its way, including houses, villages, towns and mo origin being one bird taking off for whatever reason: The trigger could be internally (an itch) or externally

(the first bird signalling danger, or just being hungry). It does however trigger all others in his vicinity to jump high into the air. And all of them group together while flying away, becoming a flock of birds on the move. Panic for whatever reason starting somewhere within a crowd resulting in a fast move outward, with all individuals being very convinced in what to do without negotiating with or consulting each other.

While these examples are colouring nicely the message of what we understand with a symmetry break, they also represent a world far from Bak s non-systemic, isomorph environment. It means we have to be very conscious about the validity of Bak s findings in a world which is more diverse. examples have in common is the increase of a symmetry break reaching criticality after which a change, a response or an adjustment takes place: The first step in the process of self-organization is a symmetry break.

*Reaching the critical point*

We consider the occurrence of self-organizing events as a consequence of mismatches or symmetry breaks between the parts of a system. These mismatches or breaks do create tensions and struggle within the system: The structural setting of the parts of the system and their functionality through which these parts contribute to the system no longer have a least effort fit. Instead of linear adjustments these brea accumulate tensions or frictions, with a critical point standing in between order (nothing happens) and chaos (turbulence breaks lose). Any small behaviour at or beyond this critical state could trigger parts of the system, eventually affecting the system as a whole.

Bak and colleagues (1987) studied avalanches in grain piles. They wondered about these piles with numerous avalanches suddenly occurring due to grain being provisioned from above. Avalanches happen the moment a critical point (threshold) has been reached. One would guess a small change would lead to a small shift in the grain pile, while a major change would lead to a massive avalanche. Bak and colleagues found something entirely different. The grain on the pile reaching a critical state shows no correlation between cause and effect. The system self-organizes its internal structure independent of external causes (Portugali, 2000). There is no correlation between the change (a perturbation) and the condition which makes this change happen (details of a perturbation). Dropping another grain onto the pile may cause a massive slide, but it may as well be that hardly anything happens. The avalanches represent a self-organized response to change. In other words: The criticality is self-organized. Bak and colleagues were the first to discover a dynamic system displaying self-organized criticality (Bak, Tang and Wiesenfeld, 1987).

While these outcomes seem fundamental, we have to question them again as they have been deducted from Bak s experiments with grain and its non-systemic, isomorph environment. Again we have to think through the validity of Bak s findings the moment we copy the seemingly fundamental outcomes to a world which is diverse. The Grain Pile case Bak uses in his experiments presents a slightly more complicated situation than the three body problem Pioncaré raised in 1887. The three body problem is about three objects influencing each other (either colliding or attracting) of which we know precisely where they are positioned in space, how much they weigh and what their speed and directions are. While

all data is there it is impossible to describe their future path and positions, as the motion of the three bodies does not proceed according to rules which can be generalized in axioms. The moving bodies are the very beginning of a discussion which resulted in chaos theory. Bak s pile of g multiple body problem. A grain will collide with various other grains, all far from being perfectly round, and all uniquely settled within the pile. With Bak s analysis we shift as well from a Newtonian perspective of ideal situations and ideal science, to real situations and science which has an eye for situation specific conditions (which doesn t mean the result cannot be an ideal ty grains therefore all have multiple friction points, which keeps them in place but do also contribute to the frictions and the criticality. At some point this results in an avalanche of which it is unknown a-priori if it will be a minor one or a big one. The human world is more complicated than Bak s pile of grain multiple categories of agents, all floating around, all interacting, with mismatches everywhere, not building up to one clear moment of criticality. Instead there are plenty, resulting in various avalanches in adjusting behaviour of which it will not always be clear to what cause the a respond to. In the human world a clear cut avalanche or straight forward adjusti necessarily the only result to be expected from a symmetry break reaching its criticality.

Nevertheless criticality is essential in a process of self-organization (Bak, 1999). Self-organization takes place in a system having reached a particular threshold (the criticality of tension, struggle or symmetry break between the parts), after which processes of pattern result is a varying degree of change, from abrupt events (grain pile) to periods of varying turbulence (Bénard cells), affected by contextual conditions ($R_c$) and structural criteria.

*Beyond the threshold: adjusting behaviour*

Remarkably, reaching the critical point leads to a period of fundamental uncertainty. It is not possible to identify a-priori outcome of this period of uncertainty. It s a contribution to non-line sublime form. It s the invisible hand all over. It has been in the world of quantum physics that uncertai has been recognized as fundamental. Fundamental uncertainty is also an intrinsic part of self-organization. The context of the system being influenced by self-organization can be influential to the creation of a symmetry break and of reaching the threshold, what follows next in the process of self-organization takes place independently from contextual triggers. Therefore the spontaneous pattern formation (step 4, the end result of self-organization) is not considered to be contextually influenced: the rules s interactions among the system s components are executed using only local information to the global pattern (Camazine et al., 2003: 8).

In other words: With processes of self-organization and their unique and abrupt events we have to accept and to address fundamental uncertainty at the human scale as well. These processes of self-organization have been studied intensely by physicists, resulting in a number of appealing examples. Bak s grain pile is one of them. According to Bak (1999) the out-of-balance critical state will lead to a chain of non-linear, spontaneous events varying in magnitudes. These events are neither regular nor

periodic. These abrupt events could range from small to major adjustments without a linear relationship in the way these events are being triggered.

The study of so-called Bénard cells is another. Bénard (1901) did his famous experiments already in 1900. He investigated a fluid in a dish which he heated from below. The result is surprising. Instead of a vertical upward movement of heat transport also a horizontal layer of convection fluid appears. A rather regular pattern of hexagonal convection cells appears, due to a peculiar mix of buoyance and gravity forces. These cells have become a landmark in the study of nonlinear developments exhibiting self-organization and pattern-formation mechanisms. It is the granddaddy of canonical examples [ ] to study pattern formation and behaviour in spatially extended systems (Newell et al., 1993).

It was Rayleigh (1916) who showed us these convection cells occur only when a critical value $R_c$ has been reached (Ma & Wang, 2007). This $_cR$, or Reynolds number , is a non-dimensional value which relates to contextual conditions (temperature difference, gravity) and structural criteria (viscose of the liquid, thermal diffusivity). It gives expression to fluid motion and heat transfer (Getling, 2008). After $R_c$ has been reached a transforming period of turbulence results in the appearance convection cells. Koschmieder (1993) adds to this the differentiation between weak turbulence and turbulence . By weak turbulence we mean irregular, nonperiodic, time-dependent flow with slow variations with time and slow motions. By turbulent we mean rapidly and randomly varying flow at high Reynolds numbers [$R>R_c$: GdR] with very fast variations with time, relative to the vertical thermal relaxation time (Koschmieder, 1993: 116).

Beyond a critical point self-organization represents the moving of parts, agents or actors seeking balance in new meaningful linkages, adjusting structurally and functionally towards a new state of congruency, consequentially becoming manifest in emerging patterns. Bak (1999) warns us not being biased with a positive attitude towards self-organization (See as well Zhang & De Roo, 2016). All is connected, is the message delivered to us from the complexity sciences. Internal adjusting mechanisms or rearrangements among the parts, agents, or actors of a system could very well be initiated somehow by external interference (sometimes called global information ). However this has no effect o formation as such, which is considered essential to the process of self-organization. Randomly related and seemingly chaotic interactions do bifurcate somehow, presenting us with a pattern. In the complexity theorists: a process of autonomous development and the spontaneous emergence of order out of chaos is called self-organisation (Prigogine and Stengers, 1984).

*Spontaneous pattern formation*

The essence of self-organization is a pattern which results from a spontaneous rearrangement due to a symmetry break. Self-organization means a (structured) change due to undefined responses which trigger adjusting mechanisms: In a non-systemic environment such as a pile of grain or a glass of water its cause is a structure break. In other words, self-organization is considered to be a systemic adjusting effect of structure breaks and structure-function mismatches which comes into effect having reached a threshold.

Self-organization in this respect means a spontaneous adjustment of a structure break, and a better linkage between structure and function, either temporarily or in a more sustained way.

In a systemic environment a mismatch between structure and function might as well be the cause of adjusting mechanisms. In a systemic environment structure and function might find a new balance, different from a past situation, through which both are able to co-evolve. If so, self-organization stands for more than being a self-replicating mechanism, self-similar, self-adjusting, self-repairing or being resilient. The merging of structure and function originates often at a lower, decentralized level through which the system as a whole is being affected. Self-organization represents a responsive situation, linking moving parts and emerging patterns with contextual change, which could result in some sort of new order, at a higher level.

The process of self-organization includes spontaneous pattern formation. The self in self organization refers to spontaneous and to formation, while organization becomes emergence of a pattern. In other words: out of an undefined cause and a non-lineair process a result comes forth which is visible, can be differentiated from placid and chaotic environments, can be given meaning to and gets identity in space and time. In a way spontaneous pattern formation is synonymous to self-organization.

The undefined cause of a symmetry break in a systemic environment could be structure related as well (as in Bak s pile of grain) but could be as well a mismatch between structure mismatch between functions. A systemic environment is in abstraction an environment of nodes being connected with each other through meaningful interactions. These connected nodes are not just structure. These can be seen as functional too. The consequence of this reasoning is quite fundamental: In case of a symmetry break caused by a structure-function or a function-function mismatch, the spontaneous adjustment that might follow could very well be functional without immediate structural consequences. In such a case spontaneous pattern formation will be a secondary outcome.

Systems do well if there is a match between structure and function. This is not a fixed match: For example a family house is a house for a family of a particular size depending on conditions and policy restrictions. A change in culture (due to an increase of migrants for example), in social conditions (children no longer leave their parents house at the age of twe married couple staying in the family home, perhaps due to shortage of houses for starters), and more, a mismatch between structure and function emerges. This mismatch is due to conditions under which structure and function operate, do relate and do have meaning. In other words structure and function, and the system as a whole are conditional, which has consequences for and could trigger self-organizing processes.

Central to self-organization is the (adjusting) response to symmetry breaks and the tensions, frictions and struggles that come with it, resulting into pattern formation. Self-organization could be entirely meaningless, coming and going without any sustainable effect, showing us sudden order a pattern in a chaotic environment. This order can fade away again, but it could as well be the start of a chain of events which affects parts, attracts agents, or matters to the observer, to those affected by it, and

to society as a whole. In that case self-organization will bring sustainable rearrangements among parts, agents or actors under tension. These rearrangements or adjustments would then be an accumulative constructive process, which connects coherently external and internal impulses.

Self-organization is responsible for situation specific, place dependent and unique events taking place. It is therefore a major contribution to uncertainty within social environments. Self-organization as a phenomenon needs in-depth understanding to be able to distinguish it from other processes taking place within the social environment. Identifying the various phases of a process of self-organization contributes to this understanding, and to allow us to identify commonalities and differences with processes of self-organization, not only in a physical environment but as well in a social environment. This brings us back again to spatial planning.

*What about spatial planning?*

It is widely recognised that the development of urban areas, understood in socio-economic and environmental terms, cannot be planned by government action in a linear way, fro action, to outcome as planned. Even where a government agency controls many of the resources for physical development and acts in an integrated and coordinated way, socio-economic and environmental activities make use of the physical fabric of urban areas in all kinds of ways that are often difficult to imagine in advance, let alone predict. What goes on in urban areas is just too dynamic, mazy (Geddes 1915/1968). Understanding mechanisms of self-organization may therefore support the planner in various ways.

This understanding may be about triggering, influencing, avoiding or even preventing processes of self-organization to happen within the daily environment for the good of society. But above all this understanding will make the planner aware it asks for another attitude than the planner is used to. There is the traditional attitude, in which the planner considers the world to be his creation assuming this to be a factual reality - with the planner being in control. And there is the contemporary position of the planner being responsible to reaching consensus among stakeholders and the construct of an agreed reality. In both cases the planner considers the world as it is , factual, agreed and likely appreciate the existence of non-linear processes of self-organization the world will no longer be , but has to be seen as becoming .

# Urban Resilience in a Post Crisis Context The Regeneration of the Dublin Docklands

Aoife Doyle

Dublin Institute of Technology / Future Analytics Consulting Ltd; aoife.doyle@futureanalytics.ie

**Keywords**: urban resilience; adaptive capacity; new institutionalism

***Abstract***

*This paper explores the regeneration of the Dublin Docklands, located in inner city Dublin, Ireland. Since the commencement of the regeneration programme in 1987, the area has been the site of complex, changing governance arrangements and has endured rapidly shifting economic conditions from the boom period of the late 1990 s to the most severe economic crisis in 2007.*

*During the boom period, the Docklands transformed from an area of derelicti become the location of Ireland s most important financial services centre. In 1997, the establishmen of a Special Purpose Development Authority (SPDA) to govern the redevelopment of the Docklands marked a radical shift in the philosophy guiding urban planning in Ireland towards more entrepreneurial style engagement with the property development sector (Mc Authority was vested with powers to fast track development in the area, ex powers from the local authority. Under this new scheme, the Docklands developed rapidly until the economic crash in 2007, which created a complex new context for regeneration.*

*This paper examines the role of urban planning in enhancing the resilience of the Docklands depicted here as the areas adaptive capacity in the face of crisis. Particularly, it focuses on the recent, post-crisis governance shift in the area the closure of the SPDA (now known as the Dublin Docklands Development Authority) and the designation of the area, in May 2014, as a Strategic Development Zone (SDZ), a scheme which continues to utilise the fast track pl*

## 1.0 Introduction

> The history of the Dublin Docklands can be read as a microcosm of the h
> *both ancient and modern. The making of the Docklands is a complex tapestry of great engineering achievement, visionary planning, intrigue, economic rise and decline, and human* triumph over adversity. (Dublin Dockland Development Authority 1997:18; in Moore 2008:15)

Over the past two decades, the redevelopment of the Dublin Docklands has radically altered the physical fibre and social structure of a significant part of Dublin s inner commenced with the launch of a significant urban regeneration scheme in 1987; just as Ireland was emerging from a difficult recessionary period. Indeed 1980s Ireland was characterised by rising unemployment (increasing from 10% in 1981 to 17% by 1986) and a surge in emigration (Allen, 2000; Clinch et al., 2002). During this period, Dublin, like many other cities in Northern Europe, experienced the social and physical effects of economic re-structuring, particularly in the areas most dependent on industrial or manual activities (MacLaran, 1984). The abandonment of the urban core by manufacturing industries, a major modernisation of port activities, and a broader suburbanisation movement resulted in significant changes in the employment and social structure of the inner city. However, the general decay and degradation of Dublin s physical and social environment, comb with a growing disillusionment around the Irish planning system (O Leary, 2014), approach to planning and development in the mid 1980s, which drew heavily on the experience of other countries. Importantly, this shift in planning thought also coincided with shifting economic conditions, and the birth of the so called Celtic Tiger (Whelan, 2013).

Following the launch of the major regeneration programme in 1987, the Dublin Docklands transformed from an area of dereliction and decline to become the location of Ireland s r financial services centre. However, it has also been the site of complex, changing governance arrangements and has endured rapidly shifting economic conditions - from the boom period of the late 1990 s to the most severe economic crisis in Ireland s history since 200 argued that Docklands represents the best and worst of Celtic Tiger Ireland microcosm of the history of Ireland, both ancient and modern (Dublin Dockl Authority, 1997; in Moore, 2008:15).

This research employs the concept of resilience to examine the transformation of the Dublin Docklands including the related and parallel evolution of Irish urban planning during the same period. In particular, it aims to utilise the resilience concept as an analytical tool to further explore the local and national responses to the most recent economic crisis and the recovery trajectory of the Dublin Docklands. Ultimately the paper argues that any effort to assess or enhance the resilience of a city involves developing a comprehensive understanding of it s adaptive capacit and transform in the face of crisis. Yet it is not the city that acts but individual or collective actors; and it is their actions that constitute change or lack thereof (Lang, 2011). Therefore, in analysing the evolution of the Dublin Docklands and assessing its resilience, we must also examine patterns of institutional change in urban governance over the same period.

## 2.0 Examining the Evolution of the Dublin Docklands through a Resilience Lens

Resilience, and more specifically urban resilience, is a fuzzy concept (Era gained increasing public, political and academic interest over the past two decades; particularly in the context of the global financial crisis of the late 2000s and continuing forms of perceived social, political, economic and financial crises in a number of European countries. The concept is typically presented as the capacity of cities to bounce back or even bounce forward crisis event. Yet despite the increasing ubiquity of the resilience concept within urban planning literature, its exact meaning and measurement remains contested. Indeed, Davidson (2012, in Gleeson, 2013: 11) asserts that

> *It is far from clear whether the term resilience enjoys a shared understanding within academic disciplines and policy are*as and also between them

Furthermore, the emergence of resilience ideas within academic and policy debates and their relative influence on practice are highly specific to institutional contexts and the perceived security risks faced in particular countries and their urban areas. National policies and associated responsibilities for dealing with disruptive challenges (which in effect build urban resilience), differ between nations and are influenced by historic policy developments and national governance structures (Handmer and Dovers, 2011). Yet these differences, in the manner in which resilience is inter remains an area which has received little academic attention to date.

In Ireland, the concept of urban resilience has not typically been used in urban (explicitly, at least) although the resilience approach is beginning to be used in streams (in attempts to promote more resilient approaches to dealing with flooding, for example). However, explicit reference to the concept of urban resilience is included in th preparatory) papers for the Dublin City Development Plan 2016-2022, where it is defined in the following manner

> Urban resilience *is a relatively new concept, and generally refers to the ability of an urban area to withstand shocks and stresses without reaching an undesired state. Achieving this involves a degree of reorganisation and adaptation, with the development of new structures* and processes (Dublin City Council, 2014: 15).

Despite the ambiguity of this definition, its inclusion indicates movement towards shaping a resilience agenda for Dublin City planning and development. According to this definition, achieving a more resilient city which is capable of withstanding stresses and shocks is linked with the ability of the city to reorganise, and crucially to adapt to such incidents. However, if Dublin is to pursue such an agenda, how can this concept be operationalised and assessed in practice? In order to address this question, this paper utilises the resilience concept to examine the transformation of the Dublin Docklands including the related and parallel evolution of Irish urban planning during the same period. In particular, it aims to utilise the resilience concept to further explore the local and national responses to the most recent economic crisis and the recovery trajectory of the Dublin Docklands. This section briefly charts the development of the resilience concept, and sets out the intended approach for examining the development of the Dublin Docklands through a resilience lens.

C.S Holling, a theoretical ecologist, is typically credited for bringing the prominence in 1970s. In his seminal 1973 paper, Holling utilises the concept to examine the behaviour of ecological systems that are exposed to unexpected external changes and disruptions, defining resilience as

> *A measure of the persistence of systems and of their ability to absorb change and disturbance and still maintain the same relationships between populations or state variables* (Holling, 1973: 14)

Holling draws an important distinction between engineering and ecological resilience defining engineering resilience as the ability of a system to return to an equilibrium or steady-state after a disturbance (Holling, 1973; 1986). Such a perspective understands resilience as a measure of the speed of return to equilibrium (Pimm, 1991). Essentially, the quicker the system bounc more resilient it is. In contrast, Holling (1996: 33) asserts that ecological resilience is concerned with the magnitude of the disturbance that can be absorbed before the system change rather than speed being a defining feature, resilience , in this instance, is understo disturbance a system can undergo while remaining within critical thresholds how it can persist and adapt in the face of disturbance (Adger, 2000). Ecological resilience rejects the existence of a single, stable equilibrium and instead recognises the existence of multiple equilbria, and the possibility of systems to move into alternative stability domains. Yet, despite this core difference in understanding, both perspectives acknowledge the existence of equilibrium in systems, be it a pre-existing one to which a resilient system bounces back (engineering) or a new one to which it bounces forth (ecological) (Davoudi et al, 2012).

Since the 1970 s, resilience has been explored in a variety of different research areas including environmental studies, climate change reduction strategies and disaster prevention. It has also continued to expand as an adapted research concept within social and human geography studies (Kärrholm, Nylund & de la Fuente 2014) and more recently, applied specifically within the urban context where it can be broadly understood as the capacity of a city or urban system to withstand a wide array of shocks and stresses (Agudelo-Vero et al, 2012: 3). However, while the equilibristic view of resilience, as set out by Holling, has become particularly influential in many of these fields, such an understanding may be somewhat problematic when applied to the urban context (Alexander, 2013). Indeed, Dudley (2010; in Eraydin, 2013: 43) emphasises the importance of distinguishing this idea of system equilibrium from concepts of *urban* resilience; A resilient system may experience fluctuations or changes in conditions or structures, and these changes may provide the very basis for an urban systems persistence over time. Such equilibristic views too easily assume that there is some future steady-state (or a return to a past one).

Davoudi (2012), attempts to address the issues associated with applying such an equilibristic view to the urban context. In doing so, she argues for an evolutionary understanding resilience requires continuous adaptation rather than a return to a previous equilibrium. This perspective is also often referred to as socio-ecological resilience (Folke et al, 2010). Here, resilience is not understood as bouncing back to normality, but as the ability of comple systems to change, adapt, and, crucially, transform in response to stresses and strains (Carpenter et al, 2005) a view of resilience is not dissimilar from that put forward by Dublin City Council in their preparatory Development Plan document. Systems, in this view, are conceived as *complex, non-linear, and self-organising, permeated by uncertainty and discontinuities* (Berkes & Folke, 1998: 12). Since cities can be interpreted as complex adaptive systems whose organisation and behaviour are comparable to ecosystems, most scholars agree that the socio-ecological or evolutionary side of the concept is the most appropriate when using the concept in an urban planning / management context.

The need for urban resilience enhancement is often justified through the argument of an increasing level of uncertainty in an increasing complex world (Berkes & Folke, 1998). In line with this, Bosher and Coaffee (2008) propose that urban resilience is best understood as a cap and human induced hazards . If we view resilience in this way the capacity to manag such challenges, which is a feature inherent to the specific place under observation, then we must link this to processes of and (institutional) frameworks for urban decision making instead of only focussing on structural determinants. Indeed, as with cities, urban planning is under constant pressure to adapt. In the midst of ever changing social and spatial challenges, planning must continually re-position itself, proving its social value and long term capacity to function and solve problems (Reimer et al, 2014). Indeed, as Friedmann states (2005: 29; in Reimer at al, 2014: 1).

> within any given setting, planning must continuously reinvent itself as c
> *In contemporary societies, politics, institutions, economies, technologies and social values are all subject to continuous , often radical, change so planners often feel beleaguered, their* profession perpetually on the brink of existential crisis

The need for planning to continuously reinvent itself (and in effect, build resilience) necessitat its institutional setting is capable of innovation. An understanding of how and why institutional change occurs is particularly important in the context of resilience studies, where crisis events are often cited as catalysts for change or for re-thinking existing systems. Yet, how can we assess and examine this in practice? This paper proposes that new institutionalism is potentially useful here, referring to a diverse family of approaches to understanding stability, change and casual processes in social and economic systems (Davies & Trounstine, 2009).

First, it is important to define what is meant by institutions . Institutions as the rules and norms that govern human interaction (Herrfahrdt-Pähle and Pahl- rules, structures and norms that create and enforce cooperative behaviour ar groups (Davies & Trounstine, 2009). While formal institutions are legally bi constitutions, laws and policies in the political system, the economic system, and the enforcement system; informal institutions include cultural norms, such as customs, moral values or traditions (socially shared rules which are enforced outside the formal governance structures). Both formal and informal institutions can enhance or reduce the resilience of a system. Although institutions are not unalterable, as Davies and Trounstine (2009) assert, they are difficult to change and embody power; so understanding an institution necessitates an examination of its origin and how (and whether) it has been altered over time.

While some studies on institutional change focus on rules and structures, others focus on norms. However, four analytical frameworks are often cited as important for the study of urban decision making Rational choice institutionalism; Sociological institutionalism; historical institutionalism and discursive or constructivist intuitionalism. This paper avoids privileging one of these factors over others but uses a three-dimensional framework to understand the process of change or stasis as the interaction of ideas, institutions and interests (similar approaches to studies of institutional change have been followed by Cox, 1995; Hay, 2004; and Murphy, 2014). In employing this organisational framework, one of the central aims of the paper is to explore how ideas, institutions and actors interacted throughout the recent Irish economic crisis and whether they maintained or intensified urban policy continuity or created a path shaping moment.

## 3.0 Phases of Irish Urban Planning

Writing in 2003, Barltey and Treadwell-Shine (in O Leary, 2014) identified three phases in Irish public policy and associated trends in planning since Irish independence in 1922. The first phase, from 1922 to 1960, was pre-industrial with a focus on economic isolationism and self sufficiency with minimal consideration of planning (limited to housing). The second phase, from 1960 to 1986, was one of urbanisation, industrialisation and seeking inward investment with authoritarian, centrally controlled planning. The third phase from 1986 was post industrial with more entrepreneurial and flexible planning. Now, in post Celtic Tiger Ireland, we have entered what is recovery phase, referred to by O Leary (2014) as perhaps the most challe discipline so far as planning seeks to assist economic growth while addressi recent past (O Leary, 2014: 20).

Many of these shifts in public policy and planning thought, particularly post 1960, have been connected or linked with crisis events. Indeed, as Murphy (2014) asserts Previous Irish crises ha proved to be path shaping in policy terms - Responses to the 1950s crisis shaped a new econo regime which reoriented and opened the economy towards international investment. The response to the 1980s crisis shaped the 1987 Programme for National Recovery which laid the foundations of the Celtic Tiger model of light regulation, low taxation and foreign direct investment (Murphy, 2014) and the move towards more entrepreneurial urban planning. It is beyond the scope of thi comprehensively analyse the complex causes of Ireland s recent economic crisis. Rather, this paper will focus on shifts in public policy and related planning trends from the mid to late 1980s, corresponding with the birth of the Celtic Tiger and the establishment of the regeneration programme for the Dublin Docklands through to the present day. Specifically, it aims to examine role of urban planning in mediating and responding to the most recent economic crisis during period .

Since the mid 1980s, urban planning in Ireland has become increasingly infused with an ethos of entrepreneurialism with growing emphasis being placed on the facilitative role of planners rather than on their traditional reactive and essentially passive modes of operation (MacLaren et al, 2007). The transformation of Irish urban planning has not been an isolated event. In fact, the institutional and political contexts for such changes were associated with the growing penetration of political strategies, throughout Europe, by a neoliberal agenda. Such a movement is summarised by Brenner and Theodore (2002: 352) in the statement

> *the linchpin of neoliberal ideology is the belief that open, competitive, and unregulated markets, liberated from all forms of state interference, represent the optimal mechanism for economic development*

As part of this, local authorities / municipalities have tended to move away from the managerial or development control approach that characterised their operation in the 1960s and 1970s towards a more entrepreneurial or innovative approach to city management and marketing. Harvey identifies three strands in this entrepreneurial approach: The first is a reliance on the concept of public-private partnerships (PPP) this is particularly evident in Docklands areas (like inner city Dublin) where many redevelopment projects have been undertaken by specially established development agencies working closely with private sector investors; the second characteristic of this approach is its speculative nature as the role of the public sector in these projects has, in most cases, absorbed much of the risk associated with projects to satisfy the private investors; Thirdly, these new developments tend to be place specific rather than jurisdictional, focussing on particular projects rather than on

redeveloping an entire local authority areas. Indeed, all three of these characteristics could be observed in Dublin throughout the late 1980s to the early 2000s.

## 4.0 A Period of Transition Responding to a Changing Dublin Docklands

One of the defining features of the Dublin Docklands has been the changing character of the area over time, and particularly during the period 1980-2008. From its origins until the later twentieth century, the area has always been a zone in transition (Moore, 2008: 165), particularly vulnerable to global economic changes. While once thriving trade resulted in a bustling port and docklands, the reverse was also true as the vibrancy of the area fluctuated in response to external conditions in the 1980s. Indeed, the history of the Docklands is quite different from the relatively more stable history of the rest of the city centre where districts have undergone less dramatic change over longer periods.

Perhaps one of the most significant periods of change occurred throughout the 1990s and early 2000s, as the area developed under an ambitious new urban regeneration programme, implemented through the use of a Special Purpose Development Authority (SPDA), first established in 1987. Two such agencies operated in the area between 1987 and 2014 first, the Custom House Docks Development Authority (CHDDA) gained responsibility for 11 hectares of the Docklands, and operated until 1997. In 1997 this authority was subsumed by the Dublin Docklands Development Authority (DDDA), an authority which became responsible for more than 500 hectares of the Dublin Docklands until its formal dissolution in 2014.

Modelled on, and drawing upon the experience of Urban Development Corporations (UDCs) in the UK, most notably the London Docklands, these agencies operated entirely outside the jurisdiction of the Dublin City Council (then known as Dublin Corporation) Planning Department and were

> *endowed with planning powers to streamline planning controls and possess the operational and financial powers to undertake infrastructural developments, acquire land, reclaim it and dispose of it at a subsidised cost to private-sector developers* (MacLaran, 2003: 10).

This creation of these agencies was driven, in large part, by a growing dissatisfaction with local authority planning during the late 1980s, which was considered bureaucratic and too inflexible (Bissett, 2008, 16) to tackle the scale of the city s problems. In Ireland, the tradition authority (the City and County Councils) had always focussed on development control. Yet in a context where very little development was taking place, this role became increasingly irrelevant and the role of the local authority began to be questioned (Moore, 2008).

The newly-created agency marked a radical shift in the philosophy guiding urban planning in Ireland towards more overtly facilitative entrepreneurial systems of engagement with the property-development sector. Yet of all the approaches and models introduced for entrepreneurial urban regeneration in, it is only in Dublin Docklands that a fast-track , planning process was est the Irish Government. This fast-track planning process completely bypasses t planning process, including the third-party appeal, as provided in the Planning and Developme legislation. Under this regime, master plans (and planning schemes) were prepared for the Docklands area. The Authority could then issue what was known as a Section 25 certificate in respect of a development, which meant that once a development was consistent with the master plan or scheme it could be exempt from the requirement to obtain planning permission. Within this process, community or public participation in the planning process was limited to the master plan or scheme making phases. Once a plan was complete and approved, the public could not appeal any development seen to be consistent with the plan.

The perceived benefits of this fast track approach were set out in a report DDDA in 2008. These benefits, clearly focussed from the applicant or developer perspective, were stated as follows (Grant Thornton, 2008):

- The planning application process is shorter than the conventional planning route due to t elimination of Third Party Appeals.
- Greater certainty is ensured in planning applications submitted as part of the DDDA planning process as once development complies the respective plans within such schemes, the development will be permitted.
- The cost of the conventional planning process is often significantly higher than costs associated with applications under the DDDA planning process. This is primarily due to the presence of third party appeals, with the involvement of the Board (the Irish appeals board) driving consultants costs and therefore, applicant s costs rise.

As the focus of the regeneration project became far more commercial in orientation, questions arose around the role of Dublin City Council during this period, and around the nature of the planning system itself -

> *The vesting of planning powers in a pro-development body...runs the risk of challenging the legitimacy of the urban planning system itself by exposing it as a tool for legitimating the* unequal distributional outcomes of the development process (MacLaran, *1993*

Particular concern was raised as the 1990s progressed, as the idea of developing an International Financial Services Centre (IFSC) became not just part of the overall plan for the docklands, but the major flagship project. In a short amount of time, the IFSC became a keystone of the entire regeneration project and today ranks as a key symbol of the new docklands. developments in other waterfront locations, and in particular that of Canary Wharf in London, the IFSC project was designed to attract international investment to Dublin with the overall aim of improving tax revenue and jump starting an ailing economy. As such, the focus of the regeneration programme, under the CHDDA, shifted as the 1990s progressed from providing for mixed use development to a far more commercial orientation. This move was also exacerbated by the changing economic climate , as Ireland experienced an unprecedented economic boom with an average growth rate of 9% in GNP between 1995 and 2001 (In contrast, most other European countries experienced annual growth levels of between 4-5%).

Hailed a major economic success by some commentators, the CHDDA prompted phenomenal demand for office space following the establishment and continued promotion of the IFSC. The focus, however, on establishing the IFSC at the site led to a predominance of office activities and a limited amount of residual development. Indeed, a report commissioned by the Department of the Environment (central government) in 1996 to examine the operations and achievements of the CHDDA found that the kinds of mixed use development and heterogeneous social profile that was intended had not emerged. The Government also recognised that planned trickle marginalised communities had also failed to happen in the now largely mono-functional landscape as a growing divide was emerging between the new Docklands area and the surrounding communities (Bartley & Treadwell-Shine, 2003; in McCrory, 2013).

In 1997, the CHDDA was subsumed by the DDDA under legislation to encompass redevelopment and regeneration of a larger area (526 hectares) of Dublin s docklands. The legislative remit of the Authority was wider than that of the CHDDA, and required it to secure three primary goals the social and economic regeneration of the Docklands area on a sustainable basis; improvements in the physical environment of the Docklands area; the continued development of financial services activities

in the Docklands area. Yet, following its establishment much of the population and socio-economic trends continued. Indeed, between 1981 and the mid 2000s, there were significant changes in the employment and social structure of the inner city. The population, declining quite rapidly between 1981 and 1991, began to increase quite substantially between 1991 and 2006 from 20,146 to 27,652 (see table 1, below).

| | 1981 | 1986 | 1991 | 1996 | 2002 | 2006 |
|---|---|---|---|---|---|---|
| **Total DDDA Area** | 23,205 | 21,708 | 20,146 | 21,341 | 24,061 | 27,652 |
| **% Change over previous Census** | -4.10% | -6.90% | -7.80% | 5.60% | 11.30% | 13.00% |

*Table 1: Population Change in the DDDA area between 1981 and 2006 (Source: Adapted from Moore, 2008)*

In addition, between 1991 and 2002, there were two notable changes to the tenure structure of the area: a large increase in the number of households in privately rented accommodation, which more than doubled from 5,611 to 13,272 households; and a 20% reduction in the number of households in social housing (resulting from the sale or privatisation of existing stock and the decline in the number of new social housing units being constructed). Since 2002, the change in tenure has been even more dramatic, with the number of households in privately rented accommodation again more than doubling to 28,286, representing 51% of all households. In 2011, households in owner occupation and privately rented accommodation accounted for 77% of the total, up from 53% in 1991 and 63% in 2002. (MacLaran and Kelly, 2014: 175)

Such developments, according to MacLaren and Kelly (2014: 178) were characteristic of an area undergoing a process of gentrification, which they define as

> *a process of broad socio-spatial change which centres on the transformation of working class neighbourhoods into middle class* residential and / or new commercial spaces .

This was also demonstrated by significant changes to the age structure of the population (there was a 90% increase in the number of adults aged between 25 and 44 years), levels of education achieved and employment rates. While the docklands came to embody all the positive aspects of the Celtic Tiger economy, it also in many ways demonstrated the underbelly of that growth, in particular the emergence of a dual city . While spatial or geographical proximity between a r had increased, the problems of social polarisation became a huge concern in the docklands and elsewhere in the mid 1990s. Although thousands of jobs had been created in the new economic activities based around the financial services sector, they did nothing to address the long term unemployed residents in the area, many of whom were either manual or unskilled workers.

## 5.0 The Dublin Docklands in a Post Crisis Context

From the mid 1990 s until the onset of the global economic crisis in 2007, Irela strongest economies in Europe. During the 1990s the so called Celtic Tiger Iri average annual rate of 7.5%, more than three times the European average at the time (Murphy, 2000).
In the last few years of this boom era however, Ireland s property market entered a high-r phase which eventually burst in 2007, leading Ireland into the greatest ec country s history. Moore-Cherry and Vinci (2012) contend that it is precisely because of the development model, described as predicated on constant growth to function (Kitchin, from 1986-2006 , heavily reliant on borrowed money to fuel an overheated property sector, that the post 2007 crisis has had such a major impact on the social, economic and physical landscape of Dublin.

Unlike as has happened previously in other Europeans countries such as Sweden and Iceland, Ireland s banks were not allowed to collapse under the debt burden created during the boom. In order to introduce liquidity into the Irish banking system the state took a two-pronged approach: (1) direct recapitalisation or nationalisation of the banks; (2) relieving the banks of their toxic assets by purchasing all property loans of 5m or more and placing them in a new state agency to behalf of the taxpayer (Kitchin et al, 2010). This state agency, established in 2009, is the National Asset Management Agency or NAMA. NAMA, having taken control of many of Irelanc unfinished developments and zoned land, became the largest land owner in the state.

Within the Docklands, and other parts of the inner city, a number of key challenges started to emerge relating to a number of large scale partly completed developments; the lack of financing across both the public and private sectors as many of the largest developers became bankrupt; and social issues relating to the impacts of emerging austerity policies. A number of sites in the Docklands which were bought by the DDDA in boom times using compulsory purchase orders were later transferred to NAMA at a fraction of their initial value. Indeed, the DDDA lost an estimated 180 million from seven property deals (Phelan, 2014) over the course of the crisis. In February 2012, in light of its emerging financial difficulties, the Government Auditor General undertook a review of the activities of the DDDA. Three DDDA Executive Board members were also members on the boards of Bank of Ireland and Anglo Irish Bank (one was Chairman of the Board at Anglo Irish Bank), where the DDDA sought funding for a number of sites. The report raises concern of potentia which may occur in these circumstances.

The huge financial losses suffered by the DDDA, combined with the findings of this report, led to the announcement in 2012 that the DDDA was to be disbanded. In 2014, the government published the General Scheme of the Dublin Docklands Development Authority (Dissolution) Bill, a stand-alone piece of legislation which provides for the transfer of certain responsibilities, rights and liabilities for the Docklands area to Dublin City Council.

As Ireland emerges from the worst economic crisis it has faced since independence, questions have been asked about the extent to which the crisis could have been minimised or reduced. The rapid and highly unsustainable development patterns experienced in Dublin over the past two decades were made possible by a combination of political and institutional factors, in particular the relationship between planning, politicians and the property development sector (Moore-Cherry, 2012). The neoliberal approach to development characterised by de-regulated planning in places like the docklands and the willing transfer of power to semi private and private interests by the state, resulted in an environment within which massive speculation was permitted and indeed encouraged. Over the course of the crisis, the legitimacy of the DDDA was called into question and the Irish planning system suffered serious reputational damage. Indeed, Kitchin et al (2010:2) affirm that as well as a catastrophic failure in Ireland s banking and financial regulatory system, there h failure of the planning system at all scales .

Today, Dublin City Council is now responsible for leading the social, economic and physical regeneration of the Dublin Docklands. Yet, the 2014 dissolution bill also refers to a continuation of fast track planning procedures, as part of a new planning mechanism to be Docklands. In May 2014, part of the Docklands (former) DDDA area (66 hectares) was designated a Strategic Development Zone or SDZ by the government. A number of special rules apply to planning and development in an SDZ. These rules make it significantly easier to obtain planning permission for development which is consistent with a Planning Scheme in force for an SDZ and prohibit planning permission for development which is not consistent with it. Similar to the DDDA approach, there is no right of public appeal against a decision of a planning authority on an application

for planning permission in an SDZ. The planning authority may also acquire land in an SDZ, compulsorily if necessary. Fox-Rogers et al. (2011, 650) contends that

> *The power to designate SDZs is an example of the Government's desire to retain the power to intervene in the planning process (Fox-Rogers et al., 2011, 655).*

It is also important to note that NAMA has an interest in 75% of the 22 hectares that are available for development (out of the full 66 ha) in the SDZ area. In light of NAMA s primary objective o obtaining the best achievable financial return on these assets , the potent future planning and development of the inner city should be a critical concern. While achieving the best financial gain may be in the tax payers interest it cannot be considered a core planning objective. NAMA must make important decisions about strategic land holdings and yet there is no overall spatial vision for NAMA assets. The incremental and disjointed disposal of property based assets, it could be argued represents a quick fix property based solution to a property based crisis. Moreov such focus on reviving stalled developments (which in many cases should never have got through the planning process in the first instance) can undermine and inhibit new attempts at innovation and entrepreneurship.

Irish urban planning is at an important crossroad and inevitably, the legacy o period will influence theory and practice for years to come. As Murphy asserts, one might expect both the scale and impact of the recent crisis years to bring about a path shaping moment. Yet Wickham (2013) argues that such shifts have not taken place and that Ireland is survi The overall character of policy and institutions remains constant and this is evident in the Dublin Docklands. While the planning and development of the area is no longer the remit of a private authority, the planning *mechanisms* remain much of the same with the overarching focus, it could be argued, predicated on quick fixes to stimulate markets and reinstate growth.

## 6.0 Conclusion

There is an extensive amount of research on *how* and *why* the global financial crisis has evolved since 2007. However, although there have been studies on *responses* to the crisis, these have typically been conducted at the national or international level. Little or no attention has been given to how municipalities and cities have responded to the crisis. This paper (and the research project from which it stems) works towards closing this gap. This paper proposes that in studying responses to the crisis, and the resilience of cities, it is necessary to understand the adaptive capacity of urban planning systems. In doing so, we must seek to explore preconditions under which spatial and institutional challenges lead to adaptations of planning system characteristics (including legal configurations, tools and spatially relevant discourses).

In Ireland, responses to previous crises (in particular, the 1980s economic crisis) have created path shaping moments for public policy and urban planning. Following the 1980s crisis, Ireland adopted a development model which was predicated on constant growth to function (Kitchi model shaped the direction of urban planning in the years to follow, including the new planning mechanisms implemented in the Dublin Docklands. These mechanisms, utilising fa approaches under the direction of private development authorities, were designed to promote more flexible or adaptive forms of planning in response to a system that was perceived to bureaucratic and too inflexible to tackle the scale of the city s problems period. Yet, the use of tools to promote flexibility cannot be considered a f planning system. Indeed, the use of such approaches within the context of contributed quite substantially to the issues the area faced as the 2000s progressed.

Indeed a number of scholars increasingly highlight a perceived inability of current (market driven) planning systems to adequately enhance the resilience of urban areas due to the sustaining nature of neoliberal ideology (Eraydin, 2013; Fainstein, 2013; Joseph, 2013). Related to this, has been a critique of planning theory in addressing urban vulnerability in a neoliberal age. Urban policy; legislation on urban governance and planning systems; and some institutional changes have emerged, but, according to Eraydin (2013), they have not been supported by a new planning perspective and this has certainly been the case in Ireland, and in the Docklands. It is thus argued that a new paradigm, focussing on the need for greater adaptive and reorganisational capacity in urban systems, is required. Eraydin, (2013) proposes that resilience thinking can form the basis of an alternative planning approach, within a process that will focus on value systems and power relation
Thus, it is argued that a more detailed theoretical understanding of institutional and organisational mechanisms shaping resilience debates and action needs to be developed.

# COMPLEXITY, PLANNING AND FUZZY RESPONSIBILITIES IN CANBERRA SINCE SELF-GOVERNMENT

Karl F. Fischer[1] and James Weirick[2]

**Abstract.** *On 1 January 2015 the embargo on the 1988/89 cabinet papers held at the National Archives of Australia was lifted. The information that has become accessible sheds new light on a critical transition point in the history of the Australian capital, the imposition of self-government on the Australian Capital Territory. The city had been a kind of national government company town since its inception in the first decade of the 20th century, subject to various forms of departmental control but with no self-government. The systems of planning and governance persisting up to 1989 were based on public ownership of land and, for long periods, high levels of political and financial support from national government – a kind of planners' paradise. These conditions led to the development of a city which has been described as a perfectionist manifestation of ideal concepts in planning (Fischer 2013; Fischer & Weirick 2013).*

*The belated imposition of self-government in 1989 – against the wishes of its citizens – marked the beginning of a period of turbulent reforms. The way in which this was handled, from Cabinet level to administrative sectors of the bureaucracy, led to increasingly complex, fuzzy governance relationships and spatial planning verging on the dysfunctional. In the light of recent policy changes in Canberra and based on the newly released archival material together with interviews conducted since 2000 the paper traces the changing nature of planning and development in Canberra since self-government through the windows (Altrock & Fischer 2014) of planning complexity and fuzzy responsibilities.*

**Keywords.** city visions, urban governance, fuzzy planning

## 1. Introduction and paper structure

The paper first places the Canberra experience in the context of the conference theme *Definite Space – Fuzzy Responsibility* (1.1). In a second step (2), we take heed of the recommendations in track 18 to *"make sure that the audience/readers have a good understanding of the region under consideration, relevant historical and actual development trends, and relevant politico-administrative aspects of national and urban planning systems."* To this end, we briefly outline the history of how planning in Canberra got to the stage of what might be described as exploding fuzziness. The paper then (3) focuses on the phenomena of complexity and fuzzy responsibilities in urban development in the Australian capital and concludes with a structural overview of the Canberra case study (4) based on Martens (2007).

### 1.1. Canberra seen through the window of the conference theme

In the context of the conference theme, the experience of the Australian capital, Canberra presents a particularly clear example of changes in urban development processes since the beginning of the 20th century. In this sense, to quote and paraphrase the conference theme, it can be said that planning in Canberra was indeed "*affected by drift from **strict hierarchic control***" by government – as pertained

from 1900 into the 1980s – to forms of governance with "*public-private partnership projects, where the actual field of public* ***government action is dissolving*** *and shared with business, with many services formerly provided by the public domain outsourced. Who should take responsibility for how cities and regions are being changed?"*

While this question has by no means been solved in a satisfactory way in Canberra, the problems encountered in the transformation process of governance are paradigmatic, and their analysis may help in the search for new solutions.

## 2. Canberra – from strict hierarchic control to dissolving government action

To understand the extent and qualities of the changes in governance, some spotlights on how the core features under consideration in this paper developed over time are required.

Seen from the point of governance, Canberra's outstanding feature during most of its history has been the degree of strict hierarchic control of its planning and development. This long history of Canberra as a kind of government company town – developed in a system approaching that of a planned economy – distinguishes the Australian capital from most other cities. Canberra's planners enjoyed an exceptionally high level of political and financial support over long periods of time. The reason lies in the cultural function the city has had to fulfill since its conception in 1900: Its mission was not simply to be an administrative capital but to become the prestigious symbol of a young federation, in fact "the finest capital city in the world – the pride of time" (King O'Malley, Minister for Home Affairs 1910, quoted in Harrison, 1995, p.6)

Therefore, the elements that shaped Canberra in the long run into the 21st century (discounting sometimes protracted hiccups in the development process) included

a *vision* for the future (which of course changed over time, sometimes even got lost, particularly in phases of stagnation),
an understanding of *history,* albeit selective,
a strong orientation *on international exemplary models of planning* and
overall tight *planning control* on the basis of public ownership of land.

Thus, the underlying principle of public ownership of land and leasehold tenure followed *international models*, but also owed much to Australia's bitter experience with a "squattocracy" of graziers and city based land-speculators through periods of boom and bust in the nineteenth century.

### 2.1 Visions created, lost and found

#### 2.1.1 The vision of the 'Griffin Plan'

The core *vision* for the future of the capital took concrete shape in the 1911 plan designed by Chicago architects Walter Burley Griffin and Marion Mahony G – a plan with amazing *international* linkages, rooted in *history* and anticipating principles in urban design and sustainable planning which planning history generally ascribes to much later phases of the 20th century.

The implementation of the plan – or rather the lack thereof – is a sad affair. This is however, not a consequence of a lack of planning control but rather of changing ideal concepts and power constellations. What happened? In his role as Federal Director of Planning and Development, Griffin did succeed in putting parts of the of City Beautiful skeleton of avenues on the ground. But World War I ended the implementation of the functionally and semantically rich concept (Weirick, 1988, pp.7-10).

#### 2.1.2 Loss of vision in the inter-war years and setting up a system of strict hierarchic control

Following the termination of Griffin's appointment in 1920, the stagnation of the inter-war years and what might be described as a cultural re-orientation of the Australian way of life to suburban norms meant that the medium-density scheme and clearly urban character implied by the Griffin Plan changed to that of a garden town of bungalow suburbs. It would be an exaggeration to call this a *vision*. Canberra entered an adolescent stage – seven oddly configured garden suburbs in search of a city or, as it seemed at the time, 'a good sheep station spoilt' – all, however, within a system of strict departmental *control*.

But then, the experience of World War II changed everything. Political support, financial sourcing and executive clout of planning were upgraded on an unprecedented scale. What caused this change were the disadvantages experienced in the process of conducting the war from Canberra, Sydney and Melbourne. Following changes to the taxation system during World War II, most notably centralising income tax revenue at the Federal level, the various defence departments hitherto headquartered in Sydney and Melbourne were to be brought together in Canberra. But this was to be only the starting shot for concentrating a majority of government departments there. An enormous building program for the transfer of departments, staff, families and services had to be integrated into a process of efficient urban development.

To achieve this, Prime Minister Robert Menzies introduced Federal legislation which in 1957 created a powerful organisation, the National Capital Development Commission (NCDC), whose responsibilities lay in planning and developing the capital. Menzies ensured that the NCDC would have a large, single-line budget and a high degree of planning control based on continuation of the leasehold system. In the event, the NCDC acted as benevolent dictator in a city without self-government – a planners' paradise in a rapidly expanding city with growth rates averaging around 10% per annum.

### 2.1.3 Creating a new vision: The Y Plan

The professional planners oriented their work on the most modern international planning practice – mainly models of British New Town planning combined with US methods of automobile-centred land-use-transportation planning. In a reinterpretation of Howard's 'Centre and Satellite' model and Abercrombie's 1944 County of London Plan, the Canberra of the Griffin Plan became the 'Central City' – today called 'Inner Canberra' – connected to a set of satellite towns in surrounding valleys separated by a continuous green belt.

Reconciling the spatial configuration, size and functional structure of these satellites in terms of population numbers, employment concentrations, retail catchments, traffic flows and infrastructure provision has been a crucial factor in the development process of the city and its long-term sustainability. Under stress since the late 1970s, the 'Centre and Satellite' model appears to have entered a new, highly problematic phase in 2015. At the core of the problem lies the spatial disposition of functions within the topography in the central area:

In the Griffin Plan, the central area functions in terms of commerce, culture and civic administration were to be developed between the two poles of the municipal axis: the Civic Centre in the west and Market Centre in the east. In the 1920s, Griffin's successors had decided to concentrate both functions at the western end. The motorisation of Australian society following World War II put pressure on this decision. Transportation studies commissioned by the NCDC in the early 1960s revealed that a city centre in this location, squeezed between the two ridges of the central hills, would experience considerable traffic congestion if it was developed as a conventional CBD within a car-based overall radial-concentric urban pattern.

The solution was seen in a more linear urban form and in a reduced size of the city centre. In contrast to a conventional CBD, 'Civic' would focus on highly specialized services, while a large share of the office employment and retail functions would be decentralised into the satellite districts. These were termed 'New Towns' to emphasize that a high level of self-containment was intended. The key to

achieving this lay in the government's power of allocating the government departments – which were the city's major employment nodes – to the individual 'New Towns'. Government was also in charge of the construction of the government offices while private enterprise built the shopping centres. Together, these elements provided the core of the town centre structure of each 'New Town'.

The development plan thus envisaged 'New Towns' stretched into the form of a linear city with 'old Canberra' in the middle; connected by peripheral freeways and a central reservation for a public transport spine carrying a rapid transit system planned for implementation when the population reached 500,000. Public transport along this spine was predicted to be more effective by dividing the city at its northern end into two branches in the form of a Y; hence the name 'Y Plan' (fig. 1, NCDC, 1970, p. 226,).

Figure 1. 1970: The Y Plan

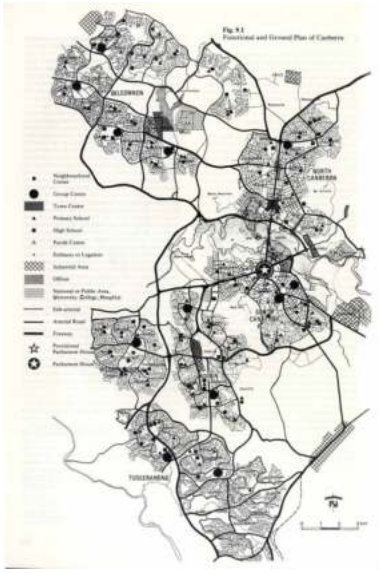

Figure 2. The built reality: Canberra's functional plan 1980

The frame of this network was fleshed out with neighbourhood units, community facilities and roads all graded in perfect hierarchies (fig. 2, Fischer 1984, p.134)

**2.1.4 Implementing the new vision**

The machinery created by the Menzies government ensured that these planning concepts were implemented with amazing precision while accommodating a population increase from 39,000 (1957) to 270,000 (1988) in three decades. This can be demonstrated by comparing the visionary artistic rendering of Canberra drawn in the late 1960s (fig. 3), which depicts the city in the manner of an aerial photograph as it might have looked at the beginning of the 21st century, with an aerial photograph from 2000 (fig. 4). The two images are surprisingly similar.

The city's functional and ground plan looks like a diagram from a planning text book (Fig. 2). But it displays the built reality of a city which can be seen as a perfect manifestation of planners' ideal concepts in the era of high modernism – a city we might call 'the ideal Garden City Metropolis' (Fischer 2013).

Figure 3. Visionary artist's rendering 1970. Source: (Reid, 2001, p.298)

Figure 4. Aerial: The built reality in 2000. Source: (Reid, 2001, p.324)

The basic principles behind this process were described in an impressive publication intended "to solidify [these principles] in a policy sense" (Nielson, 2000) and put them in print for the years to come. In its last chapters on 'Growth and Change' that book, *Tomorrow's Canberra* (1970) also reflected on the need to react flexibly to structural change. It focused on social change and consequences for the design of neighbourhoods. But it did not anticipate significant changes in the structure of governance, nor the way in which office finance and construction or more generally the urban market would change. And this is where the perfect pyramid of planning concepts began to crumble in the 1970s, in fact not long after it had been constructed.

### 3. Complexity and fuzzy responsibilities

#### 3.1 Complexity and fuzzy responsibilities enter the scene in the 1970s

As early as 1972, the leasehold system was emasculated by eliminating land rent and transforming landholdings into what, from an economic viewpoint, was virtual freehold (Stein, Troy and Yeomans, 1995). In May 1970, Prime Minister John Gorton announced that land rents under Canberra's leasehold System would be abolished. This not only destroyed whatever value Canberra might have had as a model of a potentially self-financing town, 'The Gorton Gift' also meant that 27,000 leases of land valued at $230 million had been given away, converted into virtual freehold land. While the high level of planning control based on lease-purpose clauses was not immediately affected, the foundations were laid for a new way of financing the capital based on municipal rates.

A little later, in 1974, a newly appointed Commissioner chartered a new 'Corporate Planning' course for the NCDC designed to augment the role of the private market. Private developers would henceforth not only construct housing, shopping malls and private offices, but also government offices to be 'leased back' by the government. The fact that land values and the potential return on investments were considerably higher in the city centre than in the New Town centres led to immediate pressure from the private sector on the locational strategies of the NCDC, which responded by approving office building in the city centre contrary to its own plan (Gilchrist 1988).

The youngest district commenced under the NCDC, Gungahlin, was even planned without a core of government offices. Instead, the skyline of the city centre was beginning to mushroom with quite non-descript office buildings – in obvious contradiction to the Y Plan. But it was only following self-government that the established urban hierarchy came under significant pressure.

#### 3.2 1989: Self-government

Introducing self-government appeared a step long overdue in a democratic society. But the democratic deficit was the least of the worries of Canberra's citizens. In view of the high level of Commonwealth

subsidies for the capital, a majority had even rejected self-government in a 1978 referendum. Change, nevertheless, was inevitable and in 1988, in a period of fiscal constraint, the Commonwealth forced self-government on the Australian Capital Territory (ACT) (Wettenhall, 2000).

As it turned out, however, the particular arrangements chosen in terms of urban politics, urban economics and urban planning created major problems for the city and its development. New information on the decisions taken at this turning point in Canberra's history have recently become publicly accessible following the lifting of the embargo on the 1988/89 cabinet papers held at the National Archives of Australia.

In 1988, an enquiry into the establishment of an ACT government including a review of the ongoing role of the NCDC was carried out under the chairmanship of an outside expert from the business sector, company director and former merchant banker David Block. The previous year, Prime Minister R.J. Hawke had appointed Block chairman of an Efficiency Scrutiny Unit within the Department of Prime Minister & Cabinet to undertake a review of the Australian Public Service aimed at bringing business methods and cost savings to the public sector. This was on the lines of the Rayner review of the British civil service commissioned in the early 1970's by the T hatcher Government (Schäfer, 1994, pp.84-85). Block's responsibilities also included chairmanship of an Administrative Review Unit – the combination of business efficiency and bureaucratic reform infuses his recommendations to Cabinet on the planning of Canberra, which were distilled into a 1-page (!) Cabinet minute.

On 7 July 1988, the Hawke Government agreed to the abolition of the NCDC and creation of "a small national capital planning authority . . . to prepare and continuously review a National Capital Plan, which would be legally binding; subject to the National Capital Plan, the ACT Administration be responsible for local planning and development; the construction of Commonwealth and national capital works in the ACT be the responsibility of the Department of Administrative Services." Savings of 122 positions and $6.588m per annum were envisaged (Codd 1988; Block 1988).

This decision created a weak national planning authority with nominal control over a powerful local planning authority. Stripped of staff and its role in design and construction, the national planning authority was reduced to an oversight role, with limited capacity to even undertake this role.

Further complications arose over Territory finances. Separating national capital type costs on the one hand from municipal and State costs on the other was a complex affair, with which successive commissions of enquiry had grappled. Self-government now required decisions at the level of fiscal politics, the level of institutional competences and hence too, at the level of spatial planning and design standards. Canberra's planners had always pursued a strategy of thinking of the capital city as a whole, in contrast to most other capitals. This had meant applying the design standards of the capital to the entire city – as opposed to splitting the attention between a carefully designed capital district and an 'ordinary' urban area left to develop as typical Australian suburbia. This was now to be changed.

### 3.2.1 Two organisations, two plans

The NCDC was replaced by a two-level governance structure composed of a local authority (PALM: Planning and Land Management) and a national authority specifically responsible for the areas of national importance in the capital (NCPA: National Capital Planning Authority). Beyond the national area around the lake, these areas included the hills and ridges, the buffer zones between the New Towns, the approach avenues and other landscape features safeguarding the character of the capital. They were inscribed in a **National Capital Plan**. A complementary **Territory Plan** was to ensure, "in a manner not inconsistent with the National Capital Plan, the planning and development of the ACT." At both levels, a significant quality of planning expertise was required.

But the neo-liberal aversion to planning meant that there were too many 'P's in the recipe. Consequently the NCPA was downgraded to the NCA (National Capital Authority). Inside the authority itself, delusions of grandeur facilitated the acceptance of non-explicit planning responsibility. "We wanted the authority to be seen as an organization with a broader base, than just planning – it was too easy to attack it if it was just seen as a planning authority, but if it was seen as a land manager, constructor of things, asset manager, keeper of the state, then that was something that was desirable" (Neilson, 2000).

### 3.2.2 Exploding fuzziness

In fact, the planning role of the NCA was severely curtailed. This has been a continuing process culminating in the current call for its abolition. In an era of reduced power and influence, the NCA's planning competences atrophied – not only through reduction in budget allocations but also reduction in staff, culminating in the abolition of the post of National Capital Plan Director in 2003.

Conceived in Australia's heyday of neo-liberalism (Pusey, 1991), the new **Territory Government** took office at the beginning of a long phase of turbulent reforms and changes. On the political front, election of the ACT Legislative Assembly based on multi-member electorates and proportional representation made it difficult for one political party to achieve a majority, with the result that coalition governments would be the norm. On the economic front, the Territory Government could not afford the low-density, far flung city it had inherited from the Commonwealth on the basis of tax revenues alone. On the planning front, the division of responsibilities between the Commonwealth and Territory governments proved to be dysfunctional. Let us look at these issues in turn.

### 3.2.3 Fragmentation

At the level of municipal or territorial administration, a proceeding loss of focus soon became apparent. Its functions were fragmented into a multitude of Territory departments and branches –in terms responsibilities, physical location and overlapping ministerial control – in a way that has made the co-ordination between often competing branches difficult.

Since the capital was declared to be basically complete, it seemed obvious that it did not require spatial planning on a substantial scale any more. Running a city was seen as a task of **land management**. Planners, architects and engineers could be replaced by economists and managers. Privatisation, small government, staff reduction, de-professionalisation, and radical outsourcing were the key words for the following chapter in Canberra's history.

The ACT planning authority ended up with no transport planners; its urban designers were transferred to ACT Parks & Places; its subdivision planning function to the Land Agency; its major project evaluation role and its ACT/NSW regional planning role were taken over by the Chief Minister's Department.

On the issue of cooperation between the Territory Government and the NCA, it turned out both were unable to strike a compatible balance between Territory and National Capital needs. Relations have been characterized by routine interference and micro-management by ministers and their offices.

### 3.2.3 The economic dilemma

At self-government, municipal rates were not sufficient to meet the annual budget for the running expenditure of the Territory. A substantial portion of municipal revenue, including infrastructure investment (Sansom, 2009), was therefore to be financed from the sale of the Territory's only asset – the land that had been acquired in the first decade of the twentieth century for the foundation of the National Capital.

Under the new arrangements for planning and urban development, this estate was divided into Territory land and National land in terms of ownership, with an overlay of 'designated areas' of national significance on some parts of Territory land subject to Commonwealth planning control. In the debate on the enabling legislation in the Australian Parliament, Labor member and former Minister responsible for Canberra, Tom Uren made the issue clear:

> ". . . it must be understood that the land of the ACT belongs to the people of the nation as a whole, not just to the people of Canberra. Public ownership of and the development rights on it have enabled the Commonwealth to pursue its objectives free from the effects of land speculation and private interest. Public land ownership and integrated planning and development have enabled urban development to be coordinated on a scale far greater than anywhere else in Australia . . . . Under the proposed legislation, there would be a division between national and territorial land for funding certain planning development and for management purposes . . . . Self-government has been designed so the ACT government will have access to the revenues and land and development rights over most of the ACT, and economic necessity is likely to be the basis on which the future declarations of land will be made" (Uren, 1994, pp.424-25).

This came to pass. What had once been conceived as a sustainable method of supplying building land at equitable cost for the homes of average citizens and of channelling land-value increases into the public purse was turned into its opposite. The land policy of the ACT Government now focused on maximising land values, and by 2002 the head of the new Office of Land & Assets Management declared that it could "take pride in its success of raising land prices to Sydney levels" (McKinnon, 2002). By 2004, Canberra was reported to have left Sydney suburban price-levels behind. With the cost of land soaring, affordable housing became a difficult issue, and the low-density, far-flung city the ACT Government could not afford, was further extended by that government for short-term gain in revenue from greenfields development.

### 3.2.4 The dilemma of economics and planning: consequences of small government and outsourcing

The strategies of small government and outsourcing meant hard times for planners, more so than for economists and lawyers. Contradictory trends emerged over time. In order to maximise development opportunities and to reduce capital costs of urban development, suburban projects were packaged and handed over to builders who developed substantial estates in a deregulated environment. In many cases, suburban street patterns and site plans were no longer designed by planners, but by builders and their draftspersons; building control was thinned down in a manner that became instantly visible in a dramatic drop of standards. In other cases, planners and consultants found themselves entangled in growing spiders' webs of red tape; highly contradictory indeed. The development approval process was bureaucratised to a point of absurdity (fig.5)

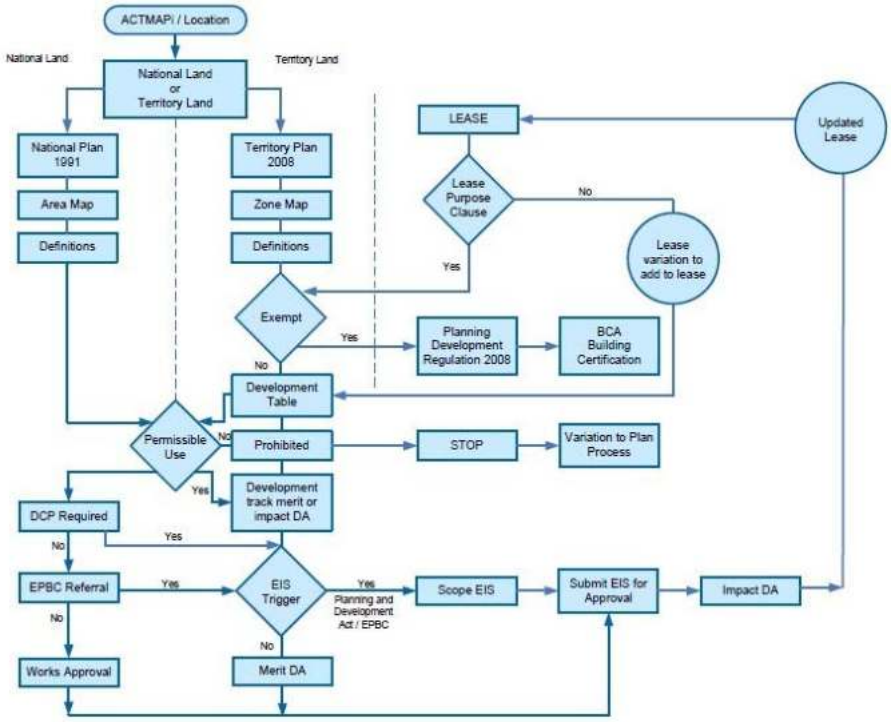

Figure 5. Development Approval process in the ACT. Source: (Sinclair, 2012)

Planning had left the path of the NCDC's (modernist) strategy of planning and development and proceeded more on the principle of 'planning by projects', wherever opportunities for development or redevelopment arose: a sports stadium; a waterfront project; a museum replacing the hospital; and so on. De-skilling and de-professionalization, the loss of corporate memory through staff reduction and the dissipation of libraries meant the loss of in-house competence. Eventually, this resulted in catastrophic, deadly consequences, when in 1997 the task of imploding the Canberra Hospital was arranged as the centrepiece of a public festival and was given to an economically competitive, but inexperienced demolition contractor, leading to loss of life among the spectators. The events of the late 1990s provide classic case study material for the study of urban politics in a neo-liberal phase.

### 3.2.5 Conflicts between the National Capital Plan and the Territory Plan

The ACT (Planning & Land Management) Act 1988 specified that the purpose of the National Capital Plan is to ensure that "Canberra and the Territory are being planned and developed in accordance with their national significance". This has, however, never been achieved. The NCA never had the financial and personal resources to fulfil their task in an adequate way, and the Territory Plan was watered down until it became simply a zoning scheme.

The division of tasks between the National and Territory produced similarly problematic results. Back in the 1970s, the NCDC had created an over-arching conceptual framework for the forested setting of Canberra in the form of an integrated network of public lands termed the 'National Capital Open Space System' (NCOSS). In 1989, responsibility for the NCOSS was divided. The Commonwealth retained control of the visually significant Inner Hills and the parklands of the Central National Area, leaving the ACT Government responsible for the ecologically significant mountain ranges and wilderness areas of the water.

In this way, a city government became responsible for a National Park and a National government became responsible for a city park – a major contributing factor to the Canberra bushfire disaster of 2003 with its loss of life and large scale destruction (Weirick, 2003).

### 3.2.6 Positive and negative dimensions of fuzzy planning in Canberra

**Enter the OECD**
At the nadir of purposeful planning in the National Capital, the neo-liberal agenda produced a positive outcome when the ACT Government turned to the OECD with an invitation to undertake one of its 'city competitiveness and urban renaissance' studies in Canberra – similar to contemporary studies of urban governance and urban innovation which the OECD had carried out in other case study cities including Berlin, Belfast und Glasgow. The study placed the ACT in the broader context of the 'urban renaissance' movement at the beginning of the 21st century (OECD, 2002).

Drawing together a broad range of local actors, stakeholders and community groups, the OECD's approach aimed at the development of locally specific solutions for the sustainable management of structural change. The OECD focused on identifying innovative structures for participation, mobilising social capital networking public and private partners in the context of civil society, integrating locally focused short-term projects into overall metropolitan strategic planning concepts, inventing and implementing new visions – an approach reflecting the state of strategy-oriented development planning as practiced at the turn of the millennium (Fischer 2007).

**New initiatives and plans**
Following an election campaign in which environmental sustainability and planning had been central themes, a change in the ACT government in 2001 to a Labor-Greens coalition led to ambitious programs following the recommendations of the OECD. Their report had criticised the absence of a strategic plan for Canberra. Now, social inclusion, increased sustainability through higher usage of public transport and innovative ways to engage different actors in new patterns of public-private partnership arrangements were incorporated in three integrated plans: a Social plan, an Economic plan, and a Spatial plan, developed in a consultative process between government and the community. They added up to a kind of strategic development plan for orientation and action that had not existed in Canberra since the all-encompassing modernist development plans of the NCDC – not as a simple repetition, however, but as something we might call 'modernism re-loaded' (Fischer 2007). Similar to the historic approach of the NCDC, this catalogue of themes addressed by the ACT government – integrated with public participation exercises– looked as if it had been compiled from a planning text book.

**Rise and fall of the 'Griffin Legacy' study**
Another promising government initiative emerged in the form of a study at the national level which projected a re-discovery and re-naissance of Griffin's City Beautiful concepts with a view to exploiting their potential for the re-urbanisation of Canberra. This combined an historical analysis the Griffin Plan with a kind of New Urbanist vision for the central area. In 2004, a lavishly produced publication with suggestive watercolour renderings presented the ideas of the 'Griffin Legacy' to the public (NCA, 2004). The concept promised to boost the city centre; to re-instate the Griffin vision of a boulevard city of cosmopolitan splendour; and in the process, transform the vast empty lawns north of the lake into prime real estate of immense value.

Certainly at this stage, the beautiful renderings should have been based on thorough analyses of the engineering and transport perspectives, heritage items, property values and other financial implications, consequences for employment, commerce and community facilities and the whole host of studies which form the basis of an urban development strategy including the phasing and timing of land release and infrastructure provision. But this did not happen. One reason can be seen in the deplorable state of the ACT and Commonwealth administration described above.

Instead, amendments to the National Capital Plan were approved in 2006, which bestowed upon the study the qualities of "a blueprint …directing public and private investment in core areas of the capital" (NCA, 2006, p.1). The assumption was obviously that this would lead to immediate investment without lengthy ground work and public involvement. A combination of factors including

the NCA's lack of control over the lands in question, lack of funding for the necessary infrastructure, and approval of a $600 million headquarters for the Australian Security Intelligence Organisation (ASIO) contrary to the plan, combined with community resistance to the fast tracking of development projects and the loss of heritage values, led to a collapse in the legitimacy of the so-called 'Griffin Legacy' project.

**Private sector initiatives**

In parallel with the public planning exercise of the Griffin Legacy, the Property Council submitted "Recommendations for an Outstanding Canberra Spatial Plan" (Property Council, 2004); and the developers of the privatised airport were employing the services of a former NCDC commissioner to develop a city centre redevelopment plan (Powell, 2005). Already in 1991, one of the major developers in Canberra's housing market had spent 1 million dollars on a study for the introduction of light rail (Winnel, 1991). These actors had played significant roles in the over-concentration of commercial offices in Central Canberra under the NCDC. But the new impulses created since the 1990s gave them a new understanding of their role.

**Privatisation and spatial strategies: The Airport and the abandonment of the Y Plan**

Further to this new role of the private sector, the public/private balance shifted significantly around the turn of the millennium in one major field. Canberra airport was privatised by the Federal Government in 1998 as a 'free enterprise zone' subject to neither the National Capital Plan nor the Territory Plan. In short order, the owners built a hitherto unplanned 'Edge City' with offices and factory outlets around the airport east of the Central City.

This led to a dramatic retreat from the principles of the Y Plan, ignoring the lessons of the transportation studies of the 1960s. With the airport 'Edge City' a *fait accompli*, the Territory planning institutions abandoned commitment to the linear disposition of New Towns and proposed a new urban growth structure based on a centralised radial pattern, similar to the one the NCDC had tested and rejected in the 1960s. The overriding interest of developing greenfield sites in order to support the Territory budget through land sales led to the establishment of a new residential satellite on greenbelt lands immediately to the west of the city. While the new satellite to the west and the privatised airport to the east embraced selective principles of sustainable design, the consequences for transportation were highly problematic. Rejecting the principle of strong functional decentralisation, the city centre was now to be built up as a conventional CBD. Forgotten were the warnings of the 1961 transport study which had predicted an overload of traffic in the city centre. Already existing traffic problems were ignored.

What thus emerged was a radial-concentric element similar to that of the first post-war development plan. Among the consequences is a traffic tsunami breaking its way along the lake shore from the new residential district in the west, past the CBD and the Russell defence offices to the 'airport city' with its competing interests of passengers, office workers and factory outlet visitors. Trying to make a virtue out of this, transportation planners proclaimed that the Y plan had now changed into an H plan, with the east-west motorway cutting through the symbolic heart of Canberra forming the bar of the H. The problems were exacerbated by the construction of a huge building block for the Australian Security Intelligence Organisation on this route. The sheer bulk of this complex sits in the urban fabric of the Griffin network like an embolism; far too big in terms of block size and outright deadly for urban life in terms of its security requirements. All of this is continuing to tear the Griffin concept, as a manifestation of good urban form, to pieces.

How could this have happened? Were the planners, and was the NCA in particular, not able to act as custodians of Canberra's urban legacy? As our interviews conducted between 2000 and 2015 have shown, they were not. Some of the reasons have been explained above, such as the NCA's scarcity of personal and financial resources and the Territory's overriding interest in maximising real estate values. Another reason lies in the fact that the NCA had lost the control over the lands even in the Parliamentary triangle. Commonwealth land had become a disposable good negotiated in the non-transparent power games between ministries. And the practice of 'leasing back' governmental office

space from the private sector anywhere in the city meant that government departments could locate wherever the market made the most attractive offer. In recent years this has had problematic consequences, with departments leaving their town centre locations to relocate in the city centre and in the airport office park.

A study carried out in 2007 had demonstrated that the jobs in the new towns were predominantly taken by residents of the new town or adjoining districts. It also identified that proximity to work was an important consideration in where people decide to live. In spite of the relatively high levels of self-containment in the ACT New Towns, the study concluded that "unless there is a commitment by all levels of governments to support the strategy, the potential benefits of employment dispersal to designated centres will not be fully realized" (Quirk 2007).

Recent developments and surveys, however, reveal that this commitment has been dwindling, and truly dramatic consequences are imminent. Following a growth of office floorspace at the airport from 4,000$m^2$ in 2001 to over 200,000$m^2$ in 2015, the level of floorspace is now higher than found at any of the town centres (EPD, 2015). The main problem with this is that the airport is difficult to serve efficiently by public transport and that the new pattern results in a higher level of travel in the city than if the development had been located in more accessible locations.

Several large departments in the New Towns have already relocated to central locations. But the most dramatic imminent shift appeared on the horizon early in 2015. The Conservative government had responded to the problems associated with illegal migration by merging the Australian Customs & Border Protection Service and the Department of Immigration into one 'super agency'. The Minister of this newly created 'Australian Border Force' announced that the combined staff of the old ministries would be centralised in one building, and that consequently, 5,500 jobs would be removed from the centre of the New Town of Belconnen to be relocated in the central area or the airport office park, now termed 'Aerotropolis'. The consequences for the commercial viability of Belconnen town centre, for the jobs in the associated service establishments, not to mention the patterns of the journey to work would be grave indeed. Recent announcements have again moved towards considering 'local impacts' when deciding where to base the Immigration Department's headquarters while emphasising that the Finance Department "will have a final call on where Immigration's 5500 ACT staff will be consolidated" (Canberra Times 11.05.2015).

### 3.3 Canberra at the centennial, 2012-2013

The cultural life of Canberra at its centennial more than demonstrated the energy and creativity of an active community but the physical form of the city remained problematic. Updated planning studies at metropolitan scale, an extensive consultation process, a new plan for the city centre, a proposal to extend the city centre to the lake and planning for a light rail line were inspired by critical reflection on the history of the city, in particular the Griffin Plan.

None of these exercises, however, did anything to change the return to the radial-concentric urban form and to the H-Plan with its problematic traffic implications. Canberra is moving towards higher densities in the centre, but at the same time adding new suburbs on the periphery. These processes are underway while the larger issue of divided planning responsibility is still being determined in the aftermath of Parliamentary enquiries and Ministerial reviews. For all the positive aspects of the centennial years, 'exploding fuzziness' remains the distinguishing characteristic of Canberra's governance and planning.

## 4. Concluding Remarks

Writing of Canberra in the 1970's, American city planner Edmund Bacon observed, "Here flourished, and continues to flourish, one of the greatest urban designs ever produced, conceived, nurtured and grown in circumstances fiercely democratic" (Bacon, 1974, p.309). Bacon was correct as far as the long-standing national debate on the National Capital was concerned but at the municipal level there

was no democracy in Canberra at that time. The introduction of self-government fifteen years later belatedly brought a measure of democratic governance to the citizens of the city. But with new actors and new institutions, the scene was set for the emergence of 'fuzzy' planning practices in terms defined by Martens (2007, p.50), "practices perceived as *fuzzy* in the sense that they are not based on a clear-cut framework about the roles and responsibilities of various actors."

Listing the main actors involved in government processes as "political institutions, governmental agencies, private business interests, issue-oriented interest-groups, locality-based citizen groups, and 'ordinary' citizens," Martens (2007, pp.44-49) usefully outlines three 'ideal models' of governance:

> the coordinative model, based on control and command – "the governing body is positioned above the governed and has the task to steer society for the good of the governed, it . . . collects information, sets goals and priorities, and selects and implements policies";
>
> the competitive model, based on the metaphor and reality of market forces – "governance is primarily seen as a competition between actors with diverse interests. Actors set goals and formulate policies independent of each other and try to achieve them through power struggles with competitors";
>
> the argumentative model, based on public participation and communicative action – "differences between governmental bodies, private sector agencies, interest groups and 'ordinary' citizens become obsolete. Every actor is respected as an equal participant . . . . The focus is on the knowledge, assumptions, arguments and solutions these actors bring to the table rather than formal responsibilities, power resources and interests of the actors."

The three models, represented in diagrammatic form as the 'governance triangle' make manifest the nature of fuzzy practices that "combine one or more models of governance" (Martens, 2007, p.50) (fig.6).

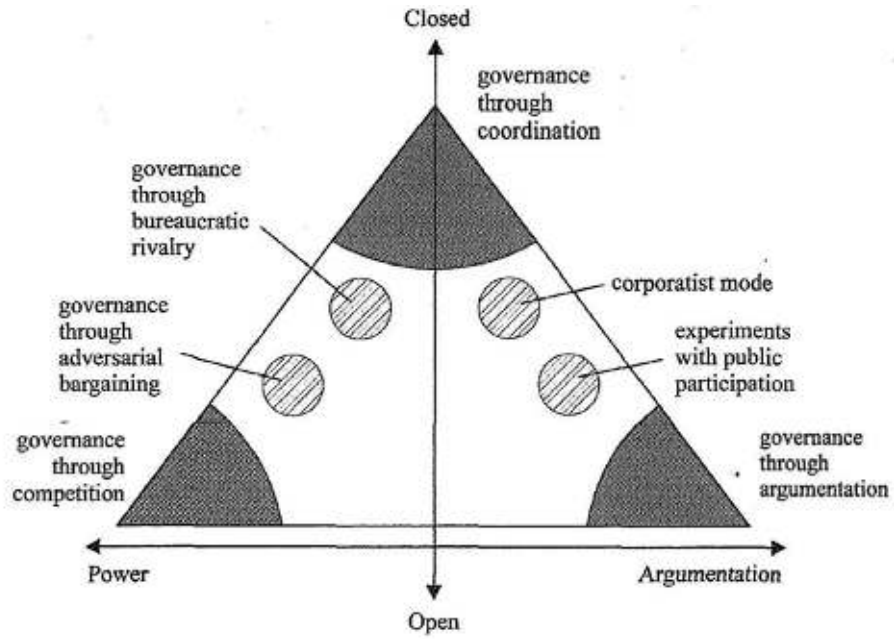

Figure 6. Fuzzy practices within the 'governance triangle'. Source: (Martens, 2007, figs 3.1 & 3.2)

This diagram from the work of Martens (2007) helps us see the emergence of fuzzy planning in Canberra in structural terms. The long history of central government 'control and command' of the development process, culminating in the work of the NCDC from the 1950's to the 1970's, is a classic case of the coordinative model in the field of spatial planning.

The first deviation from this model into the realms of fuzzy planning occurs in the 1970's when the NCDC adopts a corporatist mode, shifting marginally from a closed structure towards a more dynamic role of civic leadership together with an embrace of the private sector, in the process losing legitimacy and generating community opposition. This stimulates the move towards self-government but when this is imposed from above – the closed 'command and control' realm of the central government – its basis in the Block Report, driven by private sector perceptions of administrative efficiency, is detached from the planning traditions of the city, unleashing decades of bureaucratic rivalry and institutionalising the opposite of its intentions, administrative inefficiency. Meanwhile the private sector, advancing from the competitive model, begins to win monopoly rights over suburban development, commercial leasing and the privatised airport through adversarial bargaining. An informed public reacts to the erosion of environmental amenity and civic identity through the creation of citizen groups, which briefly aligned with OECD experts and Labor-Greens political representatives in the ACT Legislative Assembly leads to an idealistic period of participatory planning in the initial stages of producing The Canberra Plan, 2008. Private sector power and bureaucratic rivalry nevertheless quench this movement, and threats to the National Capital role and metropolitan structure of the ACT become the norm.

## 1. Introduction

This paper stems from our work on the new Master Plan for Bucharest. It chron
construct a three-tiered planning regulation system aimed at governing developme
the city. We have written it with the explicit intention of submitting it to th
AESOP Conference in Prague. Therefore, it is more of a conceptual paper than a
work progresses, we intend to expand it into detailed account, charting the ev

For the time being however, we restrict ourselves to revealing the intended arch
regulations, which will govern the new Master Plan.

Almost two years ago, we have started devising the Master Plan for what can be
complex city in Romania. For the purpose of this paper, two main dimensions
complexity are of interest to us, namely its morphological complexity and its i
Both take centre stage within the architecture of our proposed model.

## 1.1 The Morphological Perspective

First, let us summarise the major development phases that shaped the current mo
of Bucharest (Filipeanu et al., 1997, pp. 35f.):

> During its medieval times, Bucharest lacked any sort of defensive walls
> could expand into its direct hinterland, by incorporating existing vil
> settlements that clustered around the roads connecting it to the rest
> principality. Hence, the city developed policentrically from an early
> expansion implied that there were never any clear limits between diffe
> areas, thus keeping the city in a constant state of flux;
>
> When examining the architectural fabric of the city during medieval times, we
> host of fragile building materials, prone to destruction by fires, ear
> deterioration over time. Against this background, the city became a ferti
> recycling. The only building types that were spared by this process
> monasteries and the princely palace;
>
> The last important factor that impacted heavily on the urban form was p
> Over a period of about a century and a half, Bucharest experienced
> population numbers:
>
> > The first period was confined to the end of the 19th century, when the Kingdom of
> > Romania was slowly opening towards European, viz. mostly French
> > influences. This period of rapid population growth was accompanied b
> > interventions, as Bucharest gained in importance as the new capita
> > formed Kingdom of Romania (cf. Lascu, 2011, pp. 73ff.; P noiu, 20
> > They required a supporting set of urban regulations, which had to be
> > 1997);
> >
> > The second period, which spanned the interwar period, correspond
> > overhaul of the Romanian economy, which, in turn, triggered a n
> > immigration. From a morphological perspective, this period correspon
> > rise in density and building heights. Functionally, most new ho
> > displayed a high degree of differentiation, which was geared towards
> > a wider array of social classes. This newly gained interest in hig
> > functional specialisation was supported by a scientific turn in urban p
> > was later formally embodied in the Urban (Systematisation) Plan of 1
> > 2013);
> >
> > The third period started immediately after the Second World War. A
> > industrialisation produced a sustained population influx, both f
> > hinterland of the city and from other cities in the country. Conco
> > properties were nationalised. Both processes paved the way for the t
> > regulatory planning system to a decisional planning system (Filipeanu e
> > pp. 35f.). It is during these times that all the major housing pro

> gained momentum. As the production of new housing units increased,
> gradual shift form the quantitative to a more qualitative perspectiv
> prescriptions (Derer, 1985, pp. 137ff.). Thus, as private propert
> abolished, the new architecture aligned itself fully to modernis
> However, this period of Europeanization did not last later than
> Afterwards, as socialist aesthetics gained prominence, this traditi
> somewhat old-fashioned, and probably too Western European in taste.
> repeated densifications ensued, as the built-up perimeter was frozen
> As a result, the end of the socialist regime witnessed exaggerated
> and undersized public amenities.

Hence, the urban structure of Bucharest exhibits the results of a wide var
operations. As time has passed, most of them have become the hallmark of the cit
lack a comprehensive comparative perspective, in order to grasp the full impact
a wider Central European perspective (cf. Lenger, 2014).

## 1.2 The Institutional Perspective

The above chronology is sketchy at best. However, it is nearly impossible to
synthesis in institutional terms. The research upon this topic is currently
material has become more available, but a comprehensive synthesis is nowhere in
time being.

Thus, we can only make three general observations:

> First, that the pre-war period experienced a slow accumulation of or
> stemming from a wide array of different laws and codes. This proce
> relation to the growing complexity of Bucharest (cf. Lascu, 1997);
>
> Second, that planners working during the interwar period were the
> building and zoning ordinances from a scientific perspective, al
> working in a regulatory planning system centred upon private proper
> 2014);
>
> And third, that planners working under the socialist regime had to
> political pressure (cf. Olteanu, 2013). They responded by drafting d
> methodologies, while at the same time dispensing with much of th
> interests that blossomed during the interwar period.

This fragmentary evolution brings us to the present day, which is characterised
crisis in the field of urban and spatial planning, as well as by a an increased
interests, across which municipalities find it increasingly hard to manoeuvre
institutional insufficiency is further complicated by a fragmented, and sometim
of planning laws.

## 1.3 Conceptual and Theoretical Framework

Our conceptual framework is shown in Figure 1. Thus, the new Master Plan lies at
four fields: the field of urban planning, containing regulations and managem
structural field, encompassing the link between planning and its associated
functional field, which connects actors to opportunities by permanent ass
municipality, and, finally the GIS interface, which is merely a tool in suppor
and the municipality.

It is plain to see that such a complicated figure is difficult to frame in theo
the perusal of the dedicated literature, we have settled upon three theoretica
metropolitan functions, as developed by Blotevogel (Blotevogel and Schulze, 201
(Bege, 2010); the incipient theory of demand oriented urban life cycle manage
2010), as well as some insights stemming from the science of networks (Thompson,
al., 2006; Newman, 2010). The theory of metropolitan functions links the urban
scale, while the theory of demand oriented urban life cycle management links th
level. However, both theories lack a clear operational character. Hence, the
provided by the science of networks.

Nonetheless, reframing the conceptual framework in theoretical terms proved a
for two main reasons: first, because all three theories are in their infancy, a
one hand, we still lack data[1], and on the other, because available datasets display insuffi

Take for example the theory of metropolitan functions: Bege (2010) uses two s
measure the three metropolitan functions, i.e. the decision and control functi
competitiveness function and the gateway function. The difference between the t
a question of size: while reduced set uses 90 indicators, the extended set use
option surpasses the information we currently have. Hence, we shall have to
insights gained from each theory as we continue constructing the architecture of

## 2. Methodology

As this is still work in progress, this section contains a set of ideas, which w
in support of our model. As the research matures, a full account of our progres
contain an extensive methodological section.

### 2.1 Research Strategy

Compliant with current planning legislation, the new Master Plan has to evolve
stages: first, there is a background study phase, aimed at rendering the current
as well as its future prospects. This is then followed by a second stage, in
regulations is constructed, in order to provide a consistent and coherent coverag
future situations. In its third stage, the Master Plan undergoes administrative
ministries concerned with spatial development and environmental matters.

We now find ourselves in the midst of the first phase, in which a series of b
produced. However, the deadline for this first phase is well beyond the schedule
Against this background, the research supporting the architecture of the new p
necessarily limited, both in scope and in depth.

Nonetheless, we have managed to construct a system of problems that will require spec
within the model (cf. Lehnerer, 2009/2013):

1. The problem of clearly delineating public and private interests. In
problem translates into the difficulty of creating building and zoning
widespread acceptance. This issue is fundamental to any urban interventio
the right to property is a fundamental right, stipulated by the Romanian
other hand, there is currently no Urban Planning Code to moderate this ri

2. The problem of mediation, which stems directly from the problem stated
pragmatic terms, the model should allow for constructing a negotiation
public and private interests. This is a stringent requirement, as the Buc
subject to increasing pressure from private interest groups. Hence, in
model presented in this paper, we have started work on an additional
operation mechanism to aid future mediation efforts;

3. The problem of over-regulation and arbitrariness. We have tried to guar
risks within the model, by focusing on indicators that tolerate mediation
and the private interest[2], but we feel that there is still much work ahead in this

4. The problem of relevant thresholds. This problem is mainly economic in
usually a very fine line between efficiently enforcing public interest a
interests. Hence, the three tiered-structure of our planning regulation s

All four problems are of a great operational interest. If we manage to succeed
into an effective system of control indicators, then we would be a step closer
haphazard development path, which has characterised the city of Bucharest over
century, towards a more resilient trajectory (cf. Birkmann, 2004; Dro , 2004).

[2] Cf. section 3.

## 2.2 Data Quality and Collection

At present, the process of collecting data is incomplete, as about 70% of the r
missing. More specifically, we have received a few dozen datasets, over a perioc
half, and we are currently waiting for the rest. However, the real problem lies with da
is distinctly uneven.

First, there is the problem of an insufficient level of detail. To illustrate th
the National Institute of Statistics (NIS) generally works with datasets pert
Nonetheless, except for coarse-grained analyses, the census tract level is almos

Then there is the problem of accurately delineating private and public property
has been made under the INSPIRE Directive (EP and C, 2007), there is still
improvement in this field. Nonetheless, as the project progresses, we believe
bound to improve.

And finally, there are some important areas in which data is not even collecte
foremost example in this sense is commuting information. In such instances, we s
other studies, which were supported by fieldwork.

In spite of all these issues, even the data we have received thus far requires e
now, most background studies have managed to produce some workable images of the
Bucharest. However, they do not have the accuracy needed to test the feasibility
currently working on this issue.

## 3. Results

The model we have constructed for monitoring and controlling planning regulat
Figure 2. Upon closer inspection, the image reveals that the model works with
namely the city, the district, the zone and the plot. Each scale has a distinct
seek to operationalise with the help of indicators.

Thus, at the city level, we work with four related concepts: mobility, inhabitan
four concepts are related to the concept of zoning, in the sense that the
specialisation and the structure of the built environment. Practically, they
existing and possible concentrations, which need to be taken into account.

The ensuing level is the district level. Some of its characteristics overlap t
level, i.e. characteristic densities, inhabitants and jobs. However, some addi
such as the functional character of each district and its capacity for sustain
expressed in the coverage and quality of the existing infrastructure of public utiliti

One level lower, the regulation zone is the working unit for the model, in the
sort of density and distribution regulator (cf. Lehnerer, 2009/2013, p. 12)
authorised and unauthorised functions, as well as general morphological indica
characteristics[3], its building capacity[4], and the building's position[5]. Most of these
indicators have minimum and maximum acceptable values, thereby touching upon
problem mentioned earlier.

[3] Relevant indicators for this category include Lot Surface (LS), in relation to property lines, a
Depth (LD), and Curb Cut Spacing (CCS).
[4] For this second category, the relevant indicators include Lot Coverage (LC), Floor Area Ratio
(FYD), Rear Yard Depth (RYD), Side Yard Width (SYW), Building Distance (BD), and Driveway Width (D
[5] Examples are Building Height (BH) and Street Wall Length (SWL).

The lowest operational level consists of the plot itself. It inherits most of
regulation zone, and subsequently adds a few more to them, like the required
spaces per lot and the amount of area that needs planting.

Essentially, the model has the following workings: from a top-down perspective,
interplay of districts, thereby acting as a typological framework. The distri
regarded as classes within this typology, thus setting the general characteri
zones. At this level, however, another, bottom-up perspective steps in, which c
the regulation zone with the characteristics of the individual lot.

According to each zone s specific attributes, it then enters into one of the th
namely, firm regulations, flexible regulations or strategic guidelines. Howeve
each type of regulation is still a matter of debate within the team, as it has
legislation, without sacrificing the innovative character of the entire system.

## 4. Conclusions and Open Questions

Conceptually, the model described above has the capability of providing partial
problems mentioned in the methodological section. Specifically, the first two
defining and mediating between the public and the private interest have two bas
first, there is the option of direct public investment in properties[6] belonging
second, there is the option of negotiation, which is supported by allowing fo
within each regulation type. Thus, if the plot structure allows it, an increase
traded off against the provision of targeted public amenities within the bound
zone.

The latter two problems are more technical in nature, and we do not have an exa
least for the moment, because of the following two reasons: First, because the
has not finished yet, and second, because not all the relevant background stud
Thus, for the time being, we still lack the morphological study, as well as th
mobility and economic development.

However, we do have a list of open questions, to which we shall return as our re

- First, there is the question of whether we can connect our model
metropolitan functions, incipient as it may be. A successful connecti
enhance the efficiency of metropolitan planning, which is currently
institutional frictions;

- Second, we are still uncertain whether the model is clear enough f
good use by the municipality (cf. Selle, 2005);

- And third, we have not fully grasped the impact this approach will
planning legislation. We do hope, however, that it will trigger a mu
in Romanian planning culture and planning practices.

[6] Nonetheless, until we do not have a clear situation of the exact properties available to the mu
and location, we cannot form a clear picture of the scale of such public investments. Furthermor
about a land acquisition programme run by the municipality to date.

# ADDRESSING FUZZY RESPONSIBILITIES WITH INFORMAL, FLEXIBLE INSTRUMENTS: LANDSCAPE PARKS AND REGIONAL PLANNING

Andrea I. Frank

Cardiff University, School of Planning and Geography, FrankA@Cardiff.ac.uk

Keywords: Landscape Park, Regional Planning, Land Management

## Abstract

*Green belts, smart growth or minimum residential densities have been some of the planning policies and instruments employed to reduce low-density, fragmented urbanisation that is generally deemed unsustainable. However, success of such tools in metropolitan, geopolitically fragmented areas involving many different municipalities is often hampered by a combination of lack of political will and diffuse* (or fuzzy) *responsibilities in multi-actor settings. Indeed many traditional planning instruments are inadequate at regional scales. This paper reviews the emerging concept of regional landscape parks in various European countries as a mostly informal instrument that nevertheless can shape settlement patterns at regional scale in multi-actor governance settings. While drawing on several examples* throughout Europe the Stuttgart Region s Landscape Park is used as m *study. The development of the landscape park is not a legally required activity within the planning system, yet there is evidence that the voluntary leadership of the regional planning association in developing the Regional Landscape Park complements traditional landscape management and nature preservation instruments. The policy language actively broadens the discourse around landscape conservation and urban development to supersede the traditional distinctions of urban and natural areas. This allows for the inclusion of economic, social, environmental and cultural arguments in decision making regarding landscape, land use and nature protection. The analysis suggests that by drawing flexibly on ideas and concepts from different disciplines a wide range of actors and agencies can proclaim benefit and in turn assume responsibility to help build a productive, healthy, and ecologically valuable urban regional landscape.*

## 1. Introduction

For decades, planners in many densely populated industrialised nations have been searching for appropriate ways to manage urban growth and sprawling settlement pattern. Green belts, smart growth and minimum residential densities have been some of the planning policies and instruments employed to reduce low-density, fragmented urbanisation that is generally deemed unsustainable in more than one way. For one, low-density development undermines the feasibility of public transport and is positively correlated with private car ownership and use. Second, land is an essential, multifunctional but increasingly limited and contested resource required not only for urban development but for the production of food, construction material and renewable energy generation (biofuels, wind- and solar farms). The conversion of forests, open spaces and agricultural land into more or less dense (sub)urban areas has well documented environmental detriments (e.g., Johnson, 2001; Thomas, 2011), which ultimately will degrade human health and quality of life (TEEB, 2010). It is thus important to protect open land for valuable ecosystems service provisions now and in future. Despite sound scientific evidence in respect to unwanted effects, land conversion from agricultural, forests and pasture to urban and infrastructure uses remains considerable. At the end of the first decade of the 21st century, in Germany, for example, an average of more than 100 ha of land were converted into urbanised use (housing, commercial/industrial or infrastructure) on a daily basis (Bundesregierung, 2008; Thomas 2011).

DRAFT

However, the problem is not merely a quantitative one. Simply keeping land from urban development is neither a sustainable nor desirable solution. Agricultural rural landscapes although associated culturally with healthy lifestyles and nature may not feature high levels of biodiversity and ecosystems services. In fact, in some instances urban environments display higher levels of ecological quality and biodiversity (e.g., Lachmund, 2013). As the importance of protecting and maintaining not only open space *per se* but also ecological qualities such as biodiversity and ecosystems functions gains increasing currency there is a need to reconceptualise the human-society nature relationship in respect to land use management on one hand, and on the other, operationalise and implement such an alternative relationship by making it visible in the built environment.

The need to find new images and imaginations for our cities is not a new one. There is no lack of astute observations as to the changing morphologies of urban settlements over the last few centuries from compact, clearly delineated cities into modern polycentric metropolitan agglomerations, edge cities (Garreau, 1991), or metaphorically scrambled eggs (Price, 1982). The thinning of urban structures has been likened to a Fordist dispersal of production patterns regionally, nationally and globally (Schumacher and Rogner, 2001). Traditional planning instruments and even modern adaptations have had little success to halt or slow these trends which could only be reversed through considerable increases in energy costs, and decreases in income (e.g., Sieverts, 2001). Instead, it may be more fruitful to develop alternative conceptions of settlement patterns. Landscape urbanism (e.g., Waldheim, 2006) and regional landscape parks (e.g., Otto, 2006) could be starting points for the development of a new type of urban vision.

This contribution looks at the emergence of an emerging planning and land use management instrument that is increasingly employed at strategic level in metropolitan regions in Europe: regional landscape parks or regional parks. These regional parks have become a means by which actors re-imagine city-regions and metropolitan agglomerations as urban landscapes where natural open spaces are holistically integrated, made accessible and often are protected throughout. While the definition of the landscape park concept is still developing and its detailed aims and goals vary from case to case there are some general characteristics. The role of land use categories is diminished with many plans abandoning artificial divisions between urban and non-urban areas with the aim to enhance the ecological and recreational quality of *all* open spaces small and large. In many cases, this entails changing users aesthetic conceptions and understanding of natural processes, ar rather than fighting it. The approach offers interesting opportunities and challenges for future plan development at regional scale that could provide win-win strategies for high quality regional development which will need to be shaped by a pattern of multifunctional spaces that intelligently organise biophysical constraints and characteristics.

Using different examples of landscape parks in Europe and Germany in particular, the paper will derive common characteristics, policies and goals by those who are promoting, establishing and implementing this concept. Using then, the case study of the Stuttgart Region Landscape Park, we will explore implementation and operationalization successes.

## 2. Changing Conceptions of Human-Nature Relationship

Fundamentally, and theoretically, we can distinguish two opposing conception of nature. On one hand there is a holistic view of nature which includes humans. Humans are here understood not as separate but an integral element of nature, part of the ecosystem and food chains. This implies respecting nature and a valuing nature as equal. On the other there is a rationalist, reductionist perspective which perceives nature and object and conceives humans as separate and superior to nature. Nature is a

DRAFT

economically measurable resource and might even be worthy of protection as part of its contribution to ecosystems services.

Practically, human s and society s relation to nature and the environment is complex and At a personal level our views of open, rural land and nature tends to depend on the geographic locatedness and economic circumstances we live in. Values and conceptions are culturally constructed. For example, the urbanite frequently perceives open/rural land as an area for recreation and leisure providing respite from the concrete hard spaces of the inner city. This land and its natural elements therefore are worthy of protection. Yet, for a farmer, the land is a productive resource and livelihood. As the value of open space or agriculture land tends to be lower in financial terms compared to sites available for development (Thomas, 2011) there is considerable economic pressure to convert open spaces into higher valued commercial land uses. Moreover, over time, the human-nature relationship conceptions have seen considerable mutations and change. These have been documented elsewhere in detail and full coverage would be beyond the scope of this paper. Instead the only a few select re-conceptualisations with relevance to land use management will be addressed briefly.

One notable shift is an increasing realisation that economies must preserve and sustain natural capital as with and overexploitation of (non-renewable as well as renewable) natural resources economic success itself will be jeopardised. This has led to the recent attempt to value and in fact monetize the nature in respect to ecosystems assets or the services nature provides to human life and wellbeing. As such, open spaces and nature are conceived as essential due to their ability to providing a multitude of life sustaining eco-system services. They clean the air and water, and provi material etc. (TEEB, 2011) and so forth.

Another transformation is the view that the divide between nature and culture is an unproductive one particularly in respect to landscape. Rather Tress, et al. (2001) argued that all landscapes are multifunctional and multidimensional encompassing both a natural and cultural component. Phillips (2003) suggested in fact that new paradigms for protected areas have been emerging since 1990s around participatory natural resource managements, a strong alignment with needs of rural inhabitants, and alliances with grass-roots. Such protected areas are often governed and managed by multiple partners and pursue both social, economic and leisure objectives in parallel to conservation, nature rehabilitation and protection.

## 3. Regional Landscape Park an emerging definition

The concept of a regional landscape park is a relatively new one; hence it is not surprising that a common understanding and definition is only slowly emerging. More precisely, landscape parks are understood differently in different national contexts. Some countries use the term landscape park regional landscape park to acknowledge a territorial designation of an area w of nature (fauna/flora) protection within the parks boundaries. The nature protection is typically at a significantly lower level than that applicable within for example a national park. In other countries the label landscape park is applied as a soft, informal instrument to facilitate land use planning and management goals. While in the first instance, the regional landscape park designation aims to demarcate and safeguard open spaces in planning terms in the second instance the main aim is to provide and enhance leisure opportunities that make the (natural) landscape accessible to the public while maintaining and improving ecological and aesthetic qualities. It is important that the landscape parks in many cases are including urbanised areas and cities. Landscape parks build on holistic design concepts that connect the demands of recreation, nature conservation and agriculture in cities and their surrounding rurban fringe and hinterland. The landscape park represents a vision and idea that

DRAFT

initiates the development of an identity and plans which capture these ideas visually. The process of plan development creates consensus, buy-in and value.

In this sense the landscape park is not a traditional mechanism of nature conservation or preservation but rather a manifestation or instrumentalising of the concept of landscape 2006) an idea developed in the late 20th century. According to Corner (2003) and Weller (2008) landscape urbanism is seeks to reclaim structural influence over urban development plans and projects. It aims to conceptualize and then directly engage the city and its natural, chaotic ecology and to interpret landscape systems so that they in turn can influence urban form in open ended design strategies (Weller, 2008, p. 256).

3.1 Landscape parks in Germany

In Germany a host of regional landscape parks have been established in the last 10-20 years. They vary in size and governance and their goals

Table 1. Comparison of German Landscape parks: Size, Goal and Governance

| | State/ size and date established | Goals/ Aims, features | Governance |
|---|---|---|---|
| Emscher Landschaftspark | North Rhine West-phalia, 320 sqkm, ca. 1990; intent to enlarge area by 116 sqkm | Culture, nature and leisure park; network of linked green open spaces, sustainable | KVR and municipalities together with IBA office (1989-1999); from 2004 under new Project Ruhr Gmbh lead. |
| Regionalpark Rhein Main | Hessia, 1988/89 | Form network of green areas (green wedges, srips), regional identity creation, leisure access | Planning association of agglomeration Rhein-Main (no finances, weak); require to obtain support from local municipalities |
| Regionalparks Brandenburg | Brandenburg Multiple chain of parks surrounding Berlin | Retain urban edge, leisure | |
| Landschaftspark Region Stuttgart | Baden-Württemberg, ca 3650 sqkm | Identity creation, leisure, attractive environment, economic and ecological | Regional planning Association |

## 4. The Stuttgart City-Region Landscape Park

The Stuttgart region is one of 12 areas designated for the purpose of regional planning in the state of Baden-Württemberg. The region has a polycentric urban character and is home to 2.7 mio inhabitants and 1.03 mio jobs. It consists of 179 municipalities which include the state capital of Stuttgart with 590 000 residents alongside many smaller cities and villages such as the village of Drackenstein with merely 450 residents. It covers a land area of 3654 skm which makes it equivalent the size of the largest national park in the UK (Cairngorms National Park). These 179 municipalities are grouped into 5 counties. The region has a relative high population density of 732 persons/skm. Just over 20% of the land area represents urbanised land and road infrastructure, 30.5% is forested and 46% is in use for

DRAFT

agriculture. The region is economically vital with a vibrant SME sector and a high level of manufacturing and production of 40% linked to the motor industry, electronics and engineering (Frank and Morgan, 2012).

The landscape park is in its boundaries congruent with the regions boundaries. The idea to create a region-wide landscape park emerged shortly after the regional planning authority was formally established in 1994. Its underlying concept was guided by the view that landscapes with typical regional character represent soft factors that support the development of identity and increase attractiveness of the core city and the hinterland (Otto, 2006, 18). The regional landscape park as a purposeful designed and created landscape is to move beyond the simplistic division of land areas into nature preserve on one hand and productively used land resource ( Nutzland ) implication of this traditional division is that land (and the associated resources of flora/fauna) in protected areas are economically relatively unproductive whereas outside such protected areas land can be economically exploited. In practice of course the distinction has never been quite so simple and dichotomous. The emergence of eco-systems services has started to change the value attributed to seemingly un-used landscape. Another way to change the perception of nature is by increasing the appreciation of landscape design interventions and through re-designation as a park (Schmelzer and Bezzenberger, 1994; Otto, 2006).

Regional landscape parks thus are functional landscapes which mediate between different use and stakeholder conflicts while also safeguard open space for recreational use and habitat protection. The regional park development represents an informal planning instrument which integrates economic uses in respect to agriculture and forestry with sustainability. A new generation of Parks Paradigm change

## 5. Discussion

A key characteristic of the Stuttgart region as well as other land scape parks in Germany is the deliberate ignorance of traditional distinctions between urban, suburban and rural zones or existing administrative boundaries. Multiple actor systems not entirely informal act together to guarantee a minimum level of longevity and continuity in terms of communication and support structure (New CityLandscapes, 2001).

## 6. Conclusions

New concepts and methods for planning the urban realm are necessary. It is suggested that public open space (grey, green and blue) are an essential element in design urban landscapes. The integration of urban development and open space which renders the historical strict division between urbanised and rural obsolete is an emerging new concept that could overcome the antagonistic relationship between nature conservation and economic development that is increasingly criticised by science. The landscape park is one such new concept that combines ecological, social and economic benefits rather than asking for trade-offs in the traditional sense.

Opportunities to use the park metaphor to guide the development and restructuring of city-regions into new types of city landscapes with distinct identities as well as enhanced quality of life with open spaces that offer recreational opportunities as well as ecosystems services. Enhancing potentials of open spaces in cities

The dichotomous perspective of urban versus rural, open space is not helpful as it is bound to create more rather than less conflict in future. Rather than strict preservation, creation and wise management

DRAFT

of natural resources may be a more useful way forward that allows the reconciliation of human needs and environmental values and ecological processes.

## 7. Acknowledgements

The author is grateful to the interviewees from municipal planning officers who made time to discuss the value of the landscape park.

Abstract
TRANS-ADAPT project focuses on bottom-up initiatives to flood risk management different from the mainstream flood risk management measures. Our hypothesis i pursued by local stakeholders, with the aim to address local problems or to se multi-functional use of land.TRANS-ADAPT explores what and who is behind these i out the motives and key aspects of multi-functional outcomes that are relevant f The final objectives are to explore the possibilities for up-scaling and replic countries and outlining the institutional change required to facilitate local i the barriers and limitations of the current flood governance, the project aims framework. This framework will adapt the classical governance and design criteri flood risk management, providing operational indicators. The aim of the propo TRANS-ADAPT research questions, literature review and the conceptual framework can give insights to the participation issues suggested by Track04. We will pre from one French case study during the communication.

## 1. Introduction

### 1.1 Increased flood risks: how to improve policies?

In a context of climate change, recent extreme hydrological events experience focused the attention of policymakers on flood hazards. It leads to an increasi beyond vulnerability and flood risk (Fuchs et al. 2013), such as climate change exposed societies (Keiler and Fuchs 2010; Birkmann et al. 2013). As they co economic resources, transportation, interdepent networks, social and informati and urban areas are especially vulnerable.

In parallel, the context of changing role of the state in responsibility responsibilities for risk management and precaution (Adger et al. 2013; Mees et the question of other emerging flood risk strategies. Especially, the impleme

observed mostly from the Second World War onwards, even if in some situations need a l
back in the late 1900s to understand spatial and social transformations.

## 2. Research background

### 2.1. Adaptation to Climate Change

Climate change fostered by human activities is triggering more and more extre
events, including violent floods. Europe does not escape them, although its
temperate. Europe is also facing 'global weirding'. Heavy rainfall, violent stor
catchment scale make rivers step out of their beds and submerse areas vulne
European cities, towns and villages are part of these vulnerable areas, because
coasts. The risk of flooding is high in these densely populated areas. Artifici
drainage networks and embankments of river beds are making living areas more
occurrence of floods.

In this context, societies are engaging at different levels into adaptation p
(2005) define adaptation to climate change as an adjustment in ecological,
systems in response to observed or expected changes in climatic stimuli and thei
in order to alleviate adverse impacts of change or take advantage of new oppor
adaptation is a continuous stream of activities, actions, decisions and attitude

about all aspects of life, and that reflects existing social norms and proces
definitions, adaptation challenges the prevention of risks in the context of ext
in adjustments of responses, and integration of prevention against extrem
development. Societies face the challenge to continue development and at the
acceptable infrastructure and make adaptation choices based on supposed-to-happe

Whereas incremental adaptation is the fact of going further in what is alread
as Kates et al. define it (2012), transformational adaptation is bringing ne
changing context. Kates et al. (2012) define Incremental adaptations to ch
extensions of actions and behaviours that already reduce the losses or enhance t
variations in climate and extreme events. In other words, they state it means
what is already being done to deal with natural variation in climate and with ex
the challenges of climate change, urban societies are required to transform them
and their organisation. More than an incremental adaptation, societal transform
essential component of the strategies (Kates and al. 2012 ; Smith and al. 2011
Navarrete, 2011). Those transformations require to pay attention to the cons
cultures and identities, of people and places (Marshall and al. 2012). If e
shocking events, a brutal transformation can also have a devastating impact on
most of the environmental policies are top-down decision processes, especially
natural risks.

### 2.2. Flood risk management: traditional top-down policy

TRANS-ADAPT defines risk as the probability of a hazard to occur combined wit
to damage the society. It deals with two types of hydrological hazards: river fl
The combination of hazard, vulnerability and exposure seems relevant in seeing
approach. TRANS-ADAPT will analyse both hazard and flood risk, in order to
reduction. The definition of the characteristics of the hazard is useful to ev
feasibility, but also to understand the expert-based rhetoric in flood manage
experiences of flood in the different places. The aim of TRANS-ADAPT is to s
capacity to react, to face, to manage with flood risks in the context of very ce
flood management.

In flood management, after WWII and until the 1970s, 'hard engineering' solution
were at the top of the pyramid. They were essentially suggested to resist to fl
farming profitability, industrial interest and growing urban assets. There was l
social representation and local solutions, especially non-structural approaches.
« that if mitigative strategies are to be successfully implemented, then the
process must incorporate public participation at the local decision-making l
management can be no more a top-down process: actors are so numerous, diverse an
powerful than the State. The technical decision coming from the State, from a t
viewpoint, is challenged, not only in terms of protest, of political claims for
also because local stakeholders can do better, with less resources or more quic
State decision-making process. In a context of financial crisis, flood managem
purpose of the current appraisal, prioritisation in decision-making processes.

In this context, how do bottom-up initiatives lead (or not) to multi-functional
rural contexts, in the field of flood risk management?

### 2.3. Bottom-up initiatives in flood risk management: a step towards social tra

The idea of bottom-up initiatives is an organisational method to take decision a from and with the local users, not only with the elite solution makers. In management, it is an alternative to the traditional State expert-based decisio way for more innovative measures. Johnson and Priest (2008) analysed the shift a responsibility between the State and its citizens, and then, a new balance betwe structural risk management options, towards more tailor-made choices, depe social, economic or cultural characteristics of the nature of the place and the r

In its empirical research, TRANS-ADAPT wants to understand how bottom-up init innovative spatial flood risk measures and what they teach us about flood manag cases where a significant amount of responsibility is given to local authoriti suggest to define bottom-up initiatives as the decision-making process and poli which local stakeholders in a local area address problems of local interest, as share flood management between the State and the local stakeholders, and, se creative and innovative solutions to face climate changes in terms of extreme ev

TRANS-ADAPT will pay a special attention to the role of community in the emergen initiatives. Besides the others stakeholders involved in the flood policy, we d that allow to speak about community :i) a system of interrelations around a co improve their own representation of spatial quality of life ; iii) which i spatialisation in the community. Using several sources of definitions for comm Hoggett 1997; Jentoft, 2000; Orr, 2007) TRANS-ADAPT will study groups of people on land that bear specific features geographically defined, with a definite f groups include those residing in close proximity to rivers, flooded districts re political authorities, fisheries interest groups, environmental associations, et the objective of protecting their environment, their quality of life and their f for creation of recreational areas or in finding other qualitative ways to reduc

### 2.4. Integrating multiple uses of land in flood risk management

Multifunctional land use can be defined as the combination of different socio- the same area (Vreeker et al., 2004). The main goal of multifunctional land save scarce space by intensifying its use. Vreeker et al. (2004) argue that th of multifunctional land use (as a planning concept) is its emphasis on the return to supposed to create synergy effects by combining a diversity of land use fu location .

With the objective of giving rivers more space (EU Floods Directive 2007), flood consider the maintenance and/or restoration of floodplains where possible. The d could be: multifunctional use of land, in the scope of flood risk prevention, several functions or activities through space (on different plots of the same l on a same location, associating at least one use of land that serves the inter which ever the type of flood risk management it may be.

## 3. Hypotheses

### 3.1. Objectives of the research

TRANS-ADAPT aims to contribute to the analysis and evaluation of the role of lo are complementing conventional flood policies in the field of Climate Chang ultimately, to provide guidance for the design of bottom-up initiatives for floo TRANS-ADAPT focuses on community-based bottom-up initiatives for flood risk ma are clearly different or niche relative to mainstream solutions of flood risk ma

interest given the involvement of diverse actors is multi-functional use of th
functions (park, leisure, festival, shops, sport, gardening, farming, fishing...

These initiatives are pursued by local stakeholders, with the aim of protecting
preserving a certain quality of life and space. When those three components a

2007).

### 3.2. Goals of the evaluation framework

One of the aims of TRANS-ADAPT is to identify wider lessons for other European
working on the implementation of climate change adaptation strategies arising fr
& Pidgeon 2011; Hanger et al. 2013). To be able to learn from the existing pr
account explicitly the effect of scale, but at the same time to be able to prov
and actions, the evaluation framework offers many opportunities.

The evaluation framework is composed of 8 criteria that will be used to evalu
initiatives and multi-use alleviations, processes and outcomes. We have c
multidisciplinary set of criteria commonly applied in policy analysis. The fr
evaluation criteria that assess the success of the community-based multi-functio
adaptation strategies, in terms of: 1) economic efficiency; 2) effectivene
achievement; 3) legitimacy including legality; 4) accountability; 5) social just
vulnerability reduction, in terms of physical, social, institutional and econ
finally 8) technical feasibility. Criteria have been divided into two parts. Fi
criteria (efficiency; effectiveness; legitimacy; accountability; social justice
will especially be used to evaluate the process and the outcome of the bottom-up
multi-use flood management. Then, there are two design-oriented criteria
feasibility) that will be used in order to replicate initiatives in other contex
to mainstream policies.

## 4. Methods: the development of an evaluation framework for legiti accountability

This paper focuses on two governance criteria dealing with participation in gove
legitimacy and accountability. Each criterion has been studied in a conceptual w
review from geography, social, governance and risk management scholars. Then
grounded into TRANS-ADAPT research, to adapt their understanding to our resear
order to make the criteria operational in the empirical research, indicators hav

of the criteria. Moreover, a scoring is applied to each indicator, to give a example if the participation evaluated in the process can be seen as low, me scorings help the comparison between countries and case studies.

### 4.1 Evaluating legitimacy

Legitimacy has to do with the acceptance of authority by the people. It is a recognised (Dogan, 1992).Within the evaluation part of Trans-Adapt, legitimacy criteria to normatively judge and compare the performance of the TRANS-ADAPT political systems. From a political science perspective, legitimacy is essent process of the creation of acceptance of authority or justification of politica Glasbergen, 2011; Peter, 2010; Dingwerth, 2007). So it means that political sc legitimacy as a benchmark of acceptability or justification of authority or 2010). According to Bernstein (2005, 142) political legitimacy is the acceptanc shared rule by a community . In line with the above scholars it is suggested definition of legitimacy for Trans-Adapt: legitimacy is the acceptance of author political power (Bernstein, 2005; Dingwerth, 2007; Biermann and Gupta, 2011).

The study of legitimacy is tricky: how to measure legitimacy (Dogan, 1992, W One way to deal with this issue is by breaking the concept down into sub-ty legitimacy. For instance, Beetham (1991) has differentiated between i) views o system attains legitimacy in a way that is in accordance with people s views a customs), ii) views of justification (a political system is legitimate when it i shared principles, ideas and values), and iii) acts of consent (a political sy people consent with its authority through positive actions that express a cit acceptance of the authority). A very common way to subdivide legitimacy by poli governance scholars is to differentiate between input, throughput and outpu Papadopoulos, 2011; Scharpf, 1997), a differentiation that will be used for Tra be further elaborated upon in the next paragraphs. It is recommended for Tra combines conditions that refer to procedural features, i.e. to the decision- conditions about the quality of the outcomes of the decision-making process. I legitimacy refer to the first (procedural features), while output legitimacy ref the outcomes).

Input legitimacy is about what goes into the decision-making process (the input legitimacy is about the quality of representation. The idea is that input leg interests are represented (inclusive representation), and if those interests are representation). All voices should be heard. The more equal and inclusive the higher the input legitimacy is. To sum up it is about inclusive interest rep representation of all interests at stake and through the equality of represen 2006; Renn, 2006; Dingwerth, 2007; Bekkers and Edwards, 2007; Paavola, 2008 democracies this inclusive and equal representation is often reflected in repre which elected officials represent the voice of the people, and in which politica held accountable by the means of elections. This is a form of indirect represe modern democracies are sometimes also steered in interactive modes of gove networks) where the different interests are directly represented.

Throughput legitimacy is about what goes through the decision-making process. It of the procedural features. It is about the quality of participation, and relate and procedures to reach decisions, and the fairness of the process (Bekkers Dingwerth, 2007). This is in line with what Paavola (2008) refers to as procedu

adaptation. The idea is that throughput legitimacy is created when the different
the decision-making and can also influence the decision-making.
In interactive governance modes such as policy networks and public-private part
legitimacy is gained through meaningful participation (e.g. Smith, 2003; Pa
2006;Paavola, 2008) and due deliberation (e.g. Dryzek, 2000; Adger et al.,
Elander, 2010). Meaningful participation is about being able to truly influence
all voices should count. This is in contrast to the phenomenon that public deci
use participatory processes as window dressing to legitimize predetermined ou
2007), a phenomenon famously coined by Arnstein (1969, p. 218) as tokenism . D
about collective decision making being done on the basis of integrating mea
deliberation and debate (Bekkers& Edwards, 2007, p. 44; Dryzek, 2000; Smith, 20
that all stakeholders critically engage in unconstrained dialogue so that they
increase their knowledge base, widen their own perceptions, reflect and loo
preferences (Renn, 2006). Thus an enlarged mentality can be created based on m
(Smith, 2003, p.63). The process of deliberation should be conducive to making
choices, even if consensus cannot be reached. Legitimacy thus rests on all stake
and accepting the rationale behind the outcomes, although disagreement may perta

Output legitimacy is about what comes out of the decision-making process and ref
the outcomes of the decision-making. In case of output legitimacy, acceptance o
by the extent to which that authority is effective in achieving goals (Scharpf,
19) states that a democracy would be an empty ritual if the democratic proce
produce effective outcomes, by achieving the goals that citizens collective
Tatenhove (2011) argues that a system is legitimate if it has the capacity to
Both interpretations of Scharpf and Van Tatenhove are very much related to effe
to Biermann and Gupta (2011, 1858), it is about the perceived effectiveness
rather than effectiveness as in the actual solving of the issue. Perceived e
acceptance of the outcomes of the governance process (Bekkers and Edwards, 2007)
It is advised to use the interpretation of perceived effectiveness for the evalu
for TRANS-ADAPT, since effectiveness is already included as one of the other
assessing the performance of the community initiatives.

### 4.2 Accountability as the essence of answerability

In its most core meaning accountability refers to actors, organisations, leader
account to some authority for their actions according to some set standard (Mas
2000). Generally speaking accountability is about stakeholders and society being
the actions of policy-makers. It has become a term for all kinds of mechanisms t
institutions responsive to their publics.

All in all, most definitions of accountability concern the obligation of indiv
provide information about, and/or justification for, their action to other act
imposition of sanctions for failure to comply and/or to engage in appropriate ac
2004, p. 372). Mark Bovens has particularly studied the concept of accountabili
be used in (comparative) empirical studies. Therefore his following definition (
adopted:

> Accountability is a relationship between an actor and a forum, in which
> actor has an obligation to explain and justify his or her conduct, the for
> pose questions and pass judgement, and the actor may face consequences .

By adopting this definition, various questions are raised relating to who is th
forum, what is the obligation, and how the obligation can be enforced in such
may indeed face consequences. Those questions may be answered differently depe
instance, the scale and context in which accountability is evaluated (local, na

global governance, environmental governance, corporate governance, network gov
This can also change depending on the entity to which it is applied (officials,
corporations, networks, etc.) (e.g. Mason, 2008; Bovens, 2007; Mulgan, 2000;
Therefore, any empirical study on accountability should start with answerinc
questions (Bovens, 2007; Papadopoulos, 2007; Brinkerhoff, 2004; Romzek, 2000):

Who is held accountable? Who is/are the accountable actor(s)?

To whom, i.e. who holds to account? Who is/are the overseeing actor(s)?

For what, i.e. about what is the account to be rendered? This can be subst
results) and this can be procedural such as the decision-making process

How can the accountable actor be made accountable for their action
(procedures, mechanisms to correct deviant behavior through sanctions .)

## 5. Results

### 5.1 Evaluating legitimacy of bottom-up initiatives to flood risk management

Facing several definitions from social scientific disciplines, TRANS-ADAPT has p
normative political/policy science perspective, since we are dealing with the a
design of bottom-up community initiatives as a form of a political system.

We focus here on interactive governance modes such as networks, given its sig
(global) governance, and given the fact that the Trans-Adapt case studies can a
examples of network arrangements in which the local public authorities collab
private stakeholders for the planning and implementation of flood risk manageme
the legitimacy of network arrangements the procedural characteristics of the
processes are very important (e.g. Słrensen and Torfing, 2005). Acceptance
promoted through the direct participation of stakeholders (Paavola, 2008; Adger
through an open deliberative process which leaves room for reasoned debate (e.g
B ckstrand et al., 2010). Furthermore, participation and deliberation may increa
and facilitate implementation (e.g. Lemos and Agrawal, 2006; Juhola and Westerho

For the operationalisation of the legitimacy criterion into indicators it is use
the key challenges related to legitimacy in the context of interactive governa
networks. Key challenges to the legitimacy of networks include (e.g. Papadopoul
and Agrawal, 2006; Few et al., 2007):

Skewed interest representation

Limited quality of participation

Limited quality of deliberation.

Legitimacy for whom?

Here the questions arise with respect to:

the legitimacy of whom or what are we evaluating?, and

in the eyes of whom?

It is proposed here to use the community initiative including the public-privat
and stakeholders in the different case studies as the unit of analysis for t
legitimacy criterion in terms of the of whom/what question. This network of
regarded as legitimate, i.e. have authority, in the eyes of the participants o
legitimacy) as well as in the eyes of outsiders/the community in general (exter
to whom question).

The indicators that are proposed in the table below are based on the typology o
and output legitimacy.

Indicator 1: Inclusive and equal interest representation (input legitimacy)
This indicator deals with the question of who participates. Skewed interest repr
challenge to be addressed here. Networks are not sufficiently pluralist (
representative of society at large (Papadopoulos, 2007). The representation refl
relations, such that certain elites obtain a dominant voice through their p
governance network, leading to procedural and distributive inequities (e.g.
Bogason and Musso, 2006; Lemos and Agrawal, 2006). Moreover, short-term economi
(housing, tourism) may overshadow long-term non-economic interests (flood
hypothesis is that the more all interests, including weaker long-term inte
represented, the higher the legitimacy of the network.

Indicator 2: Quality of participation (throughput legitimacy)
This indicator deals with the question of how stakeholders participate. Quality
determined by the possibility to influence the decision-making by the stakeholde
regarding participation lies in the true nature of stakeholders influence on de
decision-makers might use participatory processes as window dressing to legitimi
outcomes (Few et al., 2007). The hypothesis is that the more the participants i
real influence on the decision-making process, the higher the legitimacy of the

Indicator 3: Quality of deliberation (throughput legitimacy)
This indicator also deals with the participation process. Deliberation is ab
decision-making is realised on the basis of integrating mechanisms such as delib
rather than through traditional democratic representation (Bekkers& Edwards, 200
Smith, 2003). All stakeholders need to critically engage in unconstrained dialog
share arguments, increase their knowledge base, widen their own perceptions,
beyond personal preferences (Renn, 2006). Legitimacy rests on all stakeholders u
accepting the rationale behind the outcomes, although disagreement may pertain
key issue lies in the stakeholders ability to understand complex informatic
rationales behind decision-making, in particular with lay people such as residen
and Semenza, 2008). The hypothesis is that the higher the quality of deliberat
legitimacy of the network.

Indicator 4: Acceptance of outcomes (output legitimacy)
This indicator related to output legitimacy is very straightforward and concern
the outcomes of the Trans-Adapt case study. It might still be necessary to
outcome(s) are referred to in the case studies, and whether this outcome can be
each case study, for instance the flood risk measure that is implemented. We c
leave it open, and ask the interviewees which outcome for them is most important
is that the more the outcomes of the network are accepted by the participa
community in general, the higher the legitimacy of the network.

The indicators used to evaluate legitimacy are gathered in this table (Table 1)
levels of scoring.

| | Score 1 : low | Score 2 : medium | Score 3 : high |
|---|---|---|---|
| Quality of interest representati | Some interests are under-represented; particular the weak | All interests are r but representation is direct representation | All interests are repre there is an equal representatio those interests |

| | | | |
|---|---|---|---|
| (process) | of flood protection. | interests over others | |
| Quality of participatio (process) | No real influenc decision-making in policy process b participants of the | Limited access to/inf the policy process, e in terms of the stag policy process, or in certain specific part certain issues | High access to and influence o major stages of the policy proc by all participants |
| Quality of deliberatio (process) | There is hardly deliberation, and i symbolic than according to partic the network | There is deliberati discussions are not sc constructive in the participants | There is ample deliberation; op exchange of argumentation and discussion is encouraged |
| Quality of t outcome as measured by t acceptance o that outcome (outcome) | The majority of par in the network do accept the key outco chosen flood risk me | The outcome is accepte participants of the (internal legitimacy) | The outcome is accepted by the participants and by the communit in general (external legitimacy) |

Table 1 : Legitimacy Indicators & Scoring for TRANS-ADAPT project (adapted from Mees et al., 2014)

5.2 Evaluating accountability of bottom-up initiatives to flood risk manageme

The TRANS-ADAPT project analyses community-based initiatives, in which the l authorities (municipalities) collaborate with local private stakeholders. Those classified as network arrangements. For the operationalisation of the accountab indicators to evaluate the accountability of the TRANS-ADAPT cases it will there take account of the challenges related to accountability in the context of netwo

Key risks for the accountability of public-private networks include (Papadopoulo
1. Opaque/informal decision-making procedures
2. Diluted, shared responsibilities among a large number of actors
3. Networks often operate in isolation from democratic institutions
4. Networks are not sufficiently pluralist (re interests) and representative

Indicator 1: Clear allocation of responsibilities

This indicator addresses the who question, which can be linked to the challe shared responsibilities. It is difficult to hold the network accountable, if re and diluted. Who should be held accountable for what? If the actors in the netw to basic criteria of accountability and transparency, the network itself cannot 2004, p. 200). In order to hold the individual participants in the network acc know who is responsible for which task in the network. The hypothesis is tha responsibilities are allocated among the participants of the network, the higher the a the network.

Indicator 2: Influence of elected representatives

This indicator addresses the to whom question, which can be linked to the cha from democratic institutions. Besides peer accountability (mutual accountabili within the network) which is difficult to monitor and control, it could be impo elected representatives of the community (members of council, Aldermen), for ex decisions regarding the project (so this is political accountability). It is

the interests of the actors in the network from the interests of the wider comm
by elected officials. It may well be that an important interest of the wider
represented in the actor network, and therefore political accountability will h
This political accountability enables a functional separation of power bet
formulation in the network, and the constituent power dedicated to institutions
and accountable to citizens (Papadopoulos, 2007, 485). This is a phenomenon, a
the democratic anchorage of networks (Sørensen and Torfing, 2005).

This echoes back to the 'quality of participation' in the throughput legitimacy
that the participants of the network have real influence in the decision-makin
present indicator, we look at the contrary. Both situations exist: direct re
relevant stakeholders AND decisions being accountable to the elected representa
that they should reflect the interests of society as a whole. In other words: th
the wider community that are not covered in the network. Therefore the networ
represent society as a whole. So they are complementary even if it sounds like
hypothesis is the more elected representatives can influence the major deci
accountability of the network.

Indicator 3: Transparency
This indicator addresses the for what question, and is linked to the challenge
making procedures. Networks cannot be held accountable if the procedures, vo
decision-making processes are not open to scrutiny (Benner et al., 2004). The hy
more open and transparent the decision-making processes are, the higher the acc
network.

Indicator 4: Sanctioning mechanisms
This indicator addresses the how question. It is not directly linked to any pa
is very relevant in light of the fact that the principal-agent relation in net
and therefore there is no principal to punish the agent to correct the agent
network formulated its own sanctioning mechanisms, are they dependent on externa
naming and shaming the main or even only whistle blowing mechanism? The hypothes
more sanctioning mechanisms are in place within the network, the higher the acc
network.

The 4 indicators are gathered in a table in order to evaluate the TRANS-ADAPT c
developed with 3 levels of scoring.

| | Score 1 : low | Score 2 : medium | Score 3 : high |
|---|---|---|---|
| Allocation of responsibilit | Responsibilities a clearly defined f participant and f different task | Responsibilities are defined, and clear ar participants of the ne | Responsibilities are defined per participant/task, are completely transparent to other participants of the netw and outside the network |
| Influence of elected representativ | There is no influ elected representa the major decision network | Council members/Alde were involved in decisions, but there formal ratification ( power | Council members and/or Aldermen have been able to influence the major decisions a a there was a formal ratificatio the major decisions by those council members/Aldermen |

| | | | |
|---|---|---|---|
| Transparency | There is no trans regarding the de making rules, proc etc. of the networ | There is transparency w network, but not for o | There is full transparency of decision-making process, also f outsiders. The procedures hav been written down on paper and openly pubished |
| Sanctioning mechanisms | There are no sp sanctioning mecha in place | There is a sanct mechanism in place, b widely used or not effective | One or more sanctioning mechanisms are clearly discusse and applied within the network |

Table 2 : Accountability Indicators & Scoring for TRANS-ADAPT project

## 6. Analysis and discussions

The challenge of the evaluation framework on how bottom-up and community-led in management is to build relationships between the two participation criter Accountability) and the other Governance criteria: Efficiency, Effectiveness, Sc Capacity.

Concerning efficiency, we first need to ask ourselves the question of the eff What should be efficient? TRANS-ADAPT makes a basic distinction between bottom-u multi-use flood strategy as a process (stressing the decision-making community-l an outcome. First, the criterion of efficiency seems to better fit the outco process dimension of TRANS-ADAPT. The outcome dimension corresponds to the outp of the input output ratio, the effect dimension of the cost effect ratio, and th cost benefit ratio. TRANS-ADAPT is about whether the chosen multi-use flood allev the most efficient.

Then, concerning the criteria of effectiveness, we evaluate it in terms of an inn process, or we can evaluate in terms of the outcome(s) of that process, i.e alleviations. The most logical choice seems to be to evaluate effectiveness in t the TRANS-ADAPT case studies. The evaluation will be carried on the outcomes of the on the process itself. Even the process effectiveness is based on an outcome, other policies or normative ideals. So, ideally, we should be able to provide argumentation that the community initiative has created such outcomes, and that the outcomes alleviation) were not the result of something else.

Third, the notion of who wins and who loses and how those decisions are mad contention within and between societies.The issue of social justice with respect been extensively researched. Recognising these increasing risks, a number of sch to understand the justice issues that societies face through the lens of fl management. The lack of fairness in flood risk management decision-making i vulnerability and inequality and called for nationally consistent practices structural strategies. Such an approach, coupled with greater autonomy over decisions at a local level, may alleviate the vulnerability and injustice that t In contrast, decision-making is best made at a national level with respect to f sustainability and the wider concerns of society are to be taken into considerat Priest (2008) call for a greater understanding in determining the feasibil partnerships with respect to flood risk management focusing on a combination and top-down approaches. Furthermore, they stipulate the need for more radical engage local stakeholders and their resources in the decision-making process analysis continues to act as the primary decision mechanism for flood protection

Finally, the question raises whether those most densely populated cities will be challenges of developing social capacities at individual, community and organi may prove particularly problematic for enhancing social capacity at a local recognised that structural measures alone will be insufficient to deal with economic and human losses from extreme flooding in the future. As non-structur measures gain prominence, increased public engagement and participation, and a process between stakeholders is needed to manage the risks posed by flooc management will require further co-operation between multiple actors from acros including, but not limited to, civic society and public and private sectors if losses from flooding are to be curtailed or reversed. Furthermore, adopting an i alone to social capacity building does not necessarily produce desired outcomes is argued, is too paternalistic and does not recognise the mutual learnings that builders and those with a capacity deficit. A move towards a system where i participatory capacity building measures are recognised as inter-dependent is flood risk management is to be addressed effectively. Social capacity is an ite process and needs to take account of multi-actor interactions, unexpected outc previous actions and feedback loops.

To address the challenge of linking those criteria, we will test the framework located in Le Mans, on the Sarthe river. The  Ile aux planches  is a leisure p flood control system in the city. Le Mans Agglomeration accounts about 200 000 the 1990s, the city of Le Mans has been strongly hit by floods. The  Ile aux Pla close to the city centre. It was created in 2008 on a brownfield site. It playgrounds for children, green areas dedicated to festivals and cultural events left for biodiversity.  The flood issue has been tackled within this project wit has been designed so that it can be flooded (10-year and 50-year floods) with (specific plantations, public benches secured to the ground). From the start, th by two local NGOs. After the city had been hit by major floods, some of the i supporting association. Another association of the district residents was create sustainable use of the brownfield site. At that time, it belonged to a national France, EDF), willing to sell it to building promoters.
The local NGOs fought against this project and proposed to Le Mans Agglomeration for the site as a leisure park adapted to floods and contributing to risk r Agglomeration took the responsibility for implementing it. After implementat association kept organising cultural and social events on the site. Today, it i and regularly used for public events. Its function as a spillway and retention a be successful.

## 7. Conclusions

TRANS-ADAPT will use this evaluation framework, including participation evaluat success of the initiatives and of the outcomes. The participation concern is hi case studies and the evaluation will give insights about the level of succes processes. TRANS-ADAPT also explores and analyses what and who is behind the in economic and socio-ecological pressures) and will tease out the motives often aspects of multi-functional initiatives that are relevant for their success an will be employed to present best practices and develop recommendations/guide application of such approaches in other institutional and organisational set challenges of climate change for society. Further, we will research the ext

functional approaches to risk reduction are promising in solving local problems
lessons from such initiatives.

# EVALUATING THE STRATEGIC CAPACITY OF COLLABORATIVE SPATIAL PLANNING INITIATIVES BY THE PERFORMANCE OF ITS PROCESS, OUTPUT AND OUTCOMES: THE CASE OF THE SOUTHERN RANDSTAD HOLLAND

PAPER TO BE PRESENTED AT AESOP CONGRESS 2015, 13-16 JULY, PRAGUE

Version: May 2015

**Abstract**
*Spatial planning practices are constantly evolving to be more effective in a dynamic context. In the face of the latest developments, the practice of collaborative spatial planning through the formation of regional collaborations has emerged as the contemporary solution. The practice of working with a multitude of public actors that cooperate to formulate spatial strategies for issues that transcend their own planning capacity is relatively new and the ideal structure, organization and scope are yet unclear. The ability to of a region to successfully develop joint strategies is referred to as a region's strategic capacity.*

*As a means for comprehensive assessment of the effectiveness of such collaboration projects an evaluation framework is proposed to assess a region's strategic capacity. To this end, the paper further elaborates the concept of strategic capacity. And furthermore it develops an evaluation framework specifically designed for the evaluation of regional collaborations and the strategic capacity generated. It is shown that this framework has a high potential for meaningful evaluation of regional planning collaboration projects.*

Keywords: planning evaluation, collaborative spatial planning, strategic capacity

## 1 Introduction

In the face of geographic, social and economic dynamics, Dutch spatial planning has gone through significant change from a comprehensive planning approach to a more open-ended and decentralised collaborative spatial planning style in which there is a key role for networks of like-minded governments. The collaborative spatial planning effort is one of common ambitions, goals and resources across different tiers of government, integrating policy fields and territories (Healey, 2006; Albrechts, 2010; Mastop & Faludi, 1997; Sehested, 2009). Such regional collaborations seek to align their efforts to effectively steer regional development to their joint benefit.

In the last few years, regional collaborations between different tiers of government and even market parties have emerged as the contemporary spatial planning practice (Salet & Woltjer, 2009). The changes in spatial planning practice have made old roles of government obsolete and responsibilities have shifted. Numerous regional collaborations in one form or another have popped up across the

Netherlands. Since the collaborative practice is relatively new, the numerous regional collaborations individually attempt to find the right organization, size and scope. However, best practices have not yet been identified (Hajer, 2009), and may in fact not exist due to specific contextual circumstances requiring situational solutions and approaches. Yet, whatever the exact outcome, evaluation of the effectiveness of regional collaborations may be helpful in developing a frame of reference for developing effective institutional arrangements within regional collaborations. However, an appropriate and complete evaluation framework is not yet available. This paper offers a first attempt to develop a framework for the evaluation of regional collaborations and as such forms a first step towards the development of such a frame of reference for best practices.

The paper starts with brief overview of trends in Dutch spatial planning practice. This is followed by the introduction of the methodology used to develop the evaluation framework to assess the effectiveness of a regional collaboration. The key theoretical concept along which this evaluation framework is developed is strategic capacity, a concept originally introduced by Haran (2010). This capacity, which captures a range of single indicators and regional network characteristics, refers to a region's ability to come to joint strategies and decision making. After elaborating the developed framework, the application of the framework on the regional collaboration between the national government and the so-called Zuidvleugel partners in the southern Randstad Holland is discussed. More specifically one of the concrete outputs of this collaboration is discussed: the Adaptive Agenda Southern Randstad (AASR). The paper concludes with a short evaluation of the use of the framework and recommendations for its further development.

## 2 Spatial planning in the Netherlands: overcoming the institutional void

Before the 90's, the spatial planning decisions at the national and regional level mostly involved restrictive regulation (Salet & Woltjer, 2009). According to Ark (2005), the Dutch planning system could, until the second half of the 00's, be characterized by a strict delineation between government departments, a strong territorial orientation, formal relations between different tiers of government and plans that focus on a single aspect of space. However, over time, economic and social dynamics put pressure on these protective regulations and strict delineation gradually lost ground (Raad van State, 2012).

In society, the citizen-actor is on the rise. Active involvement at select moments in the design process are used to increase citizen approval rates and legitimization of projects and investments (Hajer, 2003; Witteveen+Bos, 2012). Regions are becoming more important in current spatial policy making. Many policy issues are simply better solved at a regional level with optimal use of resources (Hajer & Zonneveld, 2000). The globalization and the EU lead to more permeable borders and due to the development of networks, territories are becoming more interconnected (Raad van State, 2012; Balz & Zonneveld, 2012). The economic crisis has further increased the urgency of collaboration between parties due to lacking financial resources (Boelens, 2010; Herrschel & Tallberg, 2011).

The changing context brings with it new demands in terms of governability and the mobilisation of stakeholders. One interpretation of governance is the self-regulation of actors in a network to *"coordinate their interdependencies in order to realise public policies and deliver public services"* (Klijn & Koppenjan, 2012, pp. 594). With regard to governance, several trends affecting spatial planning are identified by Anders Lidström (2007; 2011). These trends show that (national) governments are gradually changing their role from regulator to facilitator, thereby strengthening lower levels of government and decentralizing parts of their responsibilities. Reflecting the changing society a new Spatial Planning Act (2008) has done away with the formal hierarchy between governmental layers, introduces decentralisation and provincial autonomy, and by handing land use plan competencies to all governmental levels opened the way for more entrepreneurial and bottom up planning approaches (Buitelaar et al., 2011; Roodbol-Mekkes & Van der Valk, 2012).

The current development in spatial planning is the formation of regional collaborations in which a multitude of (public) interdependent actors (Healey, 2006; Albrechts, 2010) cooperate for purposes of

regional development. This is called collaborative spatial planning or strategic spatial planning (Healey, 2006; Albrechts, 2010; Mastop & Faludi, 1997; Sehested, 2009). In this paper, the practice of spatial planning for the purpose of spatial-economic development within an informal regional collaboration of actors by aligning their goals, ambitions and resources (Zuidvleugelbureau, 2013; SNN, 2014), is referred to as collaborative spatial planning (CSP). Parties can steer the practice of working in CSP networks, otherwise known as meta-governance (Sehested, 2009).

In the traditional top down spatial planning system, the institutional arrangements are clearly established. The roles and responsibilities of each government have been the same for decades. When governments start to participate in regional collaborations to achieve their policy goals, they move into an as of yet unknown planning arena in which the role and responsibility division is undecided. This 'in between' arena in which most CSP initiatives function is dubbed soft space by Allmendinger and Haughton (2009).

The institutional arrangements within these soft spaces with often having fuzzy boundaries are far from established and many different arrangements are set loose on CSP initiatives. Hajer (2009) refers to this as the institutional void – i.e. it is not that there are no institutions at the regional level, yet in the 'void' there are so many institutions and stakeholders that it has become unclear how they best relate to each other. New initiatives are formed and old initiatives evolve in the ongoing search for the right form of collaboration (Edelenbos, 2005). Over the course of years, widespread variations of often thematically overlapping regional collaborations have been established in the same geographic regions (in the southern Randstad: Public Partnership Zuidvleugel, Metropolitan Region Rotterdam The Hague and city regions).

Due to the multitude of initiatives, structures and forms, the optimal organization of CSP initiatives remains unclear. The question of how effective the efforts of regional collaborations are is therefore highly relevant in order to come to best practices for the optimal organization of such CSP initiatives. Addressing this question is currently not possible, as there is no adequate evaluation framework to assess regional collaborations as sketched above on. In this paper, such a framework is presented.

## 3 Research method

This paper focuses on the strategic capacity of the regional collaboration between the national government and the Zuidvleugel partners in the southern Randstad. Because there is little experience with assessing regional collaborative spatial planning practices, the main aim of this paper concerns the development of an appropriate evaluation framework for the assessment of the regional collaboration through the performance of its results.

Although the concept of strategic capacity of Haran (2010) as we will find out below, is very relevant for regional collaborations, the original framework by Haran is found to have several deficiencies. On the basis of a literature review (Haran, 2010; Mastop & Faludi, 1997; Faludi, 2000; De Bruijn et al., 2010) and an exploration into the nature of the regional collaboration and its product under investigation (Harteveld, 2014), these deficiencies were identified. The inclusion of the work of other spatial planning evaluation theorists (Mandarano, 2008; Margerum, 2002; Innes & Booher, 2003; Healey, 1998; Briassoulis, 2004) was done to ensure an enriched framework that results in a comprehensive overview of the most important (according to these theorists) indicators for effective spatial planning.

The actual case study was carried by means of participatory research way with the principle author having the opportunity to participate in the process for half a year from within the leading stakeholder's organisation, in this case the urban development department of the city of Rotterdam. The case study was carried out partly during the development of the enriched framework and after. Information on the nature of the collaboration and the results themselves was gathered and processed through a review of the available information sources. These sources include but are not limited to websites, law descriptions, the product itself and written reports about meetings, but also semi-

structured interviews with the process managers and a select group of participants in the process as well as, finally, observation.

The interviewees have all been involved in the collaborative planning process, either at the administrative, directive or workgroup level or as a process manager. Criteria for selection included level of personal involvement, position in the process and scope of knowledge on the goings on in the process and 'in house'.

Two interview schemes have been developed. The first was prepared for the process managers who designed and managed the process. The second aimed at the experiences and opinions of the participants with regard to the process and results. The interviews with the process managers were semi-structured leaning more towards the structured side. The reason for this is that with regard to the process design, there were several indicators which would help determine how the process was designed, what the reasoning behind it was and how it played out. The interviews with the participants of the process were semi-structured leaning more towards the un-structured side. The focus was on the experiences and assessments of the process, the output and the outcome. Since experiences are variable, an open structure was sometimes deemed more appropriate for this set of interviews.

Finally, theory and empirical findings were processed and interpreted, after which general conclusions on the strategic capacity per component could be drawn. The use of the framework was also evaluated based on the experiences during the case study. From these experiences, weaknesses and strengths were identified, resulting in recommendations for further development of the enriched framework. These strengths, weaknesses and recommendations form the conclusion of this paper.

## 4 Development of the evaluation framework: the concept of Strategic Capacity

Strategic capacity forms the overarching concept of the evaluation framework. The concept gives direction and context to the evaluation of the effectiveness of the CSP initiative in the southern Randstad. Haran (2010, pp. 37) defines strategic capacity as: *"[the] capacity to involve a wide number of stakeholders while producing well-defined strategies with high selectivity and internal coherency, and bringing those to implementation while maintaining the support and commitment of collaborating members."* Strategic capacity thus focusses on the effectiveness of a regional collaboration.

Haran has conducted an evaluation in of the Metropolitan Region Amsterdam, Brabant City and the City Region Arnhem Nijmegen using his framework for strategic capacity evaluation. This framework is presented in Table 1. These collaborations are comparable to the collaboration selected for this paper: they are informal, contain interdependent parties and aim to strengthen the socio-economic situation in their territories through the formulation of ambitions in spatial strategies.

Table 1 Evaluation framework of Haran (2010)

| Components | Haran's indicators |
|---|---|
| 1 Reception | Actor diversity<br>Intensity of involvement<br>Diversity/multiplicity sectors<br>Incorporation of knowledge |
| 2 Consolidation | Well-defined/ integrated strategies<br>Collective lobbying<br>Collective internal investments |
| 3 Realization | Official commitments of external parties<br>Official commitments of internal parties |

The definition and selection of evaluation subjects reflect, at first glance, the purpose of the regional collaboration in the Southern Randstad. Strategic capacity is an interesting approach for the evaluation of the effectiveness of regional collaborations. Its greatest merit is the premise that a wider group of

committed stakeholders is able to implement strategies. Incidentally, the components and indicators of strategic capacity are broad enough to further specify their definitions to create a framework that is more comprehensive and useable.

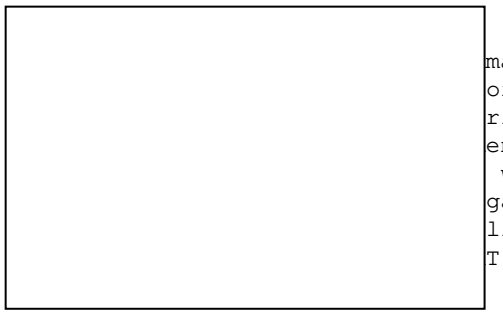
## 4.1 Reassessing Strategic Capacity

One of the main problems of Haran's (2010) framework for analyzing the Southern Randstad case is that it does not foresee in the cooperation between regional and national stakeholders. This section will explain a number of further deficiencies to create a better understanding of the type of enrichment that is needed to operationalize the framework for the evaluation of this paper's regional collaboration case.

A first problem is that the framework does not do justice to the regional collaboration process. The attention paid to the process design and management is, at best, limited. This can be concluded from the indicators under the component *reception* as seen in Table 1. A high quality process is more likely to result in high quality outputs and outcomes (De Bruijn, Ten Heuvelhof, & In 't Veld, 2010; Margerum, 2002).

Secondly, the framework provides little handholds for evaluating regional collaborations. Regional collaborations are continuously evolving, making delineation of the evaluation difficult. Additionally, the indicators offered by Haran (2010) are abstract. This makes that the framework is difficult to apply as a means to assess and compare the effectiveness of collaborations. Further operationalization of the framework will give better guidance and allows for stricter delineation of the evaluation.

Thirdly, empirical research into the case of the regional collaboration between the national government and the Zuidvleugel partners has shown that there are in fact important differences between this case and the cases of Haran. The Southern Randstad collaboration is directed by the MIRT program of the national government. It is a means of meta-governance as practiced by the Ministry of Infrastructure and Environment (Zonneveld & Spaans 2014). The regional collaborations evaluated by Haran are collaborations between governments of the region and without the national government practicing meta-governance. Another difference is that the collaboration aims to formulate a spatial strategy, rather than concrete plans. The focus of this case is on strategic issues, more in particular on the Adaptive Agenda Southern Randstad (AASR, see: Rijk & Zuidvleugelpartners 2013).



ma
ort (Multi-
ritory and
ent and
which
gard to the
ll receive
T

Fourthly, there is a gap between policy making and implementation, in a sense that implementation is not always straightforward. The collaboration will have to be effective in creating commitment to the produced strategies. The reason for this is that within a regional collaboration, responsibilities, tasks and resources are not predefined. Agreements will have to be carried out by the individual participants.

These deficiencies are not unsolvable and with the help of contemporary planning evaluation theory, they can be managed.

## 4.2 Enriching the framework: performance theory

Traditionally, planning effectiveness was studied from the viewpoint of conformance (Faludi, 2000), referring to the level in which the original intentions were carried through to the final result (Knudsen, 1988 in: Korthals Altes, 2008, pp. 13). Lately, other methods for evaluation of spatial planning approaches have emerged. The focus shifted to performance, which is more abstract in nature (Faludi, 2000; Innes & Booher, 2003). This shift in evaluation methods is in line with the

shift in planning practice itself. From hierarchical prescriptive planning by a single government towards collaborative spatial planning by a network of governments. With regard to the AASR and spatial strategies like it, depending on follow-up decision making over a long period of time, conformance evaluation is not an option.

The performance of spatial strategies can be understood as the influence the results of the strategy development have on subsequent decision situations (Mastop & Faludi, 1997). Performance defines two forms of effectiveness for the results: 1) being relevant in subsequent decision situations and 2) being accepted in subsequent decision situations (Mastop & Faludi (1997) and Faludi (2000)). Thus, deviation from the spatial strategy does not necessarily mean the strategy is ineffective as long as it remains relevant in subsequent decision situations (Faludi, 2000).

It is understood that Mastop and Faludi and particularly Faludi (2000) also include the process that led to the formulation of the spatial strategy under evaluation. They see planning as a soft process of learning and "*seemingly endless multifarious negotiations*" (Faludi, 2000, pp. 299) before results emerge.

Thus, it can be concluded that performance as understood by Mastop and Faludi refers to the results of the collaboration process and the process itself. There is a relation between process and result. A high quality process is more likely to result in effective results and effective results will create more commitment to the process (Margerum, 2002). Please refer to Figure 1.

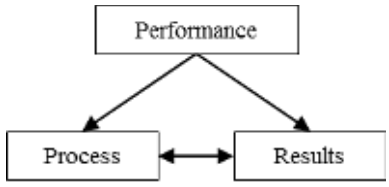


Figure 1 The relation between performance, process and results

The first factor influencing the performance of the spatial strategy is the process leading to the final strategy. The formulation of a spatial strategy is a complex process: a multitude of actors and perceptions are involved, no optimal solution is possible, the context is dynamic in time and multiple issues need to be addressed (De Bruijn, Ten Heuvelhof, & In 't Veld, 2010). It makes it all the more important to evaluate the process and determining how and where procedures can be improved: "*Process-like arrangements have consistently proven to be crucial for success*" (De Bruijn, Ten Heuvelhof, & In 't Veld, 2010, pp. 11).

The second factor of influencing the performance is the quality of the results of the process. The process serves as the breeding ground for not only spatial strategies such as the Adaptive Agenda Southern Randstad (AASR), but also for social effects such as improved relations between participants and commitment of external and internal parties to the agreed upon strategies (Innes & Booher, 1999; Mandarano, 2008). These results should, as discussed earlier, either be relevant for subsequent decision situations or reflect the potential for the realization of the ambitions defined by the regional collaboration.

By using performance evaluation for the enrichment of Haran's evaluation framework, two of the deficiencies previously discussed can be solved. First, it includes process considerations in the evaluation and recognizes its influence on the quality of the results of a collaboration process. Secondly, it allows for stricter delineation of the evaluation as performance evaluation revolves around the specific result of a process. Spatial strategies, such as the AASR, can function as the result that delineates the evaluation. Other deficiencies can be solved with the help of slight adaptions to Haran's original definitions.

## 4.3 Relating strategic capacity to performance

The concept of performance is appropriate for the enrichment of Haran's strategic capacity evaluation framework. The difference between the concept of strategic capacity and performance is their object. The objects are, respectively, a regional collaboration and a spatial strategy.

Strategic capacity can be evaluated through several means. As regional collaborations develop spatial strategies, planning effectiveness – or performance – can be regarded part of the means to evaluate the overall effectiveness – or strategic capacity – of regional collaborations.

Nevertheless, 'merely' evaluating the performance of the process and results can say a lot about the effectiveness of the collaboration. The reason for this is that within a regional collaboration, and responsibilities, tasks resources are not predefined. As discussed in Paragraph 4.1, there is a gap between policy making and implementation, making that implementation is not straightforward. The collaboration will have to be effective in creating commitment to the produced strategies. Agreements will have to be carried by the individual participants. Thus, the performance of the process and results can give a meaningful insight in the effectiveness of the collaboration. The relation is showed in Figure 2.

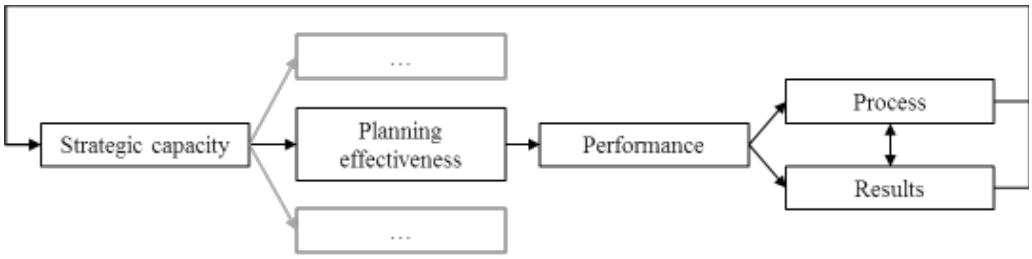

Figure 2 The concepts of effectiveness, performance, capacity and strategy

## 4.4 Operationalizing strategic capacity evaluation

Now that the relation between the two concepts is shown, the relation has to be operationalized in order to function in a comprehensive evaluation framework. With the help of the work of other researchers in the field of collaborative spatial planning evaluation, the relation is operationalized. Furthermore, the adaption of the definitions solves the remaining identified deficiencies.

Firstly, it has been shown that there are some differences between the evaluation subject of this paper and the subjects of Haran (2010). The strategic capacity definition of Haran has been slightly adapted to better reflect the intention of the regional collaboration and the developed AASR, namely to steer decision making in the MIRT by aligning and coordinating the ambitions and the efforts of the region and the national government for the long term. The policy statements in the AASR do not require direct implementation but rather continuous consideration of how paths of action fit into the strategies set forth in the AASR. Furthermore, it has been discussed that a spatial strategy is not the only result of the process. For the purposes of this research, strategic capacity is understood as:

*the ability to [involve a wide number of stakeholders] [while producing well-defined strategies with high selectivity and internal coherency] and [effectively acting upon the ambitions set forth in the strategies while maintaining the support and commitment of collaborating members].*

The trichotomy in this definition has resulted in three components of strategic capacity. These components are reception, consolidation and realization (Haran, 2010). These definitions are also slightly adapted in order to align them with the authors' definition of strategic capacity. Please refer to table 2.

Table 2 Definition of strategic capacity split into three components.

| | |
|---|---|
| **Reception** | continuous incorporation of (new) knowledge by a wider group of stakeholders through self organization and facilitation. |
| Consolidation | collectively filtering and selecting from different ideas, thoughts a action and prioritize between potential paths of action. |
| **Realization** | development of and commitment to future collaboration for the purpose of implementation of the produced strategy. |

With the help of the concept of Collaborative Planning Evaluation (CPE) of Innes and Booher (1999) and the follow-up of CPE by Mandarano (2008), the relation between strategic capacity as defined by the author and performance can be operationalized. CPE combines the collaborative character of strategic capacity with the evaluation of a spatial strategy through its use of components. CSP divides the evaluation into the components process, output and outcome (Mandarano, 2008).

Process as understood by Innes and Booher (1999) and Mandarano (2008) includes engaging a wide group of participants with relevant and different interests through common incentives, incorporating (new) knowledge while following good process design. These elements fall under the definition of reception: *continuous incorporation of (new) knowledge by a wider group of stakeholders through self organization and facilitation.*

Output and outcome are the two types of results of the collaboration process (Mandarano, 2008). The line of reasoning behind the distinction between output and outcome is that the results of a collaborative process are very different in nature. There are physical results in the form of a plan or strategy and there are more abstract results in the form of social effects.

Performance divides the results into two types of effectiveness. The first type is the relevance of results in subsequent decision situations. Innes and Booher (1999) and Mandarano (2008) justly include high quality and innovation as important considerations for the output of regional collaborations. High quality and innovative output reflect the ability to collectively select and prioritize ideas with the highest relevance (Mastop & Faludi, 1997). For high quality and innovative output, the participants of the regional collaboration should jointly filter and select appropriate paths of action based on their collective goals and ambitions as well as sound knowledge (Margerum, 2002). Consolidation is defined as *collectively filtering and selecting from different ideas, thoughts and action and prioritizing between potential paths of action*, showing that consolidation can indeed be found in the output of collaborative processes.

The second type of effectiveness in performance theory is the acceptance of a spatial strategy as part of the decision making situation (Mastop and Faludi, 1997). In the case of spatial strategies like the AASR, acceptance should be reflected by the potential of subsequent decisions being in broad agreement with the spatial strategy. Due to the abstract nature of the AASR, no concrete agreements for realization based purely on what is in the AASR can be made. Therefore, only the potential for realization through social outcomes like commitment and social capital among the involved parties is considered (Innes & Booher, 1999; Mandarano, 2008). The social effects as meant by outcome show the acceptance or commitment of the involved parties to continue participating in the collaborative process. The component realization, *development of and commitment to future collaboration for the purpose of implementation of the produced strategy*, reflects this ambition level with regard to implementation. The result of the operationalization effort is table 3.

Table 3 Operationalization of the link between strategic capacity and performance through CPE

| | **Components** | | |
|---|---|---|---|
| **Strategic capacity** | Reception | Consolidation | Realization |
| **Operationalization through CPE** | Process | Output | Outcome |
| **Performance** | Process | Relevance of results | Acceptance of results |

## 5 Introducing the enriched evaluation framework

In this section the enriched framework based on the work of Haran (2010) for the evaluation of a regional collaboration as reflected by the performance of its results is presented. The indicators are mainly qualitative. The framework provides a method to assess the strategic capacity of the AASR collaboration at the moment of execution of the research. This research is therefore a snapshot of the ongoing process of working together, formulating strategies and building social capital and commitment within the regional collaboration.

Table 4 Operationalization of strategic capacity

| | Components | Sources | Indicators |
|---|---|---|---|
| *Reception - how was the process that led to the output organized?* | | | |
| Process | Process design | (Briassoulis, 2004) (Mastop & Faludi, 1997) (Mandarano, 2008) (Margerum, 2002) (De Bruijn et al., 2010) | Self-organization; participants decide rules, groups and topics<br>Support and facilitation of the process<br>Consistent procedures for decision making |
| | Participation and involvement | (Briassoulis, 2004) (Haran, 2010) (Healey, 1998) (Mastop & Faludi, 1997) (Mandarano, 2008) (Margerum, 2002) (De Bruijn et al., 2010) | Engagement of stakeholders through common goals/objectives/issues<br>Intensity of involvement |
| | Incorporation of knowledge | (Briassoulis, 2004) (Haran, 2010) (Healey, 1998) (Mastop & Faludi, 1997) (Margerum, 2002) (De Bruijn et al., 2010) | Shared research sources and consistent information bases<br>Common assessment, integration and evaluation tools<br>Encourages creative thinking and challenges beliefs |
| | Diversity and multiplicity | (Briassoulis, 2004) (Haran, 2010) (Mastop & Faludi, 1997) (Healey, 1998) (Mandarano, 2008) (Margerum, 2002) (De Bruijn et al., 2010) | Representatives of all relevant and different interests across territories and policy fields (spatial planning, housing, transport, economy)<br>Interaction between private, public and non-gov. parties |
| *Consolidation – to what extend do the outputs have an effect on subsequent decision making?* | | | |
| Output | Well-defined and agreed strategies | (Briassoulis, 2004) (Haran, 2010) (Mastop & Faludi, 1997) (Mandarano, 2008) (Margerum, 2002) | Includes long term development strategies<br>Joining up of different policy fields and their actors<br>Joining up of policy fields between territories<br>Agreement shows innovation and creativity |
| *Realization – does the AASR have the potential to be in broad agreement with subsequent policy documents?* | | | |
| Outcome | Commitment | (Briassoulis, 2004) (Haran, 2010) (Innes & Booher, 1999) (Mandarano, 2008) | Collective action based on agreements in the spatial strategy<br>Impact in organizations |
| | Social capital | (Briassoulis, 2004) (Mastop & Faludi, 1997) (Mandarano, 2008) | Informal interaction between formal actors<br>Trust among actors |

The indicators remain quite broad. It should be noted that this framework thus does not provide a list of characteristics to be ticked off, but rather a collection of broadly interpretable aspects of regional collaborations that can cover a wide range of findings. It should be noted that it is not necessary that the indicators reflect what has happened during or after the process for the collaboration to be considered effective (Mandarano, 2008). As always with frameworks, it is the responsibility of the researcher to interpret the findings in a logical manner. While the framework thus provides a structured guide for evaluation, researchers should come to a meaningful conclusion on their own merit.

## 5.1 Discussion of the framework

The components and indicators from Table 4 have been carefully selected and assembled, based on empirical findings and the work of other spatial planning evaluation theorists. The reasoning behind the selection of the components and indicators is elaborated upon in this section.

Figure 3 Process characteristics of De Bruij et al. (2010)

De Bruijn, Ten Heuvelhof and In ‘t Veld (2010) provide important points of consideration when making process arrangements (see Figure 3). These process arrangements are essential for making a collaboration effective and will, among other notions, be used to substantiate the selection of

indicators.

### 5.1.1 Process design

The indicators *self-organization, support and facilitation* and *consistent procedures for decision making* are included as part of the process design component because they reflect the qualities of openness, progress and protection of core values of De Bruijn et al. (2010). When there is room for self-organization, parties can decide their own joint process rules, topics and work forms. This makes the process open and democratic, which is important for voluntary collaborations.

De Bruijn et al. (2010) have discussed the importance of progress in a process. If there is no progress, participants feel their efforts are not leading to results and decide to quit it altogether. (Independent) process support and facilitation can help the process further through adequate preparation of meetings and use of techniques to involve parties, even in times of conflict.

The inclusion of consistent procedure for decision making is motivated by the process considerations openness and protection of core values by De Bruijn et al. (2010). Consistent procedures lead to openness and protection of core values as all participants understand the procedure and know what criteria each decision has to pass to be accepted.

### 5.1.2 Diversity and multiplicity

De Bruijn et al. (2010) considerations of openness, substance and progress make that the indicator *interaction between private, public and non-profit parties* is appropriate. The interaction between different types of parties ensures that a variety of interests and concerns can be heard (Briassoulis, 2004).

Openness to different interests lead to substance and progress as parties will feel less need to delay. The process consideration substance is partly taken care of if *representatives from different territories*, *policy sectors* are included. It ensures that the majority of interests and requirements are covered. Varied interests and territories forces participants to think differently and search for common goals and ambitions (De Bruijn et al., 2010; Briassoulis, 2004; Healey, 1998; Innes & Booher, 1999).

### 5.1.3 Participation and involvement

The inclusion of the indicator *engagement of stakeholders through common goals and objectives* is suitable to find out whether the parties have a common incentive to participate. A common incentive, like a sense of urgency is a necessary to drive the process. When there is no drive or commitment, the process will lack progress or participants (Mandarano, 2008; Margerum, 2002; Briassoulis, 2004; De Bruijn et al., 2010).

The *intensity or level of involvement* is a relevant indicator to determine the level of commitment of parties to the process and its results (Healey, 1998; Innes & Booher, 1999; Mandarano, 2008). If a party is committed to the process, it delegates a representative who has commitment power, meaning they can work relatively independent from their superiors. The commitment power of these representatives influences the progress of the process (De Bruijn et al., 2010).

### 5.1.4 Incorporation of knowledge

The indicator *shared resources and consistent information bases* is based on the notion of Briassoulis (2004) and Margerum (2002) that common information and negotiated knowledge can help parties to achieve consensus, thereby enhancing progress (De Bruijn et al., 2010).

The data considered with the indicator *common assessment, integration and evaluation tools* also represents the process considerations progress and substance by the Bruijn et al. (2010). Common

tools can help parties to build negotiated knowledge and tools for equal understanding of knowledge and propositions, limiting the number of conflicts (Briassoulis, 2004; Margerum, 2002).

*Creative thinking and challenging of beliefs* form a twofold indicator that reflects the substance of the process. New insights and approaches make the formulation of a new document relevant and logical. If not, parties are difficult to engage in the process (De Bruijn et al., 2010; Innes & Booher, 1999; Healey, 1998).

### 5.1.5 Well-defined and integrated strategies

The indicator *innovation and creativity* is included on the basis that good collaboration and consideration of different interests is shown by the innovation and creativity of the content. It suggests that considerations have been made and prioritized (Innes & Booher, 1999; Mandarano, 2008). Furthermore, innovation and creativity in the document reveal the effort participants have made with regard to substance (De Bruijn et al., 2010).

The *inclusion of long term strategies* is an important indicator to consider. If long term strategies are the main focus of a spatial strategy, it suggests that parties are willing to commit in the long term to what they have agreed. Furthermore, it shows that there has been a consideration of the future relevance and coherence of the actions that have to be taken (Margerum, 2002; Briassoulis, 2004).

The third and fourth indicator are included, because *the integration of policy sectors, parties and territories* shows that a variety of considerations have been made and prioritized (Healey, 1998; Margerum, 2002; Briassoulis, 2004). The integration of territories, sectors and parties shows an understanding of where opportunities and threats are located and how they can be used to strengthen the region in its entirety.

### 5.1.6 Commitment

*Collective action based on agreements* in the spatial strategy shows commitment of effort and resources to bring the ambitions of the AASR about (Haran, 2010; Briassoulis, 2004; Innes & Booher, 1999; Mandarano, 2008). It is a vital indicator that reflects the potential for realization of the ambitions.

The second indicator reflecting *commitment* is the *impact in organizations of government*. However obvious it may be, the AASR should be known within the governments and organizations for it to be used and realized (Mastop & Faludi, 1997).

### 5.1.7 Social capital

The first indicator of the component *social capital* is included for two reasons. Firstly, informal relations reflect the stance of a participant towards the collaboration itself. Secondly, personal informal contact generates expectations about each other (Innes & Booher, 1999; Mandarano, 2008; Briassoulis, 2004).

Trust is necessary to engage in a process with conviction and represent each other's interests successfully (Innes & Booher, 1999; De Bruijn et al., 2010; Process Management, 2010; Mandarano, 2008). *Trust among involved parties* can be divided into two aspects, namely trust in each other on the one side and trust in the produced spatial strategy on the other side.

## 6 Case study: strategic capacity in the southern Randstad

A case study has been conducted in which the enriched framework has been used. The case is the regional collaboration between the national government and the Zuidvleugel partners in the southern

Randstad. This (test) case is briefly discussed, as it provides experiences about the use of the framework, forming the base of the evaluation of the framework itself. This evaluation is presented in section 6.2.

### 6.1 The regional collaboration in the southern Randstad and the Adaptive Agenda

The regional collaboration between the Zuidvleugel partners and the national government seeks to align their ambitions, strategies and resources for the purpose of coordinating regional development. The Zuidvleugel partners stem from the Public Partnership Zuidvleugel, which is an informal regional collaboration which seeks to develop the southern Randstad spatial-economically. Globally, the southern Randstad stretches from Leiden to Dordrecht, including a very diverse selection of economic sectors and spatial characteristics.

The collaboration stretches across all tiers of government, even including the water boards. It aims to formulate policy statements at a strategic level, rather than offering concrete paths of action. Moreover, the collaboration is structured by policy of the Ministry of Infrastructure & Environment, making it formal in that sense. At the same time it is informal in the sense that it cannot make decisions by itself or implement its own decisions. The regional collaboration is thus dependent on the social and political commitment of the participants for the implementation of the results of the process. Strategic capacity is thus a relevant concept for this type of collaboration.

For the purpose of strengthening the spatial-economic situation in the southern Randstad, several territorial agendas have been developed over the last years together with the national government (Zonneveld & Spaans 2014). The latest, the Adaptive Agenda Southern Randstad 2040 (AASR), is the object of this evaluation. In the AASR, the common ambitions and complementing strategies for the spatial-economic situation for the southern Randstad by 2040 are sketched.

The development of the AASR took place within the context of a national government investment programme called MIRT. The national government used the MIRT to give the Zuidvleugel partners an incentive to collaborate and formulate spatial strategies. Within the MIRT framework, parties could organize the process themselves, determining the level of involvement, how information was treated and how choices were made. Within the MIRT, decisions are made for investments in regional projects or the commissioning of research – MIRT explorations - so robust MIRT decisions can be made in the future.

While the content of the AASR is not new (most can be found in earlier Agendas), the approach that is taken is. The AASR advocates the adaptive approach, meaning that 1) governments and policy statements should be flexible enough to cope with all possible scenarios in the future and still be relevant and 2) governments should work with and facilitate external parties and their initiatives, allowing for adequate reactions to opportunities from the market.

## 6.2 Findings

A picture of the strategic capacity has emerged that is both positive and critical. The process has had a diverse selection of governments participating continuously and was appropriately and enthusiastically managed by the process managers, but the essence of the process – its position in the MIRT, its objectives and form – have not had the attention it required. Moreover, the lack of external parties in the process lowers the strategic capacity of the collaboration, as is experienced during the initiation phase of the MIRT explorations.

The result is a spatial strategy that is both strategic and concrete; and strong social outcomes. Some initiatives have emerged which reflect the ambitions in the AASR, showing the commitment of parties to their common ambitions. Participants are found to value the AASR, trust each other and appreciate the developed adaptive approach, but both output and outcome require nourishment and follow-through to keep them at the high appreciation levels they are now. Especially the adaptive approach

will require continuous effort to settle in the regular practices of governments at all levels and to connect with market parties and knowledge institutes. The AASR has proven to be an exemplary strategic outcome of close collaboration between regional parties (the Zuidvleugel partners) and the national government (Harteveld, 2014). Other regions refer to the AASR when trying to decide their approach to national /subnational collaborative spatial planning.

The strategic capacity of the regional collaboration between national government and Zuidvleugel partners is thus ambiguous. The regional collaboration before the finalization of the AASR seems to have had more strategic capacity than it has after the finalization of the AASR. The efforts during the development process have resulted in several initiatives such as the MIRT explorations and collaborations on issues, albeit these initiatives have not yet resulted in concrete interventions, physical or policy-wise, in the spatial-economic situation of the southern Randstad. The groundwork for interventions has been laid in the form of new research and regional sub-collaborations, showing that the regional collaboration indeed has strategic capacity by bringing this about. However, there are several elements that have emerged after the finalization of the AASR, such as the adaptive approach, which limit the strategic capacity at this moment. It seems that due to the indistinctness – or more specifically, the lack of a clear goal and purpose – the effort and commitment to the current AASR process is lowering. Focus and effort is shifting to the MIRT explorations and the regional (sub-)collaborations on specific issues.

## 7 Evaluation of the use of the evaluation framework

For the purposes of this thesis research, the conceptual framework of Haran (2010) has been enriched into a full scoped evaluation framework for the strategic capacity of a regional collaboration as reflected by the performance of one of its products. It has been developed for and tested on the case of the regional collaboration between national government and Zuidvleugel partners.

The resulting overview of process, output and outcomes forms the basis to answer the question of strategic capacity, and has shown to be useful. While strategic capacity is also dependent on other issues – like the dynamic context in which regional collaborations operate, or its legitimacy and presumably more – the performance of the process and results do give a strong indication of the level at which a regional collaboration is able to cooperate to achieve joint policy goals by producing and implementing effective spatial strategies and thus of the strategic capacity. A process evaluation illustrates the manner in which the regional collaboration cooperated, which results in social outcomes that should ideally benefit the realization of the ambitions in the output of the process; the spatial strategy. Indeed, the purpose of having strategic capacity is to effectively intervene in the current spatial-economic situation to realize one's ambitions. Thus, the evaluation framework provides the building blocks needed to answer the question of strategic capacity. This answer is relevant even though the aforementioned other issues are not actively studied.

## 8 Concluding remarks & recommendations for further research

Since collaborative spatial planning initiatives are continuously evolving in the face of the institutional void, a framework has been developed based on existing frameworks. This framework is used to evaluate the strategic capacity, or the ability of a group of actors to cooperate to achieve joint policy goals by producing and implementing effective spatial strategies.

The crucial adaption to the framework is the link between the strategic capacity of the collaboration and the performance of its product. This allows for stricter delineation of the evaluation and for an evaluation of the strategic capacity development of a regional collaboration over time based on the performance of two or more spatial strategies.

### 8.1 Recommendations for further research

The expanded evaluation framework applied on the regional collaboration in the southern Randstad. However, no comparison has been possible to other regional collaborations. It is therefore recommended that additional research is done on the strategic capacity of other regional collaborations in order to develop a frame of reference.

The evaluation framework for strategic capacity has been found to be lacking with regard to legitimacy and the context the regional collaboration under investigation operates in. This means that the collaboration in itself can be found to have high strategic capacity, but limited accountability and responsibility; and due to external developments in the context, the strategic capacity six months from now could be dramatically different. The developments of the Metropolitan region Rotterdam The Hague parallel to the Public Partnership Zuidvleugel (in which the Zuidvleugel partners come together) can and will have an impact on the operations of the PPZ and the Zuidvleugel partners.

For this reason, an adaption or addition to the evaluation is necessary. For example, the evaluation framework could be expanded to include and extra elements besides the original three that refer to the dynamics in the context of the regional collaboration and legitimacy. These elements could include indicators like the level of feedback received from administrators with regard to the practices and the commitment of administrators to different collaborations in the southern Randstad. Another direction for involving the context could be a more elaborate external actor analysis of the similar CSP initiatives in the wider region, including their stance towards the different collaborations.

## 8.2 Final remarks

This having been said, the evaluation framework has considerable potential for meaningful evaluation of regional collaborations. Even though the context of collaborative spatial planning is continuously evolving, regional collaboration which formulated the AASR has shown that strategic capacity evaluation of the collaboration itself can provide interesting insights in its performance. Regional collaborations are likely to stay and the framework allows for critical analysis and can help identify best practices. The question of how collaborative spatial planning should be practiced in the future depends largely on the effort participants and process managers will put into nourishing and improving current processes. Paired with the developments outside the collaboration, only the future will tell how collaborative spatial planning practice will evolve. The findings of strategic capacity evaluation can provide guidance towards the best practices.

# Dealing with a complex urban object: planning the covers o transport infrastructures in urban areas.

Joel IDT & StØphanie LEHEIS

Lab Urba UniversitØ Paris-Est joel.idt@u-pem.fr stephanie.leheis@gmail.com

Keywords: covers of transport infrastructures; coordination between transport an decision making-process.

Our paper focuses on the complexity, in urban planning practices, to coordinate and urban development. This is the case for transport systems organized aroun infrastructures. Contrary to what we could imagine in a first approach, there causality between the construction of such infrastructures and urban devel territories. We mainly observe an intertwining of causal links, and an interpen evolution.

This observation has implications for public policy, whether to create new tr organize urban development. Interactions are still structured at one time or an fields of public intervention strongly related. Problems should therefore be joi planning and urban planning actions differ as much in their challenges as implementation. This generates problems of coordination between stakholders backgrounds, sharing neither the same interests nor the same objectives of action. possible in this context?

To highlight the difficulties of coordination, we focused our research on a interface between these two fields: urban development projects organized around infrastructures covers. There are many reasons to cover a transport infrastr nuisances, to create new available land, or to improve the transport system. W these projects are always at the junction between construction of the structural engineering object); operation of the transport infrastructure (production a transportation system); and planning of urban development project (creation of settlements, etc.).

In a first theoretical part, we will explore the complex links between transport development, and its consequences on public policies. We will then focus on th we ll see how they constitute spaces of confrontation and interaction between planning. We will explain how coordination of collective action between th nevertheless organized in the decision-making process and in the operational completed within the framework of an interdisciplinary research program ANR CANOPE on an organizational analysis of five cover projects in France, Belgium and Ge 2015): coverage of existing railway lines coming out of the Gare d'Austerlitz Gauche (France) ; enlargement of part of the railway network around Brussels ( portions ; coverage of urban expressway and the construction of a tram line (Germany), burying the A55 highway in Marseille in EuromØditerranØe project an new urban areas (France); the coverage of an expressway section in Gennevilliers

# 1 – The infrastructure, product or motor of territorial transfo

## 1.1. The chicken or the egg? Infrastructure or territory?

There are many urban researches that theorize the articulation between transpo urban development. By creating a very schematic map of the main of them, and i that divide the natural sciences (in the study of human-environment report), we possible theoretical models to consider the links between infrastructure and ter

The first two take the form of causality in one direction or the other. We can called "deterministic" (Leheis 2011), in which the object determines its environ meaning it's the infrastructure that determines the territory. It is the oldes works that are mainly interested in the effects of infrastructure on territo example the first works of economic geography that explain the structuration transport system and travel opportunities, and thus infrastructure {like the mod Isard, Moses) on market areas (L sch, Hotelling) or land-use (Von Th nen) (see this model, transport infrastructures have a decisive effect on the territo relationship: they constitute one of the main vectors of urbanization and urban

This model finds its translation in the operational practices of the actors, and transport infrastructure. It is used in particular to support all analyzes based benefit (or model CBA Cost Benefit Analysis), which seek to justify the investm by calculating direct and indirect effects, monetized or not, of infrastructure o urban phenomena, however, are difficult to understand in this single prism. The controversies around the creation or modification of large infrastructures, whe territories crossed by the infrastructure are strongly opposed to the projects some cases it is even the inhabitants of urbanized areas with the creation of then are opposed to its expansion.

We have identified a second approach which is described as "evolutionary" (Lehe represented in urban research. In this approach, the environment determines the meaning that the territory transforms the transport infrastructure or netwo functional balance of the urban system (the same way that the principle of struc selection would according to some an optimal balance of the medium). This mo common. We find an application in the article by Luca Bertolini, about the ur conducted in Amsterdam since the post-war (L. Bertolini, 2007). He shows how policies evolved based on changes in the socio-demographic, economical, or land to him, we are facing a complex evolutionary system in the sense that: firstly periods of incremental change and radical change; on the other hand, the syste and finally, it is possible to identify transitions. The case study highligh economic and social transformations, and their effects on the urban transport sy changes have no effect, other times they produce side effects (the principle of produce a radical change, which involves the reorganization of the transport sys the urban transport system must be able to endure despite changes, socioeconomic a performance criterion). The system must also provide to adapt to changes. It i in a simple causal relationship: the characteristics and developments of trans determined by urbanization of territories crossed.

This model also finds some translations in the operational practices of the acto the engineers who make the transport infrastructure seek to size according to

areas crossed to adapt supply to demand. But the logic of this type lead to le
spillover effects on urbanization: the creation or improvement of transpor
generates new needs due to improved transport times. We can even make the h
continuous improvement of a heavy infrastructure system could in some cases lead
saturation.

## 1.2. The infrastructure as a technical object: crossed interactions betwe urban planning

It is possible to identify a third approach, which can be described as "interac
which the object and its environment (or the transport infrastructure and urban

infrastructures. In other words, the network transformation is part of a global
technical object and of the social, economic, political, or geographical dynamic
the idea that the infrastructure can not be understood without taking into
relations with the territory in which it is part (analyzing these relations unde
angle the network).

We find the foundations of this interactionist model in the theory of scienc
literature called STS (Science and Technology Studies or Science Technology an
relates the evolution of the society with technical developments. At the origin
the work of history and sociology of science and technics from Thomas Kuhn or
(Bijker, Hughes & Pinch, 1987). These works highlight the multiplicity of dia
(from symbiosis to break) between techniques and societies that produce them. Th
transformation process, they highlight the tensions and resistance forms bet
evolution.

The STS approach is dominated by three major trends, highlighted by (Bijker, Hug
In the "social constructivist" approach based on the sociology of scientific kno
to consider that the technical objects can be analyzed as social objects, t
sociology may therefore apply to it. The Tomas P. Hughes approach then conside
system, that is to say a combination of material elements but also representa
Finally, the approach of Michel Callon, Bruno Latour and John Law, at the Ecole
which technical and social-between is defined by combination or interconnectio
humans (of where the use of the network concept), is better known under the t
network. Without repeating the details of these different approaches, simply ret
lead out of a vision in which technical objects are considered a given. At the
the technical object is defined as a "socio-technical compromise." These app
relationships "environment" within which the technical object evolve. They were
first time in the work of Gilbert Simondon (Simondon, 1958) with key concepts
"associated environment", which allow him to describe an interactive process
transformation and evolution of technical object (Akrich, 1993).

The STS literature is particularly suited to analyzing the relationship between
and urban development, transport infrastructure is seen as a socio-technical ob
transformations can not be understood without taking into account its interac
system, but also with urban territories in which it is inserted. This third

emphasizes crossed causal links between transport infrastructure and urban area
considered as a social construct contributing to change their environment and in

This theoretical approach has consequences for public policy thinking around tr
It is not possible to simply describe the process of transport infrastructure p
only as responses to urban transport demand, or only through their expected effe
crossed. The action takes place in fact in an environment where the infrastruc
territories crossed evolve jointly. Any new production or infrastructure change
the interaction between transport and urban development, and therefore in t
dissociated logics of action. This situation forced collective action and
coordination problems between the protagonists acting at the intersection of
representations, or the calendars of both public intervention fields.

This is particularly true in the case of infrastructure coverage projects. A co
fact at the interface between transport and urban development. It is part of th
the transport infrastructure, particularly in urban areas where it limits the b
road or railway. At the same time, the cover is also an urban object, which tak
urban renewal operations for example, by bringing a new urban ground. Covera
interface between urban planning and transport. It crystallizes, more than o
interaction between territory and infrastructure.

## 2 - The transport infrastructure covers: urban objects at t between development and transportation

### 2.1. Interactions with the transportation field

Covers projects are a key issue in urban transport infrastructure planning. The
structured between the construction of the cover on the one hand, and management or mod
the covered rail or road infrastructure. They take different forms.

a/ The coverage project may itself result from global modifications of the trans
cover is then one of the elements necessary for a larger project related to
covered. This is the case for the Brussels RER, where the few railways cover
firstly to facilitate technically network extension (putting four-way lines), a
acceptance of the works in some cities that might oppose it, by offering sensibl
noise and improve crossing the tracks. This is the case of Kombilosung in K
burying of KriegStrasse helps to report one part of the trafic from the tram
surface and reduce the congestion. This is also the case for Paris Rive Gauche though a
the coverage of railroads is mainly induced by the urban development project,
realization of a new RER station and metro line 14. In these examples, the fi
infrastructure is integrated within the transport project: it would not have bee

b/ Even in cases where coverage is not the primary objective in a transportat
object can nevertheless interact with the challenges of transport when its reali
potential or actual - on projects transport current or future related to the
EuromØditerranØe and Gennevilliers, the covers of motorway lanes create tunn
extremely strong regulatory constraints in terms of security, and thus in c
infrastructure. In Paris Rive Gauche, coverage of railroads necessary to
neighborhood area involves a reduction in the number of tracks, which has impl
the Gare d'Austerlitz operation as it exists today, but also on future opportuni
therefore, on potential changes in the rail network.

These interactions also take the form of strong contraints generated by the realization of coverage. A major constraint is that the infrastructure remains coverage works, as is the case in Paris Rive Gauche or Brussels for the rail Karlsruhe and for Gennevilliers motorway routes. The complexity that it generat in terms of costs and therefore feasibility and programming surface projects. generates constraints on the possible structural supports of the cover, as in Pa detailed plan of structural supports was imposed by the infrastructure manager project.

c/ The cover opens possibilities to reorganize the surface mobility. The covers surface rail or road links. In Paris Rive Gauche, this will physically connect th existing city. For EuromØditØrannØe, coverage of coastal highway creates new p the new districts, and more largely the city of Marseille, to the sea. In KriegStrasse, an highway road that currently separates the station area fron significantly improve urban connections between these two parts of the city coverage RN315 is the opportunity to get a tram to the surface.

In the same way, covering operations offer opportunities to organize connection and infrastructure. These connections are typically associated with changes in conditions, for example in the case of railways creating new stations or modify reorganize traffic. We have already mentioned the case of the new RER station in district of Paris Rive Gauche, which is essential in its service by public trans conditions to implement the new stop and create new exits for travelers, etc. Th are organized mostly around a redevelopment of railway stations. Additional gr cover is used in particular to organize intermodality with buses and cars.

## 2.2. Interactions with the urban planning field

Similarly, covers projects are at the heart of urban development issues in the Therefore, interactions between projects are structured to surrounding developm and the construction of the cover on the other hand. They take also different fo

a/ The covering project can be part of larger projects development of an urban one of the elements necessary for the overall development project. This is th Gauche where coverage of railways in the Gare d'Austerlitz, as we have seen, district to the rest of the district, which is well connected to banks the Seine new facilities in Marseille EuromØditerranØe district has its immediate access is made possible by the covering of the coastal highway: the project leader reconquest of the waterfront. The case of Kriegstrasse coverage in Karlsruhe is of the project of "Kombil sung" (combined solution) by the people in a refer indeed that it is both a transport project and a project urban development: co central element in the redevelopment of downtown and in the development of attractiveness. In all these projects, the main stakeholders involved in the pr as an essential element to achieve the urban development objectives. Consequ coverage based mainly on the overall development project.

b/ Even if the cover objective is to improve transport infrastructure, urban de are still often added. Under the Brussels RER, although the covers are designed four-way lines extension, urban development issues were quickly raised, espec municipalities and local authorities. The cover of the RN315 in Gennevilliers

reducing pollution generated by the infrastructure, but the surface was then spaces.

c/ The cover opens up possibilities for urban development on the surface above t covers are creating developable land. In Paris Rive Gauche, volumes of slabs a who construct housing or offices buildings. The proceeds helps to fund the cove creates public facilities and public spaces on the slab. In Marseille, it is realized on the cover, above the coastal highway. In Brussels, the land created stations, a garden, shops, a sports field, parking, etc. And the new surface constraints on the cover. A major constraint is due to leveling of the above, organizing traffic and roadway surface and thus determines the thickness of th Gauche, leveling the Avenue de France, main avenue crossing the new district ar the maximum height of all other adjacent covers. This setting led by unusual pl solutions in order to cover: the developer carries out hedging office buildings to carry out intermediate cover slab. Another constraint is expressed in terms the cover, which must be sufficient to support arrangements from the surface, mo to buildings like the Left Bank in Paris or some covers of RER Brussels.

The cover also allows to open new development opportunities for the land on infrastructure, by reducing pollution - actual or potential - related to infr example. Burial of the coastal highway in Marseille facilitates spatial Eurom open the new area to the sea. In Paris Left Bank, the creation of the new RER t 14 on the cover railways ensures an essential public transit service to urban district.

## 2.3. Coverage in the heart of the interdependencies between transpor planning

An infrastructure coverage is, as we see, an urban object interacts with both infrastructure and the development of the surrounding urban areas. It plays an technical object between transport and urban planning at the interface between these two fields of public intervention between which it organizes interd interdependencies are structured in several dimensions.

a/ The first physical interdependencies are: formal and functional characterist linked to those of the transport infrastructure as well as those of surfa surroundings. Its leveling, width, length or location of support points, are c and functional characteristics of the existing infrastructure and urban develop the characteristics of future projects. For example, the locations of the suppo Paris Rive Gauche are determined by the locations of the existing track and structures capable of supporting buildings. But the covers of support points wi possible developments of the infrastructure (they limit the number of tracks it and developments in surface (the supports are designed for specific building difficult to change once the realized coverage). Note transitivity of these leveling of the infrastructure will constrain including the height of the cover, the leveling of the surface. Leveling the Avenue de France in Paris Rive Gauche is dete height of the covererage that is determined by the leveling of tracks. But now t completed, its leveling determines those of all future covers added or related.

b/ Interdependencies are structured between the actors involved in collective a those who realize the coverage, those managing the infrastructure and those wh

## 3 – Coordinating collective action in circumstances o interdependences between transports and urban development

As we can see, the cover projects are intrinsically linked to the field of tr
planning, two interrelated fields of action but whose logics and action fram
different. This situation raises questions from the perspective of collective a
driving these projects can coordinate and manage these interdependencies? How

action at the interface between the two fields? We have identified four types characterize how the action is organized.

### 3.1. The unthought or unmastered coordination

One might think that collective action goes with the coordination between part shows many situations where collective action is not or poorly organized, and between the different elements of the system is little or no thought. The ste transport and those related to urban development are disjointed: the actors without seeking to establish a dialogue. The question of coordination between arise, at least not a priori. Although there are interdependencies between obj disconnected. The lack of coordination is particularly strong in cases where co one of the two fields, either transports (eg expanding the infrastructure or causes) or urban planning. The action is then little linked with the other fi Gennevilliers, where infrastructure is primarily intended to cover the accepta project supported by the State towards local authorities. Urban development does objective for anyone, and are postsponed.

The lack of coordination in the decision process is most of time unfavourable to su developments, which generally come last, once the infrastructure and coverage case of the creation of the Littoral Boulevard in EuromØditØrannØe project in responsible for public spaces only starts once the cover slab (made by the man infrastructure) is achieved. The cover has structurally « always one step ahead development, which restricts the possibilities for coordination of the action, This is also the case with the RER in Brussels, where most of the covers nee infrastructure to four tracks are sized and sometimes flufilled well before the precise idea of their expectations about surface urban developments.

In this configuration, everything related to the other field of action is po posteriori, being the adjustment variable. For EuromediterranØe where burying affects the whole urban project with the creation of the Boulevard du Littoral, project results in many surface growths that become constraints to manage and i the surface facilities. The actors of urban development, who are coming in las "make do."

### 3.2. The organizational devices for coordination

In order to manage projects, stakeholders are building organizational device structuring coordination between transport and urban planning.

We first find contractual devices: partnership agreements, memoranda of under disposals, etc. The regulation of collective action between transport infrastru development goes on here by a formal clarification of the roles, skills and res of Paris Rive Gauche thus precise the division of responsibilities between the operators, which are also owners of the land above and around the tracks. In oth specifies a priori what refers to urban development and what refers to tra opportunities for actors of the two fields: rail operators take on selling la accept in exchange to follow the requirements of rail operators to enable th business. Such theoretical division of roles is to define each responsibilities it actually often leaves a place to blur, interpretations of rules and games wi example of the question of the division of land properties, mostly treated afte

and not specified in the contracts. At Gennevilliers, property lines had to be after the project: the use and management of lands do not necessarily go to pla realization.

Coordination tools can also be hierarchical, and refer to the construction intermediary to the various elements of the system. Their action covers ei infrastructure, its coverage and surface facilities. The same formal organizatio action. It manage and pilote several elements of the overall project: both th cover (MPM for EuromediterranØe, DIRIF in Gennevilliers, KASIG Karlsruhe); both and surface facilities (SEMAPA in Paris Rive Gauche); or even infrastructure, surface facilities at the same time (TUC Rail Brussels RER). In this situation internally to the structure, between staff of the different services. Some structures can be created for the occasion (SEMAPA in Paris Rive Gauche, EPA E the KASIG in Karlsruhe). All of them are explicitly entrusted with a mission to project issues between those related to transport infrastructures and thos development. This mission for instance involves piloting preliminary studies tha the overall project and built the beginnings of the division of roles. The int also have a role to boost the project or to push its progress. In Karlsruhe, t the tramway project in the planned time frames. According to the project mar calendar at best despite the difficulties is one of the main prerogatives of t the intermediate structure can finally consist in solving all the technical di discussions (including the antagonisms between transport and planning) arising stakeholders.

However, coordination difficulties in collective action between issues of tr development are relatively similar whether there is or not an intermediate stru project shows that the responsibility of a stakeholder in coordinating matters give him the possibility to force the action of others. Each project owner k interests, its terms of action and its own temporalities. Thus, far from defining a st between the protagonists, these devices work more as common frameworks in whi play, and that they contribute simultaneously to change.

### 3.3. Coordination throught the technical design

When the temporalities of project processes overlap between infrastructure, th development project, coordination can go through the design work of these tech interact one with eachother. The actors discuss and negotiate the characteristi In other words, the coordination of action suppose to agree and to modify the c so that they are compatible. The cover slab is at the intersection of transport development: its characteristics (the fact to cover or not, the length of th leveling, its lift, etc.) are often taken as adjustment variables between above the debates and are the subject of socio-technical compromises. In all our case the slab have at one time or another been discussed at a political level, eithe the elected representatives of partner institutions to stabilize funding of the controversies on whether or not to cover (Karlsruhe and Brussels), on the length (Karlsruhe, Paris Rive Gauche, Brussels), on its positioning, etc. We can see political renegotiation of cover characteristics punctuate projects, and can c project process.

The length of coverage is one of the main adjustment variables between the infrastructure and those related to surface development. Discussions can also

innovations in the organization of the steering action. This is the case in
"bridge building" that doesn t need any slab cover : the building itself is co
and so there is a single project owner for all.

### 3.4. Coordination through constraints

The last mode of coordination is what can be called coordination through constra
the very strong interdependency situations put the stakeholders in project d

the constraints. These systems of very strong rules, which apply to everyone,
only at the margin. In defining what is feasible drastically or not, they frame
reduce uncertainty and stabilize the game. They thus contribute to the coordinat
to constraints then constitutes a large part of the project activity of the
structures theirlogics of action: actors that drive the cover projects very
identifying ant adaptating to constraints.

Some of these constraints, as we have seen, are related to the contractual and
which collective action is organized. Others refer to technical rationality, jus
negotiable. For example, security constraints for the sites over the railways a
various constraints tend to cumulate on the same situation of action. This is t
Gauche project : constraints on the construction of the slab come both from the
of the slab, than from the infrastructure (the release of rail volumes) and from
(the requirements of the city and elected representatives). These situations
construction at the heart of discussions on the management of projects, as
constraints may challenge them. Technical discussions on the implementatio
particularly strong in the negociations between stakeholders and in the develop
The difficulty is to enable the execution of works despite all the difficulties
Gauche, the accumulation of constraints led to the proposal of complex, costly
work methodologies, which commit the project feasibility. These questions
(technical, phasing, workflow, ) often tend to invest the political sphere and deb
space.

However, the constraints are not completely fixed. The stakeholders have leew
constraints fields that organize collective action, and that seem to impose on
phasing, by playing on programs or on steering structures, they manage to cha
them. To do so, players first can change the content of the projects, and so t

interdependencies. In Karlsruhe, the fact of linking the rail project and the

# COPING WITH THE COMPLEX IMPLEMENTATION OF LARGE-SCALE DEVELOPMENT PROJECTS: CRITICAL QUESTIONS ON THE INTEGRATED PROJECT DELIVERY METHOD

Maryam Karimi

PhD Candidate, Politecnico di Milano, Italy
Maryam.karimi@polimi.it

Keywords: Integrated Project Delivery (IPD), implementation, large-scale development projects

## Abstract

*Our cities and societies are getting larger and complex more than ever before. As a result, urban professionals are seeking new tools and methods to cope with the contemporary urban issues from planning to the implementation process. The challenges are becoming more intense when discussion goes into large-scale development projects. These are often measured with high risks of implementation, extreme cost of construction and a large number of actors involvement. Nowadays, the use of the Integrated Project Delivery (IPD) method in large-scale projects has been deployed internationally as an efficient model among architecture, engineering and construction firms. This model is not only esteemed to enhance collaboration, sharing the project s risks and rew its stakeholders, but to serve as a successful tool for decision making and planning process. Drawing on research of this method, the paper examines the use of IPD in implementation process, not specifically pointing out on the efficiency of this model in technical terms, but instead questioning the effectiveness of IPD within different urban contexts. The paper considers the longstanding planning literature regarding implementation research and strategic spatial planning countering the typical collaborative project such as IPD practice. Furthermore, the case of the city of Abu Dhabi vision 2030 and Masdar City as an extreme case of using IPD method is examined. At the end the paper suggests that the use of IPD in various contexts has to give special attention to the actual development of place and involve the knowledge of local actors.*

## 1. Introduction

Recently, the involvement of multi- actors in planning and implementation of projects is increasing due to the rapid growth of cities and likewise in the complexity of societies. Moreover, need to consider the environmental, social, political and economic concerns are becoming increasingly influential in policy and decision makers agendas. In favor of boosting the economic crisis or exposing the political-economic power among cold-war global politics, cities governments and relevant entities have initiated in participation to urban global competitions. Year by year, cities around the world, regardless of their government system, try to be the winner of this worldwide large development war by using these large scale projects as an urban growth machine. According to Molotch (1976), most city governments can be seen as growth machines. This puts localities in competition with each other in ways that affect the vast majority of their citizens and environments. Certainly his point of view is more applicable in the social science realm, but the idea of using the term *growth machine* in built environment and urban land-use is significant in urban planning discourse. Hence, this paper applies the term of urban growth machine also with reference to large-scale development projects as the main generator of cities transformation. It is important to that this study does not intend to argue the necessity of large-scale projects in contemporary cities, neither to discuss the opportunities or risks of the role of mega projects in the development. Instead,

the main concern of this paper is on the complexity of the implementation in urban projects by oversimplifying the urban issues by using a fixed project delivery method, namely IPD. This method is being applied world-wide by urban professionals to manage complexities of projects implementation, especially in large infrastructure projects. The birthplace of IPD is the U.S., a federal republic government system where the decision making power is divided between the federal government and the government of the individual states. Its practice has been done by an elite group of international architecture, engineering and planning firms based in North America and Europe sometimes referred to as the global intelligence corps (GIC). Given that hypothetically this method might work well in the American cities context, a quick research and sample studies verify other aspects[1].

The main argument of this paper will be supported by the planning literature on implementation research mostly discussed by Wildavsky (1973), using the partisan mutual adjustment concept of Lindblom (1959), and also having a quick review of Patsy Healey s analysis on the transnational of planning ideas and practices (Healey, 2013). Considering this theoretical background, the discussion is focused concisely on the spatial strategic planning of Abu Dhabi and the future vision provided by the city government. The author believes that having the knowledge of the original stories of the strategic planning of the city, how it travels and is translated from the exogenous planning, in the way Healey (2013) describes, is one of the fundamental features of implementation studies, especially for large urban development projects. This study also highlights the importance of the government system of the city since it is one of the main key deciding factors for plan implementation. The final part of the paper discusses briefly the strategic planning of Abu Dhabi Vision 2030 as a federal monarchy and the extensive use of IPD through many GIC firms for their large development projects.

## 2. Urban Strategic Planning: Convention to Invention

In recent years, creating a strategic plan has become the mainstream among cities in order to increase their visibility in national and global milieus. Specifically developing a long-term vision with a strategic approach and introducing innovative technologies are becoming the key feat considerations. According to Albrechts (2004) only some of these strategies are strategic and it is impossible to do everything that needs to be done. Moreover he emphasizes that being strategic requires prioritizing decisions and actions as well as having a selective focus. However, the judgment process and being selective among the wicked problems as discussed by Rittel and Weber (1973) seems a crucial task in which to frame the strategic plan.

As discussed by Healy (2006) and Balducci et al (2011) the literature on strategic planning is expanding and different strategic spatial planning methods have been introduced depending on the political system, economic development, and social context of the nations. However, the question that Alberchts and Balducci (2013) address in their recent article on practicing strategic planning is still pending: *to what extent are the strategic plans different from traditional planning?* This question is becoming more noticeable as new technologies and innovative approaches such as IPD are introduced to the implementation phase of a plan, and the plan becomes the flagship and model to follow, whether it is strategic or not. In both strategic planning and project management literatures, the outline of IPD as a decision making method is delineated in a linear model. In project management, specifically in project development, linear thinking is a predictive approach as IPD. This project delivery method is

[1] The case of Caltrans District 7 HQ in Los Angeles designed by architect Pavel Getov used IPD reveals the limitation of this method in the U.S. in terms of lack of the involvement of non-experts, final users, and citizens in the planning and implementation process (Archdaily, 2011).

an approach to facilitate and optimize this predictability in the most efficient way. Besides linear thinking, IPD is also recognized as a traditional-waterfall-method. In other words, it is a sequential design and implementation process that flows steadily downward like a waterfall (figure 1).

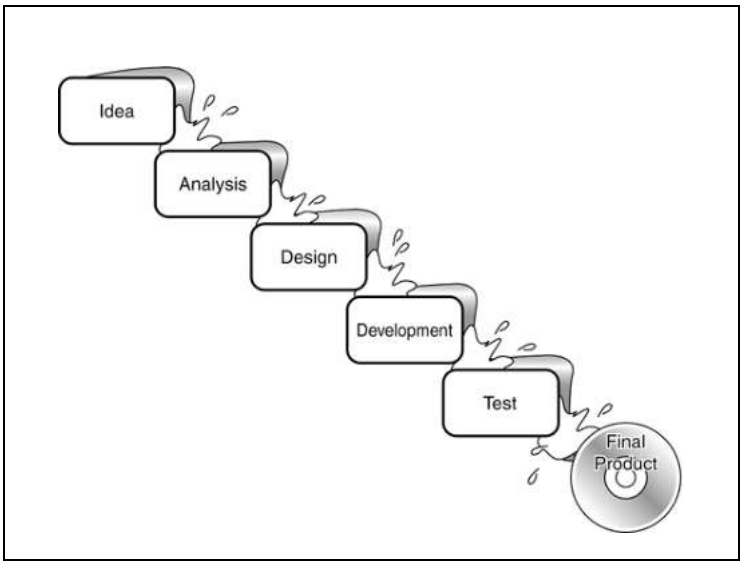

Figure1- Traditional waterfall method (Inqbation, 2013)

While this study moves forward into the use of IPD, it recognizes that this method has common features of rational linear models in planning literature: the process of realizing an issue to making logical decisions in an orderly path in a predictable and stable situation. However as Schon (1971) has argued, based on the rapid change of our society, traditional planning instruments seem to be ineffective as they are designed for situation of stability, not for cities constantly in processes of transformation. The other criticism on IPD is related to the famous discourse of uncertainty in planning issues as discussed by Christensen (1985) three decades ago. Thus, how does this new method (IPD), within its defined instruction and its inherent traditional planning structure, navigate the unpredictable urban issues? And to what extent can cities develop new innovative strategic plans since the new emerging development method is still far from being a strategic one?

In the process of analyzing a phenomenon, system or even a tool, it is crucial to clarify the point of view of the observer. The discourse mentioned above regarding the framework of IPD and its position in planning model, can be seen with another perspective, one primarily cherished by engineers, architects and project managers. Their analysis of IPD is referring to the internal framework in a way to be actually measured as a successful communicative interactive model. In project management literature, IPD would be considered as an adaptive project system[2], which helps perfectly to achieve an efficient result in terms of time and cost of projects with the minimum risks. In this manner IPD holds a strategic attitude managing the project and system, rapidly respond to changes by adopting its initial stable configurations. It is true that with this point of view, IPD is very flexible, responsible, innovative and adaptable but all of them fit within the framework of traditional planning models already proved to be ineffective as discussed in urban planning literature by the scholars mentioned above.

[2] Adaptive project system also known as adaptive resource management (ARM), is a structured, iterative process of robust decision making in the face of uncertainty, with an aim to reducing uncertainty over time via system monitoring (Holling, 1978).

According to Healey (2013), historically, the concept of the creation of strategic planning and the idea of transnational flow of planning was examined in three fields: actor-network theory, institutional versions of policy, and circulation of knowledge. This paper is using the concept of circulate the Knowledge in terms of traveling a new technology and method (IPD) into different destinations and its translation into different urban contexts. Later she mentions the best example of current urban policy modification that can found in cities like Barcelona, Freiburg and Vancouver (Healey 2010, 2013). Such concepts of circulation, especially in large-scale urban projects, raise critical questions of the adaption of the plan considering the new urban context.

## 3. Plan to Implementation: Long Adventure

As mentioned earlier, our cities are becoming more complex and the process of making a meaningful place is neither to build the single artefact nor to use strategic spatial planning, which merely makes it possible to follow if it is not under conditions of complete information as Lindblom (1959) emphasizes on it. Moreover, having a really well written and great plan doesn t guarante chance of success of the plan on the ground (Pressman & Wildavsky, 1973). Indeed, the process of implementing is the significant stage of a project and certainly lots of external actors are involved in the process of the built environment (Werner, 2004). Pressman and Wildavsky (1973) express that even if each step in the implementation of a policy seems like a fixed-task of series, certain to succeed, it can be almost certain to fail as well. According to Albert Hirschman s essay (1975), The Principle o the Hiding hand, the ignorance of future obstacles pushed society to innovate and overcome the obstacles. Through his study based on number of development projects financed by World Bank, he describes how the hiding hand would lead us to unforeseen opportunities. Once setting problems and creating plans, we engage in problem solving by creating the issues that haven t happened yet and we try to solve them through some expectations. Eventually we provide some actors to help navigate and move forward to implement the project. Even so, Hirschman emphasizes that in the process of implementation, unexpected difficulties can rise up and all the targeted calculations and expectations can fail. This stage is considered as a critical moment in Hirshman s discourse and in this stage he believes that success clearly requires creativity (Hirshman, 1975).

In the discourse of planning policy, Presmann and Wildavsky s point on policy implementation describes how the best of intentions, and even great methods and plans, fall apart when it is time to implement them on the ground (Presmann & Wildavsky, 1973). Implementation of the planning policy has always been a critical concern for scholars as well as practitioners. Of course the process of implementation is varied and dependent on the strategic planning of the city and the actors involved in the creation of plan. This process of finalizing the plan on the ground is becoming more complex when our attention shifts to large-scale development projects with the involvement of multi-actors. This complexity of implementation could turn into disasters once we simplify the projects (Hall, 1982), particularly by applying some tools and methods such as IPD. These sort of fixed - technical approaches ignore the hiding hands principles of Hirshman as well as the intell and the partisan mutual adjustment concept of Lindblom (1965). And of course the result will be those examples that Peter Hall in 1982 mentions on to uncertainty, an unavoidable feature of urban planning. In addition, often the time it happens in planning policy, the implementation part moves into more symbolic and conceptual phase rather than practicable and feasible, especially in large development projects as according to Flyvbjerg discussing in his recent overview of megaprojects (Flyvbjerg, 2014). Based on this Danish economic geographer, Flyvbjerg, most of the time the misinformation and mis-providing of data about large development project is on purpose and city governments use this technique to promote their visibility world-widely to become the winner of an urban global war of branding and commerciality (Flyvbjerg et al, 2009). How far IPD as a mainstream approach can help cities to be seen as modern and global city is a question in need of investigation.

## 4. Integrated Project Delivery: The Mainstream Approach

The Integrated Project Delivery (IPD) is one of the most recent popular project delivery methods among architects, contractors, and engineers as well as many international masterplanners (GIC). In this method, the client, the architect and the main construction contractor all sign one contract. This contract ensures that all parties share the risks and awards of the project. In comparison to other project delivery methods such as the design-bid-build, design-build, or construction management at risk, IPD is considered the best model to maximize the collaboration between the primary parties: owner, designer, and builder ensure of delivered the project to the client on time, within cost (Ashcraft, 2014). The IPD term is common in the U.S. since it was developed in the 90 s and trademarked in 2000 by the American Institute of Architects (AIA) (AIA, 2014). Recently, other countries around the world extensively use this type of collaborative project arrangements under other terms such as project partnering in the UK and project alliancing in Australia (Lahdenperä, 2012).

To understand the main aim of this research, a clear definition of such collaborative project delivery and the relevant tools must be given. It is important to mention that the main intention of this research is not to question the technical aspects and efficiency of IPD; instead the research goes one step further and explores the idea of traveling and implementing this method in different urban context. IPD as a conceptual framework for project delivery is distinguished via its standard tool known as BIM (Building Information Modeling). BIM by itself is a process of creating and using digital models for design, construction and the implementation of projects principally under the umbrella of IPD (Hill, 2009). In this paper, to avoid exerting the technical term of BIM and misleading the analysis, the author uses the key word of IPD for the rest of the project with the knowledge that in some projects BIM can be defined slightly different from IPD; however the concept of both used in this paper is slightly the same. According to the current IPD literature, this method seems very efficient in terms of providing highest collaboration between its parties, transparency during the process and sharing the risk and award of final output. As mentioned earlier, IPD is promoted and commercialized as one of the suitable method for large-scale urban projects. Significantly the use of this method is increasing among GIC as well as multinational architectural firms who are moving from designing buildings to designing decisions (Pou, 2012).

We are entering a world which problems are visualized... visualizing virtual model such BIM (IPD) enables improved decision-making and being more aware of the scope of a problem (Pou, 163). This quote is from architect Eduard Pou who believes that designing strategy is a priority step for architecture activity. In his quote, he emphasizes and applauds the ease of using BIM (IPD) and the efficiency of this model that eventually ends up developing a powerful marketing strategy and improves the brand of the architect in selling his services for the highest price. Pou is not the only one who describes IPD as the best solution for coping with complexity in large projects. A general observation shows that in different disciplines, from the business management to construction engineering, BIM is one the successful process in delivering a project. Currently in the urban planning realm, mainly architects, construction engineers and real estate developers use this method as a way to facilitate the development process and get the maximum financial benefit of their projects. Therefore it is important to know the answer of how far IPD considers the final urban context? One might answer that the practice of IPD is not meant to consider the urban scale.

### 4.1 Operationalization and implementation of IPD

IPD looks at the planning process is an operationalized way with its own operational definition[3]. This means that since the process of defining a fuzzy concept is not directly measurable it is therefore through other indicators that IPD can define the existence of problems and move forward to solve them. In some theories this concept might works well, for example in the engineering discipline where the process of defining the complexity usually is a procedure agreed upon for translation of a concept into measurement (Deming, 2000). However, in urban planning processes and large development projects, as discussed earlier, nothing is 100% secure, particularly in the implementation process which is commonly a latent procedure. By using the IPD method for the phenomenon of large-scale project, we transfer the process of implementation to an operationalized system. The system requires some familiar indicators to outline the issue. This point can be the inflection point of the IPD process; the way it continues and operates. If we assume that these familiar indicators are related directly to the final urban context and include the local knowledge in the calculation, the next step of IPD might work well and the final result is acceptable for larger systems (the city). But it seems IPD operates in the contrary way; from the stage of defining the indicators to delivery of the project, the indicators are not very relevant to the final develop place, because those indicators are already set and fixed from the first phase of the plan, which may have been developed somewhere else. In the case of Masdar city, this issue is more recognizable in the sense of implementation of the project with insufficient primary local knowledge.

The importance of this study for IPD in the planning discipline is tangible practically after the recent announcement of several nations such as the UK, UAE and Singapore making IPD (BIM) method compulsory for all government projects (Arabianindustry, 2014.). Among these nations, some go even further and mention the advantage of BIM in their strategic plan such as the UK Government Construction Strategy in 2011, which announced the government s intention to require collaborative 3D BIM on its projects by 2016. The key object for this movement is reducing capital cost and capital burden from the construction and operation of the built environment by 20% (BIM Task Group, 2015). It can be true that BIM may be a successful approach in business and management sectors, but we should also consider that by simplifying the complexity of large development projects, they can turn into disasters from a planning perspective as Peter Hall argues in *Great planning disasters* (Hall, 1982).

## 5. Large-scale Development Projects: Urban Growth Machine

Large-scale development projects can be defined in various ways depending on their scales, costs, and functions and so on. But there is a common slogan for most of them as Flyvbjerg (2003) emphasizes: over time, over budget, over and over again . A political-economic explanation of this sl according to Flyvbjerg.et al (2009) is the strategic misrepresentation, basically lying and deception in implementation from the starting point of the development of plan. This misconduct can be applied to the use (or misuse) of new tools and technologies such as IPD. In this paper the concept of growth machine from Molotch (1976) applies to describe the importance of large development projects in city. The main discussion on Molotch s urban growth machine is situated on the the commodification of place, where the place is understood to be socially and economically valued land (Rodgers, 2009).According to Molotch, in order to grow the urban machine, collaboration of actors and organizations at the local scale is crucial. However, in large-scale projects the roles of local actors are usually limited. This little involvement is more noticeable when IPD as a new project delivery

[3] Operational definition is the process of defining a fuzzy concept or measurement of a phenomenon that is not directly measurable (Bridgman, 1927).

model with defined stakeholders enters into the equation. Paradoxically, it means the engine of the city growth machine by using IPD method in the large projects doesn t work well from the starting point. Furthermore, Logan and Moloch (1987) look at the place as a concept, which becomes a commodity in future development where the emphasis on place is not just a basis for carrying on life but an object to derive wealth from. This raises the question: are large-scale urban projects considered meaningful places or just a tool to attract visitors to enter an exhibition rather than to live in a real place?

It is true that the level of megaprojects is completely different from conventional and smaller projects due to their level of aspirations, complexity and stakeholder involvements. Hirschman (1995) calls them trait making, meaning that ambitiously they have the power to change the structure of society. Besides their complexities and admirations, megaprojects or large infrastructure projects are highly costly area of business and government. Of course the downturn from 2008 has helped the megaproject business grow further (Flyvbjerg et al, 2009). According to the economist magazine in 2008, infrastructure spending for large development project was the largest it has ever been as a share of world GDP (Economist, 2008) and still after seven years it is considered as the biggest investment boom in history. Typically the cost is declared in the proposal plan and increases dramatically through the implementation process and most performance promises are modified in the process of project delivery. Flyvjerg believes that the majority of projects are started by the misinformation about costs and risks and often the final cost of the projects become at least doubled.

Cost overrun is also very common in large infrastructure projects. For example, according to Flyvjerg s study of 20 countries, nine out of ten projects had cost overruns. He emphasizes that to solve the appropriate slogan of large development project over budget, over tim again we need to minimize the gap between expectations and performance for project such a large share of the private and especially public purse (Flyvjerg et al, 2009). As discussed earlier in architecture and project monument literature, IPD is consider as a method with maximum efficiency during the process and transparency between actors, and in some cases extends to solve cost overruns and over time. In the sense of narrowing the gap between planning expectations and implementing the projects, IPD still has a long path to achieve this aim. The case of Masdar City in Abu Dhabi is a good example for this dispute.

## 6. The case of Abu Dhabi: Vision 2030 and Masdar city

Abu Dhabi is the federal capital of the United Arab Emirates (UAE) as well as the capital of Abu Dhabi emirate, the largest emirate among the other seven which form the UAE. The city is the house of federal government offices, president of the UAE who is the ruler of Abu Dhabi and member of the Abu Dhabi Emiri family (Ponzini, 2011). Abu Dhabi is also the home of important financial center such as central bank of UAE, corporate headquarters of many companies including numerous multinational corporations. Due to its discovery of oil in 1960, the city has experienced significant urban transformation from a small fishing and pearling village to a city (Elsheshtawy, 2008).Recently Abu Dhabi tries to create a diversified, globally-integrated and knowledge-based economy. In 2008, the new generation of ruler, Sheik Khalifa who has strong tendency towards western approaches decreed to create a long-term vison plan for the city of Abu Dhabi for economic progress through the establishment a common framework. With this ambition the city of Abu Dhabi developed the vision 2030 including two different documents provided by two separate government organizations with one person as the leader, Crown Price of Abu Dhabi. The first organization is the Abu Dhabi Council for Economic Development (ADCED) formulated the economic vision 2030 and one year later in 2007, the second organization; Abu Dhabi Urban Planning Council (UPC) provided the plan vison 2030. The main framework of these two visions was based on a sustainable economy (ADCED, 2008).

Due to the monocracy government system of Abu Dhabi, the prince crown of Abu Dhabi, Sheik Mohamed, served as the chairman of both organizations. In this context it might also not be a big deal to see that all urban development projects in Emirates need to be approved by the government and Executive Council over the direct mandate of Sheikh Mohamead. This means that basically any proposed master plans require the approval of its creator (Figure 2). One important observation of the Abu Dhabi plan vision 2030 is the conceptual characteristic and abstract framework of the plans, which can be modified and re-defined at any time. Reading the maps legends provided in the plan clarifies this concept of abstractions and ambiguity.

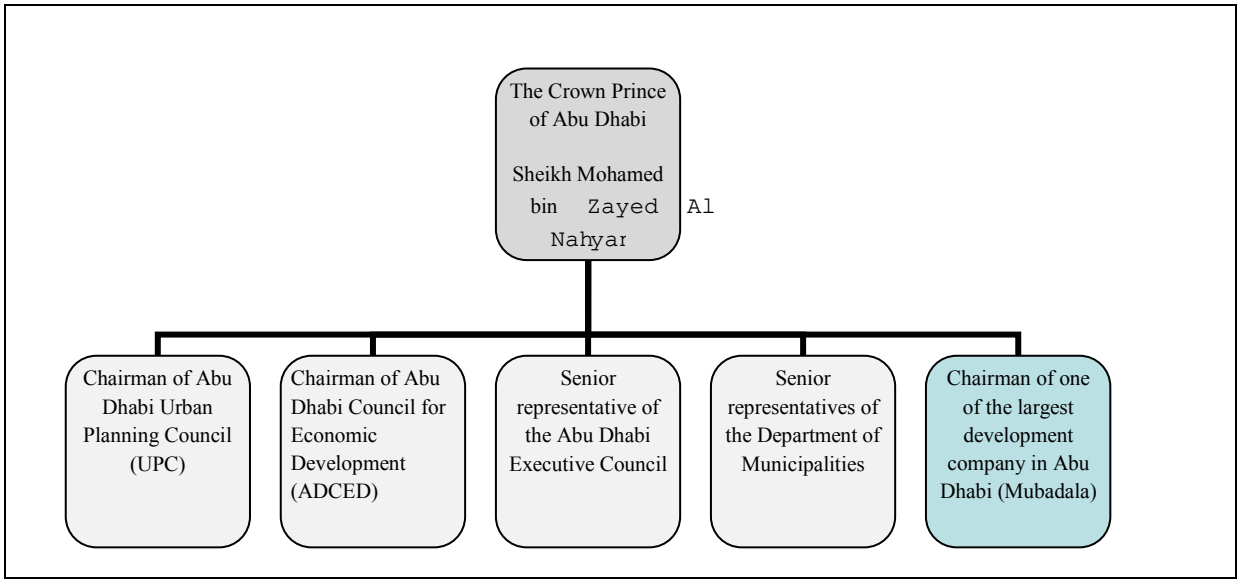

Figure 2: The table shows the power in planning system of Abu Dhabi is in the hand of one person, the Crown Prince of Abu Dhabi. All urban development projects in Abu Dhabi need to be approved by government over the direct mandate of Sheik Mohamed, the Crown Prince of Abu Dhabi.

It might also be notable to mention that the chairman of one the most dominated development company in Abu Dhabi, Mubadala, that works on many large urban infrastructure projects, is the same chairman as ADCED, UPC and Executive Council (Mubadala, 2015). As a result, the actors in decision-making process are limited and the distance of relevant actors from plan to implementation is very short. In environmental policy, Walker (1988) and Barry (1999) might look at this authoritarian manner as a more efficient one to tackle environmental problem rather than an obstacle. Also the 40 year history of monocratic regime in Abu Dhabi shields this oligarchic system within its top-down approach in planning. However, the result of planning shows that the idea of circulating knowledge, translating and modifying the policy based on the urban context do not apply in non-democratic societies such as the UAE. Moreover, the use of the new innovative project delivery model, which originally promoted transparency and sharing of knowledge among its stakeholder (even the fixed actors), is no longer applicable due to the small circle of decision makers.

The main issue arises when a project in this system introduces itself as the number one approach in the world and other cities start following its structure for future urban development. The case of Masdar City, master-planned by the British architecture firm Foster and Partners (Economist, 2012) and subsidiary of Mubadala, is a proper example of this argument. The case of Masdar City is selected primary because of its self-description as a model for what can be achieved in other cou (Nader, 2009), and secondly because of dealing extremely with IPD (BIM) in their ongoing constructions. In both economic and planning terms, the 2030 vision Masdar City is introduced as the

world s first zero-carbon, zero-waste and car-free city with the slogan One day all cities will be built like this (ADEFC, 2010). On the other side, the Abu Dhabi economic vison 2030 introduces the Mubadala Development Company as the main source to provide sustainable financial return (Mubadala, 2015). This company was established in 2002 by the government of Abu Dhabi as a public joint stock company. According to the Mubadala website the company s main mission is to stre Abu Dhabi s economic growth by investing in sustainable profit over the long term plan and act as a catalyst in diversification of the economy. In order to achieve this vision, Mubadala invests enormously in large infrastructure developments including urban projects in cooperation with world-class architectural and construction international firms. One of the active sectors of Mubadala is Masdar, also known as the Abu Dhabi Future Energy Company (ADFEC). Masdar (ADEFC) was established in 2006 as a way to develop and commercialize renewable energy solutions and clean technology in Abu Dhabi and around the world. ADEFC initiated Masdar City as one the worldwide sustainable projects that will host the headquarters of the International Renewable Energy Agency (IRENA). Looking at the plan 2030 vision discloses that the use of IPD (BIM) to visualize the masterplan of Masdar City was very successful in terms of branding and promoting the city globally. Regardless of all these promotions and advertising of the city, Masdar City is carrying out several issues relate to the implementation of projects.

Masdar City project was initiated in 2006, with a US $18-22 billion estimated cost and the city was planned to be constructed over seven phases and to be completed by 2016. This initial plan was calculated by an integrated project delivery method and applied BIM for the final 3D visualization. Over two years of starting the project only six buildings of the city were completed and occupied in 2010. The plan is already very behind on its schedule due to several unexpected and unplanned issues. The first phase supposed to be done in 2009, due to the global financial crises, was postponed until 2015 with final completion scheduled to occur between 2020 and 2035 (Khaleej times, 2010). From the initial master plan, the project has been altered in several ways, which is not very surprising from a planning perspective and literature. However, these changes massively affect the projects from the time of completion to the cost. Due to the environmental miscalculation and miss-conception, the construction of solar panels will be less effective than anticipated because of ignoring the impact of local dust storms (Crot, 2013). As a result, the main slogan of Masdar City is changed from zero carbon to low carbon and the promise of becoming the number one project in energy saving and production is no longer secure. The estimated cost also has declined due to the changing plan of not implementing solar panels on the site. Additionally, the initial design was to reach 100% sustainability and to become an eco-city by banning automobiles, but this initiative has been modified due to the overall cost and also neglecting the culture and social background in the sense of driving personal car. The issues mentioned above are just a couple of visible planning problems affected by using a complete planning method for creating cities. As discussed in implementation policy literature, there is no plan that can be implemented with 100% unpredictability and uncertainty in the process.

## 7. Conclusion

Success in large-scale urban development is typically defined as projects that are delivered within budget, on time, and with the promised benefits. To reach this level of success, the IPD method is considered the proper choice among architects, engineers, and project managers. However success can be defined in different ways and it totally depends on the actors and scale of projects. We should accept that by increasing the megaprojects the need of model delivery projects that consider managing time, cost, and benefit are increased. IPD may be a useful approach for overcoming the shortages of large projects, yet it needs to go one step further beyond efficiency and become more flexible for dealing with uncertainties. This research tried to open a new way of looking at the IPD method, from the perspective of implementation policy rather than just a technical and managerial vision. Primarily the well-defined actors and structure delivery method of the plan is oversimplified to be operational in

different contexts. This simplification of operational system doesn t share any space for local knowledge and eventually this causes the future issues in urban projects.

Until now, the idea and technology behind IPD (BIM) was able to travel from the U.S. to all around the world, but the question of its translation into different physical, social, economic and political context is yet to be answered. A city like Abu Dhabi with an absolute monocracy government system with a desert ecology needs to apply IPD in a different approach from that of California or London. Of course the decision-making process varies based on the nation and on the strategic planning of the cities; however, the planning issues occur when this project delivery method is considered as the one that is the best method to build the environment (AIA, 2014) and becomes one of the main players of the transformation of contemporary cities through large-scale development projects. According to Rapoport (2014), Masdar City project in Abu Dhabi may attract significant attention and inviting visitors, but it also may not be considered as a replicable project. The result of this project will obviously be a product of a particular set of conditions such as a large source of oil and continued economic growth. Such project as Masdar City risk becoming model towns, exhibits rather than real places (Rapopor, 2014; Keeton, 2011)

Finally, collaborative project delivery such as IPD raises radical questions of democracy in the transformation of contemporary cities through large-scale development projects and the responsibility of planners risks being limited to the mere technical aspects taken care of by architects or engineers. The domination of GIC, as the big clients of this method, also needs to be considered due to their large influence on shaping cities globally. Furthermore, in the use of IPD, not only is having knowledge of the government system of the city crucial, it is essential for there to also be a thorough assessment of the local urban, economic and political context. The extreme case of strategic planning and implementation of IPD in Masdar city in Abu Dhabi reveals this deficiency of IPD. In conclusion, the author wants to finish this paper by proposing a final question: while governments start to mandate the use of BIM (IPD) as a common standardized method for large scale projects, how do the final projects include local variables related to the urban, political, economic and social context as well as the knowledge of non-involved actors? This question requires further research in both urban planning and urban science disciplines to fill the gap between longstanding literatures from urban theory to urban practice.

**NEW WATER CULTURE UNDER FUZZINESS: using complexity to reframe water policy debates**

Ing. Martina Lazarova[1], Ing. arch. Daniela Gazova[2], PhD.

The paper focuses on the idea that the language of current urban water management is full of fussiness what address different forms of uncertainty within the city territory. Therefore the importance of water governance and its cultural adaptation has become a major issue of discussion. At the same time, concerns have been raised that traditional water culture is wrongly adapted to challenges associated with climate change, population growth, ecological and social imbalances. Integrated water management represents fully complex approach to governance in functionally specified field of ecosystem planning policy. The aim of the paper is to examine calling for new water ethics and its new culture of managing. In addition, the paper contributes to the debates about co-designing with nature and reviving success of old traditions. Indeed, management in the sense of new water culture requires knowledge of the system in its full complexity. While time lasts there will always be a struggle around water, but as Jerome Delli Priscoli (1998) states water is far more humanity's learning ground for building communities. In fact, the social learning and collective knowledge of the system are recognized as crucial step for water management. Therefore, partnerships through water sharing plans can be seen as a way to increase water resilience to such events as droughts and floods. The paper·s findings are supported by theoretical arguments and practical experiences from the project: Redevelopment of residential neighborhood ilina-HÆjik, which potential is in the way how to sha specific area of urban fringe.

Keywords: water resilience, cultural diversity, social learning

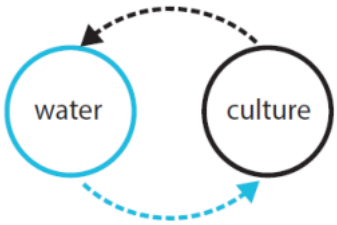
## 1. INTRODUCTION



Picture 1 Water shapes culture and culture shapes water
Resource: Author

Historically nobody has doubt about the importance of water as essential lifeblood for every civilization. Most settlements were founded to take advantage of and to be in harmony with the water element. Some of these were even built on water, whether in the river, lake or in the sea. Water has become crucial for the flourishing of cultures, and vice- versa (Figure 1). On the one hand, water has always had cultural significance. The first societies were irrigation-based cultures with ingenious water management structures as for example China, India, Mesopotamia or ancient Rome. It is therefore not surprising that water carries humanity s collective memory of management practice. A key challe for water resilience is therefore to reclaim the proven solutions of the past, though another context, to present day. And according to Cabreba et. al (2010) this is not an easy task. On the other hand, through-out history, a cultural stewardship relation towards water was crucial for the sustainability of the water resources. Especially in the urban context this becomes even more obvious, as the higher urbanization puts higher pressure on local water resources. (Nilsson, 2006) Within this view culture shapes both conflict and consensus in understanding, valuing, using, and managing water. In summary, it is our values, faiths, and ethic that ultimately drive our management solutions (Priscsoti, 2012).

The research focuses on the idea that the language of current urban water management is full of fussiness what address different forms of uncertainties within the city territory ( Pahl-Wostl, 2002, Pearson et at., 2010, Brown et al., 2001). Therefore the importance of water resilience and its cultural adaptation has become a major issue of discussion. Until just a few decades ago, the changes of water culture have caused a number of problems. Nowadays, concerns have been raised that traditional water management is wrongly adapted to challenges associated with climate change, population growth, ecological and social imbalances. Much of the call to action has been, understandably, dominated by fear and pessimism: for example, fear of destroying the ecology or fear of social conflicts. (Priscoli, 1999, Pahl-Wostl, 2002, Pearson et at., 2010, Brown et al., 2011) The core concepts utilized in this paper draw upon the traditional knowledge, stewardship and time-tested management solutions, which can help to meet the complex needs of a changing environment. The aspiration for change has been tagged in variety of way, but in this paper is referred to the concept of water resilience . The motivated by the core research question: **How can cultural diversity and social learning contribute to future urban water resilience?**

Although extensive academic research has explored the shifting from posting simple system to using more complex frameworks to understand the diversity of water resilience·s puz Falkenmark, M. Allan, M., Folke, C. Gordon, L. J gerskog, A. Kummu, M., 2014 (Folke S.R. Walker, B. Scheffer, M. Chapin, T. Rockstr m, J., 2010), a little attention has been attribute of cultural diversity and social learning in the concept of water resilience (Cabrera, 2010).

## 2. LITERATURE REVIEW: WATER RESILIENCE

According to United Nations predictions, by 2025, 1.8 billion people will be living in countries or regions with absolute water scarcity, and two-thirds of the world's population could be living under water stressed conditions (Arup, 2011). It is because, in many cities all over the world, current water is poorly managed and water policies are simple unsustainable. Great historian Edward Gibon, while walking around Rome·s ruins, wondered how such an impressive culture had fallen can be found in his statement that what does not evolve, is decadent. For this reason the challenge that the present-day society has to face is to match up to its ancestors: to give the adequate response to the moment in which that society is living (Cabrera, 2010).

Despite the recent hype in the literature around resilience, agreement on key aspects of the concept of water resilience is still missing. Resilience in general has been variously defined and its conceptualization in recent years has been called fuzzy and contested . It shares similarities with sustainable development in that it is frequently used as an umbrella concept to describe a broad array of in terrelated issues (Dovers, Handmer, 1996). The concept of general resilience has occurred in modern times primarily through the work of Canadian ecologist C.S. Holling in1973, who defined resilience as persistence of a system through change. Since then, the term started to run through almost all the disciplines and languages concerning individuals and institutions, as well as cities and territories. Its multidisciplinary and its adaptability within dynamic systems and complexity theories make the concept more and more attractive (Garschagen, 2011). Now, over 40 years later, the CMAs (Catchment Management Authorities, 2012) sustains that resilience consists of two related aspects;

- **general resilience** - the resilience of the system as a whole to any and all kinds of disturbances.
- **specified resilience** - the resilience of what, to what , which calls for ide particular limits in the system, beyond which it begins to function in a different kind of way, impacting on the quality of ecosystem services (Catchment Management Authorities, 2012)

**water resilience** - sets an ambitious goal by tackling the world s ke in the spotlight of global change

school of water landscape

school of water engineering

According to CMA, we distinguish between general and specific resilience in relation to water management, because this provides an important conceptual differences in our understanding. The general resilience is defined as resilience of an entire system to all kind of shocks. On the other hand, specific resilience is described as the ability of a particular part of the system related to specific control variable, to cope with disturbances. Specific resilience is possible to quantify and analytical explore, while general resilience is more complex and often impossible to measure analytically. Following Rockstr m et. al (2014), water play a fundamental role in supporting both specific and general resilience. Therefore, in order to usefully define resilience of water sector it is necessary to look at its origins and the current academic uses of the term **water resilience .** The foundation for this research was to compare the perspective of water landscape with perspective of water engineering, and to find out general definition for their possible interrelationships in the context of spatial planning.

## 2.1 A BRIEF HISTORICAL PERSPECTIVE OF WATER RESILIENCE

In the recent years, researchers have developed the concept of water resilience; however, it is not fully new. For the purpose of this paper we have reviewed some of the past literature, in order to determine the evolution of water resilience-based concept and simultaneously to outline new perspective of the concept based on cultural diversity (Figure 3). The historical roots of the concept reached the early 1990s. Before this period the management focus were on blue water as fully fragmented and sectorial approach to water resources that has led to poor services and unsustainable resource use (Bartone et al., 1994, GWP, 2010). After that, in response to the deepening understanding of water s fundamental roles in the life-support systems of our planet, water resource thinking has broadened from blue water only to integrated blue-green approach (also known as green water concept) (Fiorino, 2001). Put another way, as Scheffer et al., (2001) stated in his definition, the ecosystem processes modify the hydrological cycle and the hydrological cycle affect ecosystem processes. These mutual interactions affect the ability to buffer stress and shocks. Both traditional concepts were followed by a more systems-oriented approach of integrated land and water resources management in the early 2000s. During that time the attention was focused on the new situation, in which abrupt, large-scale changes in the hydrological cycles can no longer be overlooked (Rockstrom et al. 2014). However, over the last 15 years, the definition of water resilience appeared and evolved. The core of mainstream thinking has become the idea that water resilience refers to the ability to deal with change while continuing to develop (Folke et al., 2010).

Synthesizing the evolution of the water resilience-based concept, the need for a new focus on water management has recently been recognized by science community (Montanari, 2013; Cabrera, 2010). This implies a deeper insight into fundamental role played by culture in water management practice. Drawing on the huge uncertainties concerning the water hazard, it is needed to build on local knowledge,

historical experience and cultural diversity. Therefore, this study brings together a set of unsettled water-culture related challenges.

## 2.2 THE MEANING OF WATER RESILIENCE

Although the idea of water resilience is a bit messy in and by itself, in this paper two conflicting schools offer explanations of water resilience. Even Canadian theoretical ecologist, C.S. Holling (1973), who firstly developed the general concept of resilience, made a distinction between engineering and ecological resilience. On the one hand, **water engineering school** defines resilience as the ability to return to an equilibrium or steady-state after disturbances. The effectiveness of a resilient infrastructure then depends upon its ability to predict, absorb, adapt to, and rapidly recover from a potentially disruptive event such as droughts and floods (Holling, 1986, Wallace et al. 2010). In light of this definition, water resilience is mostly about delivering services regardless of disruptive events that may occur the ability to take a licking and keep on ticking (to quote the old Time resilience is mostly defined according to how long it takes for the system to recover after a shock. The emphasis is on return time, efficiency, constancy and predictability , all o qualities for a fail-safe engineering design (Holling, 1996, p. 31). Despite, this understanding is rooted in most of current water management practices.

At the other hand, the second **school of water landscape** considers water system as more than the sum of their engineered parts. They can be described as socio-ecological systems, as they require complex interactions between human, technological and environmental components. In this perspective, ecological resilience is more complex and has very broad implications (Folke et al. 2010). School of water landscape defined water resilience as the magnitude of the disturbance that can be absorbed before the system changes its structure (Holling, 1996). Therefore, it is focused on the ability to persist and the ability to adapt within critical thresholds (Adger, 2003, p. 1). The main difference between these two schools is that ecological resilience rejects the existence of a stable equilibrium and requires a mind shift in water thinking (Rockstrom et al., 2014).

To sum up, the literature review indicates that the water resilience is another intuitively appealing buzzword. However, it is worth questioning whether water resilience has simpl of intuitively appealing yet unclear concepts (such as resilience and sustainability). It s certainly no easy to define, or specify what a resilient water system might look like. Following Folke et al. (2010) and Rockstrom et al. (2014) for the purpose of this research water resilience is defined as, the complex, multi-dimensional system that is not at equilibrium. It periodically or constantly changes and adjusts. The key is to shift away from yesterday s focus on how to reduce environmenta activities, towards reconnecting economic, ecological, social as well as cultural attributes. Simply put, the research is motivated by question: Are two different approaches of water landscape and water engineering mutually exclusive? The paper considers them to be complementary and both useful at different territories and different scales.

## 3. CORE CONSTRUCT: LINKING WATER RESILIENCE WITH CULTURAL DIVERSITY

In keeping with the intent to promote both, cultural diversity and water management, this paper offers an array of ideas to understand mainly the cultural implications for growing water resilience. Therefore, the foundation for the research was the extant (Jonson, 2012, Donahue, Johnston. 1998) literature on the relationship between water and culture. Therefore the paper points out, that water resilience is shaped by the cultural perspective and historically embedded urban water values, expressed through institutional arrangements, regulatory frameworks, and physically represented through water systems infrastructure. The focus is made on the question: How to transform cities through reviving time tested solutions in urban water management, urban design, and governance.

A classical overview of **theories of culture** was provided by Keesing (1974). He distinguishes between culture as an ideational system and culture as an integrated adaptive socio-cultural system (most classical anthropological theories and schools). In the first case, culture is ultimately in the head of a collective mind and it only refers to perceptions, beliefs, norms and values. Culture in this sense can be used to explain social practices. Culture as an integrated system integrates the social practices in the concept. It emphasizes the interrelation between ideas and practices. Cultural diversity, as recognized by UNESCO (2009) is crucial to environmental sustainability; it generates the multiple human

possibilities necessary for generating sustainable adaptations in a changing world . It is with understanding in mind that human history and the evolution of culturally diverse understandings of life reflect in many ways our interactions with, need for, and use of water. Because culture is learned, lived, and expressed in broader social relationships, it is a significant dimension that shapes water resilience. This paper involves not only managing flows to sustain ecological processes, but also ensuring that the water flows are sufficient to recognize and sustain cultural ways of life.

Some of water management solutions have only been developed recently, whilst others have a considerable history behind them. While there is no one model, or concept that will be universally applicable and effective in every circumstance, there are certain universal conclusions that can be recognized (Johnson,2012, Gleick, 2006). Here, these are briefly outlined:

1) The increasing vulnerability of water resources calls for **holistic strategies** and **diverse approaches** to water management to be recognized and supported.
2) **Indigenous and local communities** are invaluable partners in this regard, representing a vast array of adaptive knowledge and practices which have not only sustained engagements with water for millennia, but also offer much potential for creativity and innovation.
3) Local water practices **do not exist in a vacuum**. A key challenge for water resilience is therefore to reclaim the proven solutions of the past, though another context, to present day.
4) Water issues must be tackled at **various levels**. Water governance therefore requires a dance between levels . When water resources are brought under centralized, bureaucratic control, the resilience of local forms of governance is often diminished. Therefore, soft path complements the twentieth-century s large-scale, centralized infrastructure with lower cost systems, decentralized and open decision-making
5) **Social learning** and **collective knowledge** of the system are recognized as crucial step for resilient water management. Collaborative practices aim at developing a shared construction of reality through the understanding of local contexts.

To conclude, trough time, societies have developed different technologies, practices, and institutions for managing water, what brought enormous benefits to humankind. But they have also failed to solve some of our most water problems, and in key ways they are unsuited to our new challenges. This paper brings to the fore the increasing scientific evidence for a rapidly changing global water agenda, shifting from a general focus on water management under assumptions of stability and predictability, to a focus on water resilience in a world of instability and surprise (Rockstr m et al., 2014). The core cor utilized in this paper draws upon water resilience and importance of cultural values and traditional management solutions in it. The next section of the paper discusses in more detail also the role of social learning.

## 3.2 LINKING WATER RESILIENCE WITH SOCIAL LEARNING

In recent years the engineering paradigm dominated by technical end-of-pipe solutions, has been replaced by a paradigm based on the notion of living with water (school of water landscape) approach the limits of control and the importance of uncertainties are clearly acknowledged. Acceptable risks and decisions are negotiated. This cultural framing supports integrated solutions and the implementation of multi-functional landscape with an increased adaptive capacity of the system. New paradigm argues for an integrated approach however, most international regimes are focused on single issues such as flood protection. The clearly perceived need to adapt to climate change requires a whole range of measures to be implemented. The processes by which adaptations to be judged at different scales will involve new and challenging institutional processes (e.g. Adger et al., 2005). Moreover, water transboundary cooperation demands improving processes of **social learning** to integrate distinct cultural frameworks that agents at different locations use to deal with their issues at stake. As Pahl- Wost (2007) states, within governance perspective, social learning is an essential element of policy development and implementation. It refers to both the learning process and to its outcome. The e moving from the need to simply know more and placing even more information to policy and ex circles to developing adaptive cross-sectoral strategies and new types of knowledge to respond adequately the changing dynamics of current world. The problem that we face when we deal with resilience lies not so much in our lack of understanding of the functioning of ecological systems, but in our lack of understanding of the governance and cultural systems and how they are structured and managed and interact with ecological systems, and how we produce science and knowledge for policy. Following Mostert ·s (2005), new institutional arrangements are needed to structure the more sustainable framework for collaborative water governance in transboundary water management (Figure 5). Therefore, the problem lies in developing new identities, as well as institutions and individual capacities, that are more socially and ecologically robust with the common goal of water resilience.

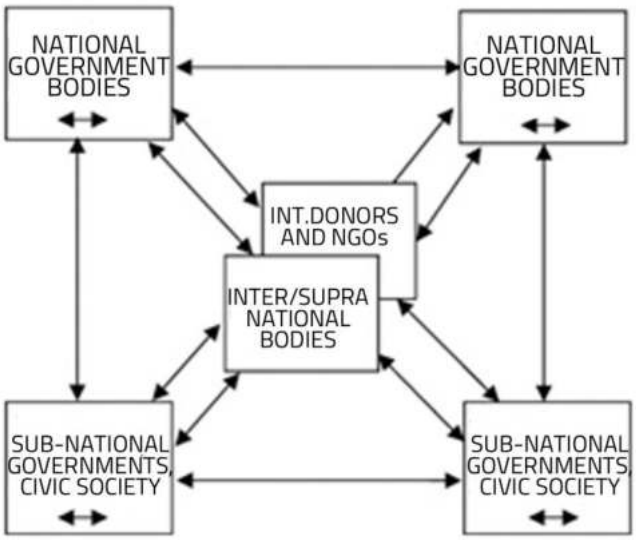

Figure 5: Organizational famework for collaborative water governance in transboundary water management.
Resource: Mostert, 2005

Mostert·s model outline the organizational framework within which social learning unfolds. It needs to take place between formal governmental authorities and stakeholder groups organized formally or

informally at different scales. Integrated water management typically requires cooperation across these sectorial boundaries:

- **National cultures** determine the nature of transboundary cooperation. They shape legislation and negotiation strategies and influence the nature of the participatory processes (Patel and Stel, 2004).
- **An individual** holds different social roles and belongs to more than one social and thus cultural group. Hence, it is possible that different cultural frames occur within individual persons and may be activated in different social contexts. They act as representatives of an interest group and represent the cultural values of these groups
- **Professional cultures** (e.g. farmers' beliefs and practices) may be more important than national cultures for some stakeholder groups and establish an identity across national scales. The influence of national cultures seems to be stronger than the influence of the technology/expert culture characterizing the community of water resource practitioners across national boundaries (Langaas and Timmerman, 2003).

## 4. SHYNTEHSIS: BUILDING WATER RESILIENCE

Based on the aforementioned theoretical discussion in literature review, the paper defines the concept of water resilience and its interrelationship with culture and social learning. The focus of the paper is to study the adaptability of water systems and to meet the new challenges in navigating ecosystem dynamics without compromising long-term sustainability. Through this chapter, we argue that:

- **H1**: Water resilience is combination of water landscape perspective and water engineering perspective
- **H2**: Water resilience is built on local knowledge and cultural diversity.
- **H3**: Social learning is a tool how to address water resilience.

Here, we outline combined nature/engineering perspective, with emphasis on cultural diversity and local knowledge. The challenge is to anticipate change and shape it for resilience in a manner that does not lead to loss of future options. It involves enhancing the capacity of social learning. In this chapter we explore the above hypotheses and present some provisional conclusions on resilient water cycles. Currently, we are living in period of constant changes. Such periods caused by disturbances or crisis are the most neglected and the least understood in conventional water management practice. This implies a shift in water management towards those institutions and organizations that can deal with nature·s dynamics in a fashion that build not only ecological or social but also cultural resilience of water resources. Otherwise, the development and well-being of human societies will become increasingly vulnerable to environmental changes.

## 5. CASE STUDY

After the literature review this section implements outlined assumptions in the model territory of southern Slovak city ilina and its residential neighborhood HÆjik. Going deeper in research on water resilience should result an understanding of the strength and limitation of resilient water system with regard to the scale in which the process take place. The model territory of HÆjik is characterized as interplay of wild natural landscape with panel housing estate. The area is widely acknowledged as holding a wealth of water resources, but on the other hand the neighborhood hides several controversies. For example the rich local diversity is continuously shift to dense urban structure

of housing estate, or hilly terrain is alternated by several lowlands. Then, local waters from underground aquifers rushes past the hills and lowlands, are infused with symbolic and cultural meanings, and after they flows into the metal pipes of modern urban infrastructure. Moreover, HÆjik is a social melting pot of native populations, mixed with other communities.

Map 1 of HÆjik, shows the location of the neighborhood within the city and the traditional drai water system, while the Map 2 introduces proposal for resilient management solution based on the combination of the water engineering mechanisms with the tools of water landscape approach. The aim of the project was to linked different type of water with leisure time activities, and most other cultural manifestations. This case demonstrates how can be designed a small-scale urban water system sustainably and how can we revive small water cycles in theory of urban fringe. To sum up, long-term ecological and economic resilience requires a multiscale institutional mechanism that acknowledges not only the biological, but also cultural diversity of the region. Effective decision-making processes that integrate local knowledge and ideas about traditional water management must be included in any development plans. Cultural difference particularly historical experience has become crucial in managing the watershed for this key shipping lane. In the best case, the new water plan will be used for social learning process of the local community.

## 6. CONCLUSION

Water is one of the most pressing development challenges of our time. Water management model built on the paradigm of engineering expertise has been dominating the water management community for decades. Such perspective requires system behavior as highly predictable. The failure to implement water resilient systems may be due less cultural-based expertise. A better understanding of cultural values and water management traditions is essential to catalyze change for integrated and adaptive water management regimes. This new approach requires knowledge of the system in its full complexity and calls for a shift to strategies that can deal with high uncertainty. The new water dynamics facing the world will require changes in governance in order to sustain and develop human wellbeing within scientifically defined resilience criteria. Water is at the heart of such a transition to global resilience as it constitutes the bloodstream of the biosphere. Therefore a planning process based on deeply uncertain predictions provides only a crude approximation of the future and is a weak basis for robust decision-making. As history has shown, this can result in problematic decisions, such as high operational costs and lock-in effects. Therefore, collaborative practices develop a shared construction of reality through the understanding of local contexts from the perspective of the involved parties in order to derive knowledge informed by context and suitable solutions. However, doing so is not easy. Paper·s contributions emphasize the role that local knowledge and underlines the physical manifestations of the water/culture relationship in the concept of water resilience. Local leadership will be vital in addressing the challenges in the decades to come. The project Redevelopment of residential neighborhood ilina-HÆjik, represents the hope for the future of urban water, which has been for ages the lifeblood for the region.

# Localization as an act of planning:
## Contextual conditions for planners' acting space

### Introduction

Localization, in the literature, has not a single, unambiguous meaning. Quite often, the act of localization is mixed with "the location" (where something is localized, the result of localization) or localization in the meaning of "making local". Moreover, these two meanings of localization (the act to localize something and the act of making local) are interrelated, especially in the discourse on sustainable development. "To make local" is quite often seen as a cure of the evils of globalization (Douthwaite 2012). This meaning of localization may also be of relevance discussing allocation of public resources in European cities, through localization as an intervention, to achieve desired changes related to socially and ecologically sustainable solutions. Davoudi & Madanipour further remind us of that "making local" is not only a different process to carry through in every new situation, but also have different and hardly foreseeable effects, depending on pre-conditions as well as the accomplishments and outcomes of the process (Davoudi & Madanipour 2015:3). Even without the responsibility of "making local", any localization is a complex affair, often with very precise aims, but quite as often with qualitatively and quantitatively different results.

Localization of public service institutions are decided on in different organizational levels; by municipal, regional, national or sometimes international authorities as well by public-private partnerships. These decisions are, together with already present location qualities, decisive for urban land use; on a macro scale shaping the map of real estate prices, thereby the distribution of the population; on a micro scale conducting urban mobility, the everyday streams of cars, public transport, bikes and pedestrians.

Public localization decisions are certainly not the only ones affecting the urban landscape; the localizations within the private sector have a great (if not major) influence on development projects, urban mobility, use of public space, social integration as well as landscape ecological issues.

The concept of localization is not 'scale proof'. We see 'location' as well as 'localization' in a wide range of discussions; in choosing the aesthetically, functionally or socially most effective location of a new cultural institution (local planning level), in pointing out cities most suitable for economic growth (regional planning level) or in companies' decisions on where to outsource manufacturing of goods (global economy level).

In critical space practice, the use and interpretations of concepts and the search for distinctions plays a crucial role. Jane Rendell distinguishes between space, place, site and location:

> "…*space* in connection to social relations, *place* as a single articulation of the spatial and *site* as a performed place. I reserve use of the term *location* to define the physical position of an art or architectural work." (Rendell 2010:20, emphasis added)

Drawing from Rendell's distinctions, 'localization' would be the act of deciding of a location; not only locations of art and architecture, but also of activities, services, businesses etc. When adding to the list of phenomena being localized it becomes endless. While it is easy to point out the grand, important, costly localizations (such as new city districts, centers for public service, sports arenas), it is hard to detect the finite demarcation lines between public and private, between corporative and personal choice, between localizations with outreaching, long lasting influence (e. g. a railway station) and small temporary localizations (e. g. parking your car on the street).

Why localization, then? Is there anything to say except for complexity, unpredictability, power play and effectual dynamism? What I am trying to do here is to scrutinize and interpret the specific gap between the *intentional concept* of localization as it is used in planning regulation documents and the *act* of localization as implementation of these regulations.

This text derives from paying respect to the intentions of steering documents for planning; with the use of the Swedish Plan- and Building act as an example; the conditions and possibilities for their implementation and fulfilment. In this particular law it is pointed at, as the foremost goal for planning, "a purposive structure and an aesthetically appealing formation of developments, green areas and routes for communication" (PBL 2010 3:2). The National Council for Planning, Building and Housing interprets this as follows:

> "The physical structure, i. e. how residential areas, working places, public services, roads, railroads and green areas *are localized, in relation to each other*, is decisive for the possibilities to accomplish a sustainable development and a good living environment for the urban inhabitants."
> (Boverket 2015, emphasis added)

It is concluded, as a point of departure, that the activity of 'localization' is worthy of scrutinizing further. It is well known that 'location' is the one criteria outstanding all others for real estate agents. But as we also know, what is a hot location today can be bad business tomorrow. The value of locations differs, which makes it the more difficult to understand 'localization'. On the one hand, it is certainly a matter of finding the right location. On the other hand, it is hard to know if this is a good location tomorrow and also in 20 years. This indicates that localization is not just to find a good location for something right now, but is also about understanding the dynamics influencing the location and its surroundings? And not less important: what effect does the location itself have, upon the surroundings?[1] Real estate agents are in favor of a single tool – the price. They do not have to be experts on any of the single factors summing up to the ideal location; the market does the job and the estate with the best price has the best location.

Planners have to reach a few steps further in understanding not only how to find good locations for all assets a municipality is supposed to afford its citizens; schools, hospitals, car parking etc.; but also,

[1] This way of reason is borrowed from Andrea Kahn (Burns & Kahn 2005) concerning 'sites'; a three-dimensional understanding of site as "the area of control", "the area of influence" and "the area of effect"; relevant since every site is becoming a location, if it is not the other way around – that the site becomes a site due to location.

according to the law, how to synthesize the *relationally* good locations into a good *assemblage* of residential areas, working places, public services, roads, railroads and green areas. This is, it is said, "decisive" in order to fulfil expectations of good living environments as well as a sustainable urban development. These are not issues to be handled at level of development plans or building permits, but in the long term strategic land use discussions (in Sweden this is usually connected to the comprehensive planning). In theory the strategic decisions are implemented in a comprehensive plan, which is in turn implemented in development plans, to assure that these are not being scattered "stamp plans", but work in accordance with a comprehensive strategy politically agreed on. Practice is more complicated, for reasons so taken for granted that they are seldom talked about. On the other hand, not taking these reasons into consideration is to admit that the plan- and building act is impossible to follow. One answer to this could be that the said plan - and building act is a "frame law"; it is expressing the values the planning and building activities are expected to follow, but on the other hand, in terms so vague that it is hard to determine whenever you have failed or succeeded. But then again – isn't it a good thing to have a law telling you to do your best as a planner, to achieve a purposive structure? Is the law a bad one because it is difficult to follow? No, not necessarily, but to have an impact, its content and values must be kept alive, by discussions, analyses and questioning. This paper is an effort in such a direction.

Another reason for scrutinizing the possibilities for planning to live up to the law's expectation, is a widely spread notion of the increasing complexity characterizing the realm of planning and building[2]. Planning theorists put light on various aspects of this complexity; analyzing e. g. effects of the increased faith in risk management (Gunn & Hiller 2014) and impressively affording increased understanding of the shifts, tensions and opportunities in planning (At the same time, our ways of experience our surroundings (through sensual sensations together with more or less conscious ways of reflections and conclusions) are the same, with the contradictory aspect of increasing mobility and an increasing disclosing from the immediate surroundings, spending more and more time "within" "virtual realities".

On the international academic scene, many planning scholars have identified, analyzed and discussed "gaps", basically referring to a wanting communication between urban development on a "planning-policy level" (by municipal authorities) and urban landscape change on a "real-life level" (the lived environment, experienced by its inhabitants). There is a vast literature dealing with a range of closely related problems; the gap between planning and practice, the gap between a socially and environmentally idealistic rhetoric and an economically pragmatic practice, the gap between optimistic participatory projects and a deficit of participatory impact, etc. (Freeman 2004, Bond& Morrison-Saunders 2011, Davoudi S 2012, Kaika & Swyngedouw 2012, Monno V & Khakee A 2012, Olowoporoku D et al 2012, Westin 2012, Bradley & Hedrén 2014, Cele S & van der Burgt D 2015).

There are difficulties with aspiring to analyze the gap(-s), trying to come to terms with possible linkages and bridges, the major ones most probable of political nature; there are more often votes to be gained through persuasive, promising messages than by messy and ambiguous descriptions of actual situations and reachable changes. Thus, there will always be present interests in keeping these gaps, as space for tactical moves of stakeholders (or authorities) without having to be questioned in the open.

[2] This statement is not further elaborated here, but derives mainly from 1) the turn from government to governance, implying stakeholder cooperation as well as citizens' participation and 2) increasing political pressure on risk management, climate mitigation, environmental safety etc. The one direction evolving with openness and flexibility, the other rather calls for a controlled development. Both point at a transition phase for urban planning; trapped between organization, regulations and routines from a social democratic paternalistic era on the one hand and on the other hand neo-liberal hegemonic politics, guiding implementations.

As citizens (or researchers) we have very rare (if any) opportunities to see, discuss or understand the silent layers of negotiations, deliberations, agreements and decisions, preceding the processes opened for democratic discussions. This could certainly be understood as contradicting both "the liberal ethos" (individual freedom) and "the invisible hand" of the market (ideally balancing between demand and supply).

Adding to these complexities, we could include in the discussions the international, national, regional and local effects of climate change. On the one hand acting rhetorically unifying ("we are all in the same boat", financial institutes using environmentalists' phrasings) the threats of unconditional economical, ecological and social change are not only encouraging risk management, but also a less co-operative general behavior, in spite of and contradictory to the general insight of the necessity of collaborations in the manifestos, policies and research literature connected to a resilient society and a sustainable urban development.

Planning regulations certainly intend to have a general appliance and significance. Insisting of investigating localization as an act of planning, could be seen as a way of starting anywhere[3], following 'planning behavior' from regulation to implementation by discussing an example; how the Swedish plan- and building law as implemented on the local level. The discussion continues in an aspiration to connect (or contrast) the language use in the text of the law with questioning (or even desiderate) descriptions of how an actual urban landscape evolves. Is the law text relevant? Does it target important actions? Is it significant?

## Planning as practice of localization – purpose and performance

According to the Swedish Plan- and Building Act (PBL 2010), it is the purpose of all plans (regional plan, comprehensive plan, development plan and 'spatial regulations'), "with respect to natural and cultural values, environmental and climatic aspects, as well as inter-municipal and regional conditions", to promote:

1) "a purposive structure and an aesthetically appealing formation of developments, green areas and routes for communication,
2) a from a social aspect good living environment, accessible and usable for all classes of population,
3) a long term good economization of land, water, energy and natural resources, and as for the rest good environmental conditions
4) good economic growth and an effective competition, and
5) building of residencies and development of the housing stock." (Swedish Parliament 2010)

This paragraph, which is the unifying steering document for urban planning in Sweden, is perfectly in tune with what is generally conceived upon as a sustainable development. It is interesting to notice the order, in which the three pillars are stated; "for social, environmental and economic concerns". Since this is the law, approved of and decided upon on highest democratic level; the Swedish Parliament; it does pinpoint what has been frequently described as 'the gap' between the rhetoric and the practice levels of sustainable urban development. Social – environmental – economic; this is the order in which planners should think, according to the law, but there are in practice few, if any, examples of anything else than the opposite order; economic – environmental – social.

When the Swedish National Council for Building and Planning (Boverket) explains the law, on their website, it says:

[3] This is to follow the example of Jean Hillier, inspired by Deleuze & Guattari, "starting in the middle" (Hillier 2007)

> ”The physical structure, i. e. how residential areas, working places, public services, roads, railroads and green areas *are localized, in relation to each other*, is decisive for the possibilities to accomplish a sustainable development and a good living environment for the urban inhabitants. If walking or biking to work, to school or for shopping is inviting, safe and within reasonable distance; this promotes both health and environment. An effective public transport can be facilitated by conscious localization of new housing development. Parks, recreational areas and meeting places are important for wellbeing and health. One of the most important tasks for the comprehensive planning is therefore to foster “a purposive structure and an aesthetically appealing formation of developments, green areas and routes for communication”. ” (National Board of Housing, Building and Planning, 2015, emphasis added)

Localization seems to be a decisive act, within urban planning processes. Through history, we have also seen a lot of examples of utopias, model cities, wherein everything is purposively localized and aesthetically appealing (fig 1-2). We also do know that very few of these model cities exist in real life, even if we can experience fragments of the grand visions in many places, reminiscent of the utopias. Yet, there is a gap to be observed already in the distinction between ‘the full masterplan’ and ‘fragments of a masterplan’. A masterplan can express – at its best – a deliberation between all different interests from all stakeholders and the public opinion. Remaining fragments are not. A masterplan can be – at its best – a result of several meetings, collaborations and negotiations, as well as qualified use of necessary knowledge and skills, to achieve “a purposive structure and an aesthetically appealing formation of developments, green areas and routes for communication”. Remaining fragments might be, but in this case more due to coincidence or intuition than to arguments, agreements and communicative rationality.

A question arises: Is the law written for the fulfillment of a purposively structured and aesthetically appealing *representation* of a desired environment, or is it written for to afford to the actual inhabitants and visitors the *experiences* of a well-functioning and appealing environment? Certainly, there has not to be a conflict between these aims, but a truth is that architects and planners learn their history, culture and skills more through representations than by observations of actual urban landscapes. In collision with this representational practice, another truth is that the personal notions of your surroundings; the house, the backyard, the street, the encounters with the urban landscape in your everyday movements; are not represented but first hand bodily experienced. “How residential areas, working places, public services, roads, railroads and green areas are *localized*, in relation to each other” is a task solved by expertise by means of, and resulting in, representations. How residential areas, working places, public services, roads, railroads and green areas *really work*, in relation to each other, is understood by bodily sensations. Localization is dealt with, professionally, in the masterplan, but the experienced result is dealt with, personally, in everyday urban life. There are, in fact, very few learning loops between these two realms.

Localization of developments, green areas and infrastructure, in a purposive way, is prescribed in law. The question is if this demand is possible to obey. The law does not prescribe that the purposive structure should be fulfilled in the plan (on paper or digitalized). The law prescribes that a purposive structure is going to be built, for people to live in (and spend their money on). A crucial distinction is that mistakes done in making this structure have to be corrected during the planning process; otherwise it will be too late for making any corrections other than just superficial, i.e. not concerning the purposive structure, founded in purposive localizations. One logical conclusion from these premises must be that the representations (of a new development) would have to be made not just in order to sell a vision and a project, neither for the purpose of coming to a consensus between land owners, builders, public authorities and other interests, but in order to make it possible to understand (for everyone possibly affected by this development) how the urban landscape is going to be transformed.

Figure 1. The Ideal City, unknown artist, 15th century

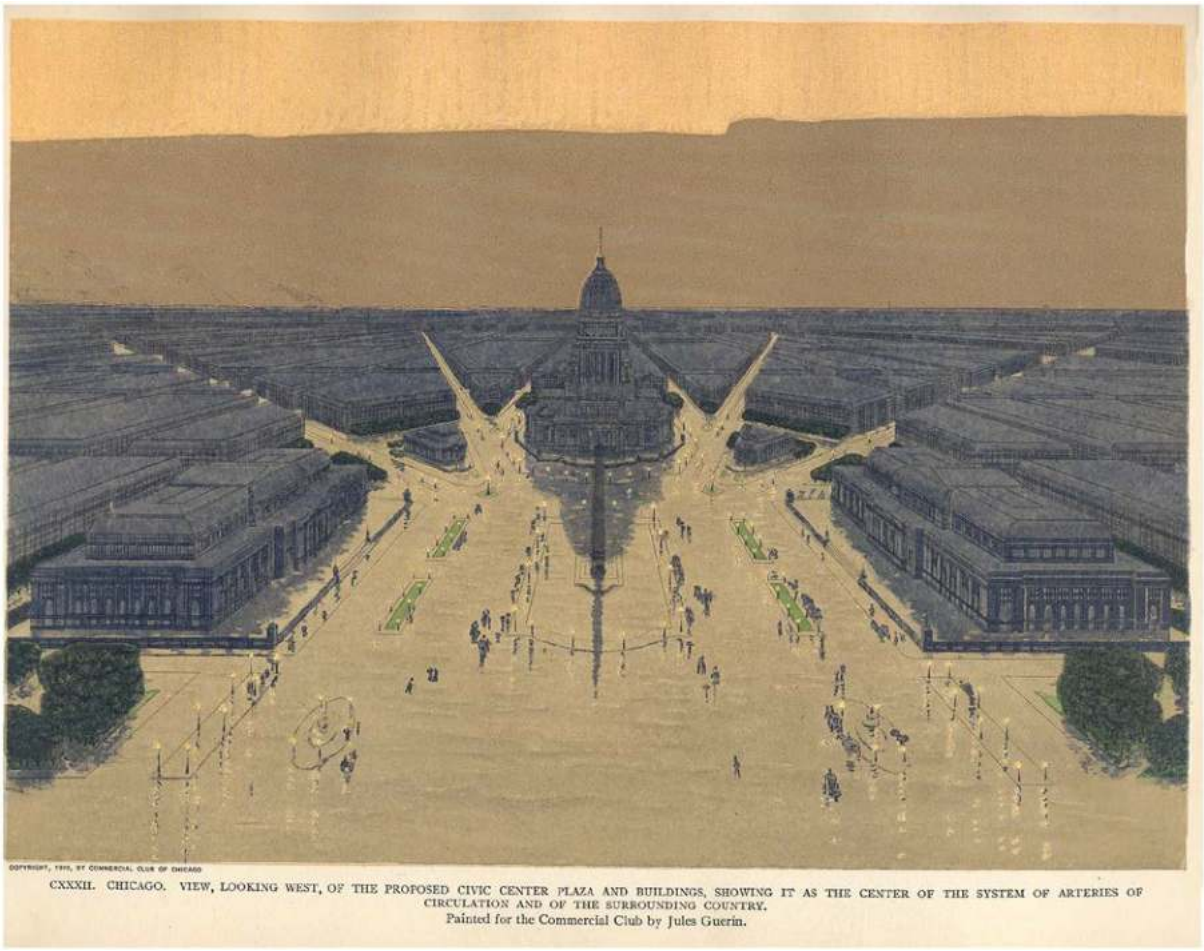

Figure 2. The Burnham Plan for Chicago 1909[4], illustrated by Jules Guerin.

[4] The Civic Centre, the impressive buildings around which the rest of the city of Chicago was thought to circle in the Burnham plan, was never realized in the visualized configuration. Other parts of the plan, such as the huge park envisioned in the front corners of the picture, actually were materialized nearly a hundred years after the plan was made. This exemplifies the unpredictability with which a vision is affecting urban landscape change.

For hundreds of years, urban planning projects have been discussed on the basis of visual urban landscape representations (figure 1 & 2). These pictures help planners, politicians and investors alike to understand, discuss, alter and decide on what choices, agreements and decisions of localization are needed to make the vision come true. If the non-transparency and opacity of these negotiations could be added to these pictures (as visual representations of the probabilities of their fulfilment), the visions would soon become obscure. If the visions where changed according to new deliberations, new pre-conditions and new possibilities; as a method of making a planning process literate; this might foster new kinds of trust and collaborative spirit.

As paradoxical it may seem; in order to diminish the gap between 'the representations of urban landscape in urban planning' and 'the effects of urban planning in the urban landscape', new kinds of representations would have to be tried out. If the representations of the urban landscape used in urban planning do not make understandable how the new development is going to function and be experienced; it will not be possible to achieve sustainable development in any sense conceived of so far.

> "people know *what* they do; they frequently know *why* they do what they do; but what they don't know is what what they do *does*"
>
> (M Foucault, quoted in Dreyfus & Rabinow, 1983:187, emphasis added)

The quotation from Foucault describes on the one hand the inevitability in the existing gap between an intention and a vision on the one hand and the effectuation and result on the other hand. At the same time, it does in itself open for both rhetoric and experimental bridge-building, in order to affect what is going to be the pre-conditions for future planning acts.

Today, everyone has access to satellite pictures of the bigger part of the world. GIS archives are accumulating data, more or less publicly accessible. Why are these informational resources not used to 1) create understanding for the continuous changes of the urban landscape and 2) create alternative scenarios for future development, iteratively testing and up-dating visions? In spite of real-time statistics and financial updates, animated advertisements and self-generating computer games; there is seemingly no interest of up-leveling information about our own surroundings. The difference between urban landscape representations used in planning processes 2015 compared to 50 years ago is negligible. Building project visualizations are nowadays made in Photoshop instead of being drawn by hand, but this is just a superficial dissimilarity which does not make any difference. To provide continuous representations of urban landscape change, including on-going projects, and offer also alternative visions for the future; would make role of planners and municipalities more influential and increase the opportunities for rational decisions and localizations.

## Localization by public actors – allocations of common resources for public good

Seen from another angle, "the purposive structure" could be achieved, not by erasing something existing, fulfilling the perfect scheme from a 'tabula rasa', but through additions. Many re-constructions of plans and fill-in projects; many new spatial additions to the urban landscape, such as green structures or biking road systems have over the years accomplished a updated (upgraded?) purposive distribution and relationship between buildings, green areas and infrastructure. Such examples serve as indications of the necessity of planning as public service, taking on the responsibility of "purposive structure".

In spite of its prominent position in the frame law, localization is seldom mentioned in planning regulations, and when it is, it serves very specific aims. Thus, there is a "localization principle" in the

environmental act; activities possibly annoying people should be localized as distant as possible from urban areas. There also exist instrumental techniques to destine a localization through measuring the factors affecting the effectiveness of it from a rational point of view. To localize a fire engine station a formula for the driving distance of fire engines combined the time of driving with acceleration capacity and the distance for reaching ground speed, has been widely used to decide the locations of fire stations.

$$T(D) = \begin{cases} 2(D/a)^{1/2} & \text{om} \quad D \le 2d_c \\ v_c/a + D/v_c & \text{om} \quad D > 2d_c \end{cases}$$

Figure 3. Formula for calculating the optimal localization of a fire engine station. (Kolesar, 1975)

Localization of public services such as day care centers and primary schools has since long been a task for achieving added values, managed by public authorities. During Sweden's international fame for successful residential areas (1940-1960) the aim of social integration was built in by purposeful localization of schools so that the uptake of pupils (with reasonable distance from the school area) would contain children from different social groups.

There is a difference in how this kind of basic public service affordances are managed (or have been managed), i. e. the results of a deliberation not only between interests of urban land, but also as an effect of an interpretation of scenarios and empathy with the complexities affecting new spatial orders; and the way more instrumental services are handled.

To conclude, public localization (given the decision resource) seems to combine instrumental effectiveness with heuristic interpretation of complexities. It is also obvious, from the example of the school, that localization is not only guided by functional effectiveness, but is also one of the more effective political tools to be used in planning. Localization is a mode to allocate resources to fulfill democratic and integrative aims, with is effective and long lasting.

**Localization by commercial actors – allocations of resources for profit maximization**

Localization by commercial actors is not a way to accomplish "the just city" (Fainstein 2010). In the commercial sector, profit maximization is a principle and a prioritized aim. Retail localization applies certain rules related to the spatial pattern and urban mobility in city centers (A-, B- and C-locations).[5] Offices in need of advertising area often want locations near to transport infrastructure. Factory premises also favor the nearness to transport infrastructure in localization decisions, not so much for the exposure as for the cheap land. These dynamics seem to be the same regardless of political majority. The profound change, experienced only a few decades, happens when public authorities sell out what was earlier public service; not least in terms of localization.

When Europe's a social democratic hegemony (1945-1975) changed for a neoliberal hegemony (around 1980), leading to unquestioned market forces, 'public service' changed meaning from something decided on by local politicians, and afforded by the managers of common resources and their civil servants to be a commodity among others, to be demanded and consumed (see e. g. Bauman 2010). What happened was that health care centers, schools etc. became run by private companies,

[5] Different combinations of price on land, rent level, nearness to customers and urban mobility, proximity to others in the same branch (clustering) are calculated. To identify these combinations as A-, B- and C-locations is a common way for e. g. city commerce cooperation to support local entrepreneurs and businesses.

using tax money (the common resource) as a guarantee, but with commercial actors' principles. This has been very much debated from a point of view of justice, but hardly at all from the spatial planning point of view: The privatization of public services has bereft the public authorities the possibility to use localizations of the services as opportunities for achieving added values (in former times often called equality, in present times more often "social sustainability"). This means that localization of schools and day care centers often follow the same criteria as applied by retail companies; a striking example of how the effects of privatization go further than to management and profitability is how the localization of schools put less attention to outdoor environment (Nordström 2007, Hjelkerud Nilsen 2014).

This kind of critique of localization, viewing the planning activity as "torn between dialogic ideals and a neo-liberal reality" (Sager 2009); questioning the profit maximization as principle for public service; needs to be widened and deepened, in order to understand and preclude the long term spatial impact of this 'tyranny of small steps'. One pre-condition for this, I would argue, is to understand and respect each act of localization, not as the first step in a chain of actions, ending up after a planning and building process, in materialized buildings or infra structures, changing the urban landscape for unlimited time. Instead, it seems important to appreciate a situation of urban growth, not only as a free market where property companies are shopping land and building permits, but also – just as the law actually states – an opportunity to govern the work with preliminary localizations, relative to each other, with the aim to localize primary building projects as well as public service needed as well as public space and green structure.

## Changing perspective: Localizations as drivers of urban landscape change

The claim for a purposive structure and localizations in the Swedish Plan- and Building Law seems to be more in tune with a former social democratic society than with the present neo-liberal politics. In order to frame new possibilities within a new political landscape is here suggested an increased research for a future-oriented urban landscape management. Seen at large, on a regional or national level, cities have extremely different conditions for planning. While a few municipalities have immense hardship to produce enough plans for new residencies, many municipalities are facing problems with empty houses, increased outwards commuting and a descending population trend.

With "urban landscape management" is here meant how to handle existing resources and values, for the whole cluster of management of urban land; from the comprehensive planning strategies to the considerations of a single real estate owner. It is suggested here, that "localizations", as deliberations out from an entire urban landscape perspective, could be used as means to prevent a "tyranny of small steps" and on the contrary be a driving force to instigate "the blessings of steps". This implies to change urban planning from a present defensive state of moderating between strong stakeholders, (claiming nothing else than existing stop signs, mostly from the environmental regulations) into a capacity for accumulating, presenting, communicating knowledge, and a position to produce frameworks for planning and building (fulfilling the aims of the law).

*Here I have identified a section (10-20 lines) which was not yet publishable – I will work further with this one until the conference.*

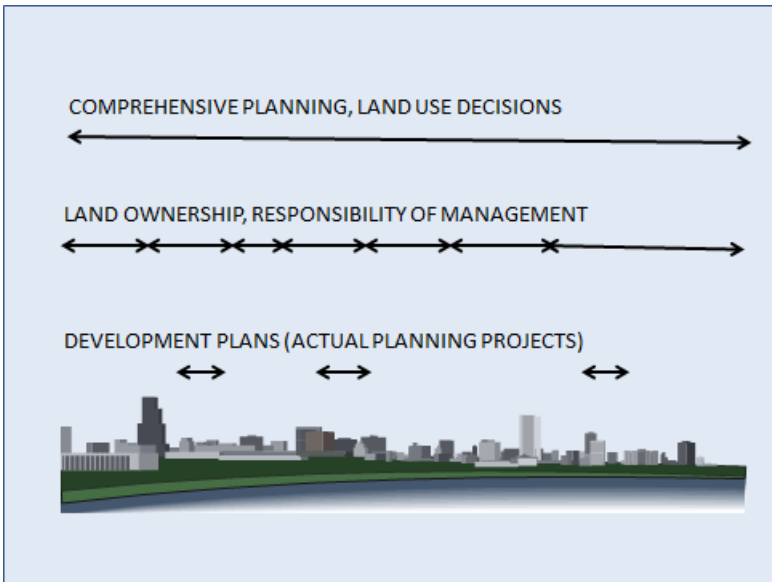

Figure 4. Spaces of action and responsibility are different for comprehensive planning, land ownership and development planning. A purposive structure demands both common landscape representations and arenas for development of common urban landscape strategies.

## Discussion: urban landscape representations for alternative future purposes

The example above; localization of schools governed by different politics; is used to show the difficulties met when privatizing services which by tradition have been provided by public authorities. One reason is a lack of both responsibility and means for to overview the whole urban landscape and the opportunities at hand for localization (see figure 4).

To conclude, the concept of localization gets added characterization when trying to merge public and private interests and when trying to discuss a 'typology of locations'. The reason to analyze the different aspects of localization as part of planning activity, was found in the increasing difficulty to make distinctions and arguments for one of the founding objects of planning; the public interests. While the law (the Swedish plan- and building law was used as example) prescribes "a purposive structure and an aesthetically appealing formation of developments, green areas and routes for communication" the practice of localization in planning today displays something more in tune with the reductive location-hunting practiced by real estate agents and guided only by price tags.

There is certainly not a total lack of ideas, alternatives and urban landscape representations. In the planning departments themselves there are, at least in the bigger, growing cities, constantly ongoing alternative ways to tackle the balancing between providing plans in time for awaiting building projects and the political pressures to answer for the needs of public services and public space needed both for the new projects and as renovating and upgrading of older city districts. Also workshops and communicative innovations in relation to new planning projects, in different formats, are common; architecture competitions, student invitations, internships and municipal PhD-projects, contribute to new ways of understanding urban landscapes and city development.

There is however, lingering routines and organizational peculiarities hindering new methods to emerge (Hillier 2014), including implementation of new policies even decided on. It is also understandable that for a public organization fighting with diminishing resources, innovative methods for more sustainable long term strategies, are not first priority. Planning research could here play a more active role; investigating and testing, on an experimental level, new ways of working with alternative futures.

A common way to reason in such terms are alternative developments based on scenarios. As important however, is to learn ways of understanding the imbued driving forces for urban landscape change, whether planned or not. Localizations will continue a lead part, whether we want to see it or not.

# AREA VASTA 2.0
# A NEW FORM OF LOCALISM IN ITALY: CHALLENGES, RISKS AND OPPORTUNITIES FOR SPATIAL PLANNING ACROSS LOCAL BOUNDARIES[1]

Lingua Valeria *

* University of Florence, Department of Architecture (DIDA),
Section of Urban and Regional Planning, valeria.lingua@unifi.it

Keywords: joint planning, strategic planning, duty to cooperate

***Abstract***
*The papers aims to understand the forms and outcomes of cooperative spatial planning practices at a supra-local level in Italy. Assuming co-operation as one of the key challenges for planning strategically across local boundaries, the research will deal with the rescaling of formal planning activities carried out by joint local authorities, under a cooperative attitude that, in a Localism era, is supposed to replace sub-regional planning strategies.*
*The research focuses on the changes occurring in the Italian planning system after the Laws n. 135/2012 and 56/2014 that, in the name of the spending review, obligate the 10 main regional cities to form joint metropolitan city governments by abolishing the provincial level, and municipalities with certain population requirements to come together into "Unions of competences", including spatial planning.*
*Of course, the need of co-operation on strategic issues is not new in Italy. Some institutions have an old history of working together to address planning issues of common concern. Nevertheless, the emergence of cooperation as a duty certainly poses some questions concerning the redefinition of planning spaces and responsibilities, the role of the planner, the access to the cooperative arena, the need for regional design practices.*
*Through the analysis of some medium cities socio-economic and spatial planning contexts, the paper discusses the forms of governance in place, the different boundaries they assume and the responsibilities they encounter. The aim is to contribute to a better understanding of the way strategic spatial planning can works in Italy, in order to define the issues to tackle and further directions for research.*

## 1. The context: the arising of localism in Europe and Italy

In many European countries, important changes are arising both in the institutional system and in that of planning, for repositioning objectives, forms, tools and methods of planning in a context of increasing globalization, Europeanization and, at the same time, of growing of the importance of subsidiarity and of the local.

[1] This paper refers to the research project "AREA VASTA 2.0. A new form of localism in Italy: challenges, risks and opportunities for spatial planning across local boundaries", that has just been founded (june 2015) with 0,5 million euros by the Ministry of Education, Universities and Research within the framework of the prestigious SIR Programme (Scientific Independence of young Researchers) aimed to support young researchers at the start of their independent research activity.
The Programme is designed for the funding of research projects with high scientific quality, developed by independent research teams, under the scientific coordination of a Principal Investigator (PI), either of Italian or non-Italian nationality, resident in or moving to Italy, who has been awarded their PHD (or medical specialty training) up to 6 years prior to the publication of the call for proposals (http://sir.miur.it/). The SIR programme is the Italian correspondent of the ERC Starting Grants, designed to support excellent Principal Investigators at the career stage at which they are starting their own independent research team or programme.

This paper is concerned with the forms and outcomes of strategic spatial planning practices at a supra-local level, dealing with the rescaling of formal planning activities carried out by joint local authorities, under a cooperative attitude that, in a Localism era, is supposed to replace regional and sub-regional strategies.

This issue is grounded on a debate involving the Western Europe in respect to the emergence of a widespread neo-liberalism (Waterhout et al., 2013), that has conveyed to processes of State space rescaling (Brenner, 2004) and a strong affirmation of localism. Although there are clear differences in its amount and real effects in planning across Europe, there seems to be a clear direction toward the rescaling of planning systems, that could be associated with reducing government. Indeed, every level between the national and the local is now up for discussion, and, in some case, even abolished, as happened to the English Regions in 2011. In other cases (and particularly in Italy) competences are nominally shifted between governance levels, making sub-regional/provincial spatial planning weaker.

To the rescaling of formal competences corresponds the increasing development of spatial visioning for non-statutory areas. In France, Germany, and the Netherlands, we observe an increase of spatial visions for all kinds of 'new' sub-regions or soft spaces (Haughton et al., 2010 for the UK), both at metropolitan level and at rural one. Cooperative planning practices engaged by neighbouring municipalities convey to different and quite fuzzy geographical regions, aiming at developing regional identities and mobilizing public, private, and civic stakeholders for achieving major competitiveness developing economic and territorial potentials, as proved by the French national policies for motivating such relatively voluntary planning processes, focusing on competitiveness and spatial development (Dikeç, 2006).

To this rescaling of formal competences corresponds the increasing development of Strategic Spatial Planning approaches based on strategic visions moving beyond administrative limits, so that they convey to the definition of soft planning spaces with fuzzy boundaries (Allmendinger & Haughton, 2010).
The emphasis on strategic planning as a socio-spatial process (Healey, 1007, 2007; Albrechts, 2004) in the spatial strategy making process advocates the importance of collaborative and inclusive governance for developing regional identities and mobilizing public, private, and civic stakeholders.

Nowadays, the emergence of cooperation as a new obligation for Local Authorities certainly poses some questions concerned with the redefinition of planning spaces, the role of planners, the access to cooperative arenas. If these are typical problems of strategic spatial planning practices, the government expectation for plan-making authorities to undertake joint work on supra-local concerns affects issues of governance rescaling and accountability for planning.

In Italy these questions arise in a framework in which, in spite of several attempts of innovation of the national planning system (Lingua & Servillo, 2014) and diverse regional reforms (Campos Venuti & Oliva, DeLuca) – even after the failure of the "comprensori" season in the '80s and the proved weakness of provincial planning (Gerundo & Lingua, 2011) – the outcomes of already-in-place voluntary inter-municipal practices and the relationships between strategic and statutory planning have yet to be focused (Fedeli, 2013). Moreover, an interdisciplinary reflexion on the relationship between localism and the re-organisation of institutional levels could lead to a better understanding of their effects on inter-municipal and metropolitan planning practices and outcomes (Oliva, 2012; Sbetti, Feralino et al., 2012).

The paper analyzes the changes that are occurring in the Italian planning system and practices following the revision of the institutional system, as well as their impact on the system of governance

in planning at local and sub-regional levels, in order to define the issues to tackle, the challenges to face and the connected risks and opportunities for spatial planning across local boundaries.

## 2. The challenges of the Italian institutional reform to the planning context

The Italian planning system is still based on the original National Spatial Planning Law n. 1150 dated 1942, that organizes the competences of the land-use planning system into different levels in quite a hierarchical way, the plan corresponding to the level of the institution in charge.

After the reform of the Constitution in 2001, the State is responsible for guidance and coordination, while the subject of planning is constitutionally attributed to the regional institution, that is required to make indicative laws within the limits of the principles laid down by the laws of the State, nowadays changed in a more enhanced federal perspective. Being absent a territorial framework at the national scale, three tiers characterise the Italian planning system at the subnational level:
1) the regional plan;
2) the provincial plan (Piano Territoriale di Coordinamento Provinciale - PTCP) at county level[2];
3) the municipal plan (Piano Regolatore Generale - PRG) at local level, that in some region is divided into two acts: a structural plan and an operational one (land-use regulatory).

Despite a reform of the national spatial planning law has no longer been on the agenda of the national government, new and most innovative spatial planning laws have been adopted by some regions, whose conception is in line with the substantial autonomy that Regions have gained with the reform of the Constitution in 2001.

In this framework, the municipal level, through different experimental forms of land use plans, remain the fundamental actor in managing the urban growth and the territorial changes[3]. All the reforms and the growing complexity of the planning system (including the use of different paradigms and the introduction of diverse tools according to each region) slightly affect the primacy of municipalities as main planning actors and the land use plan as main technical devise (Lingua & Servillo, 2014a).

However, the presence of 8,092 municipalities and 110 provinces, with different planning tools and different speeds of implementation, creating overlaps and conflicts between the different levels (Gerundo & Lingua, 2011), together with the global socio-economic crisis, in the last five years led to an important reflection on the cost of politics and the difficulties of territorial government.

[2] At the provincial level, the Territorial Plan of Provincial Co-ordination - (PTCP - Piano territoriale di coordinamento provinciale) contains prescriptions and indications on landscape and environmental constraints, which local authorities must conform to in the exercise of their respective competences. It determines guidelines for the different zoning according to the predominant use. It defines also the sites for major infrastructure and lines of communication, the areas for erosion prevention and water flow control, and the areas of nature reserves or parks. The plan may cover all the provincial territory. It has no time limits. Lower authorities (Municipalities), in preparation of their own planning instruments, may respect plan contents as a guidance and a regulation.

[3] In the 1990s, the cultural debate led by the Istituto nazionale di urbanistica (INU - National Town Planning Institute) about the necessity to innovate the planning system found a fertile political context for proposing a a new Planning Law (1995) in which the local planning level should be divided in two different acts: the "structural plan", containing the future scenarios as the strategic vision of the territory, with spatial development strategies based on structural characteristics of the territory as peculiar invariants; and an the "operational plan", containing the land use indications that pursue the contents of strategic plan. Despite no longer being on the reform agenda of the national government, the INU's proposal became an important reference for some of the new and most innovative spatial planning laws adopted by some regions from 1995 to 2000 (e.g. Tuscany, Liguria and Emilia Romagna), and then in the new millennium spatial planning laws (of Lazio, Veneto, Lombardy etc.), whose conception is in line with the substantial autonomy that Regions have gained with the reform of the Constitution in 2001.

In this context, the key words of the (Law 214/2011), promoted by Prime Minister prof. Monti, were those of cost reduction and simplification, even concerning the levels of government by the suppression of the provinces and the unification of small municipalities. On this trail, the actual prime minister Matteo Renzi conveyed to the approval of Law 7 April 2014, n. 56 (the so called "Delrio Law" from the name of the Minister in charge) that formally transforms the "provincia" in a second institutional level, in prevision of a change in the art. 117 of the Constitution to revoke it.
Actually, this series of laws and connected decrees provide the "reorganization" of local entities through a process of "rationalization" that includes:

1. the transformation of all provinces in second level institution, with non-elected assemblies and with a reduction of their competencies;
2. the suppression of provinces who insist on 10 major regional capital cities (Roma, Torino, Milano, Venezia, Genova, Bologna, Firenze, Bari, Napoli e Reggio Calabria) and their replacement with "Metropolitan cities", sub regional organizations which are attributed to the fundamental functions of the provinces and, in particular, of spatial planning.
3. the unification of municipalities with a population of up to 5,000 inhabitants, which have an obligation to associate the exercise of their competences (including spatial and land use planning), through the conclusion of agreements or the establishment of a "union of municipalities" [4]. In any case, the optimal size cannot be less than 10,000 inhabitants (or 3,000 in mountain areas).

De facto, the questioning on the role of provinces and this climate of constant change necessarily involve a deep reflection on the adaptation of planning tools and processes (Camagni, 2012). Indeed, different types of cooperation are emerging, more or less coercive, at different scales: the regulatory measures include an obligation to cooperation at sub-regional and local level, for municipalities submitted to defined roles for regrouping. The same obligation involves the municipalities of the metropolitan areas which have not yet ever undertaken processes of metropolitan planning[5].

The municipalities that meet the demographic requirements, instead, remain excluded from the obligation. In these cases, outside the modalities of cooperation imposed by law, the weakening of the role of provinces, however, seems to prefigure the need for a greater use of inter-municipal or joint planning for strategic matters and issues of sub-regional interest.

Of course, this need has already gained good practices, but it has speed, times and methods differentiated according to the region. Forms of voluntary cooperation are already in place in some regions that provide and promote inter-municipal cooperation in planning (i.e. Emilia Romagna, Veneto), in addition to sporadic episodes in other regions, due to the need to jointly address strategic issues et sub-regional level, defining informal spaces of planning.

The *fil rouge* that links these practices is definitely that of cooperative governance, understood as the ability to work-with to achieve objectives of development and planning going beyond the mere administrative boundary (De Luca & Lingua, 2012).

[4] This form is midway between inter-municipal cooperation and inter-municipal consolidation; member municipalities keep their legal identity but all functions are managed by the Union which is a sort of consortium.
[5] Some metropolitan areas have already activated forms of cooperation for strategic planning (Turin, Genoa, Milan), but these have never led to forms of metropolitan spatial planning.

## 3. Strategic spatial planning in the era of localism: assumptions and principles

The context of change that has affected several European countries in the last decade has generated a considerable debate on the issues of regional and sub-regional planning. Firstly, it was focused on the potential of *strategic spatial planning* as a way of comprehensive planning, capable to get through previous regulatory land-use planning approaches, by improving engagement with stakeholders and the public in order to define long-term strategic visions (Albrechts 2010), improve integration across sectoral plans and activities (Tewdwr-Jones & al., 2010) and approach sustainable development in a wider perspective (ODPM, 2005; Raco, 2005). Criticism of this approach (Newman, 2008; Allmendinger& Haughton, 2010; Haughton et al., 2014; Kunzmann, 2011) addressed the incapacity to deal with these assumptions and goals with a win-win-win approach, and on the difficulties encountered by its planning tools (in particular at the Regional level) to address strategic issues in a relevant way and with authority, being approved by non-Elected assemblies.

In Italy, the debate has concerned the so-called "pianificazione di area vasta" (inter-municipal or "wide-area"/sub-regional planning), both in its formal aspects (the coordination plan drawn up by the provinces) and in the emerged spaces of soft planning (strategic planning and planning agreements on different topics, from urban renewal to territorial development). In particular, the Territorial Coordination Plan (PTC), which starting 1990 became the responsibility of the provinces, is intended as a new space of interaction which can embrace broader horizons than local plans, and lead to convergence sector plans including, especially, landscape planning.

Two decades of planning practices allow, on the one hand, to point out some deficiencies in the provincial planning (Lingua, 2011; Gerundo & Lingua, 2011), such as excessive "rigidity" of the plans, very long timing procedures, different speeds of planning between Northern (now in the second generation of provincial plans) and Southern Italy (where many provinces do not yet have a PTC). On the other hand, some planning practices at the intermediate/subregional level (inter-municipal planning, co-ordinate planning, planning agreements) are multiplying, carrying to significant rescaling in the spaces of cooperative governance (Zanon, 2013; De Luca & Lingua, 2012). In both cases, the considerable effort to open to multi-scalar planning, to sectoral coordination and integration (Swain et al., 2012; De Luca & Lingua, 2010), is not lost, but has led to a redefinition of the planning levels through the introduction of new paradigms and new modes of action.

Of course, the need of co-operation on strategic issues is not new. Institutions have an old history of working together and with other bodies to address planning issues of common concern. Nevertheless, the emergence of cooperation as a duty, i.e. as a new obligation for Local Authorities in all fields (not only in spatial planning), in both countries certainly poses some new questions, which are:

- the extension of cooperation, which is based on parameters (previous provincial boundaries in metropolitan areas, population in little municipalities) that are often divorced from socio-economic dynamics, territorial specificities and cooperative practices already in place;
- the presence of overlapping spaces of cooperation, between joint local development plans (coming from formal or informal spaces of planning) and development planning documents;
- the effectiveness of cooperation: the duty to cooperate implies that all relevant government over local issues, if affected by the plan, ought be involved. This results in a rescaling of cooperative governance in spatial planning, which takes varying boundaries. At the same time, the duty to cooperate cannot become a duty to agree (Geoghegan, 2012)**,** so what does it happens in case of disagreement, conflict or refusal to cooperate?
- the role of the planner, not only to demonstrate the link between plan and rules, but in activating practices of effective strategic planning across local boundaries;

- finally, the effectiveness of cooperative planning results, in terms of shared supra-local strategies, formalized in specific agreements or in a joint plan and implemented in local planning practices, that conveys to a need for activating regional design practices.

The redefinition of planning spaces, the role of the planner, the access to the cooperative arena are typical problems of strategic planning as a forms of collective action (Healey 2007, Albrechts 2004). But a voluntary practice in itself is now transposed in a context of obligation, where local planning authorities are obliged to cooperate on specific issues. An already focused concept is now putted into tension and has yet to be analysed in its full potentials for supra-local planning and its local implementation. The Italian planning system, being established on Provincial Plans abolition, now rely on informal arrangements for strategic planning: the governments expect plan-making authorities to undertake joint work on supra-local planning issues. This expectation affects issues of governance rescaling and accountability for planning.

## 4. Medium metropolitan cities in the face of localism: the issues to tackle

The literature review has led to define the state of the debate, for identifying the specificity and the common aspects of the process of localism that affects the Italian institutional system and that challenge the planning system in different ways and with different speeds. As a matter of facts, the metropolitan cities government are now in place, while the duty to union for little municipalities is delayed to the end of 2015.

Because of the obligation to revoke provinces governments prior to the 31$^{st}$ of December 2014, the metropolitan councils (composed by the mayors of all municipalities composing the metropolitan area and by the capital city major acting as the "metropolitan major") are now in place and have already approved their metropolitan statutes. Nowadays, they are starting to deal with inter-municipal management of the urban region and the connected challenges for the governance system.

In such a dynamic framework, this paper refers to the analysis of the forms of governance in place, as well as of the different boundaries they assume into supra-municipal planning practices, in three Italian medium cities where the debate on joint planning is arising because of the non-correspondence between institutional boundaries and socio-economics, housing and population dynamics. The profiles of the practices are presented in Table 1.

The analysis of the Italian case studies has allowed to focus on the main issues in the debate and on their translation into practice. In particular, we identified four major themes concerning strategic spatial planning in the context of the institutional reform:

1. the **re-scaling of the statutory planning system**, that convey to a shift in scale and focus of planning practices and responsibilities
2. the **extension of cooperation** and the presence of **overlapping spaces of cooperation**, between joint local development plans and sectoral and economic development programs
3. the need, for planning officers and practitioners, to achieve **new negotiation and participation skills** in activating practices of effective joint planning across local boundaries
4. the **effectiveness of cooperative planning results**, in terms of shared supra-local strategies, formalized in specific agreements or in a joint plan and implemented in local planning practices.

Table 1. Italian Case studies profile

| **Case** | **Current Planning Instruments** | **Co-operation practices in place** | **Involved Authorities** | **Motivation for co-operation** | **N. of Involved authorities by Law 54/14 (Provincial boundary)** |
|---|---|---|---|---|---|
| *A. Turin* | Regional territorial Plan<br>Regional Landscape Plan<br>Provincial Territorial Coordination Plan<br>Local PRG (Land use plans) | **Strategic plan (3rd generation) "Torino metropoli 2025)** | 18 municipalities | Socio-economic development | 315 municipalities |

Florence* | Regional territorial and Landscape Plan<br>Provincial Territorial Coordination Plan<br>Local Structural Plans | **- Structural development framework ('90s)**<br>**- Strategic regional projects (Piana area)** | 18 municipalities in Florence province +<br>n. municipalities in Prato province +<br>n. municipalities in Pistoia province | Socio-economic development, further addresses for cooperation by the Regional spatial plan | 42 municipalities in Florence province |
| *C. Naples* | Regional Landscape Plan<br>Provincial Territorial Coordination Plan<br>Local PRG (Land use plans) | - | [gravitational area composed by 173 municipalities:<br>92 municipalities (the whole province of Naples) +<br>36 municipalities in Caserta province +<br>35 municipalities in Salerno province +<br>6 municipalities in Avellino province (SVIMEZ, 1999)] | | 92 municipalities in Naples province |

*1. The re-scaling of the statutory planning system*

The institutional reform conveys to a move of direct control over and ownership of the strategic-planning function at the local level (Gallent et al., 2013, Zanon, 2013). Nowadays, to manage this great shift, Italian local authorities could refer to three main frameworks:

The strategic framework provided from previous provincial Territorial Coordination Plans
Existing and new soft planning spaces
The big picture of current municipal structural plans.

The first reference is the weaker one: planning activities of the Provinces started in 1990, in the framework of law n. 142, and in Northern Italy they are now at the second generation of provincial

plans, with some best practices whereas Bologna Territorial Coordination Plan is the most cited one. However, provincial plans were usually concerned with landscape and sectoral issues (as water and mobility management) and their strategic frameworks were usually affected by a lack of involvement of municipalities. That means that the vision of the provincial area they conveyed were not a shared one, and municipalities conceived it as imposed.

Existing and new soft planning spaces can be a possible way to achieve shared visions, whereas some of the ones created during previous strategic planning practices can be now formalised, and others may be opened (Haughton et al., 2013). However, the formalization of soft planning spaces seems to be a constraint in their development as pertinent planning arenas: can a Memorandum of Understanding or a Strategic Statement resist to administrative changes?

Finally, the big picture of current municipal structural plans has to be explored: being the metropolitan council just putted in place, a coordination in planning offices has still to be conceived. Joint political board, supported by Joint technical board are envisaged (see point 3) for systematising all the local strategies in order to identify common and conflicting visions and shaping a shared image of the future of the urban region (point 4).

*2. The extension of cooperation*

The defining and redefining of sub-regional boundaries convey to new planning spaces dealing with diverse functional areas. The extension of cooperation and the overlapping of functional areas and new planning spaces emerge as huge constraints.

The re-organisation of institutional boundaries is based on two parameters (existing provinces & population) that are often totally **unrelated** to territorial specificities and cooperative practices already in place.

Given that the obligation to union and to form metropolitan governments is not a duty to agree, after the revocation of the provinces a vast gap between functional areas and political convenience has emerged. Many difficulties in involving neighbouring authorities in a real cooperative governance process are due to different visions of the future development and to the balance of powers: political convenience or the perceived hierarchy or dominance can be a concern, as well as the perception that the partnership, being led by the mayor of the regional capital city, is not balanced in powers and financial allocations.

Finally, the reform doesn't take into account the presence of overlapping spaces of cooperation, between joint local development plans (coming from formal or informal spaces of planning) and sectoral and economic development programs. This is the case of the city of Florence, whereas the socio-economic gravitational area is extended to the neighboring provinces of Prato and Pistoia on the Pisa-Florence development system, as well as of the city of Turin, that is now conceiving the second strategic plan as an inter-municipal development plan among the municipalities of the first and second belt, while the metropolitan area is extended until Susa Valley, in the Cozie Alps.

*3. The need for rebuilding governance structures and for new skills for planning practitioners*

The dismantling of the provinces in metropolitan areas has led to voids in formal officer and Member governance structures at the cross-boundary, functional area or sub-regional level. These are now to be re-built to face strategic planning issues, in the context of the metropolitan government.

Concerning little municipalities obliged to convey into unions, in the shift from a provincial obligation for co-ordinating planning activities in sub-regional areas to a completely free discretion for local Authorities in choosing pertinent neighbouring authorities to cooperate with, these new "governance structures" have to face with diverse concerns: different visions of the future development as well as diverse expectations in the balance of powers and diverse views on housing provision.

If Localism represent a big challenge for planning officers culture (Sturzaker 2011), in the framework of the process of strategic spatial planning, negotiation and mediation becomes one of the main concerns. The discussion about the formalisation of soft planning spaces and the previous informal arrangements is the backdrop to some reflections on the role of planning officers and practitioners, as well as members.

The planning officers in the Localism Era are asked to act as collaborating planner (Clifford & Twedwr-Jones, 2013) in order to face the new challenge of metropolitan spatial planning. But even for tackling the issues of strategic planning there is a need for a more proactive attitude in setting-up and resourcing joint working arrangements, that was not required in a province-led framework.

The same skills become fundamental for members, mostly wherever the union with other municipalities remains contentious and is unwanted by local communities. A local authority councillor is asked to be able to meet the needs of his communities and fulfil his leadership role better through understanding the process and what his role can be in the context of the union or the urban regiona.

This concerns on the function of councillors seem to be lacking at the beyond-local level, conveying the State government to prospects a key role for the Regions, either acting as the co-ordinating body in setting-up the co-operative arena. Given the real difficulty for local members to deal with controversial issues connected with the processes of joining with other municipalities, a support from the regional government could be useful.

In any case, a joint political board seems to be the best solution to face strategic planning issues and to convey to the adoption of joint or aligned core strategies, because it avoid a process of continuous mediation between politician involved in the process and their councils and the resolution by committee on joint planning issues decreases decision times. Finally, the Joint political and technical boards guarantee transparency and political continuity in the planning process and delivery.

*4. The strategic spatial planning effectiveness and the need for Regional Design practices*

Being the metropolitan cities just born as formal government institutions, and the union of municipalities having to be shaped before the end of the year, the definition of **shared** supra-local strategies, **formalized** in specific agreements or in a joint plan and **implemented** in local planning practices is still a far away perspective.

Local authorities are still working to implement – whenever not to impose – their vision for defining the urban region and the priorities for its development. A great need for Regional Design practices is emerging (Lingua 2014, Lingua & De Luca 2015) for shaping the boundaries of the urban region and conceiving a shared vision of its spatial development.

Regional design is intended as an institutional process of common visioning, capable to shape the physical form of regions and to «portray a vital vision of what a region can look like, and how to achieve it» (Neuman, 2000:118). In this sense, representations of the urban region are generally

intended to indicate physical changes and to encourage debate on spatial planning coordination and responsibilities at supra-local/sub-regional and local levels.

Balz and Zonneveld (2014) relate regional design to a discursive dimension of planning concepts. They assume that spatial representations are used in processes of frame reflection by integrating and explicating analytical knowledge and allocating meaning in politics and policy-making.

In this perspective, Italian metropolitan areas are starting to engage in regional design processes that – through its discursive function –, are conceived as a pertinent ways for envisioning the spatial futures of urban regions, in order to enhance inter-municipal strategic spatial planning.

A Design-Led Approach to spatial planning is envisaged for systematizing all the current visions provided by the statutory planning system in place: municipal structural plans already provide a vision of the socio-economic and spatial development priorities of the Local Authority, without avoiding to collocate it into the dynamics of the whole urban region. The same does the Provincial Territorial Coordination Plan. Regional design approaches can convey to overcome limitations that the statutory planning system – strongly based on the local level – poses to inter-municipal planning.

This is happening in the Metropolitan city of Florence, whereas the *Regional design Lab* of the University of Florence has carried out the attempt to join local strategies for defining a common vision of the urban region, within the framework of the "Report on Metropolitan Cities" national research project carried out by the National Town Planning Institute (Istituto Nazionale di Urbanistica – INU). This vision is intended as the framework within defining the spatial representation of the urban area.

Employing spatial representations of urban regions in argumentations about political priorities, territorial change and spatial transformation can be the way to engage collaborative processes among councilors of the new born "Metropolitan Council", as well as planning officers, experts and the whole metropolitan community, in the formulation of metropolitan development strategies and projects.

## 5. Conclusion and directions for further research

The paper focuses on the changes occurring in the Italian planning system after the Law 135/2012 that, in the name of the spending review, aims to abolish the provincial level, obligating municipalities with certain population and territorial surface requirements to come together into "Unions of competences", including planning, and obligating the 10 main regional cities to form joint metropolitan city governments.

The case studies of Italian medium cities governance dynamics in the phase of shaping the urban region and defining priorities for spatial planning and development has evidenced four main issues to be tackled. *The re-scaling of the statutory planning system* has to take into account three main frameworks provided respectively from previous provincial Territorial Coordination Plans, from existing and new soft planning spaces and from the big picture of current municipal structural plans.

The *extension of cooperation* is the main issue: based on two parameters (existing provinces & population) that are totally unrelated to territorial specificities and cooperative practices already in place, it doesn't take into account the presence of overlapping spaces of cooperation, between joint local development plans (coming from formal or informal spaces of planning) and sectoral and economic development programs.

For defining the pertinent extension of urban regions and putting in place the governance structures to manage them, planning officers and practitioners need to deal with the lack of coordination and communication, as well as situations of disagreement or conflict, given that the duty to union is not a duty to agree. So, planning officers and practitioners are asked to achieve *new negotiation and participation skills* in activating practices of effective joint planning across local boundaries

Joint political board, supported by Joint technical board are envisaged for systematising all the local strategies in order to identify common and conflicting visions and shaping a shared image of the future of the urban region. In this perspective, Italian metropolitan areas are engageing in regional design processes for envisioning the spatial futures of urban regions, in order to enhance inter-municipal strategic spatial planning.

The analysis carried out so far allows to trace some perspectives for further research, in an ongoing cross-disciplinary and comparative project finalized to understand the forms and outcomes of processes of cooperative planning practices at a supra-local level in Italy, within the framework of a widespread process of diffusion of Localism in Europe[6].

Notwithstanding the obvious differences in the institutional systems and planning cultures, the research aim to provide a comparative perspective with other West European countries where this obligation is active since several time (i.e. the "agglomerations" system in France, introduced in 1999) or has just been putted in place (i.e. the obligation for municipalities to face strategic issues under a "duty to cooperate" in England, under the Localism Act 2011) or in other countries where the national or regional governments incentive cooperation (i.e. the "Regionale" in Germany or ongoing sub-regional planning practices in The Netherland as the process of "Regiona design" in place). Despite the strong differences between countries, Italy could take advantage from looking to these experiences, that have conveyed to questions and answers very close to the demands for change in place.

Of course, the need of co-operation on strategic issues is not new. Institutions have an old history of working together and with other bodies to address planning issues of common concern. Nevertheless, the emergence of cooperation as a duty, i.e. as a new obligation for Local Authorities in all fields (including spatial planning), certainly poses some questions concerning the redefinition of planning spaces, the role of the planner, the access to the cooperative arena. If these are typical problems of collaborative planning, the government expectation for plan-making authorities to undertake joint work on supra-local concerns affects issues of governance rescaling and accountability for planning.

The research aims to systematize the lessons learned from the solutions given to strategic issues in previous Italian and European sub-regional/ supra-local co-operative practices, in terms of shared strategies, in order to define:
-the pertinent extension of cooperation, in relation to the concerned issues and typologies of agreements
-a model for evaluating the effectiveness of cooperation
-a virtual platform for managing supra-local planning.

The research project approaches inter-municipal spatial planning as a complex system of interaction, influenced by several variables, that will be systematised through the concept of "platform", conceived

[6] In the framework of the project "AREA VASTA 2.0. A new form of localism in Italy: challenges, risks and opportunities for spatial planning across local boundaries" founded by the Ministry of Education, Universities and Research within the prestigious SIR Programme (Scientific Independence of young Researchers, see note 1).

as a support both for implementing cooperative planning processes and for evaluating their effectiveness.

An evaluative framework will be thus outlined to assess the emerging co-operative planning efforts under the duty to cooperate, in terms of how they are changing local planning agencies capacity to manage their territorial systems. In order to explore how these developments may be really changing the concept of planning strategically across local boundaries, in contemporary times affected by localism tendencies, a systematic appraisal will begin by disaggregating such conceptual frameworks into different elements that can enlighten and implement the platform: rescaling of cooperative governance, definition of new planning spaces with varying boundaries, management of disagreement, conflict or refuse to cooperate. Assessing the efficacy of cooperative practices across local boundaries is conceived for informing and explaining what planners 'really' do and can do, not only to demonstrate that they comply with a procedure, but in activating practices of effective strategic planning across local boundaries.

Finally, the definition of an innovative technical tool is intended to overcome the limitations inherent the traditional processes of cooperation (lack of comparable data, need to compare simultaneously diverse proposed project). Planning, as a discipline, demands the dual engagement with academic discourse and professional practice and crucially requires research that moves from theoretical analysis and understanding to pro-active visioning and implementation via multi-disciplinary pursuits. The project, by involving advanced software developers, aims to develop a virtual geo-referenced interactive platform, specifically targeted to spatial planning and intended not only as a virtual platform for data sharing, but as a working space for joint planning.

The expected results are concerned with the definition of policy recommendations for join supra-local planning, addressed to Local Planning Authorities and practitioners. The challenge is the redrawing of inter-institutional relations and spaces of planning on cooperative basis, for defining relevant planning visions across local boundaries within the framework of Regional Design processes.

The project is based on an innovative methodological approach to explore new paths for planning at a supra-local level. Planning criteria for inter-municipal and supra-local planning practices are defined and systematized through the concept of "platform", intended both as a methodological grid for the co-ordination of the diverse issues affecting territorial and urban inter-municipal planning and as a virtual platform to be used by the involved authorities in managing supra-local planning processes.

**Meta Synthesis in Exploration Urban Planning Responsibilities Regarding to Vulnerable Groups**

Jianpu Lu[1], Anna Zhao[2]

College of Architecture and Urban Planning University, Tongji University, Shanghai, China, 340449463@qq.com[1]
Urban Development Planning Branch, Shanghai Tongji Urban Planning & Design Institute, Shanghai, China, 340449463@qq.com[2]

*abstract*
*At present, vulnerable groups are easily found in all walks of life, especially in cities with population concentration. Due to neglect of vulnerable groups, however, imperfect urban planning systems pose problems destabilizing the society. If not well dealt with for a long period, the problems can grow worse.*

*In the paper meta synthesis in computing is applied to urban planning. Specifically, with urban planning expertise, data & information system and computer in proper combination, a highly inclusive, man-machine integrated smart planning system is created to safeguard vulnerable groups using computer data support instead of limited human brain thinking, smart objective approaches instead of subjective planning.*

*Based on meta synthesis from qualitative to quantitative (hereafter referred to as meta synthesis), the theorization of the paper is outlined as follows:*

*1. Suggestion of a experiential hypothesis ( judgement or conjecture) after refining of scientific theories, experiential knowledge, expert judgment;*

*2. Statistics collecting and analysis of elements relating to vulnerable groups with the help of computer technology;*

*3. Proposal of a preliminary draft after model construction for numerous parameters;*

*4. Experiments on different types of beneficiaries regionally and communication & survey with the beneficiary.*

*5. Repetition of (3)(4) to get feedbacks and recommendations for the best urban planning.*

*Research summary:*
*1.Reduce potential difference among vulnerable groups from top-down combining scientific*

*theories and experiential knowledge;*

*2. Establish a discontent-defusing mechanism from bottom -up according to hierarchical structure of complex giant system*

The research takes urban areas with typical vulnerable groups iss
guide urban planning system through *meta synthesis* and enhance inclusi
groups, therefore reducing and defusing conflicts. In addition, i
vulnerable groups.

Keywords: meta synthesis, vulnerable groups, smart approaches, social responsibilities

1.General situation of the urban planning structure of vulnerable groups

Under the background of rapid development in contemporary China, the research of city social space transformation is gradually unfolded. With the differentiation of social structure and the influence of globalization coming, it highlights two level position in the labor market, income, housing between city Multi-National Corporation staff and migrant workers. As a result, began to appear in what was known as the so-called high level community, villa district , Zhejiang village, Anhui village, and other resettlement village. The new urban areas appear, differentiation of social space has become today's urban residents daily experience of urban impression. At the same time, the phenomenon of residential differentiation also began to be the concern of the planner, as early as in 2004, the fourth edition of "urban planning" has three articles respectively explore the residential space differentiation in Shanghai, Xi 'an and Hefei.

In the recent 30 years, the western cities is undergoing tremendous changes. The economic development based on faradism and the welfare policy under the influence of Keynesian were also happening profound transformation. Time-space compression, under the background of economic globalization, internationalization, the development of information technology, contributed to the current global production of diversification restructuring. The research of Sassen shows the globalization on big cities, especially the so-called "global city" in New York, London, Tokyo. With the gathering of global Multi-National Corporation headquarters and the international elite talents in these cities, urban industrial structure's biggest growth actually comes from the underlying services. At the same time, the structural tightening in the manufacturing and the increasing international migration, provide the necessary labor for the service industry development which just need low technical requirements and low level of wages. City structure adjustment caused the polarization of social structure, then both ends expanded and the middle reduced. Meanwhile, city space has become more "differentiation" and "fragmentation": On the one hand, the elite gathered in the luxury community, and their living space is generally not for outsiders in recent years (especially in California, USA ), that formed the so-called gated community. On the other hand, low income people and minorities, living in the poor community. Especially in the black community USA, due to its marginal status even constitute the so-called "underclass". Therefore, the contemporary western city is known as the "two cities", "broken city", "multicolour city", etc. Marcus and Van Cape discussed the city spatial polarization under globalization indicates whether a new city space full arrival, although their basic conclusion is no , this new phenomenon of city development should not be ignored, which drawbacks also require a long

time, downy, comprehensive improvement.

2. Objective problems and psychological demands of vulnerable groups

A fair and just social structure, is a hot topic in today's society. However, in a fair and just society, safeguard the interests of the disadvantaged groups is the basic premise.

Vulnerable groups, refers to the "crowd with low social survival ability caused by its own factors", such as the disabled, the elderly, minors (especially orphans). In China, it also include the Laid-off unemployed which as the main body of the poor in city, as well as poor farmers, the city migrant workers, etc. All of them have been ignored, discouraged, forgotten, ignored and marginalized. The basic rights of these groups have been greatly damaged, than they have to be at a disadvantage in the distribution of social resources, and unable to carry out normal social competition with other groups, finally, had to withdraw from the mainstream society.

The characteristics of vulnerable groups is generally composed of their physiological, experience, family background, social environment and cultural factors. Can have a correct understanding of the essential characteristics of vulnerable groups in contemporary Chinese social, is the key to effectively solve the problem of social protection and support for vulnerable groups.

2.2 Objective problem of vulnerable groups

2.2.1Life pauperized, living in poverty, lacking of material possessions. Mainly in low-income group, such as that who faces failure in the competitive market, laid-off, disability, or retirement. In their consumption structure, most or all of the income used to buy food, daily life use cheap goods, wear old clothes, no culture and entertainment consumption, and drop out of school or other bad consequences. Living in poverty is the typical characteristics of the vulnerable groups.

2.2.2Politically marginalized, this is mainly manifested in the pursuit of their own interests and abilities. The powerful group has an important influence in the process of making public policy, in contrast, it is difficult to truly implement down their wishes for the vulnerable groups. Now, although there is some improvement, some people in vulnerable groups have dared to stand up and express their opinions, their own voices, but the question is how many people can listen to, and how much can hear.

2.2.3Social exclusion, mainly manifested in a lack of participation in some universal social activity for some individuals or groups, which is a systemic process of marginalized and isolated. Their living environment is often neglected. Indeed, they live in the institutional exclusion, moreover to be posted disparaging and insulting label. Such as Shenzhen Airlines forced two disabled persons signed the "life and death "before allowing them on the plane, and so on. Because of this conflict involving living, so the conflict itself will with a more violent character.

2.2.4Mentality marginalized and extra malization, vulnerable groups is at the bottom of the social stratification system. Due to the lack of basic social resources and conditions, they lost the basic right of discourse in social development. And then it lead to the fault between social groups. If the vulnerable groups lose the hope of climbing, they will produce a feeling of despair, also their psychological pressure will continue to increase. When they feel they did not cause the attention of the society, even be

abandoned by the society, sometimes will have the idea of revenge to the society, and may show extreme behavior.

2.3 Rationality of system and impartiality of welfare

A fair and impartial social welfare is not only an important condition for the comprehensive development of individuals and the happiness of life, is also an important content of social civilization. Meanwhile, impartial social welfare is dependent on the rational social protection system. Excellent system and fair welfare policy plays an important role in guiding the national happiness to improve. As any group of non-governmental organization shall actively cooperate with related government for the study of improving the lives of vulnerable groups, provide the rational and wisdom theoretical basis by each subject's point of view, thus as the fundamental guarantee of rational system.

4.2.2Intelligent survey of vulnerable group: breaking the bottleneck of the lack of information

The status of intelligent survey, breaking the bottleneck of the lack of information: traditional urban planning survey, simply by manual work of planning staffs to collect and process information.

That involves all aspects of urban and rural status information, data quantity is huge, limited brain power is difficult to remember all the spatial information for the planning staffs, not to mention to space the profound social, economic and other transactional information into physical space. Lack of informa hard to collect has became an excuse of the planning is lack of science and ope

In recent years, Shenzhen introduced professional companies with GIS technicians to achieve the separation of planning and survey in battle of statutory plan . They have gained some underlines the effectiveness of intelligent survey to the status of vulnerable groups. But this separation of investigation and planning of intelligent survey also have some shortcomings:(1)Lack of the effective interface between the planning government and other departments which have already established an effective information.(2)Fail to meet demand-oriented in planning work, and did not achieve restructuring , consolidation of information and establish an effective urban status database, insufficient information utilization efficiency. (3)Not really refined to individual planning from area planning, and listen to voices.

The basic information of intelligent status survey includes two categories, spatial information and non-spatial information. The vulnerable groups most concerned about non-spatial information. Spatial information's are not only from the urban planning, underground pipeline information and outcomes of urban planning information, but also from the information of land use survey, mineral resource survey, geological hazard survey conducted by land, forestry, transportation and other department base on GIS platform. Non-spatial information includes the operation and construction information of education, health and other department; Land prices, property prices, rentals and other economic information, disaster prevention ,environmental protection, heritage conservation; As well as industry development planning, social undertaking development, and other related planning

In the GIS platform, the gathering of spatial information and the specialization of non-spatial information will urge various factors that describe the city to show as data information, urban planning gradually became a decision-making progress which depend on quantitative urban information

4.2.3Reorganization planning information: avoid data rich but information poor

The spatial and non-spatial information of intelligent survey conducted by each departments are diverse and complex. With the widely used of information technology in all sectors of modern city, urban information data will continually aggregated, resulting in useless data rich, usab

In the intelligent survey, planning demand oriented information restructuring is to systematically organize obtained information, unified scientific classification, enable the distributed information become systematize, change exclusive information to shared information, change mess data to standardization, make single-factor information to comprehensive information, thereby significantly improving utilization rate of basic data.

Planning demand oriented information restructuring is using the method of data fusion which is to complete the decision-making, evaluate tasks and comprehensively process obtained data of stats survey under certain rules. Data fusion can be divided into data level fusion, feature level fusion and decision level fusion.

In the reorganization of planning information, data level fusion refers to integration of spatial coordinates. Such as there are differences in analytical data for vulnerable groups because of diverse foundation from place to place. However in the planning data reorganization we should concentrate around each city's analysis data , use the bottom line data as basic guarantee.

Feature level fusion which belongs to the intermediate level of fusion, it first selects features from raw data, then associates features information with each other, then combine these information according to decision task oriented. In the reorganization of information, the features level fusion is overlay analysis for similar information. For example, in order to get the distributed information of female vulnerable groups, we should not only extract partial information from census authorities, but also from employment sector, the medical sector, the education sector etc, then overlap these information to get detailed distributed information of female vulnerable groups.

Decision level fusion is the highest level of integration, it first use feature selection technology which make judgment, identification and classification for complex information based on judging criteria. We finally get integrated decision-making results according to the credibility of each decision and some certain guidelines. For example, to obtain the population information of all kinds of urban land, we can overlap cadastral maps, topographic maps and satellite image to extricate residential construction information; We can interpret layer number and units number from satellite image, then we can calculate the resident population in each region, thus providing the foundation of the accurate population distribution information.

In the age of urban basic information explosion. Reorganization planning information based on data fusion technology can meet the maximum characteristic information requirement of decision making analysis. It can greatly refined complex data, so as to avoid the situation of data-rich but information poor.

4.2.4 Planning information mining: discovery the knowledge of urban laws

In the modern information technology, we emphasize the use of Knowledge to di
things. Knowledge consists of facts and rules. Truth is defined as an event, such as there is a traffic

accident at the east street and second ring road intersection, the height of Eiffel Tower is 300m or Beijing is the capital of China.

Rules can be understood as the methods ,standards, principles, processes, rules and etc, in general, it is expressed as IFTHEN in the information world. In facts the rules are the result such as the fact that Beijing is the capital of China is the result of information connection between China and capital. The rules that bring an umbrella if it rains is the result of information connection between rain and umbrella.

The data mining of smart city planning is spatial data mining, which extract implied knowledge, spatial relationships and other meaningful patterns from urban spatial basic database, then reveals the law of vulnerable groups development in the urban development. The main types of knowledge can be found include:1,Spatial distribution pattern ,analyzing the spatial distribution pattern of target.2,the law of spatial characteristics, describe the geometry and attributes of a set of spatial targets.3,spatial association rules, such as adjacent, connected, contain and etc.4,space classification rules which similar features are classified into same cluster.5,spatial distinction rules that differentiate between different types of space target.6,spatial evaluation rule which shows the variation laws of spatial target with time.7,spatial variation knowledge, that is the description of the difference between each spatial objects and extreme.8,object-oriented knowledge, that is the subclass structure and common features of complex object.

For example in the research of a city's neighborhood service facilities, we can extract the information of road function , width, section form and the disabled population, barrier-free facilities, barrier blind spot, barrier-free information service in each parcel. We can use qualitative and quantitative met synthesis to mine the information of the spatial distribution rules and spatial association rules, to find the distribution laws of handicapped population density, obstacle-free routes, the area with limited service, laying the foundation of planning adjustment.

4.2.5 Planning information update: based on work-flow principle

With the development of city, the related information of urban planning keep changing. If it lacks updating mechanism the intelligent planning will be a pool of stagnant water, we cannot check the results of planning, and correct unreasonable and non real time results, and lose the sustainable development livelihood.
Intelligent urban planning not only provide the manager a blueprint for future planning, more importantly, the achievement of planning work is the control and guidance for dynamic process, and provide the manager a dynamic process control and implementation mechanism.

Planning information will be updated not only based on the remote sensing monitoring and other modern technology, and more importantly we can construct perfect stats information database, planning deliverables information database and planning permission information database, and complete the association rules construction between each information database, providing a update platform for information. In the basis of this platform, we can use the work flow principle to establish information flow to track and monitor the process of system platform. In the daily business process of planning management and cooperative work, we can realize the dynamic update of planning information, through the information sharing between approval department and other competent departments. In this way, we

can keep related planning information up-to-date and conduct data mining in the work flow to modify unreasonable planning results and the component which lack of up-to-date.

Currently, many Chinese cities have established a picture planning management i update the approval information more maturely, but due to inadequate information sharing between relevant departments and lack of data mining in the work-flow, so we still not achieve dynamic update of comprehensive planning information which truly cover the vulnerable groups

5conclusion

We can use quantitative analysis to support the policy influence, which is the mainstream of urban planning studies in many developed countries. But for the city, the open complex giant system, it is hard to find the results just rely on computer logic, it must be complemented by human imagination and creative thinking, which means the use of human-machine interaction, using qualitative and quantitative methods to search the problem solution for complex system.

Integrated intelligent urban planning is not the universal tool to solve all the problems about urban fairness , but it will adopt an open attitude . With the development of human cognition to the world, we can integrate more sophisticated theories and methods to solve various issues ,make the development closer to origin.

# Simplicity and Complexity in Cities and Their Planning

Abstract

What are the contemporary conditions of complexity and simplicity, and their contestation the context of urban sustainability? The primary objective of this paper is to critically ex range of contemporary efforts that creatively engage these issues as we c transform the urban experience in the 21st century. A fundamental hypothesis theoretically, based on a preliminary synthesis of the laws of thermodynamics dynamics, and socio-econo-political theory. The hypothesis is that the more si the less complex a system, the more sustainable it is. This hypothesis accelerating degrees of complexity of societies in a global era is a key drive is coupled with and indeed underlies and makes possible two other factors tha often cited as the key drivers of sustainability: the increasing population an and human activities such as production, consumption, and their impacts; alon accelerating rates of change of human phenomena, so that together in combinat lead away from sustainability due to the fundamental principles of various including and especially thermodynamics and ecology.

Furthermore and more fundamentally, the degree of complexity of a system, esp dynamic human social systems of varying forms as well as ways of va scalar and temporal dimensions, underlies and gives rise to the possibility scales of magnitude of social systems such as cities, organisations, insti infrastructure networks, for example, and simultaneously gives rise to the acce of change of human processes that flow through those systems, such as the information and knowledge flows attendant to routine economic transactions o Giving rise to the possibility , in this context, means to provide the infras and administrative armatures that enable all human transactions, most often en institutions. Heidegger referred to this collective of enabling m technology (Heidegger 1977). In a global society these refer to but certainl to big data, the cloud and the numerous apps, softwares and hardwares that con ever-expanding, ever more interactive, and ever more complex constellation networks.

To the extent that this premise is true, this means that the measurable degree of human society and its social constructs and processes is fundamental to thei in an essential and ontological way. In an important way, complexity thus condi prospect of social institutions and processes being governable and sustainable,

degree. Moreover, following this logic, it is hypothesised that the degree c
inversely correlated with the degree of governability and the degree of sus
institutions and other social collectivities and their activities.

The complexity of a dynamic and living social system is based upon its abili
energy and information in order to support its growth and evolution. The more
information that is directed towards its development, the greater its degree
(Schneider and Sagan 2005). However, if this energy is not produced and ut
sustainable way, as much energy is nowadays, then it leads the system that uses
away from sustainability. Much the same can be indicated for information, whic
to both the development of the system – norms, rules, data, knowledge –
management and control. However, information gathering and processing consu
great deal of energy, and in increasing amounts. In this manner, complexity
and underlies the increases in scale and rates of change of a system; rath
alongside the latter two as co-equals. Furthermore, according to this view, c
not mere increases in scale and rates of change, is more fundamentally respon
current state of human affairs and their increasingly unsustainable and ungover
Increases complexity are demonstrably less and less capable of being mana
controlled by existing mechanisms and institutions as currently constituted, a
key driver away from sustainability today.

The paper continues below with an exposition of this argument and then ends with c
analytical remarks that suggest several new lines of research regarding the i
complex and simple components and aspects of eco-socio-technical systems are pr
for the development of planning practice and its theory. These lines are yet to
at the time of this writing.

Background and Literature Review: Social science perspectives on complexity,
increasing, are still limited in scope and quantity, relative to natural scienc
management, where there are more (May 1973, Batty 2007, Berkes, et al. 2003, U
Porter 2012, de Roo et al. 2012). There is even less scholarship on the notion
(Elgin 1993, Miller 1993, Etzioni 2004, Maeda 2006). Scholarship on their inte
virtually non-existent (Gell-Mann 1993). In the realm of the city, these inter
almost unexplored in urban planning and social science (Portugali 2011, de Roo e
These gaps have critical consequences. The most critical of these gaps is
increasing complexity of urban society and our inability to manage it and its c
largely and silently responsible for our current predicament.

However, in contrast, complexity is acknowledged as not only the overarching contemporary times, but it is even celebrated, sought, and planned. Ever larg complex socio-technical systems are evident in corporate and government institu and infrastructural mega-projects, big data and telecomm networks, and the the necessary for deep explorations of space, oceans, and particulate matter, or ex most apparent manifestation may be the city itself. In the realm of human se size of urban agglomerations is exploding, leading to an increasing variety of label mega agglomerations, such as the megalopolis and the mega-city region (Ne Hull 2011). The overall urban population of the planet is also increasing, b and relative / proportional terms. The overlapping and interlacing multiple ne economies, infrastructures and the other characteristics of urban life inters expanding complexity that increasingly spins out of control. In so doing, w that the largely negative (on aggregate) indicators of social, health, environm and political well-being abounding mark its mark our collective desc complexity to chaos. This is due to the fact that we have not been able complexity we have unleashed, but rather merely marvel at its portent.

Complexity, it appears, is difficult to manage because it is emergent, evolvin contemporary society without precedents in type, form, scale, and its rate of c metropolitan areas, and city regions are recognized as increasingly difficult t fully ungovernable (citation). This is because increases in complexity require and sophisticated data, management, and resources, not the least of which are technology. This unintended consequence of complexity, the need for more infor energy to attempt to control it, is itself extraordinarily energy intensi International 2012). This leads to increasing consumption of energy and other support management and governance infrastructures, and the people that are en those activities. Is urban planning and governance up to the challenges?

In policy arenas, including its scholarship, the role of complexity is inex whereas neoliberalism, globalisation, climate change, terrorism, etc. are pinp usual suspects in the court of responsibility for our current predicament as networked world. [insert a section here regarding the inter-relationship betw and these global predicaments] Underlying these conditions which I hav predicaments is the premise that at least part of the reason for which they traced to a complexity that extends not only beyond our capacity to cope and t the organizational, urban and societal scales; but it extends more crucial personal or individual abilities to understand and thus to navigate in order to and give meaning to our lives, and how to go about making them more meaning

sustainable in the future. In this context we begin to see that while simplic complexity lauded, these stances mask fundamental insights that have im consequences for society and fundamental relevance for the future.

Exposition of the Argument: An underlying premise of the paper is that what li complexity and simplicity with sustainability are their differences. Simple s have fewer parts. They tend to be smaller, have fewer interactions, follow phys be more predictable and more reliable. Complex systems tend to have more parts. systems tend to be larger, have more interactions, follow natural as well as ph dissipative, emergent, and thus less predictable and reliable. When the com system exceeds a set of limits that cannot be pre-determined, and cannot be ma the system itself (that is, the system cannot be self-organised), then it will its self-governance capacity as well as surpass the capacity of its environs. instability, and over the longer run, crisis. Here crisis means the inabilit change sufficiently to respond to altering conditions and perturbations in orde itself sustainably. When a system loses its ability to reproduce itself, it go outcome of a true crisis is the demise of the system, or its radical transforma type of system.

The rates at which these phenomena occur highlight the importance of understan as processes (Neuman and Churchill, 2011). Natural ecosystems, for example, are and their complexity evolves in dynamic equilibrium over the long run via ad other natural mechanisms the inescapable laws of nature. One key fact distinguishes natural ecosystems from human ones (cities, societies) is the ra of these mechanisms and processes. These rates of change are gradual, they naturally in a trial and error sequence of adaptation to surroundings and circ biologists call evolution. Moreover, these rates of change in the natural worl at least, are sustainable ones. As such, these rates of change and processes (adaptation, evolution) should inform current debates about urban progress, eco politics.

However, complex social systems including institutions, cities, societies, nati and so on; are subject to fluxes in conditions that are not necessarily only ev are also punctuated events and phenomena that lead to catastrophe such as respond to catastrophe, such as famine or draught. While learning and progres these circumstances, more often than not these catastrophic events reveal that conditions of human society are not sustainable, equitable, and respectful o other beings basic rights. [transition section here from the importance of th

to the nature of management and governance being linear, rational and thus hamst
capacity to respond to complexity, chaos, and catastrophes.]

Another key factor that distinguishes complexity from simplicity and complex s
simple systems is that the degree of complexity in nature is managed via evolut
to exceed its capacity, while in urban society complexity has been managed la
rational, linear tools that cope poorly with interdependencies among a multipli
and with their dynamic uncertainties. The latter factors that complicate matt
magnified by the accelerating rates of change and scales of impacts. The i
among all these factors give rise to degrees of complexity that lie beyond
capacities to understand, much less manage, these processes and their outcon
impacts.

Yet we rush headlong into more complexity due to the thrills, the convenience
productivity increases it affords. Think of the cloud, digital games, films,
media creations, and an endless list of other gadgets and capabilities. The
conveniences that occur throughout the city are enabled and put into place
complexity: international trade, globalisation, and elaborate governance and a
apparatus attendant to the global political economy. At what costs, to
communities, societies, other species and planet does Are we rush ourselves
blindly into this rush, with deficient decision mechanisms (Kahneman 2011)?

Compounding this complexity is parallel and increasingly intertwined dual worl
virtual, with prospects unknown and unknowable. The outcomes spinning from real
virtual reality and their interactions defy nature as they draw us in deep
humanity from the grounding of nature. Within urban society we are increasingl
computer-generated algorithms we do not control, or think we control, while the
spins consequences and implications we can scarcely imagine, much less control.

In this context, people increasingly opt out , move away from the big city, a
of means in order to simplify, cope, and survive. They adopt and adapt a mu
strategies in order to navigate the complex urban realm (de Certeau 1984).

The remainder of the full paper will address the intersection between sim
complexity by addressing two aspects. First is a brief critical history, explo
which themes of complexity and simplicity have been mobilized both as concep
political economy agendas in cities. Second is a preliminary mapping of co

DRAFT DRAFT

responses Key questions in the analysis of the intersection between simpli complexity include: Are societies destined to collapse due to their unstoppabl towards ever-increasing complexity (Tainter 1988)? Is simplicity the only pa sustainable survival? (Alexander and McLeod 2014) Are there intermediate ways?

Conclusion in abstract form: expl This atory research seeks to make new sense of th continuing and seemingly intractable conundrum of the consumer urban society policies that enable it in the urban context. It will also target the key i existing political economy arrangements guiding urban planning and governance advantage of the opportunities in the twenty-first century, or are new norm necessary? In sum, the paper will have engaged the intertwined issues of sim complexity, as well as their implications, in order to draw conclusions that are especially in the urban governance context.

Keywords: Probabilistic models, Prediction, Land Use/cover

## 1. Introduction

A cellular automata (CA) model is characterized by phase transitions that can generate complex patterns through simple transition rules. As such, this technique seems suited to model the complexity of urban systems (Clarke and Gaydos, 1998; Batty, 1995). Unlike most conventional urban models that focus more or less on the spatial patterns of urban growth, cellular automata based urban models usually pay more attention to simulating the dynamic process of urban development and defining the factors or rules driving the development. By applying different transition rules, a model based on cellular automata seeks to explore how the urban system has been developing and how this system changes under certain rules or forces.

The central component of a CA model is the transition rules that represent the logic of the process being modelled and, thus, determine the spatial dynamics of the system (White and Engelen, 2000). The transition rules define how changes the state of a cell in response to its current state and the states of its neighbours. This is the key component of CA because these rules represent the process of the system being modelled, and thus are essential to the success of a good modelling practice (White, 1998). For a restricted CA, the transitional rules are uniform and applied synchronously to all cells within the system. However, it has been pointed out a large number of different ways to define the transition rules.

The several approaches used to define transition rules, based on the understanding of the urban system and its evolution from different perspectives, resulted in different types of urban CA models. These approaches range from very simple to extremely complex. For example, in the diffusion limited aggregation (DLA) model developed by Batty a vacant cell just changes state (to occupied) if in its neighbourhood there is a occupied cell (Batty, Longley and Fortheringham, 1989). However, other urban CA based models combine different rules in order to simulate the complex behaviour of the system.

A popular approach used in cellular automata (CA) based urban modelling is to incorporate other modelling methodology into the model, especially for defining the transition rules for it. In the effort of using various mathematical approaches to configure the transition rules of a cellular automaton, it is obvious that the primary purpose of employing mathematical approaches in the modelling practice is to evaluate the adequability or probability of land for development. Therefore, this type of model is also regarded as a adequability based CA model (Li and Yeh, 2000).

In our CA urban model, we simulate different scenarios of urban growth to 2021. Our approach is to use different trends (last 2, 8, 10 and 13 years) with and without restrictions and, most important, to apply several different methods for transition rules definition. The methods test site was the Almada municipality in the South bank of Tagus River, near Lisbon (Portugal).

The mathematical models, i.e. submodels, used to define transition rules include artificial neural networks (supervised [MLP] and unsupervised [SOFM and ArtMap]), genetic algorithms (GARP and GARPOM), supported vector machines (SVM), decision trees (CRT and CHAID), generalized linear models (GLM), generalized additive models (GAM), maximum entropy (MaxEnt) and geometric distance models (Euclidian, Manhattan and Chebychev).

## 2. Material and methods

The study area, use to test our methodology, is the Almada municipality (Figure 1), belonging to the Lisbon Metropolitan Area. The choice of this municipality is due to diverse factors of great importance, such as: is near the capital (Lisbon); enjoys of increased accessibility since the construction of the Tagus bridge; as the possibility of urban expansion and rare natural potentialities and, between 1967 and 1986, the territory attended to a unmeasured urban pressure, resulting in a irreversible ground occupation in areas of strong physical restrictions. Between 1991, 2001 and 2011 (dates corresponding to the population census) its population did not stop to grow, even that in differentiated rhythms. The outward job dependence is a reality that the in-out movements between Lisbon and Almada corroborate.

Figure 1. Geographic location of Almada Municipality.

The proposed evaluation method combines cellular automata, with Markov chain analysis and a wide set of submodels, relying on six phases: i) data pre-selection; ii) data normalization; iii) spatial autocorrelation and multicollinearity analysis; iv) transition rules integration; v) Markov time series trends allowing predict future uses; and vi) simulation of future scenarios. In this point we will discuss all points except vi), that will be further analysed in the discussions of the submodels simulation performance.

### *2.1 Data pre-selection*

One of the first things to consider in a model is the selection of the variables to be used. The Geographic Information systems (GIS) allow generating and manipulating information in a way that would not be possible otherwise. As the acquisition methods used, 3 types of variables are produced: (i) variables that result from vectorization of simple themes, e.g. qualitative variables such as hydrological network, road network and land use/cover; (ii) variables resulting from spatial interpolation techniques, e.g. digital terrain model; and (iii) variables resulting from processes of local, focal and zonal operations e.g. slopes and densities. The first type is typically handled in a vector environment, whereas the latter are exclusively handled in raster environments. The proposed model is based on a raster structure, adjusting to the operational characteristics of classic CA models.

There have been developed important efforts to improve the understanding of the mechanisms of production and reproduction of the urban space, as in the case of differentiated development-related positions (Harvey, 1975; 1989), auto-organization (Holland, 1998; Portugali, 1997; 2000) and the study of complex systems (Allen, 1997; O'Sullivan, 2001). Following these experiments and the work of Rocha et al. (2007) we identify the factors of greater importance on explaining urban growth in Almada (Table 1).

Table 1. Pre-selected variables.

| Variable | Type |
|---|---|
| Slope | Quantitative (%) |
| Road Network Intersections | Quantitative (n"/km2) |
| Road Networksit Den | Quantitative (/km2 |
| Distance to Road Network | Quantitative (m) |
| Distance to Urban Areas | (Quantitative |
| Accessibility to Lisbon | Quantitative (m) |
| Accessibility to Almada | Quantitative (m) |
| Accessibility to Caparica | Quantitative (m) |
| Territorial Attraction Index | Quantitative (adimensional) |
| Territorial Valorisation Index | Quantitative (adimensional) |
| Built Up Dynamics | Quantitative (construction licences/ km2) |
| National Ecological Reserve (REN) | Qualitative |
| National Agricultural Reserve (RAN) | Qualitative |
| Planning Master Plan (PDM) | Qualitative |

*2.2 Data normalization*

The input data is developed using a set of transition rules that quantify the spatial effects that prediction cells have on land use/cover changes (Pijanowski et al., 2000). During this conversion process, the cells are encoded to represent constraints (restrictions) or probability of occurrence (factors). In the first case represent binary masks, where the zero (0) represents the absence (or denial) and one (1) presence (or acceptance), and in the second case are continuous variables, normally ranging from 0 (0% of adequability) to 1 (100% of adequability).

To make our data match this 0-1 scale we need normalize (standardise) it. We use fuzzy membership functions (Zadeh, 1965). on the standardisation of the variables. Identify exactly which function to use, depends on the knowledge and understanding of the relationship between the criteria and the set of decisions, as well as the availability of information to infer the degree of membership. In the vast majority of cases, the sigmoidal or linear functions are appropriate to the modelling of reality. The sigmoidal function was applied to the factors which constitute continuous (quantitative) variables and linear function to which correspond to discrete (qualitative or categorical) values.

*2.3. Spatial autocorrelation and multicollinearity*

Some of the common problems that models contain are the autocorrelation and multicollinearity. Statistically, the autocorrelation is a measure that reflects how much the value of a random variable is able to influence its neighbours. For example, how the existence of a higher value influences also high values in is neighbourhood. On the other hand, multicollinearity is a common problem in models where the independent variables have exact (or approximately exact) linear relationships.

The spatial autocorrelation can be measured in different ways. The Moran index is the most widespread statistic and measures the spatial autocorrelation from the product of the standard deviations. This index is a measure of global autocorrelation, as it indicates the degree of spatial association present in the data set.

If the covariance between contiguous cells is null, the neighbourhood has no influence on the values of the variable. In this case, there is no spatial autocorrelation. If the neighbours resemble each other more than the distant cells, then there is a positive spatial autocorrelation, i.e. clustering. If the distant cells resemble more than the neighbours then there is a negative spatial autocorrelation, i.e. sprawl.

In the present we choose to use two types of neighbourhood in the spatial autocorrelation calculation: Moore and Von Neuman (Table 2). Of this analysis, we conclude that all factors have acceptable values of autocorrelation, regardless of the type of neighbourhood adopted in calculations.

Table 2. Spatial autocorrelation.

| Layer | Moore | Von Neuman |
|---|---|---|
| Accessibility to Almada | 0.9822 | 1.0133 |
| Accessibility to Caparica | 0.9844 | 1.0313 |
| Accessibility to Lisbon | 1.0055 | 1.0450 |
| Territorial Attraction Index | 0.9195 | 0.9228 |
| Slope | 0.8570 | 0.8736 |
| Distance to Urban Areas | 0.9817 | 1.0227 |
| Distance to Road Network | 0.9836 | 1.0194 |
| Territorial Valorisation Index | 0.9532 | 1.0340 |
| Road Network Intersections | 0.9949 | 1.0294 |
| Road Network Density | 0.9937 | 1.0206 |
| Built-up Dynamics | 0.9841 | 1.0043 |
| Planning Master Plan (PDM) | 1.0049 | 1.0358 |
| National Agricultural Reserve (RAN) | 1.0049 | 1.0382 |
| National Ecological Reserve (REN) | 1.0049 | 1.0382 |

The clearest indication of the existence of multicollinearity is when the R2 is quite high, but none of the coefficients are statistically significant according to conventional t-statistics. The consequence of multicollinearity is high standard errors in the case of moderate or severe multicollinearity and even the impossibility of any estimation if the multicollinearity is perfect. The absence of multicollinearity is one of the premises to establish a correct model. However, some authors state that it is not a serious problem if the objective of the model is the prediction.

Thus, the choice of the variables to use in the model should take into consideration their possible multicollinearity (Guisan and Thuiller, 2005). This can be detected, among other ways, through the correlation matrix. Other techniques used are the tolerance value or its inverse, called the variance inflation factor (VIF), whose high values indicate the existence of collinearity:

$$VIF \quad \frac{1}{1 \quad R_j^2} \tag{1}$$

where $R_j$ comes from $x_j$ regression with the other variables, i.e. the coefficient of determination of the regression equation.

It is suggested, when collinearity occurs, that those variables are removed from the analysis. In Table 3 we can see that all the factors have values within acceptable parameters, and the only one that stands out for having a higher value is Accessibility to Lisbon. Crossing the values of R2 and VIF, we left out two factors: Accessibility to Almada and Road Network Density. In both cases there is a strong correlation with Accessibility to Lisbon and the Road Network Intersections, respectively. However,

despite the latter having higher values in relation to the first, they are chosen in virtue of the analysis of in out trips still emphasize the importance of movements to Lisbon and the nodes (intersections) represent a real access to road network which does not happen with the routes, e.g. highway access is only possible in some intersections. In addition, although with higher values, both parameters are within acceptable parameters.

Table 3. Multicollinearity values.

| | Factor | R2 | VIF |
|---|---|---|---|
| 1 | Accessibility to Almada | 0.376923 | 1.604938 |
| 2 | Accessibility to Caparica | 0.245495 | 1.325373 |
| 3 | Accessibility to Lisbon | 0.761179 | 4.187239 |
| 4 | Territorial Attraction Index | 0.077739 | 1.084292 |
| 5 | Slope | 0.197143 | 1.245552 |
| 6 | Distance to Urban Areas | 0.473995 | 1.901123 |
| 7 | Distance to Road Network | 0.287069 | 1.402661 |
| 8 | Territorial Valorisation Index | 0.262954 | 1.356768 |
| 9 | Road Network Intersections | 0.588384 | 2.429452 |
| 10 | Road Network Density | 0.321538 | 1.473923 |
| 11 | Built Up Dynamics | 0.564097 | 2.294087 |
| 12 | Planning Master Plan (PDM) | 0.234892 | 1.307005 |
| 13 | National Agricultural Reserve (RAN) | 0.141907 | 1.165375 |
| 14 | National Ecological Reserve (REN) | 0.445719 | 1.804140 |

*2.4. Transition rules integration*

A problem of CA models is determining the weights to assign to each factor. The solo simulation involves the use of several spatial variables. The contribution of each of these variables for the simulation is quantified by a weight, or parameter. The value of these parameters has a important effect on the results of the simulation, i.e. different combinations of values lead to totally different urban forms.

In most situations it is necessary to calibrate the CA model in order to ensure that the simulation generates results close to reality. This calibration is extremely difficult to accomplish. There are two main types of calibration processes: those based on trial-and-error approaches and those based on mathematical/statistical methods. In the first case it is not necessary to use rigid mathematical methods. A simple method is comparing visually the results of simulations made with different combinations of weights. However, when there are many variables it is difficult to define the combinations and access the results visually, since the generated patterns can be very complex.

In the second case, we refer to a fairly common approach in urban modelling with cellular automata, which is the incorporation of other modelling methodologies in the model, with a special focus on the integration of their transition rules, i.e. predictive submodels. The most used mathematical models include the multicriteria evaluation (Wu and Webster, 1998; Wu, 1995), in particular together with Analytic Hierarchy Process (AHP) developed by Saaty (1980, 1986), multiple regression (Sui and Zeng, 2001) and principal component analysis (Li and Yeh, 2002).

In an effort to use various mathematical approaches to configure CA transition rules, normally becomes obvious that the primary purpose of the application of these approaches is the evaluation of their

adjustment to urban develops adequability. Therefore, this type of model is also known as adequability CA model (Li and Yeh, 2000). From here we can see that there is a high and diverse number of statistical integration models can be used in modelling (Guisan and Zimermann, 2000). Their role is to obtain response values that translate the adequability through the combination of the independent variables values relating to the known distribution of the phenomenon.

Taking into account this large variability, the choice of a single method implies the loss of several potentialities present in others. In addition, the holding of several methods simultaneously is suggested on modelling as a way to decrease the uncertainty of the process (Pearson et al., 2006). Considering these prerogatives and the potential gain in predictive performance, we opted for the use of several different models.

The applied methods include maximum entropy (MAXENT) (Jaynes, 1957; Philips et al., 2006), generalized linear model (GLM) (Guisan et al. 2002), generalized additive model (GAM) (Hastie and Tibshirani, 1990), support vector machine (SVM) (Vapnik, 1995), Chi-squared Automatic Interaction Detection (CHAID) (Kass, 1980; Thuiller, 2003) and Classification and Regression Trees (CRT/CART) (Breiman et al., 1984; Thuiller, 2003), artificial neural networks (supervised [multilayer perceptron MLP ((Rumelhart, Hinton and Williams, 1986)] and unsupervised [self organizing feature maps SOFM (KOHONEN, 1993) and adaptive resonance theory ARTMAP (Carpenter and Grossberg, 1987)]), genetic algorithms (genetic algorithm for rule set production - [GARP] and genetic algorithm for rule Set production open modeller [GARPOM]) (Stockwell and Peters, 1999) and geometric distance models (Euclidian, Manhattan and Chebychev) (Tsoar et al., 2007).

### *2.5. Time series trends*

One of the key components of CA models is time, i.e. the change of a cell state at a given time is controlled by the state of the cell itself and the state of his neighbours in the previous step. Thus, the model needs to be configured not only spatially as well as temporally. However, the current practices of urban CA based modelling focus essentially the spatial dimension of urban land-use change. There is little concern with the temporal dimension of the model.

The Markov chain is a mathematical model that describes a certain type of process that moves in a sequence of steps and through a set of States (Baker, 1989). The attractiveness of the Markov chain lies in the fact that the model parameters are easily estimated. The transition probabilities can be estimated statistically from a sample of transitions that occurred during a certain time interval. In this way, the Markov chain only requires the establishment of a finite number of states and that transition probabilities are known. Time steps correspond to land use/cover binary maps (urban/non-urban) obtained by photo-interpretation (Figure 2). Depict having a database from 1960 to 2008 we chose to use just the data from 1995 and later, because this maps were made over ortophotomaps and have a higher positional accuracy than the other (based on aerial photograph).

The Markov chain analysis generated two tables with, respectively, the transition land use areas (Table 4) and the transition probabilities (Table 5), for 4 periods.

The 4 periods considered were of 13 (1995-2008), 10 (1998-2008), 8 (2000-2008) and 2 (2006-2008) years. Based on the values obtained we can then predict the probability of land use transitions to 2021 based on different growth trends, i.e. different periods (4).

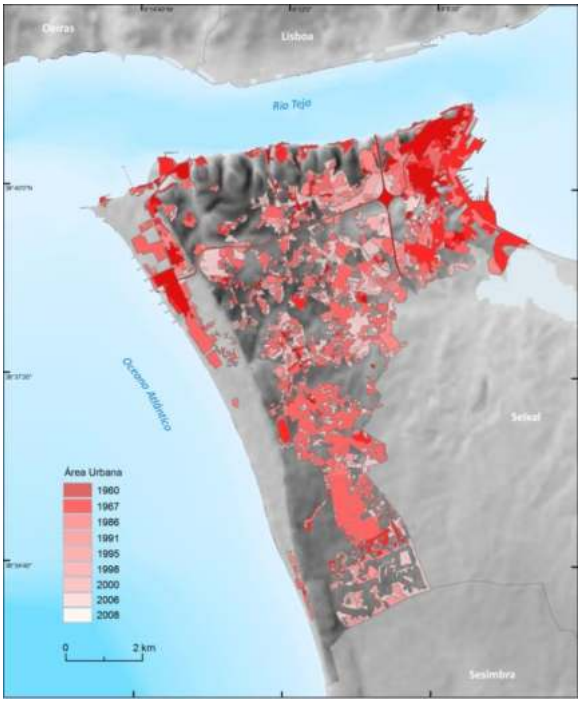

Figure 2. Land use/cover from 1960 to 2008.

Table 4. Transition areas (km2).

| | 1995 – 2008 | | 1998 – 2008 | | 2000 – 2008 | | 2006 – 20 | |
|---|---|---|---|---|---|---|---|---|
| | Non-urban | Urban | Non-urban | Urban | Non-urban | Urban | Non-urban | Ur |
| Non-urban | 25.9464 | 8.1779 | 25.2250 | 8.8993 | 25.0907 | 9.0335 | 32.1285 | |
| Urban | 0.0000 | 34.4108 | 0.0000 | 34.4108 | 0.0000 | 34.4108 | 0.0000 | |

Table 5. Transition probabilities.

| | 1995 – 2008 | | 1998 – 2008 | | 2000 – 2008 | | 2006 – 2008 | |
|---|---|---|---|---|---|---|---|---|
| | Non-urban | Urban | Non-urban | Urban | Non-urban | Urban | Non-urban | Urb |
| Non-urban | 0.7604 | 0.2396 | 0.7392 | 0.2608 | 0.7353 | 0.2647 | 0.9415 | |
| Urban | 0.0000 | 1.0000 | 0.0000 | 1.0000 | 0.0000 | 1.0000 | 0.0000 | 1 |

## 3. Submodels Validation

A receiver operating characteristic (ROC), or simply ROC curve, provides tools to select possibly optimal models and to discard suboptimal ones. Because ROC graphical plots dissociate classifiers performances through the asymmetry of class and cost errors, they have advantages over other evaluation measures.

The usual approach is to establish a threshold or cut-off value in order to split the response variable in dichotomous classes. The value of the threshold is usually set equal to the a priori occurrence probabilities of the phenomenon under study. However, the definition of a threshold is more a matter of using the model than a feature of the model itself. For this reason, it is better to use threshold-independent methods.

Usually ROC curves are used to generate summary statistics. One of the most commons is the area under the ROC curve (AUROC), or just area under curve (AUC). When using normalized fuzzy maps, the AUC is equal to the probability that a classifier will rank a randomly chosen high instance (e.g. 0.8) above a lower randomly chosen one (e.g. 0.2) (Fawcett, 2006).

Table 6 shows the AUC values for all submodels tested against 2008 land use. The results are globally satisfactory ranging from 0.61 to 0.85. It is interesting to note that distance based models, despite being conceptually simpler, are among those who get the best results. This data can be important in a future dissemination by non-specialized users, where the simplification of procedures takes on greater importance.

Understanding that all models have their virtues but also some drawbacks, but being unable to work with all of them, we select those who demonstrated a performance rated as good. So, henceforth our analysis will focus the generalized linear model (GLM), the generalized additive model (GAM), the model of maximum entropy (MaxEnt), the two genetic algorithms (GARP and GARPOM) and the model based on Manhattan distance (Manha).

We should bear in mind that all considerations concerning the parameters obtained by the models are valid only for the range of values (presences and absences) used. As such, these relationships between variables can be widely different, arising from the use of different samples, e.g. for a more extensive study area. All selected submodels, including less performance ones (GARP and Manha), can be used in conjunction, in order to better characterize the potential existence of urban areas. This method consists in the addition of consistent areas of all the six models, using as a limit of adequability the AUC value that maximizes the results of each one, i.e. weighted average. This procedure is relatively similar to that proposed by Araujo and New (2006), for the reduction of uncertainty in predictive modelling.

Table 6. Submodels AUC values.

| Submodel | AUC | Accuracy | Submodel | AUC | Accuracy |
|---|---|---|---|---|---|
| GLM | 0.851 | Good | MLP 1 hidden layer 12 neurons | 0.787 | Reasonable |
| MAXENT | 0.838 | | MLP 2 hidden layers 12 neurons | 0.783 | |
| GARPOM | 0.820 | | MLP 2 hidden layers 4 neurons | 0.782 | |
| GAM | 0.816 | | MLP 1 hidden layer – 8 neurons | 0.779 | |
| GARP | 0.811 | | ARTMAP | 0.771 | |
| MANHATTAN (MANHA) | 0.802 | | CHAID | 0.768 | |
| CHEBYCHEV | 0.792 | Reasonable | CRT | 0.767 | |
| EUCLIDIAN | 0.792 | | SVM100 | 0.757 | |
| MLP 2 hidden layers – 8 neurons | 0.788 | | SVM200 | 0.725 | |
| MLP 1 hidden layer 4 neurons | 0.787 | | SOFM | 0.613 | Weak |

## 4. Submodels Comparison

Analysing submodel-by-submodel (Table 7), it may be noted that, on average, the GLM, GAM and Manha, favour the probability of occurrence of urban use. However, the Manha has a minimum adequability of 0.4941, which does not correspond to reality. This is due to the use of pseudo absences that may not be true negatives. The GAM and the genetic algorithms (GARP and GARPOM) have the higher standard deviation values.

Table 7. Submodels descriptive statistics.

| | N | Average | Minimum | Maximum | Standard deviation |
|---|---|---|---|---|---|
| MANHA | 2729908 | 0.8295 | 0.4941 | 0.9412 | 0.0653 |
| GAM | 2729908 | 0.8336 | 0.0000 | 1.0000 | 0.2369 |
| GARP | 2729908 | 0.5824 | 0.0000 | 1.0000 | 0.3683 |
| GARPOM | 2729908 | 0.6716 | 0.0000 | 1.0000 | 0.3977 |
| GLM | 2729908 | 0.8557 | 0.0000 | 1.0000 | 0.1870 |
| MAXENT | 2729908 | 0.3292 | 0.0039 | 0.8510 | 0.1968 |
| AVG6M | 2729908 | 0.6836 | 0.0000 | 0.9412 | 0.2180 |

Comparing the submodels with each other (Table 8), we can find that they are relatively related, presenting correlation values that oscillate between 0.60 ( GLM GAM ) and 0.96 ( AVG6M GARPOM ). The AVG6M has the greater correlation with all the others (between 0.96 and 0.79), which goes alongside the idea of its use.

To compare the variances of the different submodels we used F-ratio statistic. The F-ratio is used to determine whether the variances in two independent submodels are equal. If the F-ratio is not statistically significant, we can assume that there is homogeneity of variance. This value is obtained by dividing the largest variance for the smallest. If the F-ratio exceeds the critical value, i.e. there is no difference between the variance of the submodels, the null hypothesis is rejected.

Table 8. Pearson correlation coefficient between submodels.

| | MANHA | GAM | GARP | GARPOM | GLM | MAXENT | AVG6M |
|---|---|---|---|---|---|---|---|
| MANHA | 1.00 | | | | | | |
| GAM | 0.76 | 1.00 | | | | | |
| GARP | 0.81 | 0.70 | 1.00 | | | | |
| GARPOM | 0.87 | 0.66 | 0.86 | 1.00 | | | |
| GLM | 0.84 | 0.60 | 0.68 | 0.85 | 1.00 | | |
| MAXENT | 0.77 | 0.61 | 0.80 | 0.83 | 0.79 | 1.00 | |
| AVG6M | 0.92 | 0.79 | 0.93 | 0.96 | 0.86 | 0.89 | 1.00 |

In our case, because the degrees of freedom are always greater than 1000 (>>120), the sample is statistically regarded as . Thus, regardless of the degree of confidence selected (0.10; 0.05; 0.25) the threshold corresponds to 1. The F-ratio values (Table 9) always exceed this value (1), so there is a statistically significant difference between the variances of the models. Despite all, the AVG6M is the one that presents values closer to the threshold, namely 1.36 (with GLM), 1.23 (with MaxEnt) and 1.18 (with GAM). A visual comparison can give the notion of areas where the one submodel (column) has higher (green), equal (yellow), or lower (red) prediction values than another submodel (line).

Table 9. F-ratio statistic for inter-model variances.

| | MANHA | GAM | GARP | GARPOM | GLM | MAXENT |
|---|---|---|---|---|---|---|
| GAM | 13.146 | | | | | |
| GARP | 31.765 | 2.416 | | | | |

To quantify the relationship of each submodel with all others at the same time, we carry out a multiple linear regression (MLR). In table 10 we may find the results of MLR calculations. The diagonal values correspond to the value of the line intersection and the other values match the relationship of each submodel with the one that is being analysed. Here we can see that the AVG6M is a valid option, showing values of R and R2, near 0.999 (higher values among all submodels tested). The residuals, i.e. difference between the observed and expected values, for all the regressions carried out. The areas where the values are higher are those where the worst model represents all others (the green represents positive values and negative red).

Table 10. Multiple linear regression parameters by comparing a submodel (dependente) with all others (independent).

## 5. Results Analysis

The previously discussed 7 submodels calculated served as basis to simulate future scenarios of urban occupation using a 5x5 extended Von Neuman neighbourhood. As the largest gap between records of land use/cover is 13 years, i.e. 1995 2008, it is not advisable to create simulations beyond 13 years into the future, which based on the year of the last record (2008), limits the time horizon to 2021. However, it is common knowledge that the simulation models perform better for small periods than for more extended ones. So what can be done to decrease the risk of developing a simulation so ahead in time? The solution can be easily explained by an analogy to golf training.

The golfer shoots several times the ball toward the hole and the result will be a set of balls around the hole (assuming that it is difficult to get it right in the hole at the first time, as a model does not predict exactly a future situation). Some of those balls fall on left side of the hole, others on the right, still others ahead and so on, forming a cloud of balls. Statistically, there is a high probability of the hole location being in the geometric centre of the balls distribution. This probability increases as the number of balls raises and, consequently, their density increases.

With models the situation is the same. Despite very often the purpose of the model is not to accurately predict a situation, but rather to explain the influence of factors in a given system and make it possible to identify how the system reacts to changes in the parameters, its power of simulation can be greatly increased through the creation of several alternative scenarios. This means that creating various scenarios of evolution of urban area to 2021, assures that there is a much higher probability of find the future real situation between them.

Hence, the importance of the time horizons considered (4 in total). As inferred from the land use/cover evolution changes in Almada municipality, the evolution of urban area did not happen always in the same way in space and, especially, in time. So, it was decided to adopt a set of four situations ranging from the overall trend of the last decade, e.g. last 13 years (1995-2008) and 10 years (1998-2008), to the

latest trends, e.g. 8 years (2000-2008) and 2 years (2006-2008). From the combination of all the elements, we have established 7 predictive submodels and 4 distinct trends of urban growth, originating a 7x4 matrix.

This matrix was further subjected to two distinct approaches. First, the predictive submodels were introduced without changes, i.e. fully consisting of factors. Remember that in the elaboration of these submodels, factors such as REN and RAN, were considered as highly conditioning, but not restrictive of urban use. That leads to 28 urban occupation scenarios for 2021.In the second approach, REN and RAN were used as binary masks, where the existence of the factor would correspond to zero, i.e. inability to build and the absence of a factor, i.e. possibility to build. Therefore, these two sets of information were considered as constraints in all submodels by multiplying the firsts by the seconds. In this way, we fully prevent urban sprawl within areas of REN and/or RAN in the simulations carried out. This second approach resulted in another set of 28 scenarios of urban area in 2021.

In a more quantitative analysis (Table 11) we can observe that the simulations follow the trends of land use/cover change. So, as the last two years (2006-2008) were of urban growth strong slowdown, the simulation based on this rate of growth is the one that generates less urban area for 2021, with values ranging between 35.866 km2 (AVG6M) and 35.869 km2 (Maxent). The most fruitful period is the 8 years one, spanning from 2000 to 2008. The predicted urban are for 2021, according to the 8 years trend, oscillates between 42.74 km2 of GAM and AVG6M, and the 42.751 km2 of manha. As the simulation based on the growth of 2006 to 2008 predicts a small increase in the urban area, it is understood that the 8 years dynamic is due essentially to the situation between 2000 and 2006.

Table 11. Quantitative results of the simulations (UR means unrestricted and RE means restricted).

| | 2 years trend | | 8 years trend | | 10 years trend | | 13 years tre | |
|---|---|---|---|---|---|---|---|---|
| | UR | RE | UR | RE | UR | RE | UR | RE |
| Edmanha | 35.867 | 35.869 | 42.743 | 42.751 | 42.613 | 42.620 | 41.910 | 41.913 |
| GAM | 35.868 | 35.868 | 42.740 | 42.744 | 42.608 | 42.613 | 41.905 | 41.908 |
| GARP | 35.872 | 35.871 | 42.745 | 42.742 | 42.614 | 42.610 | 41.908 | 41.908 |
| GARPOM | 35.869 | 35.869 | 42.744 | 42.746 | 42.612 | 42.615 | 41.908 | 41.912 |
| GLM | 35.867 | 35.867 | 42.742 | 42.746 | 42.613 | 42.616 | 41.909 | 41.913 |
| Maxent | 35.877 | 35.872 | 42.742 | 42.744 | 42.610 | 42.613 | 41.906 | 41.910 |
| AVG6M | 35.866 | 35.870 | 42.740 | 42.743 | 42.609 | 42.613 | 41.903 | 41.911 |

The two next simulations, give predictions of successively smaller urban area. Indeed, considering the trend of the last decade (1998-20008) the urban area in 2021 would oscillate between 42.608 km2 in the case of GAM and 42.62 km2 to the manha. Finally, following the trend of the last 13 years (1995-2008) we have a decrease in growth trend, standing just above the trend of the last two years, although with values much closer to the other two simulations (10 and 8 years) than this last (2 years). The trend of the last 13 years varies between 41.903 km2 of urban area based on AVG6M and the 41.913 km2 generated by manha. In short, we can build three groups of scenarios, one with a fairly moderate growth (trend of the last two years), a steep growth (trend of the past eight years), and an intermediate situation, although tending to be closer to the larger dynamic situations (the last ten and thirteen years).

Still in a global analysis, immediate upraises the fact that, perhaps paradoxically at first glance, the simulations with restrictions predict greatest amount of urban area than the ones without restrictions (Figure 3). The only exception is the simulation based on biennial trend. This was due to the fact that with 2 years of trend, spatial relations are still dull and the time window is too small to model a complex system, as the urban. In this way, the linear functions prevail and the built-up area expands, in this context with logic, more easily than by the more restricted space.

In the simulations based on more years, the interactions between microelements increase, coming into sight non-linear behaviours and the emergence of new behaviours. This forced the urban sprawl to follow alternate routes, because of the restrictions imposed, finding new realities that encourage new behaviours, which in turn enables the discovery of new routes and so on.

In a submodel level analysis it can be seen that in the simulation based on 2 years trend the submodel that more urban area generates is the maximum entropy (MAXENT). The entropy is a measure of the amount of uncertainty in a probability distribution or a system subject to constraints. Entropy measures the number of different microstates that may arise in a particular macrostate. The term has been used as the basis for the maximization of entropy models of spatial interaction.

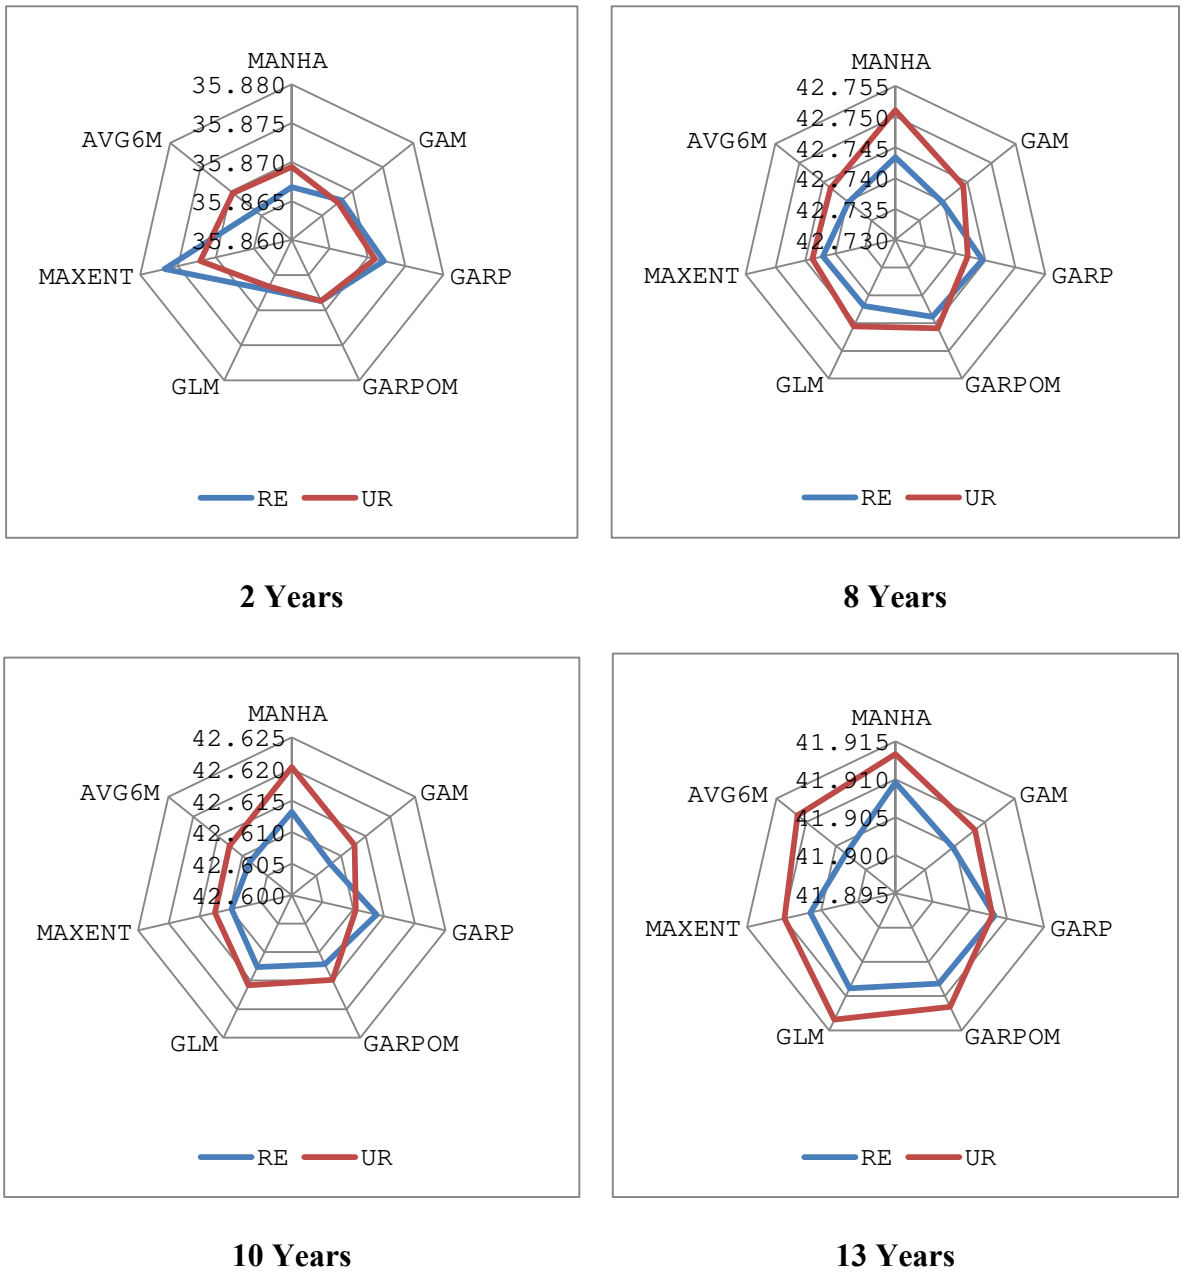

Figure 3. Quantitative results of the simulations.

The maximum entropy models are statistical models to identify the pattern of a spatial location, most likely a system subject to constraints. This approach was introduced in geographic modelling by Wilson in 1967, as the basis for a stricter interpretation of the gravity model. The model of maximum entropy make it possible to easily calculate the effects of new housing, and have been used in varied urban models, e.g. in the Lowry model. As in the situation of two years, there is a relatively small period to set the trend the system don't get auto-organized, predominating, due to the many possible behaviours, the existence of microstates.

In the remaining three simulations, based on 8, 10 and 13 years trends, the system tends to the auto-organization and the MAXENT begins to lose protagonism. In this context, the effect of distance gets predominance from what the model that stands out is the manha, which is based on Manhattan distance. At first (8 and 10 years trends), the manha is the more productive simulation in generating built space when the model is run with restrictions.

With the absence of constraints, the urbanizing space available increases and, therefore, there is an increment of the possible paths to follow. This multiplicity of solutions comes from a competition for space, which favours the genetic algorithms, which duplicate by analogy from biology the competition between species (land uses in this case). Therefore, it is not surprising that when we face an unrestricted space, GARP is the simulation with highest performance.

These claims can be confirmed by comparing the relationships between the simulations with and without restrictions. In the simulation based on two years trends, the two submodels generate more urban area with no restrictions than with restrictions, namely Maxent and GARP. Then, with 8 and 10 years trends, the only submodel that can create greater urban area without restrictions than with restrictions is GARP, for the reasons already pointed out. We cannot help to note, because it is interesting and reinforces our analysis, that GARP being more productive without restrictions, behaves in the opposite way when operating with restrictions.

Finally, in the simulation based on the trend of the last 13 years, as the system is already auto-organized, neighbourhood and proximity relationships acquire particular emphasis, and the manha is the predominant submodel, both with as without restrictions. Once again, when it comes to simulate with restrictions, GARP is the one that generates least urbanized area but, at the same time, is the one whose value are closest in the two simulations ( with and without restrictions). To reinforce the importance of the distance, we must also mention that with restrictions, manha performance is matched by the Generalized Linear Model (GLM).

Analyzing the agreement between the simulations results, we can easily see that this is less when these are made without restriction. This situation is logic, to the extent that there are more possible states and the system can evolve in many different directions. Even so, in 8, 10 and 13 years trends, the number of cells assigned to urban use in all the seven models amounts to 75%. This value is higher, accounting for 94% , in the biennial based simulation, which makes perfect sense, because if this is the least dynamic, when there are fewer state changes it will also be less error probability.

When there is not total agreement, predominates the result presented by just one model (2%), which reflects the specificity of each submodel algorithm. All other combinations have equal distribution among themselves and between models, with the exception of the two-year simulation, whose intra-simulation as also equitable distribution, but in an inter-simulation comparison, their percentages present lower values.

When we use restrictions, the situation is similar but with a slight change of scale. The unique solution continues to represent about 2% in all the simulations, as well as the common result to the seven submodels. However, the decline of the relative importance of the agreement of 6, 5, 4 and 3 submodels in detriment of the 7, allows expanding the percentage of perfect agreement good to 92%. As in the

previous situation, the particular case of simulation with 2 years presents spatially results slightly more consistent, with a value of 96% of total agreement.

In spatial terms it may be noted that the highest degree of disagreement arises on the South side, in every simulation of 8, 10 and 13 years trend, This happens mainly because the South is, in part, a luxury gated community, which does not generate the same rules as the rest of the territory, suggesting that it should be the subject of further studied.

The disagreement is also high in the northern part of the municipality, in the simulations with 8 and 10 years and with restrictions. Here, essentially two zones fail, located at Northwest and Northeast, being created by excess by only one of the models. These areas although theoretically good for housing, are not valued by the population. This situation should have been guarded by the use of the valuation tax of the territory (IMI), but its weak predictive potential turned out to condition the result.

One way to quantify the agreement is through the Kappa index. The Kappa Index of Agreement method ( ), KHAT or KIA is based on a simple cell-by-cell comparison, which checks for each cells pair on two maps if they are equal or not. This results in a comparison map that displays the spatial distribution of the agreement, without requiring any previous parameters. This method evaluates the agreement between the result of the simulation and a purely random assignment of classes to the cells (designated by agreement due to chance).

Another simple cell-by-cell statistic is the correct fraction, also known for overall accuracy. This statistic is calculated by dividing the number of correct cells by the total number of cells. However, the overall accuracy is considered unreliable as a general measure of similarity. The reason is that the correct fraction is a biased method, i.e. tends to consider maps with few categories and/or unevenly distributed, more similar than the ones with many categories and/or equally distributed.

The following (extreme) case illustrates the difference between the kappa statistic and the overall accuracy. Having a model to predict parks locations in an urban area, we have also a binary map of presences and absences. In reality, there is only one park per 100 cells. This means that a model that predicts wrongly parks in this place still gets an impressive result of proper fraction of 0.98 (absence on both maps). Another model predicts the presence of houses in the same area. These are found in 50% of all locations (i.e. cells). A model that predicted 80% of these locations would only achieve a overall accuracy of 0.8. Thus, even though the parks model is clearly worse than the model of the houses, the first produces a correct proportion much higher, simply because of the uneven distribution of absences and presences.

The Kappa values are generally lower than those obtained for overall accuracy. This difference is expected, since each index use different types of information from the contingencies table. Overall accuracy only uses data that lie along the diagonal of the matrix, excluding the omission and commission errors. On the other hand, the Kappa index incorporates the diagonal elements of the matrix as a product of the marginal values of rows and columns. It is impossible to unequivocally point the measure that must be applied and when. Usually, it is desirable to calculate and evaluate the two.

However, in order to obtain a more balanced similarity we often use the Kappa index. The Kappa statistic results from two types of similarities, the similarity of quantity and the similarity of location. In this case the amount refers to the total number of cells attached to each category found on the map, i.e. the histogram, and the location refers to the spatial distribution of the different categories of the map. To know to what extent the measures of of location and quantity similarity are represented in the Kappa statistic, we divided it into two statistics, the Kappa histogram (KHisto) and the Kappa location (KLoc). It can be found more information about the KHisto and KLoc in Hagen (2002). The relationship between the 3 statistics is given by:

$$\text{Kappa} \quad \text{KHisto} \quad \text{KLoc} \tag{2}$$

These statistics were calculated for the simulations carried out without restrictions (Table 12). This option was taken because this is the actual situation, i.e. there has always been urban growth in areas of RAN and REN. In addition, the new legislation of the REN is more permissive in terms of use, establishing some activities compatible with the various levels of protection. These condition, associated with the fact that the management of both the REN and RAN, is made by the local authorities, points for this scenario as the most suitable to follow. For all the reasons already pointed out, we choose as final submodel the average of all models with good performance of AUC, weighted by its predictive power, i.e. submodel AVG6M. The kappa statistics were only calculated for this final submodel.

In Table 12 we can observe the good agreement of the submodel AVG6M with all others, showing always values above 90% (0.9). The agreement of the histogram of the submodel AVG6M with the manha, GARP, GARPOM and the Maxent is always total. The overall accuracy and Kappa are very homogeneous, despite of using 8, 10 or 13 years trends, and increase a little when using only a 2 years trend. This demonstrates that in the first moments of expansion, transitions are more assertive. In all cases the Kappa is always less than the KHisto, due solely to lower values of Kloc, which indicates that even when evolution takes place in same quantity it not necessarily occurs in the same direction.

Table 12. Agreement of submodel AVG6M without restrictions with all the others.

## 6. Conclusions

In our CA urban model, we simulate different scenarios of urban growth to 2021. Our approach is to use different trends (last 2, 8, 10 and 13 years) with and without restrictions and, most important, to apply several different methods for transition rules definition. The mathematical models used to define transition rules include artificial neural networks, genetic algorithms, supported vector machines, decision trees, generalized linear models, generalized additive models, maximum entropy and geometric distance models.

In the second part of our work we select the 6 best performing submodels. In addition, another submodel (named AVG6M) was created through a weight mean of these six best submodels. Using the six selected methods and the newly created one, we simulate urban area growth scenarios to the year 2021. Overall, 56 simulations were carry out, using 7 submodels, 4 tends, and 2 different approaches (with and without restrictions). All the simulations were compared in relation to the predicted amount of urban area, spatial distribution of predicted urban area and geographic agreement between them.

In an effort to use different mathematical approaches to configure CA transition rules, it becomes obvious that the primary objective of the application of these approaches to modelling is the evaluation

of suitability or probability of the cell to develop, i.e. change of state. Therefore, we can see that the number of statistical integration models that can be used in correlative modelling of a phenomenon distribution of is high and diverse. Their role is to obtain response values that translate the suitability of the space by the combination of the values of the independent variables, concerning the known distribution of the phenomenon.

Possibly the most important feature of the models, which has been the subject of several studies, relates to the comparison of their predictive performance (Brotons et al., 2004; Tsoar et al., 2007), yet these models differ in several other features that often influence or potentiate their use in modelling. Taking into account this high variability, the choice of a single method implies the loss of several advantages present in others. In addition, holding several methods simultaneously is suggested on modelling the distribution of a phenomenon, as a way to reduce the uncertainty of the process and the variability of the models.

# GROWTH MISMANAGEMENT, RESIDENTIAL OVERSUPPLY AND HOUSING CYCLES – THE MANIFESTATION OF UN-CONTAINMENT PLANNING POLICY IN ESTONIA

Antti Roose[1], Martin Gauk[2]

[1] University of Tartu, antti.roose@ut.ee
[2] University of Tartu, martingauk@gmail.com

*Urban sprawl remains a controversial issue in Estonia similarly to many Central and Eastern Europe countries in the spatio-temporal evolution of housing market. In the midst of the debate over flexibility in urban planning and joint-up territorial governance, neo-liberal planning framework coupled with the fact that 97% of the housing stock is owned by private sector has proven itself too weak for growth management, in particularly in urban fringe. This study carries out a comparative analysis of the spatio-temporal behaviour and magnitude of market shocks in uncertain macroeconomic fluctuations and residential development patterns between 2000 and 2013 in Tartu urban region. The results show that the speed and scope of planning cycles have been lagging behind real estate business cycles, having different delays and strengths of path-dependence across councils and spatial allocations. The mismatch between supply and demand amplified by the absence of strategic plans and housing policies has led to extensive detail planning which in turn manifests itself in massive 'overbooking' of residential land parcels as only one fifth of the planned development has been carried out in the suburbs and one third in the city. The discrepancy between issuing plans and the reality of urban development indicates that plans in an uncontrolled planning framework and volatile market are often too rigid respond to change, plus legal fixes as dynamism in national economy, housing market and population of urban region are often undermined by locality-specific local economic and political conditions. A profit-driven supply-side entrepreneurial intervention to planning during the growth years put too much emphasis on delivery of quantity, namely land supply, rather than the benefits of quality, allocation choices and social dimension, often overriding regulative frameworks.*

Keywords: land use, suburbanization, housing

## 1. Introduction

Positioning residential land development and land use planning in changing cities, especially considering the conditions set by a massive economic growth and sudden recession in the last decade has been a challenge for urban planners. Rapid urbanization, along with socioeconomic changes and environmental concerns, rearranges the scene of urban sustainability, switching from business cycles to steady state economy. Uncertainty in financial markets, shifting economic growth drivers, changing demographics such as household size, social equity and e-democracy are just few crucial factors to consider in the discourse of neo-liberal planning (Sager, 2011). In the midst of the debate over flexibility in urban planning and multi-level governance, a neo-liberal planning framework has now proven itself to be unfit to manage urban complexities like never-ending suburban growth, fill-in at heritage areas, brownfield redevelopment and infrastructure provision (Allmendiger & Haughton, 2013). As built environment and urban problems expand and shift to rural surroundings both in physical, environmental and socio-economic aspects, urban dynamism and impacts should be explored as urban region. Among other themes, housing policy and the residential development should deliver a supply of dwellings that satisfies current and expected future demand while minimizing excess (Ford & March, 2012).

The latter, however has proven to be a difficult task, as real estate developments are cyclic in nature and usually lagging a little behind the real economic cycle. Depending on legislative context, planning system and practice, a rather slow public process relates to democratic accountability, participatory civil society and institutional efficiency. As economic growth starts, property developers usually react by initiating new developments in great volumes, and as growth lasts, it turns speculative in nature. So when a sudden decline hits the economy, these foreseen developments are often not fulfilled or can lead to high number of empty unsold dwellings. In a way, the housing market could be almost as

volatile as the stock market. Speculative land use planning in the deregulated neo-liberal conditions can create massive problems in multitude features and implications starting from undeveloped infrastructure with a decline in quality of life to just wasteful use of land as basic commodity. Therefore, it is essential to better understand these processes and develop policies to intervene to these failing market forces accordingly. A key issue for city regions is the ability to adjust to the new socio-demographic conditions, though even strongly economic situation. Tackling with strategic issues and wider, often global trends in local and urban context with flexibility and tolerance is expressed by mutual tension between statutory and non-statutory planning (Evers, 2008).

Urban areas in Central and Eastern Europe alike in Estonia are still sprawling and rapidly transforming. In a European context, Estonian planning system is characterized by comprehensive planning with very strong detail planning at municipality level, legally and strategically very weak regional levels and strong private interest (Roose & Kull 2012). During structural reforms and global economic recession the planning system in Estonia has not been changed though political reorientation towards more neo-liberal planning policies is notable with an increased tension between efficiency and legitimacy alike in the mature Nordic countries (Mäntysalo, Saglie, & Cars, 2011). Against this backdrop, this study takes upon a task to assess the complex inter-relations between economic growth, planning practice and housing development in the Tartu urban region (TUR), a second tier city and regional growth pole in southern Estonia. The aim is to explore complexities of land use and urban growth, how suburbanisation as a process has evolved through uncertain economic conditions and transforming planning practices by examining the spatiotemporal disparities of supply and demand for housing. The paper provides new dimension by focusing on housing market-driven outcomes, discussing what happens to regional city when housing markets respond to the rapid growth in monetary terms as well housing supply. Modelling exercise explores cyclic processes of urban development, physical, temporal and spatial barriers of planning depending on economic cycles, stability and accumulation. A particular emphasis is given to examining the time-to-plan and time-to-build, the reactions of development and planning processes to shocks in the real estate value chain.

## 2. Planning context and framework

Many of the countries in Central and Eastern Europe have undertaken fundamental reforms to the body of planning law to enable changes in the elaboration and operation of their planning systems. In some countries, however, planning system and code have not kept pace with the reality of spatial development and housing market (Economic Commission for Europe, 2008, OECD 2013). Phasing out centralised planning systems and steadily introducing new decentralised systems with high degrees of complexity has been a challenge for all Baltic states (Adams et al 2013). Besides stable legal framework and credibility of public administration the cultural approach has gained the prominence as different 'values', 'truths', and 'interpretations' of discretional planning decisions appear (Knieling & Othengrafen, 2009**).** The shift was more influential in terms of values and learning, less in spatial plans themselves. Approving new planning regulation in late 1990s and harmonising Estonian environmental legislation before entering European Union in 2004 did not automatically mean that these rules are immediately implemented across the society. It has meant gradual institutionalisation and empowering all major stakeholders in planning chain of strategic spatial planning from central government down to municipalities, agents, sectors and spatially aware consultancies. Europeanization for territorial cohesion and insights for balanced growth has embodied in major public infrastructure projects (Raagmaa & Stead 2014). In some European countries, land-use planning has changed significantly to make the planning system more strategic, faster and to provide more effective ways of engaging with governance agents and all sections of the society (Allmendinger & Haughton, 2009).

House-building industry in Estonia is very scattered. The building companies have to progress through multiple stages in the production of the built environment, involving land purchase; application for planning permission; development design, housing construction; and marketing and selling. If availability of land is non-restrictive alike in Estonia, the planning process is often most problematic due to time consuming, bureaucratic, public awareness matters. At these points developer or house-builders and the planning system come into direct conflict.

Land use planning in Estonia is organized hierarchically in the national Planning Act (2003). There are four types of plans in the Estonian planning system: national spatial plan, county plan, comprehensive plan and detailed plans. The latter three are essentially land use plans, while the national plan is a more general strategic development guidelines for the country. The new national plan, Estonia 2030+, was issued in 2013 and its main principles are safeguarding spatial accessibility of basic human needs by means of improved mobility, preserving the qualities of settlement pattern and landscape, spatial balancing of settlement structure, good spatial connection to the rest of Europe and preserving the good condition of the natural environment (Estonia 2030+, 2012). These give general development directions for the counties and local authorities for urban and rural development. The national plan declaring spatial diversity and poly-centricity promotes low-density urbanised territorial structures for integrating compact cities, suburbs and traditional villages, providing the human scale, keeping environmental values and urban networks. County plans deliver regional level planning by directing the territorial development and aiming to keep the specific character of regions. The county plans set the conditions for the development of settlement systems and the location of the major infrastructure for local authorities in a generalised manner. Nevertheless, county level planning has steadily contracted since the early 2000s and retreated to inspecting and supervising detailed plans of land use.

Instead, planning monopoly is given to local authorities, who primarily process detailed plans. Local councils are the focal decision makers for spatial development. Local comprehensive plans which determine functional zoning, general directions and conditions for the development of the territory were issued massively in the second half of the 2000s though due to residential development, facilitation of social and technical infrastructure have been out-dated in many cases. The instant framework for land use development is set by detailed plans or master plans which formally and physically operationalize urban development. Given extensive and excessive residential zoning on the general plans, the allocation of sites for residential development depends of private interest to convert agricultural land to residential one. *Ad hoc* planning practices which are based on masterplanning and focus on siting and speed tackling a specific growth issues are expressed in particular on the city region level and within suburbanisation processes (Roose & Kull, 2012). On the other hand, going beyond traditional land use planning to bring together and integrate policies for the development territorial policies and programmes linked strongly or even loosely to Europe influence the nature of places and how they function. The major public infrastructure projects co-funded by European Union frame other minor developments, including residential. The Europeanization of spatial planning has contributed progressively to the emergence of new discourse, concepts and insights of territorial cohesion in Estonia (Raagmaa & Stead, 2013).

**3. Data and methods**

This survey has mapped the issued master plans and developed a spatial database in order to analyze the residential land supply delivery in the TUR from 2000 to 2014. In order to assess the implications of mismatches between development outcomes and planning objectives, data on the new residential buildings were also added to the database. The planning records were gained from municipalities' planning authorities and the data for population and housing through national statistics databases. The database provides a comprehensive overview and enables to compare master-planned housing supply and actual demand along with the timeframe meet these demands from the initiation of the plan to a completed development both in the core city and in the fringe. In addition, there are around 270 binding local comprehensive land use plans at municipal level and thousands of master plans in Estonia. However, the local and regional governments are having setbacks of the cumulative outcomes, confronting impacts and unwanted synergies of separate residential plans. In temporal scale, the analysis covers the stages of rapid economic growth, following recession and recovery during 2000–2013.

Complementing the typically qualitative nature of spatial planning objectives, the approach quantifies the supply of master-planned residential land and the demand for actual construction characterized by the implementation of these plans, then uses common metrics to measure the duration and scope of

these developments to enable an assessment of the sustainability of the current approach in residential land use planning.

The university city of Tartu with its five fringe municipalities in Southern Estonia with an extent of 740 km$^2$ was chosen as a case study area. Tartu is the second largest city in Estonia which belongs to the group of medium-sized cities on the European scale with its population of 98,000, in addition 22,000 inhabitants in the fringe municipalities. As the regional pole of Southern Estonia it fulfils a central role as Estonia's leading research, educational, health-care, and administrative centre. Currently, the regional importance of the Tartu city has been growing supplemented by functional and demographic expansion of urban region. The extensive cyclical waves of urban development have been ongoing since the late 1990s which makes this mid-size regional case representative and appropriate for other Central and Eastern European countries.

## 4. Results and discussion

Uneven geographies characterize urbanisation process in Estonia in 21st century. Housing development means also unbalanced demographic composition of urban communities: growing elderly population in 1960–80 built core city neighbourhoods versus growing young family population in 2000s built periurban neighbourhoods, high residential mobility in the centrally located neighbourhoods as well low fertility rates in particular in core city. New geographies delineate mismatching of structures, increasing fragmentation of settlement patterns and labour markets which affects directly mobility of labour market and service areas within urban region.

A new wave of urbanisation in Estonia began in the early 2000s driven by economic growth, characterized by extensive master planning and rapid construction of new housing. Between 2000 and 2014, 2360 new homes (4720 residents) were built in the core city out of 6897 planned homes compared to 2694 homes (8082 residents) in the fringe out of 11432 planned homes (Table 1). That is a 10% increase in the total number of housing stock in the core city and 41% in the suburban housing stock in a mere 12 years. In morphological terms, built-up areas enlarged by 93 ha in the city and 450 ha in the fringe, a 10 km transition zone between urban and rural areas establishing 111 km$^2$ urbanised mono-centric settlement pattern. 5 km periurban zone had been a principal locus for new house building attracted by a high quality rural environment within very near commuting distance of Tartu. The fringe development is characterised by parcel-wise low density housing without a clear strategic planning at urban region level (Figure 1,2). As a result, the land use pattern in the suburban zone has become fragmented and patchy, chaotically built-up with detached houses delivering an average residential density in the fringe 40–70 in/km$^2$. The latter is irrational and inefficient in terms of utilities, urban infrastructure and public services.

Table 1. Implementation of adopted master plans of residential development in Tartu urban region, 2000–2014.

| Municipality: urban/ suburban | Adopted master plans | Master plan area (ha) | Planned dwellings | Completed dwellings | Not developed |
|---|---|---|---|---|---|
| **Urban: Tartu city** | **237** | **333** | **6897** | **2360** | **4537** |
| Haaslava | 58 | 357 | 1602 | 97 | 1505 |
| Luunja | 90 | 508 | 1947 | 524 | 1423 |
| Tartu | 110 | 667 | 4206 | 923 | 3283 |
| Tähtvere | 58 | 221 | 497 | 137 | 360 |

| **Total suburban** | **444** | **2293** | **11432** | **2694** | **8738** |

Figure 1. New residential plots in Tartu urban region, 2000–2013 (in black).

Figure 2. Sporadic development of new suburban dwellings in Jõeääre, a new suburban settlement in Haaslava parish.

There is constant oversupply of development projects in the form of issued master plans in the core city and surrounding fringe areas. During 2000–2014, every third planned swelling was actually developed. In comparison, the development/construction rate of master planned plots in urban fringe is about 24%. The pace of adopting master plans for residential development at local councils has remained constant in recent years, but the pressure of initiating the plan is once again on the rise since

the recession hit. 4537 dwellings in the core city and 8738 dwellings in fringe are to be developed. As a maximum limit of residential growth, the comprehensive plan of the Tartu city can theoretically in present densities accommodate more than 18000 dwellings which could increase the core city population from 98000 to 135000 inhabitants. Given the economic and demographic trends, it is highly unrealistic. As development rate as well processing speed of plans is higher in the fringe, the core city continues to fade away instead increasing compactness which dominates the political rhetoric. The renovation of inner city neighbourhoods steers gentrification and increasing densities.

Forms of suburban development differ significantly from place to place and vary from greater and rather autonomous new settlements to individual projects of separate single-family dwellings. Inevitably, there has been some dilution of sharply distinguished uses, to create a unique landscape, interfacing town and country, labelled the rural-urban fringe. These areas have been created more by accident than comprehensive planning and design: less favoured urban uses such as sewage works, processing units, wholesale centres have been pushed away from residential areas. Like in most other European suburban developments, there is a clearly distinctive feature affecting suburban development in its early stage – due to an ongoing land restitution process there is a spatially continuous suburbanization along roads. A highly urbanized landscape is actually more homogenous and better-connected than a rapidly urbanizing landscape in the case of Tartu. In-fill development, which can help reduce patchiness, has been rare, though the degree of fragmentation is expected to be reduced through bigger residential developments.

The impending economic recession since 2007 has opened up a phase of increased concern with environmental and social justice and equity in suburban planning. The shocking explosion of price bubble and the moves of financial sector to tighten mortgage lending have cooled the property market. Until 2013, many families were stuck in houses that are worth less than the mortgages on them. Slowing down of residential planning during the recession gave local councils time to reassess the housing trends and streamline planning practices with tightening national level supervision, the adoption of comprehensive plans, land consolidation and cross-municipality thematic planning. The present land management regime, allowing separate agreement of municipalities with developers, promotes further losses of productive farm land, and causes further deterioration of the green network and environment. The old pattern of rural settlement confronts the sprawl but, at the same time, municipalities would like to attract capital in housing investment.

At the operational scale, speed and scope of planning cycles have been lagging behind real estate business cycles, having different delays and strengths of path-dependence across councils and urban districts. In terms of planning process, in average, the getting planning permission has took 5-10 month longer in the city than in the suburb (Figure 3,4).

The housing market in Tartu has been relatively stable due to the growing student population and the dominating public sector. As the market is rather small, it could be volatile by segments, the issue of affordable housing becomes acute. Short-term fluctuations are induced by investors' sentiment, the limited purchasing / borrowing power and the completion of new dwellings. In latter case, the demand for new dwellings is saturated for 4–6 months. Up to one fifth of the new dwellings bought are buy-to-rent. The housing share of real estate market rose to a record 80% in 2013 which is explained by a weak entrepreneurship.

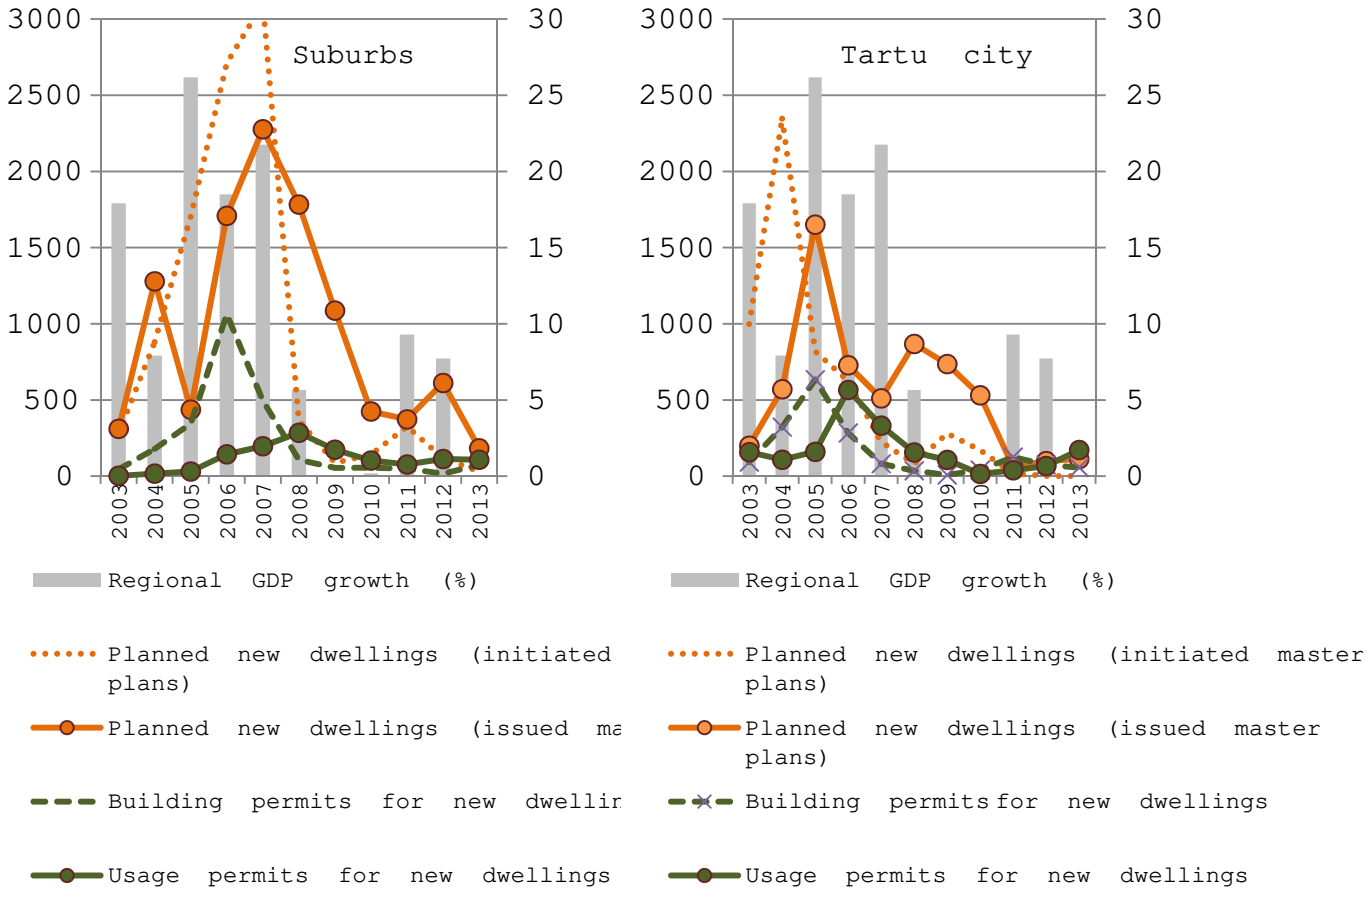

Figure 3. Building permits and completed dwellings in relation to regional GDP change in Tartu city and county (Data: Statistics Estonia 2014).

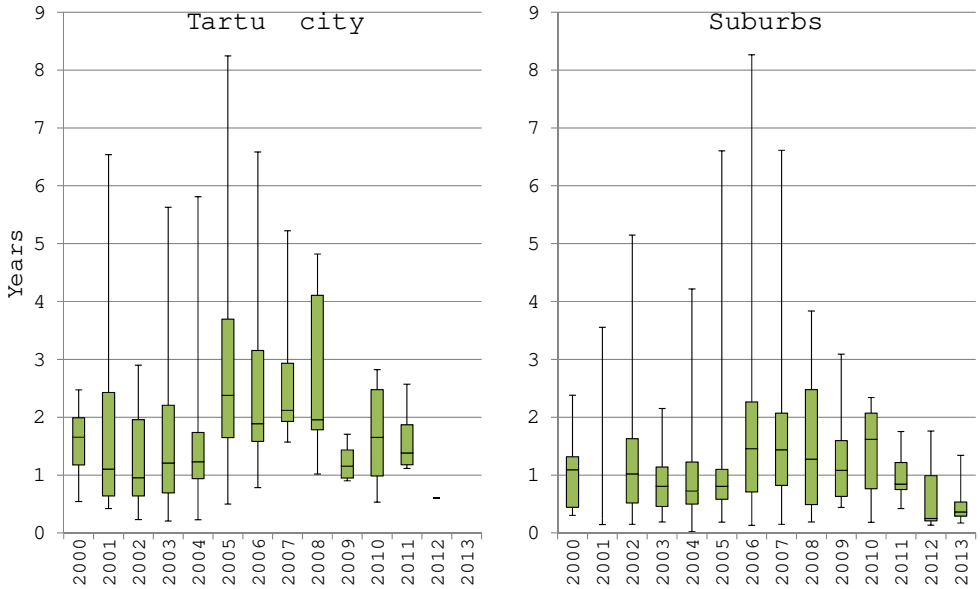

Figure 4. Short-run dynamics of detail planning.

## 5. Conclusions

The Estonian case study of cyclic oversupply of residential development exemplifies hectic and volatile real estate market with few policy and planning instruments. It can happen in the conditions of liberal-conservative market ideology with modest planning. Land management remains biased between aggressive development pressure or unsystematic use. The results show that having uncertain urban growth trajectory with conurbanisation pathologies of fragmented decision-making with no specific planning instruments for urban containment and choice preferences, its manifestation in the housing market and local planning practices, call for a more strategic, integrated and participatory planning between core city and fringe municipalities. The planning 'problem is amplified by the economic recession in addition to inability and inexperience of central and local governments to buffer market fluctuations. The main reasons for excessive oversupply of residential developments are as follows:

- Legal framework is liberal in issuing planning and building permits.
- Moderate or non-existent intervention of central government and regional authorities.
- Long-term strategies and general plans are replaced by tactical and discretional decisions of local politicians, pressurized by developers.

Developers, investors and decision-makers in both public and private institutions are increasingly under pressure to operate in short-term frameworks. The realization of planning projects becomes imperative. Masterplanning remains complex, bureaucratic, time consuming, and static. Aiming to increase the efficiency of planning, planning system attempts to streamline project-by-project decisions and to introduce the development 'flow', compromising quite often public interest. While adjusting legal and institutional framework for planning, adaptive role-setting for authorities as well as for plan-making expertise with a stronger emphasis on community and business needs is contemporary requirement.

To restrict further scattered residential development and plan-making for speculative purposes, the major step could be drafting a new comprehensive plan for the core city as well for fringe municipalities. The new plan should consider realistically demographic trends, declining student population, developments in education, health and service sectors dominating in Tartu labour market. The global economy means the urbanization and concentration of human capital. Tartu is faced with critical threshold in terms of its economic potential in globalisation processes. Within the drafting county plan for smart, sustainable and cohesive development of urban region as, the residential growth zones should be allocated by housing forecasts of residential market and site quality, preferably in-fill mode. The de-concentration of the central city is generally a favourable circumstance, apart from the fact that it poses a great challenge to the administrative and planning capacity of the local government. Land consolidation could be an integrated part of a urban fringe development policy for densification and necklace.

The recession since 2008 has changed sharply planning practice as quality of planning and legal enforcement has improved. Policymakers and developers demonstrate institutional learning and in developing and promoting land use planning capacities to intertwine the key actors of periurban development. The strengthening of urban region and dynamism in urban fringe is also another manifestation of soft planning as Allmendinger and Haughton (2009) discuss the new generation of "soft spaces" and "fuzzy boundaries" that characterize emerging political objectives within new relations, all of which are causing a changed agenda for planners and others charged with formulating territorial-based strategies.

Collaboration between municipalities of urban region is a key to strengthen and consolidate the implementation of county plans, as cases are to be solved on joint spatial developments instead of adopting a competitive approach to land allocations for residential development. A vertically organised political and financial system as well as eclectically designed legislation does not support

cooperation and joint action between neighbouring municipalities. In broader context, the political process is related to amalgamation of local authorities within urban region. On the local level, the major issue is empowering local authorities to implement their comprehensive plans. In the case of suburbanisation, comprehensive plans adopted in late 2000s are already outdated. The concern with the efficiency of the planning system, the appropriateness of procedures and institutional arrangements for decision making need to be continuously addressed (Raagmaa et. al., 2013). The 2000s express neo-liberal pragmatism and fragile inter-municipal cooperation on local level though there are signs of the transition from government-led to governance-led approach in spatial development policies and spatial planning.

# RESIDENTS AND FLOOD RISK MANAGEMENT IN FLANDERS: TWO WORLDS APART?

Barbara Tempels

Centre for Mobility and Spatial Planning (Ghent University), barbara.tempels@uge

Keywords: flood risk management; Flanders; residents

Although flood risk is usually framed as a physical problem, there is also an i
side to the issue. Potential damages are influenced by a large number of indivi
location choice or private flood protection measures. Flood risk management i
including these elements through responsibilization of spatial planners and civi

However, since flood risk management in Western Europe is strongly government-
were usually confined within the boundaries of the water system itself, there is
to do this. Therefore, this paper looks into the point of view of residents in f
a survey (n=183) in the Dender basin (Flanders, Belgium). The paper first discu
residents knowledge, risk perception, location choice, sense of responsibility,
and seeds of self-initiative. The survey shows that residents are very much atta
at the same time take little action. Remarkable is that even though Flanders
tradition in spatial planning, residents place responsibility for living in fl
government, and therefore they feel entitled to public protection.

## 1. Introduction

Under influence of increasing flood risks and uncertainty, many Western Europear
recently adopted a risk-based approach to flood management (Kellens et al., 201
While the earlier flood protection paradigm considered the socio-spatial contex
and tried to find solutions within the confines of the water system itself
altogether, the risk-based approach incorporates the socio-spatial aspect o
urbanization in floodplains and increases in sealed land. Subsequently this ri
emphasis on avoiding damage due to flooding (Johnson and Priest, 2008). Th
dimensions of natural hazards are becoming more and more important (Raschky, 20
reciprocal interaction between society and water management (Tempels and Hartman

Consequently, there is a growing awareness that spatial planning could play an i
risk management (Jong and van den Brink, 2013, White, 2013, De Smedt, 2014, Pa
2012). Flood management is no longer reactive to changes in spatial developmen
integral part of spatial planning and the conception of spatial developments (Wo
line with the tendency in spatial planning theory towards actor involvement (Bo
press), societal actors should play an increasingly important role in flood ris
et al., 2014, Penning-Rowsell and Pardoe, 2012, Fleischhauer et al., 2012). Ta
limited resources of governments, climate change and inherent limitations o
involving residents in flood risk management can become an important part of th
et al., 2011).

However, until now flood management research has mainly focused on the isolated
technical) systems (Pahl-Wostl, 2007). As a result, the frequency of flooding a
have been well studied (de Moel et al., 2009), while the role of societal acto
debate. Only in the United States, social issues in relation to flood risks
subject to research for some time (Waterstone, 1978, Montz and Gruntfest, 19
Western European context they gained relevance only recently due to the high de
responsibility (Kreibich et al., 2005, Bubeck et al., 2013, Terpstra and Gutte
most of these topics, such as flood risk knowledge and awareness, risk perceptio
individual responsibility and protective behavior, including the economic, psy

mechanisms behind them, have been mainly described individually within diff
geographical or political contexts (see further). Therefore, an integrated unde
risks and societies interact, and how this affects spatial planning and flood
lacking.

This paper analyzes a wide array of interactions of residents with flood risk
(Flanders, Belgium), based on a survey amongst residents in flood-prone areas
include (1) the availability and use of knowledge, (2) the way risks are experie
chose their location and the extent to which they are willing to move, (4) who
for different aspects of the issue and (5) what they do to protect themselves.
these interactions contribute to flood risk management, and how they could becc
flood risk management in the future.

As such, this research contributes to the existing knowledge in two ways. On the
specifically on residents and spatial planning, since the debate on flood ris
conducted from the perspective of water managers. On the other hand, it discus
topics from psychosocial aspects such as awareness and knowledge, to behav
eventually the translation to policy.

In what follows, we will give an overview of the state of the art on resident
based on literature review. Next, the main elements of flood risk management an
Flanders (Belgium) will be discussed, as a context to the survey results pres
paper ends with a discussion on what these results imply for flood risk manageme

## 2. Research design and case study area

### 2.1 Key topics

#### 2.1.1 Knowledge

Knowledge on flood risks is a prerequisite for taking action. As memories of f
trough time, risks are disregarded. Therefore, risk communication is an impor
strategy to activate residents. However, the rigid institutionalization of risks
maps can give rise to a biased and oversimplified perception of complex concep
(e.g. return period). Accordingly, local knowledge is often undervalued.

#### 2.1.2 Risk perception and experience

Since knowledge of risks does not always translate into personal worry, merely p
about risk is not enough (Parker et al., 2009, Willis et al., 2011). Risk percep
personal characteristics, situational factors and risk characteristics (Lind
Explicitly dealing with risk perceptions in risk communication can make flood ri
effective (Buchecker et al., 2013, Grothmann and Reusswig, 2006, Kellens et a
Klijn, 2004). Flood forecasting and warning play a central role in this (Brilly

#### 2.1.3 Location choice and willingness to move

Filatova et al. (2011) state that low individual flood risk awareness leads
developments and increased flood risks. They argue that by increasing individua
likely that flood risks are integrated in the individual economic decisions at
housing prices are often lower in flood-prone areas (Tobin and Montz, 1988, Eves

Individual decisions on private risk mitigation measures and location choice are
extent to which insurance premiums internalize actual variations in risk and

subsidized by the whole population (Bouwer et al., 2007). Possible incentives reduction might include lower premiums, higher coverage and lower deductibles (P However, in practice, premiums generally do not as risk is reduced (Penning-Rowsell and Pardoe, 2012).

### 2.1.4 Sense of responsibility

The limits of the capacity of the state to manage flood risk is widely recognize an overall plea towards more individual responsibility in flood risk management 2008). However, the division of responsibility between state, public organizatio management of flood risk is often not clearly established. Lalwani and Duval (2 personal responsibility is not assumed when there is no clear information inc personally responsible for threat management, even under conditions of high resources to deal with the risk. When governments are assumed to provide protec reluctance to accept responsibility. The strong reliance on and confidence in hampers the private sense of responsibility (Grothmann and Reusswig, 2006). responsibility is clear, it is mostly accepted if individual resources or instru available (Filatova et al., 2011).

### 2.1.5 Protective behavior

Risk perception and awareness are often analyzed in the light of understandi precautionary action against flooding (Waterstone, 1978, Grothmann and Reusswig al., 2013). However, perceived risk does not contribute directly to taking prot et al., 2009). Several studies have shown that there are wider socio-psychologic These include risk appraisal elements (e.g. risk perception, awareness, poten exposure) and coping appraisal (e.g. self-efficacy, resources and outcome expe ratio), within an institutional context (e.g. political focus and reliance (Grothmann and Reusswig, 2006, Waterstone, 1978, Kreibich et al., 2011, Zhai et

On the other hand, the impetus for individual adaptation can be reduced or technological or financial assurances (Smithers and Smit, 1997). The confidence and centrally led, engineered solutions implicitly triggers a low risk awarene efficacy and practicability of private damage prevention, which may contribute towards autonomous adaptation measures (Grothmann and Reusswig, 2006).

The above shows that the interaction between residents and flood risk manageme complex economic, psychological and social mechanisms. Therefore, the transit residents involvement and a more active role for spatial planning in flood man in literature and policy plans alike, is difficult to realize. Existing flood ma a way self-preserving as they reproduce themselves through feedback mechanisms Brink, 2013). The path dependencies following the high expenditures for flood low responsibility awareness among the involved citizens.

## 2.2 Flood management and spatial planning in Flanders

Flanders, the low-lying northern part of Belgium, is densely built (more than and has a dense river network, causing it to be sensitive to flooding. Accord water assessment maps 71,556 ha or 5.3 % of Flanders have recently been floode return period of 100 years with a flood depth of 30 cm. According to the Fle Agency 36,000 to 56,000 buildings and 23,000 building parcels are located within

Until the 1990s, flood risks were not systematically included in the conception plans, due to a variety of reasons such as the limited knowledge on flood risks

political prioritization of flood-related issues in planning, and even fr
(Boussauw and Boelens, 2015). In addition, the impact of the enormous increase
up land and the subsequent increase in flood frequency was not anticipated in
and Van Rompaey, 2009). Moreover there was a strong belief in an engineering
prevention, as exemplified by the Dutch Delta Works. After the 1976 floodi
materialized in the Sigma plan. Within this plan, a remarkably strong divide be
and spatial planners was maintained. Controlling flooding through engineer
considered to be the main or even sole responsibility of water managers, while d
was still not a core issue for spatial planning. Therefore, little effort was
development in flood-prone areas. It was only in the revision of the Sigma pla
based approach was adopted, in which spatial planning for the first time pla
limited to providing space for retention basins.

Since the Spatial Structure Plan for Flanders (in Dutch Ruimtelijk Structuur
1997 and the adoption of the principles of integrated water management in 2003,
is receiving more attention in planning practice. Nevertheless, the integratio
spatial planning is difficult since water management (especially for larger riv
scale, while spatial planning is practiced – to a large extent – on a local le
This complex actor network makes integration, responsiveness and decisiveness ha

To deal with this, the 2003 Decree on Integrated Water Management has led to th
Coordination Commission on Integrated Water Management (CIW), which brings the
domains and levels within the Flemish government administration together (Van
Sutter, 2014, Wiering and CrabbØ, 2006). Over the last decade, they have develo
and tools to improve this situation. Examples include the so-called water asses
mandatory part of the approval procedure for buildings or spatial plans, and th
of signal areas where rezoning is considered because of imminent water issue
The goal is to have a more steering role through regulation, especially fo
However, decision-making remains the responsibility of the individual planning i

Additionally, regulations on insurance and damage compensation, and information
been developed. Federal legislation from 2007 stipulates that flood damages are
the private fire insurance. Even though fire insurance itself is not obligato
households buy such insurance, as it is often a condition for obtaining a mort
risk maps indicate where residents pay a higher premium, as determined by the
legal limit of a 90% surplus premium related to natural disasters. For houses
2008, insurers are free to decide whether they want to provide insurance and a
This accommodates a certain, but limited solidarity principle.

Since 1992, the location of real estate in a flood risk zone (following the fede
be disclosed in the real estate deed. Since 2013, flood risks (based on the re
maps) also need to be mentioned in publicity for real estate for sale or for lon
information on flood risks and possible measures residents of flood prone are
available online, but not actively disseminated. Moreover, the different flood
regional) cause inconsistent communication towards citizens and therefore ambigu

The above shows little involvement of residents in flood risk management on t
weak planning tradition on the other. While the first element suggests a relati
awareness and responsibility, and therefore no inclination toward self-initia
suggest the exact opposite.

## 2.3 Study area: Dender basin

Within these settings, the Dender region is one of the areas with the most freq
devastating consequences within Flanders. The most recent floods took place in

2002-2003, 2010, 2011 and 2014 (Coninx and El Kahloun, s.d.). The Dender basi

already reported in the 1960s by Van Nuffel (1969)), the outdated infrastruc
coordination with the Walloon Region, both during floods as in general (CIW, 201

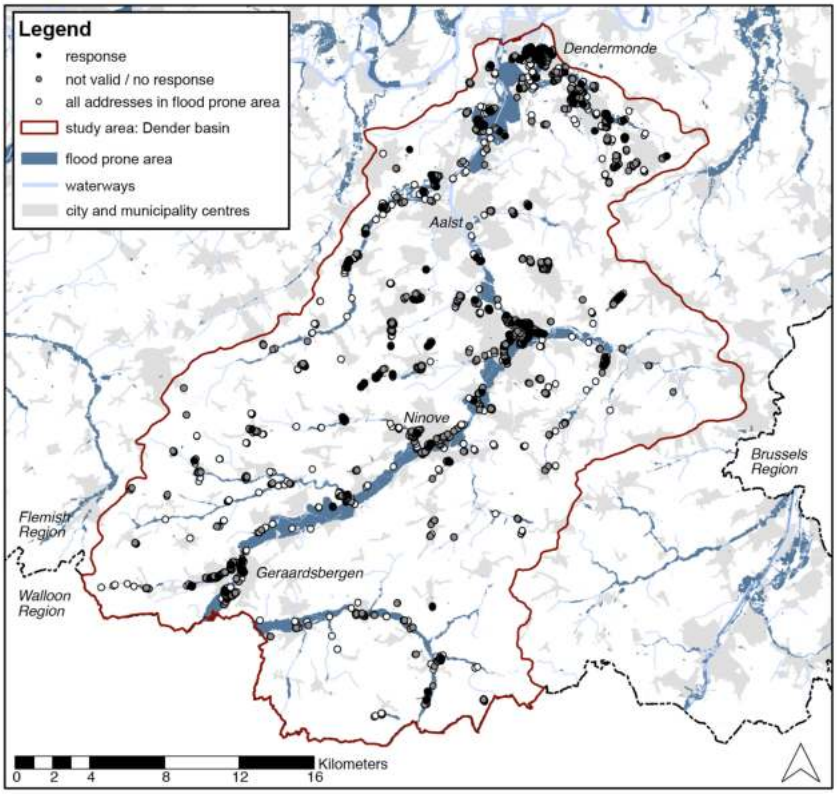

Figure 1. Map of the case study area: the Flemish part of the Dender basin, wit
prone areas according to the water assessment maps and the sample of the

## 2.4 Research hypothesis and design

We conducted a survey amongst residents of flood-prone areas in the Dender basin
attitude and behavior of residents in relation to riverine flood risks for the
questionnaire comprised 66 questions and resulted in a database with 317 u
discussed the respondents experience with flooding, their knowledge on the ris
measures, their housing location choice and flood protection behavior, and the
management. It was the explicit choice of the authors, in line with the researc
broad and comprehensive questionnaire, addressing a wide range of flood-relate
relation to the role of spatial planning in flood risk management, as illustra
given above.

In September 2014 the survey was distributed amongst residents of actual flood-p
the Water Assessment maps (version 1 September 2014). These areas have recently
flood return period of 100 years with a flood depth of 30 cm. From the populati
1,100 were sampled. Businesses and public institutions, vacant homes and incor
omitted, based on onsite assessment. This led to a sample of 916 active pri
relatively small sample was chosen in order to use the available resources to

possible response rate and therefore better representativeness. In order to max
the questionnaire was personally delivered and could be returned on paper and on

We used different explorative methods, including bar charts, chi square tests
Subsequently, we analyzed the pairwise relation between variables from the su
Spearman s bivariate rank tests for non-parametric variables (such as likert

correlation coefficients ($r_s$) and significance level (* = 0.01 < p < 0.05; ** = p < 0.01) a
the Mann-Whitney test, the significance level is reported. Some socio-economic
survey that did not yield significant correlations were left out.

## 3. Results

We received 184 completed questionnaires. One response was excluded be
double entry, resulting in 183 valid responses (response rate 18.8%). Co
of the questionnaire and the relatively small population, this was consider
Representativeness of the sample could not be tested because socio-economic dat
(residents of actual flood-prone areas) are not available for privacy reasons.
the sample can be found in Table 1.

Table 1. Descriptive statistics on the survey sample

| | | total |
|---|---|---|
| N | | 183 |
| age, mean (standard deviation) | | 57.0 (15.5) |
| gender | male | 61.2 % |
| | female | 38.3 % |
| occupation | retired | 39.3 % |
| | non-active | 7.1 % |
| | active | 53.0 % |
| flood experience | none | 41.2 % |
| | without damage | 25.3 % |
| | with damage | 33.5 % |

Following the research design, the results are discussed in five themes: (1) awa
(2) risk perception, (3) location choice and willingness to move, (4) sense of
protective behavior and seeds of self-initiative.

### 3.1 Awareness and knowledge

About two thirds of the respondents are aware that they live in a flood-prone ar
the respondents think their residence is not situated in a flood-prone area. This
with flood experience ($p<0.01$, Mann-Whitney). This is confirmed by the fact that
respondents indicate they were aware of the flood risk when they moved there. Th
to the length of residency: respondents that have recently moved were at that ti
more aware of the flood risk. However, younger respondents are better aware of f
moving ($0.01<p<0.05$, Mann-Whitney).

However, the knowledge on the flooding issue is rather limited. A bit more than
(57.5%) say they know little or very little about the flood risk. Here again
experienced is of significant relevance ($r_s=0.16^{**}$), but also length of residency ($r_s=0.154^{*}$) and
ownership ($r_s=0.25^{**}$). Respondents that were aware of the flood risk at the time of
that they know more about the flood risk ($p<0.01$, Mann-Whitney). Respondents t

they are living in a flood-prone area however do not necessarily feel that the
flood risk (p>0.1, Mann-Whitney).

About 80% of the respondents say they know little about measures they can take
the knowledge on flood risks, the respondents who have experienced more flood
have lived longer in the same house ($r_s$=0.165*), indicate that they know more about possible m
Respondents that know more about flood risks ($r_s$=0.51**) and were aware of the flood risk at th
of housing choice (p<0.01, Mann-Whitney) know more about measures. However risk
not yield a significant correlation (p>0.1, Mann-Whitney).

The above suggests that knowledge on flood risks and measures is for a large pa
This is confirmed by looking into where this knowledge is coming from (Figure
experience, the most important actors that provide information on flood risks ar
parties, followed by governmental bodies (especially local governments) and b
relative importance of these actors in information dissemination is generally t
and possible measures, with the exception of the differences between civil part
smaller for information on measures.

Although over half of the respondents (59.2%) know the water assessment maps, o
respondents (36.9%) know the correct classification. Only18.7% of the respondent
water assessment maps, which is nevertheless most of all information sources (e
conversation, brochure or newsletter). Also the governmental website with infor
reaches 13.7% of the respondents, which is similar to informal conversatio
information.

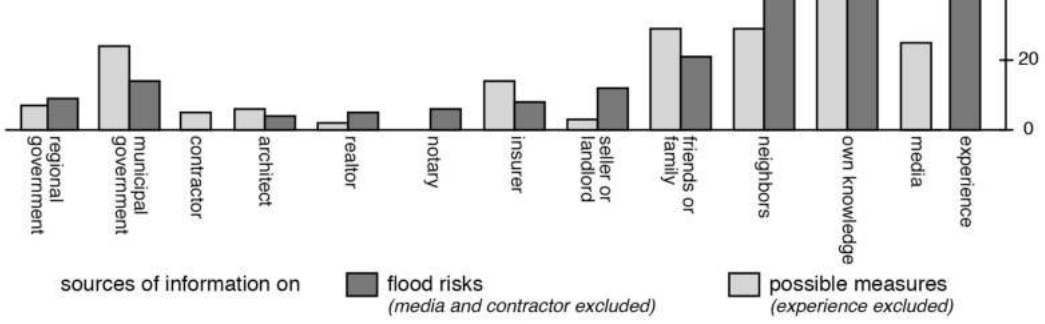

Figure 2. Sources of information on flood risks (a) and measures (b), measure
respondents that have accessed these sources.

## 3.2 Risk perception and experience

Around half of respondents (55.6%) indicate not knowing when the next flood wil
(21.3%) think it will be in less than 5 years, and another fifth (19.1%) betwee
respondents live in areas that have a modeled return period of 100 years (or les
at least 30 cm, these answers might indicate that there is no real underestimat
but rather that there is a great uncertainty or lack of knowledge on the fl
significant difference between the estimation of the current expected flood freq
flood frequency in 2050 (p>0.05, Wilcoxon Signed Ranks test). This indicates tha
expect a substantial increase in flood frequency.

The emotional impact from the flood risk is analyzed for three different aspec
worrying. About 40% indicate that they suffer from these emotional impacts. T
emotional impact is fearing floods (m=3.02 on a 5-point Likert scale, s.d.=1.47
the flood risk (m=3.00, s.d.=1.41), while suffering from the flood risk is p
important emotional impact (m=2.64, s.d.=1.45). All three emotional impacts (
worrying) show similar patterns of association with other variables. Signific
found with the age of the resi$_s$=0.28**, resp$_s$=0.22** and 0.20**), flood experience
($resp_s$=0.61**, $_s$=0.45** and $_s$=0.43**) and risk awareness ($p<0.00$ for all three va
However, only for suffering correlations were found with kn$_s$=0.25**). The flood
suffering and fear also associations were found with len$_s$=0.22** and
$r_s$=0.20**) and state of resi$_s$=0.26** and $_s$=0.19**).

Subsequently, the impact of flooding in terms of the way different types of dama
respondents (with flood experience) was examined (Figure 3). Emotional impacts
effort to clean, and the uncertainty, fear, shock and helplessness appear to be
frequent impacts. More temporal effects, such as the difficult accessibility and
life are frequent, but less disruptive. However, more long-term effects such
negotiation with insurance companies and contractors, and financial and materia
to be less frequent, but very disruptive. These findings largely correspond
Gutscher (2008) have observed. However, it is remarkable that in this case fina
as quite hindering, which is not in line with Siegrist and Gutscher s obser
impacts are greater than material and financial ones.

(b). The response categories for this question inspired by the findings from S
(2008).

## 3.3 Location choice and willingness to move

The respondents like living where they reside: more than three quarter of respo
their home and 60.7% are planning to spend the rest of their life there, while o
away within five years. Respondents who know more about flood risks more often
they liv$_s$=0.18*) and plan on staying the$_s$=0.24** longer. Besides that, mainly non-floo
related variables play a significant role. The pleasure of living is associat

residence ($r_s$=0.22**) and income ($r_s$=0.20*). On the other hand, desired future length of r
correlated with ownership ($r_s$=0.32**), how long respondents have lived there ($r_s$=-0.33**) and age
($r_s$=0.33**). It is remarkable that respondents with experience of flooding do no
the idea of staying, as no significant correlation for these variables was found

The overall satisfaction with their home is confirmed by the fact that only 14%
their choice of location. There is a strong correlation ($r_s$=0.49**) with flood experien
respondents that regret their location choice have experienced floods. However,
having regrets correlates with the pleasure of living ($r_s$=-0.38**) and the state of the reside
($r_s$=0.22**), but not with the intended length of residency: respondents that regr
are not planning to move away faster. Respondents that were not aware of the flo
of their location choice, also regret having decided to live there more often (0

The question comes up why respondents live in flood-prone areas. The main motiv
choice are non-water related factors, such as accessibility, proximity of facili
residence and social ties with the area (Figure 4a). These are far more importan
to the location in the flood-prone area, such as proximity of water or possibly
So there is no clear link between location choice and flood risks. On the other
environment is an important attractor as well, but it is unclear whether this is
flood-prone area, or rather to the broader (rural or suburban) environment.

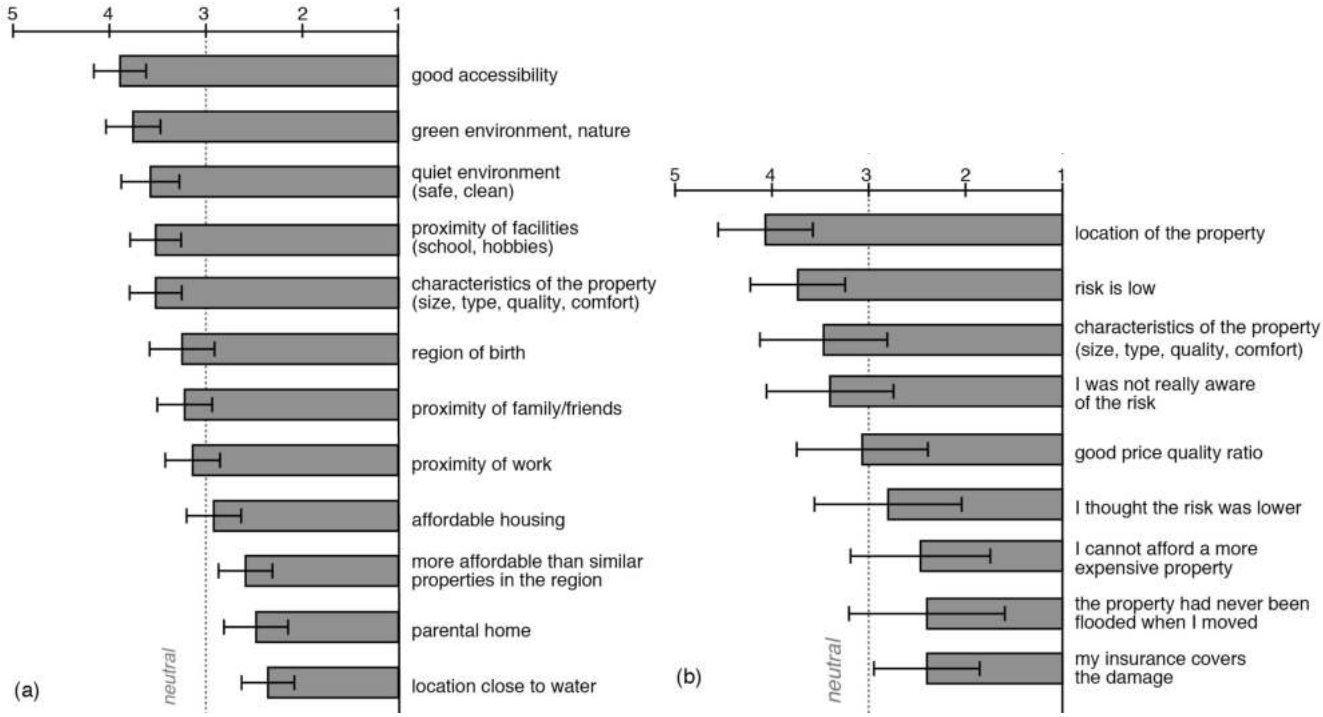

Figure 4. Reasons for housing choice in general (a) and for respondents aware
moment of housing choice (b), measured in mean score on a 5 point Likert scale,
95% CI

For respondents that were aware of the flood risk at the moment of locatio
considerations for their location choice are that the risk is low on the one ha
and characteristics of the residence are favorable on the other (Figure 4b).
desirable from a flood management perspective, such as misjudgment of flood
insurance and financial deprivation are of less importance. This might indicate
for respondents aware of the flood risk is well informed. However, it is possib
be higher than expected and issues could emerge in the near future.

In line with the finding that respondents like to live where they live, the des
low: 5.4% want to move, while 85.5% do not want to move. The desire to move i
flood experience ($r_s$=0.27**) and risk awareness at the moment of location choice (0.01
to the state of the environment ($r_s$=-0.17**). Also the willingness to move (as a flood protecti
is low: only 10.8% are willing to move, while 89.2 % are not willing to move. T
correlate with risk-related variables such as knowledge or flood experience, bu
related variables such as age ($r_s$=-0.21**) and length of residency (rs=-0.19*): the you
respondents and the shorter they live there, the more willing they are to move.
and willingness to move away is associated with high emotional attachment ($r_s$=-0.22**) for respec
suffering (only desiring to move, $r_s$=0.37**), and $r_s$=0.29** for fearing, $r_s$=0.37** and $r_s$=0.29** for
worrying, $r_s$=0.39** and $r_s$=0.38** for regretting their location choice.

When asked after how many floods respondents might want to move, 40.5% of respo
that they would never move due to flooding. Surprisingly this persistence corr
flood experience ($r_s$=0.25**). This means that respondents with flood experience are m
in wanting to stay there than respondents without flood experience. These are
with the highest knowledge on risks ($r_s$=-0.22**) and measures ($r_s$=0.31**), and the respondents that
have lived there longest ($r_s$=0.28**).

Parallel to the considerations of respondents aware of flood risks at the moment
main reason why respondents do not want to move is that the risk is low (Figure
second most important reason is that the respondents can live with the flood ris
a certain acceptation of the flood risk, although again, it is possible that
Notwithstanding the low desire to move, 20.1% of respondents indicate that if
would be at least partly because of the flood risks, and a third of the respon
they would move to a similar residence outside of the flood prone area if it wou

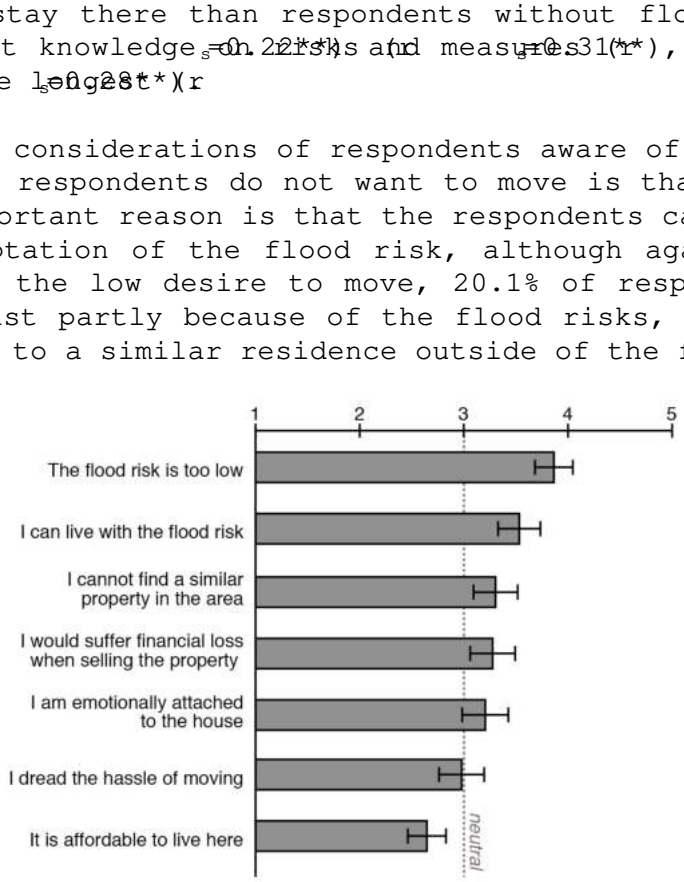

Figure 5. Reasons not (willing) to move, measured in mean score on a 5 point Li
indicate 95% CI

Thus, the attachment of respondents to their homes is rather associated wit
variables, such as socio-economic and real estate characteristics, while flood
not necessarily reduce this attachment. Also the willingness to move seems to
economic variables, rather than flood risks.

## 3.4 Sense of responsibility

The respondents consider the government (both local and regional) to be the mai
existing flooding issue, while they perceive the residents to be least respon

remarkable that there is a large consensus on this: the vast majority of respon
with the statement that the government is responsible for the existing problems,
with the statement on residents being responsible for the existing problems.

The extent to which different actors are expected to be able to help in resolvi
shows a similar pattern: 89% of respondents also deem the government to be respo
the issues, while only 19% believe that residents can help resolving the issues.
respondents wish to be involved in finding solutions to the flooding issue.

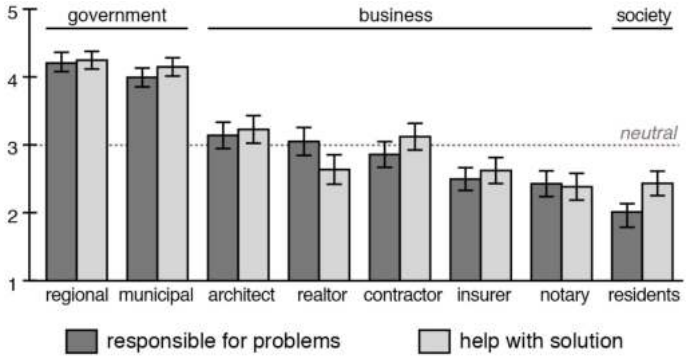

Figure 6. The extent to which different actors are responsible for the existing
help solving problems (b), measured in mean score on a 5 point Likert scale, er
CI

In relation to location choice and flood risks, 70.6% of respondents agree with
authorities have allowed me to come and live here, they are responsible to
flooding , while only 19.5% of respondents agree with the statement I have m
responsible to protect myself against flooding . This is quite remarkable con
regional zoning plans originally did not sufficiently take flood risks into acco

So the government is perceived as the leading actor in both causing and solving
respondents see only a limited role for themselves. However, the extent to whic
themselves to be responsible for the existing problems and can help in resolvi
with knowledge on flood risks ($r_s$=0.28**, respectively $r_s$=0.18*) and knowledge on measures (resp.
$r_s$=0.19* and $r_s$=0.30**). High levels of knowledge are thus associated with a hi
responsibility. Also risk awareness at the moment of location choice is of rele
were aware of the flood risk at the moment of location choice put less responsi
problems on the government (0.01<p<0.05) and more on residents (p<0.01), while
more often that residents can help in resolving the issue (p<0.01). This indic
knowledge on risks and measures, and risk awareness at the moment of location
responsibility.

When asked to what extent governments and residents take sufficient action
respondents indicate that they themselves take sufficient action while only 30%
does so. This is associated with flood experience: respondents with flood exper
that the government is not taking sufficient action ($r_s$=0.19**) while they themselves do so ($r_s$=0.26**).

## 3.5 Protective behavior and seeds of self-initiative

About a third of respondents indicate they have taken initiative to inform them
risk and the measures they can take. These respondents indicate that they know
risk (p<0.01) and the possible measures they can take (p<0.01). Information-seek
risks seems to be inspired by risk awareness at the moment of location choice
information-seeking behavior on measures is related to flood experience (p<0.01)

A bit less than half of respondents (43.4%) are willing to take measures against that are willing to take measures have more often sought information on risks possible measures (p<0.01). The willingness to take measures is also associated ($r_s$=0.33**) and knowledge on measures ($r_s$=0.27**). Considering under which conditions respon would be willing to take measures, we see that an increased flood frequenc incentives such as subsidies, tax reduction and practical support are most pre low score for the option  if the rest of the neighborhood does this as well  inc collective action.

If we look at what type of measures the respondents are willing to take, it is low-cost and low-key measures are preferred (Figure 7b). However, it is remark action scores high, especially since the previous results showed little belief capacities in dealing with flood risks.

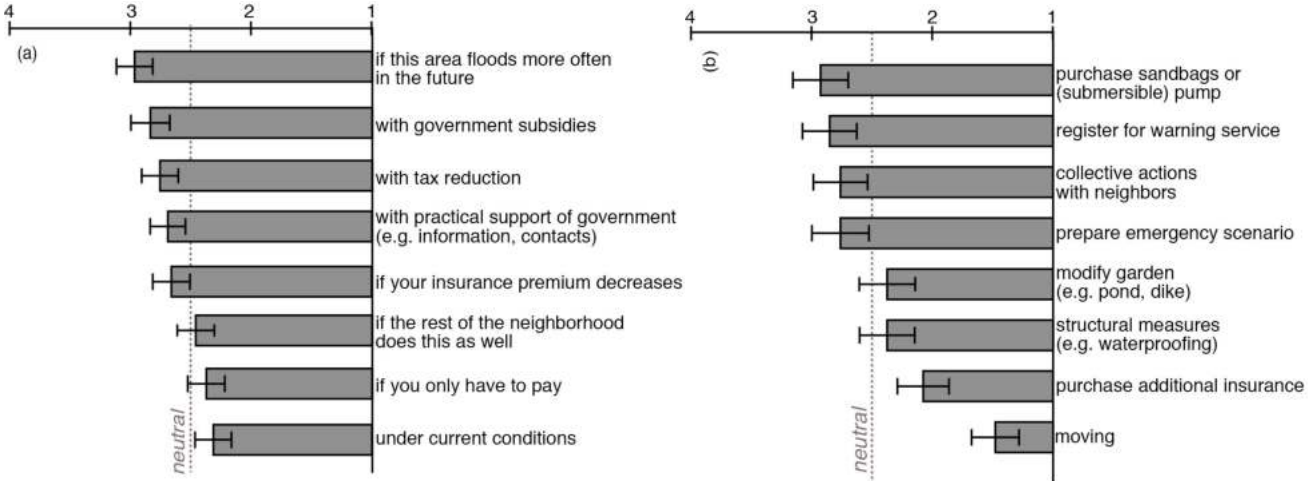

Figure 7. Willingness to take measures to reduce flood damage under different c type of measures (b), measured in mean score on a 4 point Likert scale, error b

Nevertheless, half of all respondents have already taken action to reduce the co Taking action is mainly associated with flood experience ($r_s$=0.63**), where of respondents without flood experience, 47,6% of respondents with flood experience without damage respondents with flood experience and damage have taken measures. This indicate is mainly reactive to flooding. Other significant flood-related variables ar ($r_s$=0.22**) and measures ($r_s$=0.31**), information-seeking behavior on risks (0.01<p<0 measures (p<0.01), but also non-flood related variables such as condition of th and age of residence ($r_s$=0.27**), and length of residency ($r_s$=0.34**) play a significant role.

However, the investment in these measures is rather limited: 60% of the respond action, invested less than  500 in these measures. The invested amount is a experience ($r_s$=0.31**), knowledge on measures ($r_s$=0.29**) and the extent to which respondents to live there ($r_s$=0.30**). The most frequent measure is purchasing sand bags or installation) (73%), followed by storing valuables on an elevated spot in the measures (around 30%), while only a small fraction (around 5%) joined a neighb waterproofed their interior, registered for a warning service or purchased an ad again, low-cost and low-key measures are preferred above structural measures observe very little collective action, although the findings above have indic willingness to take collective action. About half of the respondents that have t with the measures they have taken. Nevertheless, only about a third of respo measures protect them sufficiently against flooding and feel more at ease since

The motives to take action (Figure 8a) are mainly flood-event related. We notic
more ad-hoc decisions in the context of a specific flood event, rather than
reasoning. In addition new information appears to be quite unimportant as a mot
So even though our survey has showed strong correlations between knowledge lev
responsibility on the one hand, and willingness to take action on the other, it
itself is not sufficient as an incentive to take action. However, if we lo
respondents do not take action (Figure 8b), we see that the main reasons are
collective action and government responsibility, followed by the consideration
the distrust in individual actions. Personal circumstances were mentioned least.
in collective action again conflicts with observed protective behavior.

action (b), measured in mean score on a 5 point Likert scale, error bars in

## 4. Discussion and conclusions

Research in water management and planning often presents the flooding issue as
matter, while the interrelationship with broader social dynamics and institutio
discussed thoroughly. We have therefore conducted a survey that assesses how r
prone areas in the Dender basin (in Flanders, Belgium) deal with the risk to wh
Our survey has probed for the residents knowledge of the flood problem, thei
associated risks, the measures they take, the satisfaction with their home
responsibility. We started from a sample of households whose residence is design
area in official maps. This research base is interesting since Belgium is kno
position in steering development (Boussauw and Boelens, 2015, Verbeek et al.,
neighboring countries such as the Netherlands. This context would suggest tha
active role in flood risk management. However, very little efforts have been
activate residents in flood risk management, as opposed to for example the Un

would suggest that residents included in our research would show a relatively awareness and responsibility, and would not be inclined toward self-initiative.

This hypothesis has largely been confirmed. A large majority of residents ar informed, have little or no intention to relocate, and strikingly often impose risk they run on the authorities. Residents do not really see themselves as bei do not believe they can actively contribute to managing flood risks. Neverthele action, but these actions are low-key, individual and ad hoc. So far, recent gov as publishing and regularly updating flood risk maps, adjusting insurance polic mandatory notification on flooding issues when a house is sold, seem to bring li

These findings represent a clear connection with the Belgian institution of re area-wide set of land use plans that are in force since the seventies and dis which in principle could be developed, and zones that are intended for agricul (and where construction is, in principle, not allowed). Although these plans hav managed to keep some open space areas free of any construction, they also impli build on land that was actually never thoroughly evaluated as being appropriat Therefore, today a number of flood-prone areas are still considered to be const by owners, developers and residents, while the responsibility to keep the lot c the house on it as well) is placed on the government.

A number of measures that are currently being taken by the government, aim at i and raising awareness and sharing responsibility between governments and citizen in the future these will contribute to improved control of the flooding issue. (2001) state that increased knowledge does not necessarily lead to declining dam of flood-prone areas may be in denial about the flood risks, and expect to be recent developments in policy-making are looking into the possibilities to loo between a particular land use designation in the zoning plan and the actual rig cases to cancel such existing, although inappropriately awarded development ri still unclear what how these policies will be implemented. Moreover, a st governmental technical protection has proven to be counterproductive in te community refusing responsibility. Therefore, we should also look at the unin common protective policies. In the context of budget cuts and uncertain clima growing need to rethink this position.

This research contributes to this discussion. On the one hand policy-making sh what residents think and do. On the other hand, individual action is framed by even if this is not addressed explicitly. Flood risk management choices generate towards civil society and the way they deal with flood risks through experience long time, flood protection was a governmental activity and flood risks were no account in spatial plans and developments. Dissemination of information has only form and there is very little experience in private flood protection measures. transition towards citizen responsibilization does not comply with the p responsibilities in flood risk management, and therefore, this discussion needs

From a resilience stance, one cannot expect that residents are spontaneously sel deal with flood risks has co-evolved with a flood risk management paradigm t importance to a technical, top-down approach. The shift towards more resident i needs to be openly addressed and supported in all aspects of the interactions risks. In this light, the survey provides some promising results. Respondents a their current homes, and civil parties play an important role in knowledge disse there is quite some confidence in the power of collective action, although cu seems to be lacking to put this into practice. These elements can be interpret could lead to more resident involvement and active contribution in flood risk conditions of appropriate support.

## Abstract

*The Munich Metropolitan Region (MMR) is experiencing strong population and employment growth. Already under strain, housing, infrastructure and services need coordinated region-wide efforts to cope with the rising demand and infrastructure bottlenecks. These efforts, however, call for thorough analytical knowledge about locational choices of households and employers, as well as the requirements for transport infrastructure and services, and how these three structural dimensions interact simultaneously with each other.*

*This paper introduces a study that aims to understand this complex interplay within the MMR. It includes preliminary results of a web-based survey, which invited newcomers to the region as well as citizens who have recently moved to state their locational preferences. The respondents geo-referenced and assessed qualities of their present and former places of residence and work as well as locations considered during the process of apartment search. With this data it is possible to uncover trade-offs and preferences.*

*A key hypothesis and preliminary finding of the survey is that functional relationships within the city-region have become increasingly integrated, polycentric and complex. This is in contrast to the hierarchical but fragmented administrative reality, which consists of multiple overlapping layers of formal and informal regional planning between diverging local and federal state agendas, further complicated by artefacts like the airport and its economic and governance embedding. A truly regional, strategic approach might be better suited to handle the consequences of growth.*

## 1. Introduction

This paper discusses recent developments in the spatial organisation of housing, employment, and mobility, and their impact on planning and policymaking on the case study of the Munich Metropolitan Region (MMR). In a residents' survey conducted in late 2014 and early 2015, we asked more than 7,000 individuals who have recently moved to or within the metropolitan region on their motivations for moving, the locations they chose for work and residence, and locations they considered during their apartment-search. The paper is footed on the premise that public administration is most efficient if functional and administrative spaces are congruent, and it examines the current governance setup in Munich on the backdrop of this premise and the survey results. After demonstrating the theoretical background in section 2, we will describe the circumstances of the Munich case in more detail in section 3. In section 4, we will outline the methodology used in our survey before we will present the first preliminary results. We will show how functional relationships across traditional nested hierarchies are now significant in our study area in the fifth section. Finally, we will ask what this means for the local and regional decision-making structures and policies on urban and transport development in our concluding remarks.

## 2. Theoretical Background

Territorial organisation is a fundamental aspect of public administration. The problem of good territorial delineation for an efficient delivery of public services and the question of the right scale for certain policy tasks has thus often been discussed in geography, political science, and planning theory and practice (Blotevogel, 2001; Swyngedouw, 2005; Gabi, Thierstein, Kruse, & Glanzmann, 2006; Parr, 2007). As opposed to socio-cultural or physical geographic attempts to regionalise space, economic geography is interested in spatial economic relations as explanatory factor for such a delineation.

An important aspect of this debate is the congruence between functional relations within geographical entities on the one hand and their administrative subdivision on the other, and the alleged negative effects of its absence. From an economic point of view, a high congruency of administrative areas with functional units, such as commuting areas reduces external effects and therefore inefficiencies and transaction costs for collective action problems. In planning, this challenge is best known to arise in situations where a municipality provides certain amenities that the population of neighbouring municipalities can use as 'free-riders' without contributing to its construction and upkeep with their taxes. The idea to avoid inefficiencies of differing incidences today lies at the heart of spatial economic benchmarking models (Frey, 1984) and is used by NGOs, consultancies and international organisations such as the OECD as a policy standard (OECD, 2013, p. 38).

Accordingly, the first practical attempts to address the problem were territorial reforms to re-match functional and administrational spaces. Early practical approaches for a rational regionalisation of a territory date back as far as the establishment of départements in post-revolutionary France. The territorial reform agenda was strongest throughout the first half of the 20$^{th}$ century as part of the modern project, with a late heyday in the 1960s and early 1970s, when urban growth was strongest. During this time, many European countries went through several waves of municipal and regional incorporations, mergers, and reorganisations. In then West Germany, for example, the number of independent entities at the lowest local level was reduced from about 23,000 to 8,000 between 1969 and 1978.

Despite some positive effects on public service provision (Priebs, 2005) academic debate and public opinion on the matter reversed soon after, often in contrast to the political reality of public administration (Evers & de Vries, 2013, p. 537). The majority of the body of literature on the topic today takes a critical stance on territorial reform on the grounds that constant adaptation to functional contexts is futile and compromises citizen identification with the local authority (Evers & de Vries, 2013, p. 543). This was associated with a general shift of the policy mode from hierarchical government to more multi-stakeholder 'governance' and from comprehensive to incremental planning (Lindblom, 1959). The problem of differing scales for old and new policy areas remains, however. To solve this, the need for (often sectoral and voluntary) cooperation within existing territorial boundaries is emphasized instead (Salet, 2006).

In the German case, many regional transport authorities founded in the 1980s are generally considered a good example of the success of this model of sectoral cooperation (Evers & de Vries, 2013, p. 544), and so are the regional municipal co-operations started in the last decades, such as Stuttgart with an elected regional legislative, or Frankfurt with an integration of regional plan and comprehensive land use plan (Freund, 2003; Heeg, 2003).

Despite the success of the model of joint decision making, it has sometimes led to a proliferation of increasingly fuzzy administrative structures with dispersed responsibilities, especially when it was expected to take place on a voluntary basis, effectively excluding matters that could not yield win-win situations. The effect can be observed best on the backdrop of areas that are characterised by rapidly changing – often growing – functional interconnectedness, where functional urban structures

of the past often continue to exist in the form of administrative delineations (Boussauw, Allaert, & Witlox, 2012).

From the late 1990s on, "new regionalism" emerged as a new paradigm within human geography (Brenner, 2003). The forces of globalisation and liberalised markets as well as the rise of information and communication technologies, it is argued, lead to a weakening of the traditional welfare state, new functional spatial arrangements on a (metropolitan-)regional scale and thus the pressure for territorial administration to reconfigure accordingly (Brenner, 1997; Lambregts & Zonneveld, 2004, p. 300; Evers & de Vries, 2013, p. 539). Metropolitan regions world-wide were seen in growing competition with each other for skilled labour and investments, requiring former local rivals to team up to compete on the global stage (Sassen, 2001, p. 30).

This was accompanied by insights from evolutionary economics that extended the neoclassical economic model. The release of the idea of an inter-regional equilibrium meant that permanent imbalances between regions, lock-ins and path dependencies were theoretically possible, as well as regional specialisations and complementary division of labour within regions (Martin & Sunley, 2006). This also meant a shift of the focus of research towards a polycentric and complimentarily specialised organisation of economic activity in space, which could be identified in different cases (Meijers, 2007; Burger, Meijers, & van Oort, 2014), linking formerly independent cities to form networked mega-city regions (Hall & Pain, 2006).

These trends, together with the deficits of the incremental governance mode, ultimately also meant an increased pressure for administrative restructuring on a metropolitan scale. Metropolitan Regions are in constant state of flux with overlapping forces of centralisation and decentralisation. These developments are strongly linked to the choices of individuals (Storper, 2013). For example, employees have their own spatial logic in order to combine private and working life. Firms depend on the qualification of the labour market and proximity to local partners. These spatial logics might cross the boundaries of administrative regions. While working life is becoming more and more flexible with regard to the place where people work and the time when they work. Consequently, individuals have multiple anchor points within their daily lives (Parr, 2013, p. 10). The question arises what the differences between the individual uses of space and the ascription of functions to space are.

## 3. Case Study: Munich Metropolitan Region

*Economic and Demographic Situation*

The city of Munich with almost 1.5 million inhabitants is the third largest city in Germany and a major centre in terms of economy, education, culture and transport. It holds political decision functions as the capital of the federal state of Bavaria and is the seat of several important high-tech and manufacturing enterprises, such as BMW and Siemens, as well as advanced producer services, especially insurances. It also hosts several renowned universities. Since the 1950s, it has shown a remarkable phase of economic growth that is unrivalled by other German cities and that continues until today, making it one of the most prosperous places in Europe. At the same time the high recreational value of its surroundings and its cultural institutions continue to secure it high positions in quality-of-living-rankings.

Together with the surrounding districts it forms a functional city-region of 2.6 million inhabitants, using a travel-to-work area definition. This functional city-region is, according to (Storper, 2013, p. 4), "the principal scale at which people experience lived reality". Pütz (2004, pp. 137-138) accordingly describes it as the "everyday region", as opposed to the "business region" in the core, which attracts most company headquarters.

But Pütz also finds a third type of functional region in the Munich case, a "marketing region": It also integrates the neighbouring regional centres of Augsburg, Ingolstadt, Kaufbeuren, Landshut, and Rosenheim with their respective hinterlands. This larger "Metropolitan Region Munich" (MMR) can be interpreted as outcome of the debate on increasing global competition of cities and the formation of metropolitan regions (Blotevogel, 2002; Fürst, 2003), as well as polycentric mega-city regions with internal division of labour (Goebel, Thierstein, & Lüthi, 2007; Lüthi, 2011). The MMR exhibits a growing functional interconnectedness and complementarity as well as similar characteristics in terms of economic structure (Goebel et al., 2007; Bentlage, Thierstein, & Lüthi, 2015, forthcoming) much more than only in the tourism sector. In its spatial extent it covers 35% of the state of Bavaria, but almost half of its population and more than 50% of its GDP. It is home to 5.8 million inhabitants in 2015 (Figure 1).

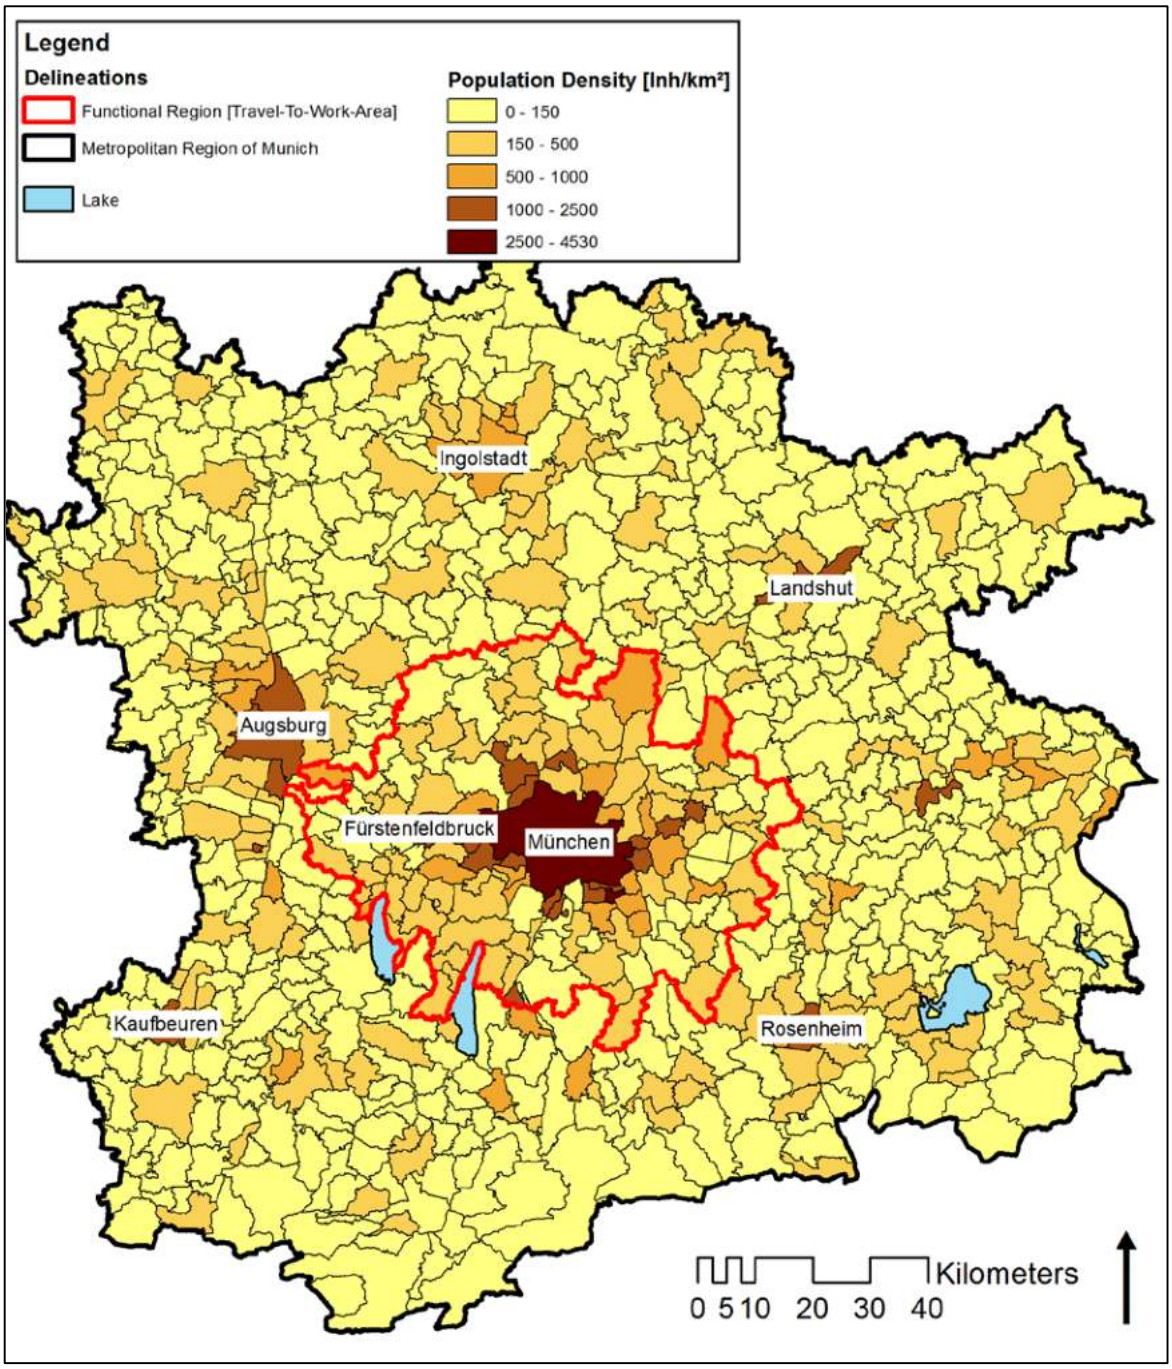

**Figure 1: Functional Relationships in the Munich Metropolitan Region**

These favourable conditions continue to attract businesses and people, so that Munich and its hinterland are expected to grow further (BBSR, 2014). Despite strong effects of demographic change in other parts of Germany, the official population projection for the city of Munich predicts 1.73 million inhabitants in 2030, an increase by more than 15% compared to today. The population growth is mainly due to migration from other parts of Germany and other European countries, but also positive birth rates. The majority of the influx are people between the age of 25 and 40 (Landeshauptstadt München, 2013, p. 19). Further growth is also estimated for the for the associated city-region, though not as pronounced as for the city itself, and a stable development for most of the wider metropolitan region (Bayerisches Landesamt für Statistik und Datenverarbeitung, 2014).

For a long time, Munich could profit from a good infrastructure and public service endowment that partly came as a legacy from the 1972 Olympic Games. With a certain vanity, city administration and parts of the local population long maintained an image of Munich as a 'large village' or a 'city of villages', a world-city by importance, but not in its built environment.

The recent upsurge in immigration as part of an international trend 'back to the city centres' however puts this narrative into question, and the land markets as well as public services and infrastructure under increasing strain. Munich is a victim of its own success: It shows growing signs of residential segregation on a regional scale, and key workers find it increasingly hard to sustain their livelihood. At the same time, many inner-city building potentials have been used and both public transport and road infrastructure have reached their capacity limits on key sections (Thierstein, Förster, Conventz, Erhard, & Ottmann, 2013; Büttner et al., 2014).

In this context, it is important to note that historically Munich had a relatively monocentric structure in functional terms, with a strong concentration of workplaces and retail in the centre of Munich itself. The most prominent descriptions of this spatial disposition of the Munich region certainly goes back to Walter Christaller (1933) and his central place theory: Christaller, whose research area was southern Germany and whose work has been very influential in German regional planning had described the (conflicting) forces of segregation (administration) and supply (function) on spatial structure and the location of towns. Christaller characterised the spatial structure of Munich as above-average monocentric and the surrounding regional centres as underdeveloped and functionally dependent in comparison to other large cities in southern Germany. He also identified cases where the "administrative" principle of segregation had prevailed over the "supply" or "transport" principles, which dominated spatial structure under unimpeded circumstances in central place theory, leading to a higher number of sub-centres oriented towards Munich, such as Augsburg and Passau. This structure prevails until today, and is reflected by the built radial structure of public transport and highways, but to a large degree also by commuting patterns. The recently identified upscaling of interdependencies from the Munich functional region to the larger metropolitan region could not reduce pressure on transport infrastructure so far.

*Administrative structure and planning powers*

The growing functional complexity and upscaling in the Munich Metropolitan Region is in contrast with its administrative (non-)organisation. It consists of a five-tiered government as part of a federal nation state, with at least three more additional bodies with relevant powers in the planning field (see Table 1, Figure 2).

| Administrative Entity | Planning Powers |
|---|---|
| National government | Nonbinding national planning strategy |
| Federal State of Bavaria | Binding state plan |
| European Munich Metropolitan Region | Voluntary association of municipalities, districts, public institutions and enterprises for marketing and strategic purposes |
| Administrative Region [Intermediate tier] | Building Permission Appeals<br>Planning of large infrastructure projects, e.g. airports |
| Outer Munich Planning Cooperation | Voluntary association of municipalities and districts, consultation on planning matters |
| Regional Planning Area | Binding regional plan |
| Regional Transport Authority | Strategic Transport Planning |
| Districts [Cities have functions of Municipality and District] | Building permissions, Heritage conservation<br>Property valuation, reallocations and expropriation |
| Municipality | Binding land use plans (zoning)<br>Comprehensive land use plans for entire municipality<br>Setting of land tax multiplier, beneficiary of land tax and business rates |

**Table 1: Important planning and related powers in the German planning system for the case of Munich**

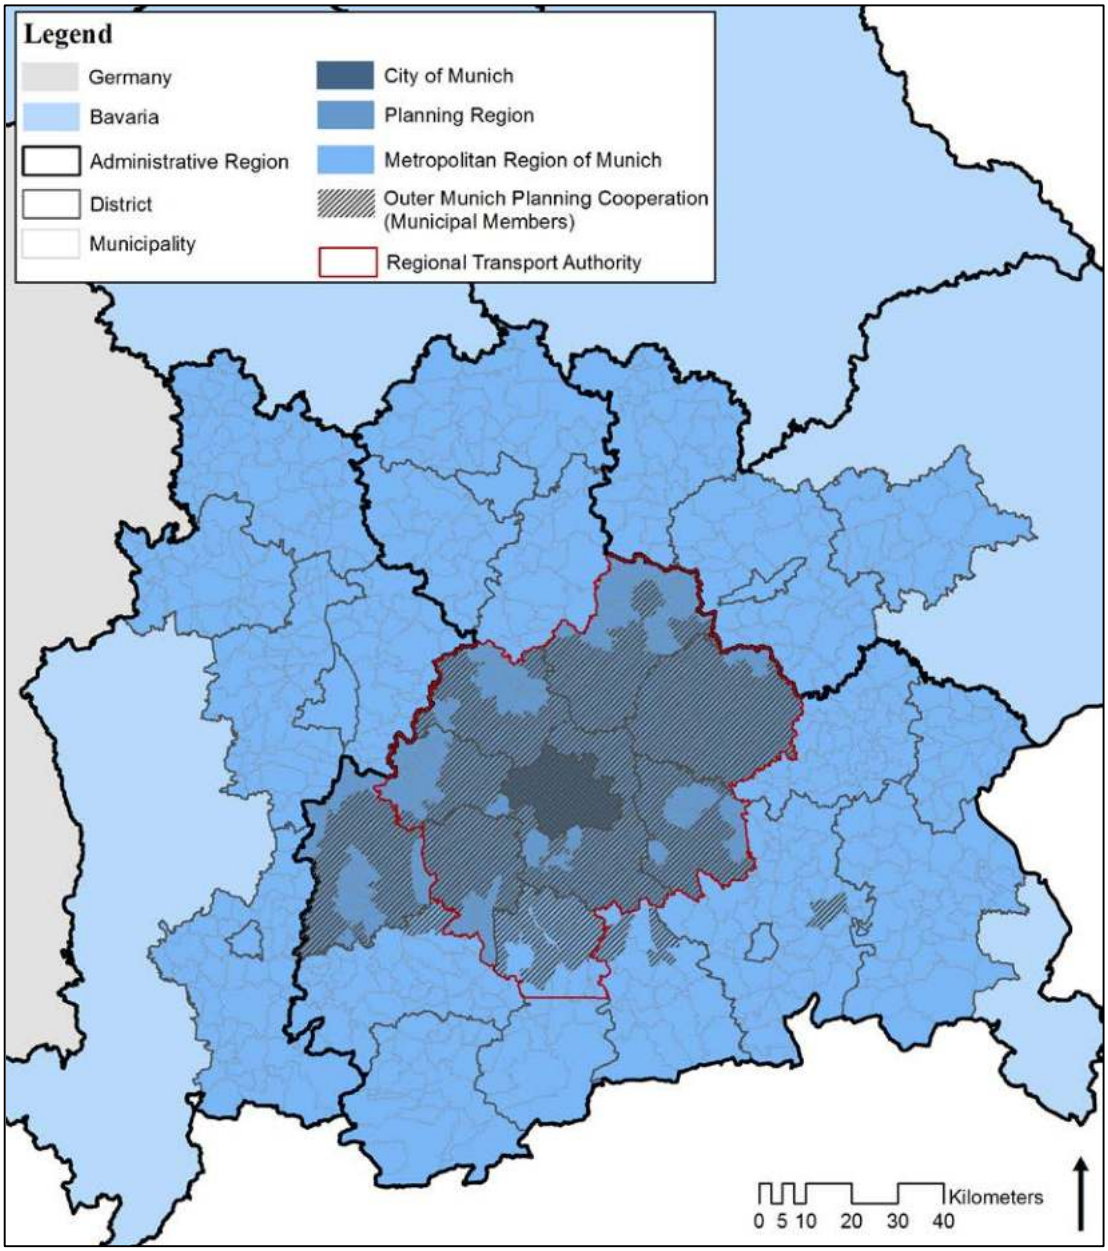

**Figure 2: Governance Structures in Southern Bavaria**

Planning powers in Germany, like in most jurisdictions, mainly rest with the municipalities as lowest tier of government. They have the responsibility to set up two different types of plans: On the one hand, binding land use (zoning) plans ("Bebauungsplan") for single plots or larger areas which legally determine allowed construction in terms of both use and dimension. On the other hand, a comprehensive land use plan ("Flächennutzungsplan") for their respective territory, which is however only legally binding for the administration itself and has a more strategic scope. Binding land use plans and comprehensive land use plans may not be in conflict, however, and either has to be adapted in case of a change to the other, which occurs frequently. For new construction to take place it is not necessary that a binding land use plan is in place – in fact, most neighbourhoods that were built before the 1960s have no binding land use plans. In this case the usage and size of the existing surrounding built environment determines the allowed form of construction instead, for example in the case of infill housing.

Municipalities are not entirely free in their decisions on land use, since the municipal plans have to conform to the relevant aims set out in the applicable regional plan and the state-wide plan. These set out land use decisions of regional importance such as transport infrastructure and large industrial zones as well as strategic decisions on growth poles, central places and axes (Bayerische Staatsregierung, 2013). Their functioning is not entirely top-down, however: For their development, existing municipal plans have to be taken into account in turn. Thus the plans on different layers of government influence each other mutually (Principle of countervailing influence). Studies on the functioning of regional planning in Munich have shown however that its actual capacity to direct development is limited, as municipalities manage to exempt development frequently (Pütz, 2004, p. 156; Thierstein, 2015). The German national spatial plan on the other hand is non-binding, as regional planning powers rest with the federal states. All plans include statutory participation processes in their preparation.

In the case of Munich several other institutionalised stakeholders are also involved in planning: The "Outer Munich Planning Cooperation" is a voluntary cooperation of municipalities and districts in the functional region to pool expertise on planning issues and consult on questions of regional importance. It was founded in the 1950s as a first attempt at regional coordination and is thus older than the regional planning bodies. Despite personal overlapping with the regional planning authority, their membership differs significantly.

A very recent addition to the regional governance is another voluntary association, the "European Munich Metropolitan Region" (EMM). It unites municipalities, districts, public institutions and enterprises and covers a much wider area also encompassing neighbouring centres within the Metropolitan Region with their own travel-to-work areas such as Augsburg, Ingolstadt and Rosenheim. It has no planning powers, however, and so far mainly fulfils marketing purposes, even though it is trying to spark a common identity in the region. The EMM can be interpreted as an outcome of the up-scaling of functional ties and global competition of metropolitan regions.

These co-operations have to be understood on the background of the political alignment of Munich and its surrounding municipalities. While Munich is governed by a social-democrat majority for almost 70 years in a row, the environs municipalities as well as the Bavarian parliament are largely dominated by the conservative party since the post-war times.

Further government agencies are important players in the region: The regional transport authority Münchner Verkehrs- und Tarifverbund GmbH (MVV) covers an area that is almost congruent with the regional plan and strongly influences commuting patterns as well as a sense of community. Munich airport, the seventh largest in Europe, is located 40 km north-east of the city and has a profound influence on spatial structure. The airport premises sit amidst two municipalities and its airside operations have been followed by strong non-aviation activities on the landside. The municipalities within the airport corridor between the City of Munich and the airport itself have shown above average benefits from the continuous settlement and expansion of companies in the past few years since the start of the airport's operation in 1992 (Droß & Thierstein, 2011). From an

economic point of view, the axis between the airport and the city of Munich is considered the most powerful airport-city corridor across Europe, and it is home to a variety of multinational corporations, such as SAP, Microsoft, Baxter, Airbus-Aerospace, BMW, GE Electric, Swiss RE, and others.

To sum up, planning in the Munich Metropolitan Region is characterised by a multitude of hierarchical layers of government, weak regional governance, overlapping and fuzzy but influential informal governmental bodies and private actors. Of course, planning and its organisational structures are just one player in the management of complex urban regions.

It has not followed other metropolitan regions towards greater institutionalisation so far. At the same time Munich faces strong economic and population growth. It is also important to note here that the city of Munich itself has a relatively small perimeter, which also makes it one of the most densely populated places in Germany statistically. The city administration resisted schemes for an amalgamation with neighbouring municipalities in the 1970s in order to retain the two-tiered internal administrative structure (Vogel, 2015). Now, few land reserves are left within the city and regional effort to cope with the rising demand are needed.

## 4. Methodology

*Study*

As described above there is an awareness among scientists of the deficiencies that a mismatch of functional relations and administrative responsibilities can cause. Hence, there is a need for a thorough understanding of households' decision making processes and their influence on spatial developments on the macroscopic scale. In order to obtain new findings on these interrelations we conducted a large resident's survey that addresses three main issues: housing, working and mobility and underlying interdependencies.

Core element of the study is a web-based survey, in which inhabitants – newcomers and long-established – as well as people working in the Munich Metropolitan Region were invited to report residential and workplace location choices they made. A condition for participation was that a change of either workplace or place of residence had occurred in the last three years. The study has been supported by a large board of stakeholders, consisting of not only public authorities but also enterprises based in the region and interested in the topic. This cooperation provided the opportunity to spread the survey throughout various channels. The survey was conducted between November 2014 and April 2015.

The survey is largely based on the approach of revealed preferences, which means household's preferences are indirectly expressed by their decisions made in the past. Survey-participants therefore provide not only information on their current residential and workplace location, but also on former locations as well as locations considered during their last apartment search, including quality assessments and price information. The questionnaire is linked to an interactive map, so that all indicated locations are geo-referenced, which allows a comparison by spatial features among them. Additionally participants are asked about the importance of certain spatial characteristics such as accessibility of the indicated locations (stated preference). Questions on peoples' mobility enable analyses of their mobility behaviour before and after residential or workplace relocation. The revealed preferences are combined with socio-demographic data such as income of the household.

*Hypotheses*

Preliminary works and literature research led to a set of hypotheses, which where the base for the development of the research design of the study and the questionnaire. There are numerous underlying socio-economic trends, which are highly diverse and complex: reorganization of labour, changes in household structures, which go along with a shift from suburbanisation to reurbanisation and an unprecedented importance of networking for individuals and enterprises combined with growing individualization at the same time.

People choose their locations based on a number of influencing factors, which are highly individual and very much dependent on a household's specific situation. The choice is usually result of complex considerations; however, compromises often have to be made. The revealed preferences approach ties up on these compromises by analysing taken decisions.

One of our main hypotheses was that, besides a general increase of commuting distances, a high level of commuting patterns across municipal borders could be detected. By the analysis of individual search patterns, which can be detected by the geo-referenced locations, we expect not only data to test our hypothesis, but also to better understand trade-offs and patterns of changing spatial preferences within the MMR.

A second hypothesis was that, on a regional as well as inner-city scale, centripetal forces of the knowledge economy and the "trend back to the cities" would lead to a more pronounced polycentric functional structure instead of dispersed development. This polycentric structure would, as described earlier, be characterised not only by its network, but especially by reciprocal complementarity.

Therefore we combined a macro-perspective analysis of indicators of socio-economic structures and spatial accessibility with the micro level of individuals who face decisions where to live, where to work and how to optimize daily mobility patterns. Comparable longitudinal data on simultaneous workplace and housing decisions was not available for Munich before, and it is rarely available for other areas in Germany.

## 5. Preliminary Results

After the closure of the survey on April 19, 2015, and a data quality assurance phase, we could undertake some first evaluations. Due to the short timeframe between the end of the survey and the finalisation of this paper, the results presented here have to be seen as a first approximation to the data and are of a preliminary nature.

The questionnaire was answered by 7,308 respondents, which is equal to 0.126% of the MMR inhabitants. The turnout was higher than expected, also thanks to a distribution strategy that involved both social media and traditional channels such as mailing lists of cooperation partners and flyers. With 2,523 respondents living in Munich, the city itself is slightly overrepresented in the sample (0.17% of inhabitants). In some municipalities, the turnout was exceptionally high due to the participation of the municipal administration in the promotion (e.g. Ohlstadt 1.48%, Pfaffenhofen 1.41% of inhabitants). It is hence very important to consider the impact of this uneven spatial distribution on a small scale if generalising statements for certain areas are made. This also applies to the sociodemographic distribution of participants, since the dataset is also biased towards people with a high social and educational status.

In a first step, we examined the location pairs of residence and primary workplace for the respondents who were in employment (Figure 3). Due to the even distribution on a region-wide scale, generalising statements can be made.

Expectably, the commuting patterns show a strong concentration on Munich as the dominant centre of employment in the region. To a lesser degree, regional centres around Munich such as Rosenheim, Landshut, and Ingolstadt emerge as commuter destinations. Regarding the choice of transport modes, the dominance of private transport in the regional centres is surprisingly high (65%), while a high share (61%) of in-commuters to Munich use public transport. Cycling only plays a significant role within the larger cities Munich, Augsburg, Landshut, and Rosenheim.

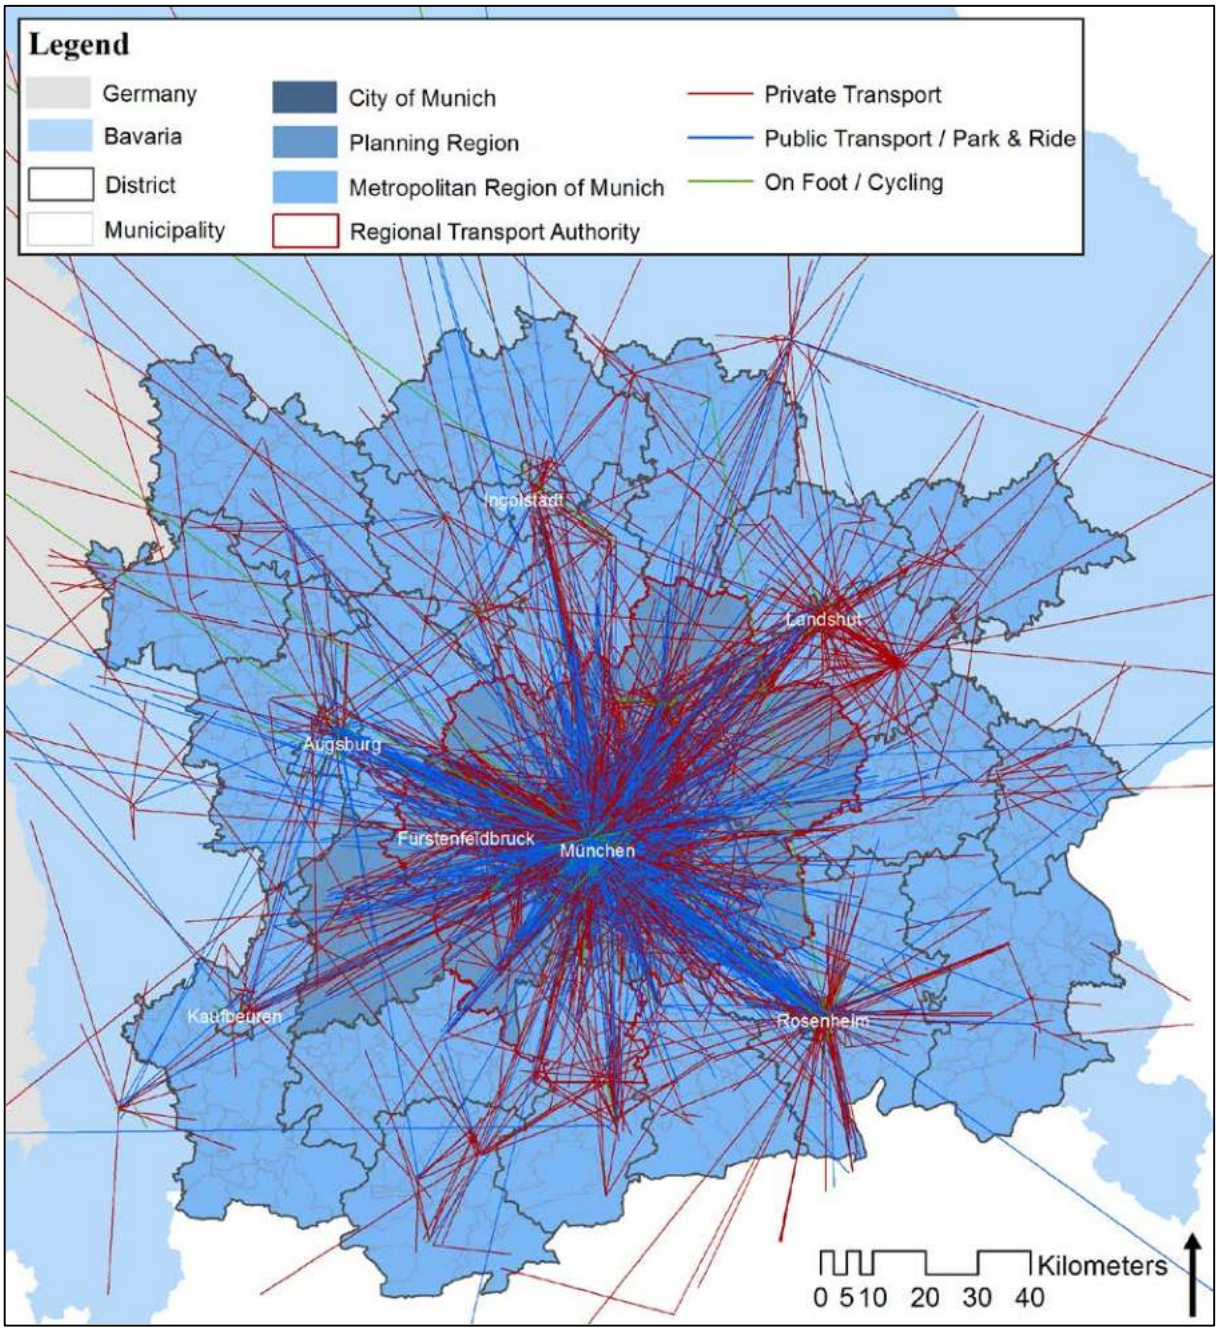

**Figure 3: Commuting Patterns in the Munich Metropolitan Regions**

Regarding our first hypothesis, it becomes obvious that a large share of the functional relations within the Metropolitan Region is not contained within the boundaries of the Planning Region, or the Regional Transport Authority. Instead, regional centres like Augsburg and Ingolstadt, which used to be relatively independent city-regions, now show a significant level of functional interaction in the Metropolitan Region, confirming basic tenets of the "new regionalism". The high rents in Munich contribute to an overspill of population to the wider region, as stated by many respondents (27.9% of those moving further out).

Households aim to optimize distance and transportation costs between residence and work place without consideration of municipal borders. Statistical analyses of past spatial developments show clear links of the development of residences and employment. But a zoom to the smallest scale of municipalities also reveals that the links on this scale are not as distinct as on the regional scale. It seems that there is a general trend towards short distances until a certain scale, the actual choice

however is highly dependent on local circumstances, whereas municipal borders become less important.

As for our second hypothesis, an emergence of a polycentric metropolitan region cannot be observed from the first evaluation of the residential location movement data. More respondents moved from the centres (Munich, Augsburg, Ingolstadt, Landshut, Rosenheim, Kaufbeuren) to other districts then vice versa (Table 2).

| | | Before Moving | | | Total |
|---|---|---|---|---|---|
| | | Regional centres | Other districts in MMR | Outside of MMR | |
| Now | Regional centres | 1340 | 642 | 744 | 2726 |
| | Other districts in MMR | 1121 | 1457 | 650 | 3228 |
| Total | | 2461 | 2099 | 1394 | 5954 |

**Table 2: Movement between regional centres and other districts in the MMR and outside the MMR**

On a region-wide scale, a trend away from the cores seems to prevail. To appreciate this result better, one has to take into account however that our dataset covers mainly people in employment (83,7%), most of them in their 30s and 40s. This group has the highest share of 'family starters', who typically move outwards. Students, who have the opposed movement profile, represent only 9,8% of our sample. Furthermore, Munich is a special case within the German and most European Metropolitan Region since it is growing strongly and thus causing a high overspill of movement into the region. Thirdly, people moving from outside the region to the MMR predominantly chose the centres as their new residential location, contrary to the inner-region trend.

From statistical government data, we know that areas with access to a high number of opportunities and to a choice of different transport modes are characterized by the highest growth rates within the MMR. The general societal trends lead to an increasing need to be flexible, stay connected and able to easily adjust to changes to remain successful in competition for labour and housing. In this context accessibility becomes one of the key location factors, and thus a driver for a more central location choice. So, polycentric development might still be happening, but it needs further analysis on different scales, combining also workplace and residential location changes. Further clarity in this question can also be expected from the study of the location options not chosen in the course of apartment-searching which we also asked for in the survey.

## 6. Discussion

What do these preliminary results mean for the management of the Munich urban region? We want to raise three points here.

Foremost, the observed increase in functional relations across boundaries requires steps to rematch functional and administrative space, i.e. a stronger cooperation of relevant municipalities in the metropolitan region, especially on the domain of transport provision, integrated transport and settlement development policy, as well as open space protection. The perimeters of the Planning Region and the regional transport authority are too small for these institutions to adequately deal with the challenges resulting from the upscaling of functional relations. We think that, for these policy areas, the recently founded voluntary municipal association for a "European Metropolitan Region" (EMM) reflects a more suited scale. The existing fuzziness and fragmentation with respect to regional governance furthermore prompts that the Munich Metropolitan Region needs not only more cooperation, but also a certain streamlining of forums and hierarchies. A truly regional, strategic approach might be better suited to handle the consequences of growth.

Second, the evaluation of transport modes for commuting in the metropolitan region has shown that while for radial commutes public transport dominates, it is almost absent for tangential relations. A sustainable, transport oriented development policy must aim to encourage a polycentric settlement structure where adequate on the one hand to make public transport more efficient on these tangential links on the other. This goes with the mentioned extension of the regional transport authority. Furthermore, the airport has turned out to function as a significant centre of employment, which is however only appropriately served by public transport in direction to and from the city of Munich. All commutes from other residential locations, especially to the east and north, are done with private transport. Here, adequate tangential links should be established.

Third, by asking the citizens themselves about their locational choices, preferences and wishes in a survey, we can hope to trigger innovations in our management approaches for example by creating a broader understanding of existing challenges. This can also contribute to initiate a change in awareness and provide further arguments for future research and policy-making that are ultimately necessary to cope with the challenges of growth.

# COMPLEXITY, SCALE AND PRAGMATISM IN SUSTAINABLE URBAN REDEVELOPMENT

Rien van Stigt

Utrecht University of Applied Sciences, Centre for Technology and Innovation, rien.vanstigt@hu.nl

Keywords: devolution, multi-level governance, scale mismatch

## Abstract

*In complex cases of sustainable urban development, particularly in high-density, mixed-use areas, it is argued that (inter)nationally issued environmental standards may be too restrictive and that, instead, local stakeholders must negotiate joint objectives to meet all of their interests, including an adequate environmental quality. In this contribution, we present two case studies examining the practical outcome of trade-offs between environmental standards and other objectives in highly complex inner-city redevelopments. These networked decision-making processes, involving multiple stakeholders in multiple arenas, can be classified as aggregate complexity. Complexity science has contributed modelling methods to try and understand how stakeholders interact in such intricate networks. In practice, we found a great deal of pragmatism with stakeholders taking sides in an argument which transcends the simple conflict between environmental quality and other interests. Rather, economic interests of stakeholders at higher spatial and temporal* scales, local resident s health and the ar environmental quality on the one hand conflict with the municipality s (and the *and social interests on the other. Highly pragmatic attitudes of stakeholders in decision-making arenas at different spatial scales appear to defy theoretical modelling and justify the conclusion that trade-offs involving environmental quality standards cannot be left with municipal authorities. Higher tiers of government play a necessary role in safeguarding both environmental and economic interests that transcend the local scale.*

## 1. Introduction

Sustainable urban quality is the outcome of a decision-making process in which economic, social and environmental interests are weighed (Campbell, 1996). Environmental quality in a strict sense, namely the level of pollutants, noise and risk is an integral part of this negotiating process. Particularly in cases where land is scarce, where different types of land use are in close proximity to one another and where many stakeholders have claims on the little space that is left amidst a host of activities, environmental impacts are usually high and cumulative and desired spatial development may be hampered by environmental standards that put limits to the levels of noise and pollution in the area (Howley, Scott, & Redmond, 2009; Van Rij & Korthals Altes, 2014; Van Stigt, Driessen, & Spit, 2013). As cities all over the world respond to the challenge of sustainable urban development by converting previously developed land into high density and mixed-use urban areas (e.g. Chen, Jia, & Lau, 2008), such conflicts between environmental quality and urban development are widespread.

Generally, as a way out of the aggregate complexity (Manson, 2001) of which this type of conflict is an example, administrative powers are devolved from the central state upon lower levels of government typically municipalities and upon non-governmental institutions, in a process of decentralization (De Roo, 2000; Lane, 2003), often in combination with deregulation, understood as the deliberate relaxation or complete abolishment of (environmental) regulations.

As some aspects of decision-making about spatial plans are left to the discretion of municipal authorities, all within certain limits and under certain substantive and process conditions, other aspects remain within the competence of higher tiers of government. Thus, an intricate legal framework is created, in which rules, laid down by national government are interpreted and implemented by lower levels of the state to create their own, local, decision-making framework.

Decentralization and deregulation originate not only from the necessity to improve decision-making in highly complex societal contexts, but demonstrably also from a neoliberal political agenda (Lord & Tewdwr-Jones, 2014). It can be argued that, as a result, in spatial planning *inadequate weight is given to pollution prevention* (C. Miller & Wood, 2007). Similar fears have been uttered in Scotland (Prior & Raemaekers, 2006) and the United States (Allison & Lents, 2005).

In this paper, we illustrate how decentralisation and deregulation may work out in the Dutch context, where municipal authorities are allowed more room for manoeuvre in cases where, in the pursuit of sustainable development, urban space is used in a particularly efficient and economical way. In the Netherlands, policy instruments have been implemented that permit local governments to make trade-offs between environmental quality and other interests (Glasbergen, 2005; Runhaar, Driessen, & Soer, 2009; Verschuuren, 2010).

We examine how one of these policy instruments is used in practice and how trade-offs are made, i.e. what interests are at stake, who is involved in weighing them and how they interact. More particularly, as it can be expected that economic interests prevail over ecological considerations (Hofstad, 2012), we are interested in the level of environmental quality that results from these trade-offs. The research question that is being addressed in this paper therefore is: in what way is environmental quality influenced by allowing local authorities to make trade-offs between environmental interests and other interests in pursuit of efficient and economical land use?

The paper is constructed as follows: First, we look at the interactions among scales in environmental governance. Second, we discuss the Dutch approach to enlarge local governments room for manoeuvre. In section 4, the paper describes the research method used, after which the case study is presented. The paper then discusses these results and draws conclusions about the effectiveness of the approach and how this is influenced by the complexity of the issue.

## 2. Dynamic interactions among scales

### 2.1. Scales, levels and cross scale dynamics

Cash et al. (2006) define scale as the spatial, temporal, quantitative, or analyt used to measure and study any phenomenon and any point on such a scale is termed a l Here, we are interested in the *ecological* or geographical (Cumming, Cumming, & Redman, 2006)and *jurisdictional* scales (Cash et al., 2006). The geographical scale is determined by the spatial and temporal extent of the bio-geophysical processes that underlie an environmental problem and by the resolution of our observations (see also Görg, 2007). Typical levels on this scale are local, regional, fluvial, continental and global. The jurisdictional scale is a social construct (Bolin, Collins, & Darby, 2008) describing the institutions and social processes involved in managing the ecosystem s resources (Cumming et al., 2006). On this scale, e.g. municipal, provincial, national and supranational levels can be distinguished.

To avoid scale mismatches, i.e. a misalignment of geographical and jurisdictional scale (Cumming et al., 2006; Termeer, Dewulf, & Van Lieshout, 2010; Young, 2006), environmental governance can be rescaled from the national level, either upwards or downwards. Authority is devolved upwards to the supra-national tier in order to deal e.g. with trans-boundary air pollution at the level of the European Union (EU) or with climate change at the level of the United Na Convention on Climate Change. It is devolved downwards to regulate regional and local environmental problems (Van Rij & Korthals Altes, 2014), such as odour nuisance and traffic noise.

If, however, a phenomenon occurs at multiple scale levels, there also will be multiple interactions between geographical and jurisdictional scale. Noise, for instance, is considered to be a local phenomenon, yet it is influenced by local environmental policy e.g. permitting industrial

activities as well as regional policies regarding infrastructure or even national policies concerning aviation. Cash et al. (2006) term this *cross scale, cross level dynamics* or *multiplicity*. Termeer et al. (2010) argue that these cross-scale and cross-level issues are dealt with by increasing the fit between scales and improving the links between administrative levels.

## 2.2. Repairing scale mismatch: devolution and subsidiarity

Which government tier is most suited to secure environmental quality? And how should securing environmental quality be institutionalised? In the scientific literature about environmental governance, these questions are addressed from different frames, invariably involving both devolution and participation. Newig and Fritsch (2009, p. 197) frame the debate as a response to insufficiently effective environmental policies. They argue that one response is to adapt the level of governance to the spatial scale of the environmental problems to be solved. Such devolution addresses scale mismatch quite in accord with the subsidiarity principle, which states that *decisions within a political system should be taken at the lowest level consistent with effective* action (Jordan & Jeppesen, 2000, p. 66). This principle can be traced back to political theories from the second half of the 19th century, in relation to efficiency of government action, but has gained a more specific meaning in the context of the European Union (EU), where it pertains to the allocation of national and supranational responsibilities (Jordan & Jeppesen, 2000).

The other response observed by Newig and Fritsch (2009) is to enhance participation of non-state actors in decision-making about solving these problems. Participatory governance *is expected to* contribute to improving the quality of decisions by incorporating locally hel *opening up the political arena for environmental interests* (Newig & Fritsch, 2009, p. 198).
Lord and Tewdwr-Jones (2014) observe the same trend towards downwards devolution of authority and involvement of non-state actors, but frame it, in contrast, as part of a neoliberal agenda in western countries that, at least in England, was motivated by a necessity to fix the sys *grounds that it is a chronic obstacle to growth* (Lord & Tewdwr-Jones, 2014, p 346).

Thus, subsidiary devolution and participation of non-state i.e. civil society and business actors lead to a multi-level governance landscape, in which lower tiers of government, rather than replacing higher levels of the state, execute the authority that was devolved onto them, in deliberation with civil society and business actors and all within certain limits and under certain conditions set by higher tiers of government (Hooghe & Marks, 2003; Steurer, 2013). These conditions can be either substantial or procedural. In the case of substantial rulings, the result of participative deliberation at the lower-level must comply with regulations issued at higher government tiers. This may cause friction between objectives of authorities at different levels, sometimes referred to as cross-level issues (Cash et al., 2006; Termeer et al., 2010), that may lead to stalemate in local development.

That is why Garmestani and Benson (2013) argue that environmental law and institutions are too rigid to account for scale and to accommodate experimental solutions at the local level. They suggest *legal reform by identifying the principles of reflexive law as a possible mechanism for achieving a shift to resilience-based governance and leveraging cross-scale dynamics to provide resilience-based responses to increasingly challenging environmental conditions* (Garmestani & Benson, 2013, p. 1). In such a decentralised reflexive setting, national government merely establishes procedures in order to secure that all relevant interests and actors are involved in the conclusive deliberations (Gaines, 2002). Thus, the required level of environmental quality results from a deliberative process, conducted at the appropriate scale, and aimed at finding a tailor-made solution.

Decentralized reflexive environmental regulation, however, is not uncontested. First, Moss and Newig (2010) conclude that participation introduces difficulties of legitimacy and power (see also Richardson, 2005). In much the same vein, Cumming (2013) worries that the interests of actors in colloquial terms: the interests of polluters and those impacted by pollution are fundamentally

too far apart to be negotiated about in a reflexive law setting; he therefore advocates implementing reflexive law arrangements in tandem with conventional regulation.

Moreover, in cases of environmental dispute, actors are known to rescale an issue by linking it to issues at other, higher, spatiotemporal scales (Bolin et al., 2008). In doing so, they also link to the matching governance levels. As a result, an intricate web of governance relationships is created which easily complicates decision-making (for an example see Bolin et al., 2008).

### 2.3. Is devolution the solution to pollution?

In sum, instead of facilitating decision-making in environmental governance and enhancing considerations of environmental aspects, downward devolution, together with deregulation that often accompanies it, can be expected to result in quite the opposite. However, deciding about environmental quality at higher tiers of government may paralyse local decision-making. Different elements of urban development appear to require decision-making at distinct levels of governance, introducing a problem of co-ordination between these levels. In the remainder of this paper, we will investigate how devolution and participation work out in cases of inner-city urban redevelopment where desired spatial development is hampered by environmental standards that put limits to the levels of noise and pollution in the area (Howley et al., 2009; Van Rij & Korthals Altes, 2014; Van Stigt et al., 2013).

## 3. Addressing cross-level issues: a Dutch approach

The Dutch City and Environment (C&E) approach (Eerste Kamer, 2005) is a decentralized reflexive approach that allows local stakeholders to set aside regulations issued by higher tiers of government and to renegotiate the desired level of quality locally. The C&E approach is intended to promote efficient use of space and reaching an optimal quality of the urban environment in highly-burdened mixed-use developments (Boeve & Van Middelkoop, 2010; Evaluatiecommissie Stad en Milieu, 2004; Van Staalduine & Simons, 1999). In cases where, demonstrably, state-issued legal environmental quality standards cannot be met, it offers local administrations the opportunity to define their own quality standards, deviating within certain limits from the generic legal framework. Accompanying this relaxation of standards is a procedure regulating deviation, ensuring compensation of quality loss and ensuring participation of all stakeholders.

The procedure consists of three steps: First, environmental aspects must be considered from the onset of plan making. Second, in case national environmental quality standards are expected to be violated, the urban design must be tailored to prevent non-compliance. Thirdly, and only after it has been demonstrated that neither the usual measures nor tailor-made creative solutions can secure compliance with national environmental quality standards, deviation from these standards is in order. If lower, local environmental quality targets are set, compensation must occur in such a way that the total urban quality of life is optimized, i.e. turns out to be highe of the plan. Such an optimum quality is not determined by individual standards for air, water, soil, noise et cetera, but is the result of a trade-off among the stakeholders preferences regardin whole range of quality aspects, including architectural design, urban landscape, the presence of amenities, the proximity of public transport facilities and so on. Deviating from national environmental standards requires a formal decision by the municipal government. This so-called step 3 decision must be underpinned by the municipality s vision on the level life being pursued, the way in which compensation is offered and the way in which stakeholders have been involved in the deliberations.

Driessen et al. (2012) have characterised several modes of environmental governance according to three basic types of features: policy content, institutional features and actor features. In much the same way, we characterise the C&E approach, based on the prominent perspective on urban environmental quality, the role of law, the way in which responsibilities are allocated to actors and the interaction among these actors. Table 1 summarises these main characteristics.

Table 1. Characterization of the C&E approach

| | |
|---|---|
| Perspective on urban environmental quality | Holistic; focus on urban quality of life.<br><br>Accounting for objective as well as subjective quality aspects. |
| Role of law | Reflexive, i.e. regulating procedures for establishing quality objectives as a last resort, ensuring compensation and participation. |
| Allocation of responsibility | Devolved onto local state and non-state stakeholders. |
| Interaction among actors | Local government, market parties and civil society interact in open planning process, arriving at broadly supported urban environmental quality objective. |

## 3.1. Perspective on urban environmental quality

The literature about urban environmental quality recognises that it is multidimensional and multifaceted (Moore et al., 2006). Depending upon the disciplinary perspective taken, urban environmental quality may comprise merely the classical environmental aspects noise and industrial safety or include aspects that belong to the domain of urban design, such as the vicinity of amenities, the availability public transport, the amount of open and green space or the identity of the built environment, conveyed by e.g. architectural features and cultural heritage. From a reductionist point of view, each of those aspects must meet a certain criterion, e.g. an environmental quality standard for water or air (Davis, 2005; Davis, 2007) or for the area of green space per dwelling (VROM, 2006). In the literature about urban quality of life, a more holistic approach is taken, in which the quality of the urban environment is explained to some varying extent by individual quality indicators.

Some of these urban environmental quality indicators can be expressed in objective terms, often using some quantitative measure like microgram per cubic metre or decibel. Other quality indicators take into account the perception of these objective conditions; when assessing noise, for instance, it is the degree of annoyance that is relevant, rather than the objectively measured sound level. These indicators are fundamentally subjective in nature and, thus, are highly dependent upon the preferences of the people involved (Howley et al., 2009).

In the C&E approach, the central concept is urban quality of life, which amounts to a holistic and predominantly subjective approach.

## 3.2. The role of law

States seek to protect weak interests, such as environmental quality, biodiversity and other aspects of sustainable urban development, by law. National environmental standards, however, by definition do not provide enough flexibility to adapt the level of protection of the environment to the particular circumstances at the regional or local level. Furthermore, issuing national standards may well provoke evasive behaviour on the part of those regulated. In order to amend these shortcomings, reflexive law (Teubner, 1983) proposes the establishment of legal procedures that assure adequate deliberation amongst stakeholders, rather than issuing substantive norms in advance (Dernbach, 2008; Dorf, 2003; Gaines, 2002).

In Step 3 of the C&E approach, clearly there is procedural, rather than substantive regulation. The C&E approach can therefore be characterised as reflexive. This third step clearly is a last resor can only be taken after it was proven, in both preceding steps, that standards cannot be complied with, not even through tailor-made solutions.

### 3.3. Allocation of responsibility

From the 1990s and, more pronouncedly, from the 2000s, Dutch environmental policy has shifted from a centralised to a more decentralised and interactive mode of governance (Driessen et al., 2012). This is not to say that one mode has completely replaced the other; rather, the new mode has gained prominence, whereas the existing mode still prevails.

The C&E approach has several features of decentralised interactive governance: in Step 3 of the C&E approach, responsibility for establishing urban environmental quality objectives has to a large extent been devolved onto the municipality. In an open planning process, civil society as well as market parties involved can have their say and, if they feel unheard, have a right to court appeal. Ultimately, it is the municipal Council that has to validate the outcome of this process in a formal Step 3 decision. Although there is no formal new jurisdiction, this gover does remind of what Hooghe and Marks (2003) describe as Type II multi-level governance, where authority is distributed among different state and non-state actors.

### 3.4. Interaction among actors

In the C&E approach, local government, market parties and civil society interact in an open planning process, to arrive at new urban environmental quality objectives that can count on all stakeholders support. Such a process of interactive governance requires legitima al., 2012) which, in theory, is conferred by the legally established process ensuring compensation and participation. Here, trust is also important (Lange & Gouldson, 2010).

## 4. Method

Only a handful of Step 3 decisions have been made in the Netherlands under the Interim law C&E. We selected two cases in which municipalities made use of Step 3. Table 2 provides the important features of each of these cases.

Table 2. Characterization of the cases used in this study

| Case | Type | Problem | Status |
|---|---|---|---|
| Roosendaal | Mixed-use development in railway and industrial zone. | Industrial noise above maximally allowed level. | In part being executed; rest on hold due to economic crisis. |
| Vlaardingen | Mixed-use waterfront development near industrial zone. | Industrial noise above maximally allowed level.<br><br>Flood risk; increasing due to climate change. | Overturned by appeal court. |

Our analyses are based upon desk research into the underpinnings of the ste underlying documents (land use plan, master plan) and, in case an appeal was filed, the appeal court rulings. Desk research was complemented by interviewing representatives of stakeholders.

Spit and Zoete (2006) distinguish three types of actors: those with only a private (business) interest in the development as such, those with an interest in the solution the development offers in a societal problem and those who have an indirect interest. We had interviews with representatives of the first two groups: municipal project leaders, their political administrators, their environmental advisors, the developer and, if applicable, representatives from local and regional industry. Interviews were conducted either face to face or by telephone, in a five-month period (January through May 2015). Interviews were semi-structured, lasted between half an hour and an hour and a half and were digitally recorded. A summary was prepared in writing and sent to individual interviewees for approval.

## 5. Case descriptions

### 5.1. Roosendaal

In Roosendaal, a former industrial estate near the train station has gone derelict. It is situated in between the historic city centre (on the other side of the railway) and, since the late 1950s, a residential area. Transformation into a mixed-use (amenities, education, offices, including a new city hall, and residential) area was thought to improve the city s spatial sti Acquiring and remediating the land would be costly; a relatively high number of houses and apartment buildings was planned in order to optimize the proceeds of the real estate.

The remaining industry causes levels of noise that exceed national standards and, in one small corner of the area, odour nuisance. The odour problem was solved by repositioning vulnerable real estate and planning less sensitive buildings instead. Railway noise falls below national norms; rail transport of dangerous substances causes a high level of societal risk for which type of risk, however, no compulsory national norm is in vigour.

The urban planners, realizing that the noise resulting from the remaining industry was severe, had optimized the positions of the residential buildings. However, some dwellings could not be made to comply with regulations concerning industrial noise. Noise reduction at the source had been accomplished at an earlier stage and, after extensive deliberations with the companies concerned, it was concluded that any reduction of source levels at the time would be offset by the desired future expansion of the industry. The obvious solution to accommodate future expansion would have been to fit the buildings design with a so-called deaf fa ade (i.e. a fa ade tha and as such does not have to comply with noise regulations).

For some of the buildings, the view of the surroundings was thought to contribute much to their specific quality and the idea of a deaf façade was rejected (Gemeente Roosendaal, 2008). The C&E approach was therefore deemed necessary to alleviate the restrictions due to excess industrial noise. Affected buildings will be equipped with an extra insulation. In dwellings where noise was particularly problematic at night, bedrooms were situated at the least impacted side of the building. Possible damage to residents health was deemed negligible (Gemeente Roosendaal, 2008 relatively small excess of noise was compensated for by an unusually high quality design and layout of buildings and public space. A step 3 decision to deviate from nati and guarantee compensatory measures was taken by the city council and approved by the provincial authorities. During preparation of the plans, deliberation with the companies in the area and public participation was secured through the usual channels.

One of the remaining industries just outside the area filed an appeal to th arguing that insufficient compensation was offered to potential residents and that compensatory measures were not legally secured. The court ruled that compensation was indeed in accordance with the C&E approach. It also ruled that some of the compensatory measures were not firmly established and ordered repair of the decision in this respect. The appeal was unsuccessful.

## 5.2. Vlaardingen

Vlaardingen is situated near the River Meuse, close to extensive industrial estates on either side of the river. Over time, the historical centre has been cut off from the river bank by an industrial area that recently has become derelict as some plots were abandoned. The municipality arranged for the few remaining industries to be located on a new industrial estate elsewhere within municipal boundaries, so as to restore the connection between the river and the city centre. The area, that is bounded by the historical harbour, will be redeveloped allowing amenities and high density residential use. Users and residents are expected to have a great view of the river, while enjoying the proximity of the city centre.

The area is surrounded by several industrial complexes, including the Port of petrochemical industry and therefore considerable noise and odour nuisance exist. It is also prone to incidental flooding, which is expected to be worsened by climate change. It is, however, the last available piece of municipal territory where a new residential area can be developed within the framework of a larger plan to modernize outdated neighbourhoods consisting mainly of galleried flats. Developing the area would not only upgrade it, but also improve Vlaa structure, reducing the current barrier formed by the river dike and the road on top of it.

The area is heavily impacted by industrial odour and noise (Gemeente Vlaardingen, 2004). Dutch environmental law limits exposure of residential buildings, with an exemption for existing homes and small extensions of residential areas situated near a sea port (where noise levels may be up to 5 dB higher). However, the Vlaardingen development did not qualify for this exemption because of its size, about 2000 dwellings, which was not regarded as a small extension of a pre-existing residential area.

During a previous regional remediation programme, emissions of industrial noise had already been cut back, so that further limitation was deemed unfeasible. Yet, as the area was deemed to be attractive, a participative process was initiated to systematically assess environmental threats and opportunities (Gemeente Vlaardingen, 2006). With respect to noise, highly impacted residential buildings were designed in such a way that bedrooms were at the side of the building that, at night, was least burdened. A Step 3 decision was necessary because at some points, e 5 dB above permitted levels and the project did not meet the criteria for the sea port exemption which would have allowed for such high levels (Gemeente Vlaardingen, 2003).

There is a high amount of tension between the intentions of the Port of Rotter the left bank of the river, to expand and the municipalities in the area, on the right bank, to build adequate housing for their residents. At the regional level, Rotterdam, and other municipalities, the industry and the province had jointly established a framework for further local agreements about building and industrial noise. The framework stated that no new development would lead to further restrictions on industrial noise emissions and that municipalities would communicate to prospective residents about the level of noise they were about to be exposed to. Vlaardingen, acting in accordance with the framework, expressly opted for a Step 3 decision in permitted noise levels that would not further restrict industrial emissions. Compensation was offered to residents through providing extra insulation up to 5 dB and situating bedrooms on the quiet side of the building; other compensatory qualities include the river view, the proximity of the train station, the city centre and other amenities.

Nevertheless, the Rotterdam area industry s organization Deltalinqs and a number of i companies filed an appeal because they feared that future extension of activities would be limited by the piecemeal encroachment on the area by apartment buildings. The appeal court ruled that this particular objection by Deltalinqs was inadmissible. Although the court was given a favourable advise about the underpinning by its technical advisor, it overturned the ste grounds that in preparing it, the municipality had failed to assess compliance with the limit for the

daily average concentration of particulate matter (although it did assess compliance with the yearly average limit, as was common at the time).

There is also friction between national resilience policy and local trade-offs between flood risk and cost. The municipality intended to level up the area, looking ahead 50 years. The national authorities demand considering a longer time frame of 100 years. This, however, would bring extra cost and change the area in what one interviewee termed a fortress .

## 6. Discussion

### 6.1. Perspective on urban environmental quality

Both municipalities that took a Step 3 decision substantiate it by meticulously underpinning the necessity of the area s development and by detailed calculations of environmental impacts. Although environmental impacts, particularly industrial noise, are relatively high, exposure is deemed limited because of extra insulation and smart layout of homes. Yet, we found neither the actual exposure of residents nor the compensation of this loss of quality to rest on any scientific assessment of overall quality in the area. In other words: a holistic vision could not be observed.

### 6.2. The role of law

The Roosendaal and Vlaardingen cases illustrate the reflexive role of law (Gaines, 2002) in relaxing national standards in favour of a more integrated perspective on urban environmental quality. However, such a relaxation is not necessarily in the interest of industry. Rather surprisingly, we found that surrounding industries, in fear of future conflicts with the new residents interests, argue against the relaxation of standards, intended to residential areas in their proximity. This illustrates that law also plays the traditional role to protect citizens against undue use of authority by the government.

Particularly the Vlaardingen case makes clear that state-issued standards serve to protect not only environmental interests, but also economic interests i.c. of the regional industry at higher geographic levels and interests at higher temporal levels i.c. flood risk in the area.

### 6.3. Allocation of responsibilities

The C&E approach in Vlaardingen shows that devolution and participation only in part solve the problem of scale mismatches, precisely because urban environmental quality dimensions of a local development are manifest at multiple spatial levels. This is in line with other research that found no significant correlations between governance effectiveness and decision making scale, nor between policy delivery and institutional fit to ecosystem scale (Newig & Fritsch, 2009). In Sweden, the results of the so-called Constructive Dialogue were disappointing (Smedby & Neij, 20 terms of environmental quality reached.

### 6.4. Interaction among actors

Both cases show that trust is important. Neither in Roosendaal, nor in Vlaardingen, extensive deliberations with industry could ultimately prevent all parties from filing appeal. In Vlaardingen, the harbour industry s lobby organization, despite the acceptance of high levels of noise and smel through the Step 3 decision, industry felt that planning residential buildings in the area was against the agreement framework to respect the industrial noise contours. Playing the public health card, industry expects provincial government to draw clear borders between zones of industrial activity and areas with sensitive types of land use in the greater Rotterdam area; this is in line with findings by Bolin et al. (2008). This seems to be highly pragmatic behaviour, as ultimately the appeal court based its ruling on formal grounds that were brought forward, rather than considering the

municipality s perspective on urban environmental quality. Unfortunately, there whether this particular trade-off between economic use of space, and urban environmental quality would stand up in court.

In both cases discussed here, participation was carried out following the elaborate procedural regulations prescribed. This is quite according to the principles of reflexive law. Yet, concerns of abuse of such a reflexive approach cannot be totally dismissed by our results: in both cases, municipalities are known to have invested a great deal of money in acquiring land in the area; one way or another revenues must come from these investments. Communications about the new residential areas (in area visions and plans) stress that noise standards are exceeded to merely a small extent and a quality discourse (Hofstad, 2012) highlights the unique features of the place: view, the character of the area, amenities, proximity of public transport and the city centre, and the like.

Meadowcroft (2007) argues that participation of actors who have no democratic constituency like, in our cases, industry introduce the question of legitimacy and that, therefore, there is always a role for the state. Aspects of that role could be clear guidelines for municipalities with regards to goals and means, hierarchical regulation of polluters and better alignment of policies among government sectors (Hanssen, Mydske, & Dahle, 2013).

### 6.5. Dealing with complexity

The type of issue discussed here is complex because of multiple interactions among multiple actors in multiple decision-making arenas, trying to achieve distinct objectives that impact environmental quality at various spatial and temporal scales. Manson (2001) terms this aggregate complexity . Complexity theory offers modelling methods to try and understand how stakeholders interact in such intricate systems. Theoretically, a combination of development scenarios, environmental impact models and an agent based model (cf. B. W. Miller & Morisette, 2014) could support planning in the face of uncertainty and complex interactions. In practice, however, we observe that municipal decision-makers act in a highly pragmatic way: they slice up the complex issue of urban environmental quality into separate quality aspects, such as noise, and focus on local rather than regional or even wider ranging effects as well as on short-term rather than long-term impacts. Furthermore, actors who fear that their future interests are compromised, may pragmatically fight local decisions.

## 7. Conclusion

We conclude that trade-offs leading to stretching environmental limits cannot be left with local authorities alone and that higher tiers of government play a necessary role in safeguarding both environmental and regional economic interests at higher spatial and temporal scales. Admittedly, environmental standards here were exceeded only to a small extent. However, in rapidly growing megacities in newly industrializing countries situations much worse than those in relatively quiet and well-regulated cities and towns in the Netherlands can be expected to occur, both in terms of affected population density and of noise levels.

In both cases, but more pronouncedly in Vlaardingen, we observed a conflict between the surrounding industry s economic interest, local resident s health and environmental interests one hand and the municipality s (and the developer s) economic and social inte This conflict is shaped by the complexity of the issue, resulting from the fact that a single urban development has environmental impacts at multiple spatial and temporal scales and therefore requires attention in multiple decision-making arenas at multiple administrative levels. Although, obviously, we merely explore the issue here and more research would be needed to come to grips with it, our findings provide a first suggestion that a wide gap exists between complexity theory and the practice of governing sustainable urban redevelopment and its impact on environmental quality.

# ADVANTAGES OF SELF-ORGANISATION IN URBAN PLANNING – LOCAL LESSONS OF URBAN DEVELOPMENT IN HELSINKI METROPOLITAN REGION

Sirkku Wallin,
YTK/ Department of Real Estate, Planning and Geoinformatics,
Aalto University, e-mail sirkku.wallin@aalto.fi

Jane Jacobs asked already in 1961: What kind of problem is problem in organised complexity . However, in complexity theorie thinking, the problems caused by organisation represent just one ty other types are simple problems and problems of disorganised comple methods of different types of complexity differ from one another. organizing urban planning, and the contest between local development regional ones. Action research is way to conduct studies on u It provided methodology not only to collect data, but also to from the perspective of stakeholders in the Herttoniemi neighbourho of Finland. The paper will answer three questions: What is urban complexity? What is of citizen activism in complex urban development? How can comple turned into an advantage in urban planning?

Key words: Urban complexity, self-organization, action research

## 1. Introduction

The objective of urban planning has been to plan and design well-functioning urban environments. However, many urban problems are complicating this task (Christaller, 1933; Bettencourt and al., 2007) and the expanding scope and scale of problems have turned the latter into ´wicked` ones. Wicked problems are intricate by nature comprising several environmental and societal issues at the same time (Skaburskis, 2008; Weber and Khademian, 2008). There has been two ways to respond to wicked problems in urban planning. The first one has focused on the substance of planning, aiming at a better physical appearance and performance of urban functions. The second one has laid emphasis on the procedure; processes, their actors and the stages of planning.

Unfortunately, the analysis of the current urban development of the Helsinki Metropolitan Region reveals severe defects in the application of both approaches. I will reflect in the following on the development of a Helsinki neighbourhood called Herttoniemi. As one of the oldest suburbs of the capital city, with a central location and good accessibility, it has followed the urban transformation of the Metropolitan Region and faced the problems and promises of urbanization: shortage of housing, required urban densification, and belt-tightening of public expenses which have transformed the neighbourhood. The population has increased up to 53 000 inhabitants during the

past ten years, and the change will continue (Statistical Districts, 2014; Helsinki City Plan Draft, 2015). Herttoniemi can be regarded as the mirror of urban development in the Helsinki region in which the internal and external push and pull factors take turns, enabling and constraining one another.

Herttoniemi provides a rich context for studying urban complexity. For example, the idea of enhancing sustainable urban development through densification and a compact urban structure has become an accepted norm in urban planning. It is assumed to provide better services nearby and therefore less traffic. However, densification has not led to a more sustainable environment in Herttoniemi, because service policies are not following housing policies. The former service structure developed in 1950s is being replaced by the structure of 2010s in which services are concentrated in large scale units that are shared by several neighbourhoods. Services that used to be designed for 5000 or 10 000 inhabitants are now produced for 50 000-100 000 units of inhabitants. This has become tangible already in health and child care services. The former is an important daily service for elderly people and the latter for young families. The hospital of Herttoniemi was put down already in 2014. The health station will move to another neighbourhood, Kalasatama, in two years. Accessibility of the daily services is related to the mobility and consumption patterns (Heinonen, 2012), which together are increasingly burdening the ecosystem as an increasing number of inhabitants is trying find services.

At the same time, it has become ever more difficult for citizens to shape their own living environment and daily life. According to service surveys (Häkkinen and Wallin, 2005; Jarenko, 2007), as well as heated debates in local newspapers, the inhabitants are not willing to give up their local public services. Neither are they willing to have more neighbors especially, if it reduces the green space and recreational areas (for example the Kivinokka area). However, the aspirations of citizens are not reflected in the administrative and decision-making system. Even if public participation is endorsed by legislation, the statutory measures in urban planning are limited to the specific phases of the planning or zoning process. At the same time, the role of citizens is very small in social and health policies, as they are steered by other type of legislation, detached from urban policies. As the Metropolitan and City administration has not mobilised local people, these have adopted other coping mechanisms to design and produce their everyday urban functions.

The aim of this paper is to analyse the role of self-organising citizen activism in the urban planning and development of Herttoniemi. The paper is based on action research and longitudinal data gathering during 2004-2012 (Wallin and Horelli, 2010; Saad-Sulonen and Horelli, 2010; Wallin and Horelli, 2012; Wallin, 2015). The paper asks and answers three questions: What is urban complexity? What is the role of citizen activism in complex urban development? How can complexity be acknowledged and turned into an advantage in urban planning? The paper sheds light on action research as a method in urban planning as well as the local patterns of urban development.

## 2. Three types of urban complexities

The city has been described in urban planning research with diverse concepts. In the era of modernism, rational planning conceived the city as a machine. It was an engine, produced by design and steered by administrative systems. The machine was a source of livelihood that promised a society where global economic and political domination was possible (Faludi 1973; Porter, 2011). In the post-modern era, cities have prevailed their role, but the concept of urban planning and development has changed. Due to urban growth, social segregation and economic differences, cities look more like a self-organising organism than a disciplined machine (Taylor, 1998; Urry, 2003).

Jane Jacobs asked already in 1961, in her book Death and Life of a Great American City: "*What kind of a problem is a city?"* She answered that: "*A city is a problem in"organised complexity"*. In complexity theories based on systems thinking, the problems caused by organising represent just one type of complexity. The two other types are simple problems and problems of disorganised complexity (Baynes, 2009). The management methods of different complexity types vary from one another. According to Baynes (2009, 215), *"The basic assumption behind simple problems and disorganised complex problems is that the system being described seeks equilibrium and that this can essentially be approached with reductionist, deterministic methods*".

In this paper, simple complexity is a problem, which can be solved. At least, it can be split into units that can be detangled and therefore solved. Simple complexity is not about simplicity. Quite the contrary, it can also be intellectually a highly demanding problem. Traditional engineering questions seek to answer these issues. Examples of solving methods are life-cycle thinking and efficiency consumption calculations that are used in the planning of urban structures and functions.

Problems emerging from disorganised complexity are difficult to perceive and comprehend, as they take place in changing situations, contexts and logics. They have to be studied by applying advanced statistical analyses and modelling. Methods like forecasting and evaluation, are common in the field of economics and policy studies, but these are also being applied in urban development issues, such as demographic change (Baynes, 2009). Disorganised complexity cannot be solved as such, but it can be examined and anticipated which provides solutions for adoption and adaptation.

Organised complexity differs from the other types of urban complexity. Baynes (2009, 215) claims that " *The problems of organised complexity are characterized by heterogeneity, coherent local interactions, irreducibility, and persistent disequilibrium. Deterministic approaches and statistics cannot adequately represent the diversity or importance of interactions and dynamics that lead to aggregate observations in organised complex systems"*.

Organised complexity is a meshwork of formally acknowledged organising, apparently rationally-led and well-steered but, when implemented in practice, they often end up in a ridged, competitive and overlapping system of administration that triggers wicked urban problems. Splitting them into smaller units does not solve the consequences of organised complexity, but this might even worsen

it. In addition, the mere description of the complexity is not enough, since the causes of the problem are known even without new research. The resolution lies in deliberation and social reconciliation, new models of governance and practical innovations that take over current systems and practices. However, they are seldom plausible. New technology or political decision might be ”a juggernaut of destruction”, a new layer on the prior mess, which makes the situation even more complicated (Urry, 2005).

Consequently, the different types of complexity affect the scope of urban planning, the understanding of what urban planning is and the means that can be used to resolve wicked problems. Administrative and resolution devices that are based on the deterministic approach have limited impact on urban planning. Knowledge production that is based on the causalities of phenomena and quantitative methods, such as technical and economic statistics, falls quickly into a cul-de-sac in the changing context (Fainstean, 2001).

Also a lack of capacity prevails concerning the understanding of organised complexity in urban planning processes. According to research on participatory urban planning, the participants – local actors, inhabitants, entrepreneurs and different service provider communities – have not been sufficiently integrated in urban planning (Innes and Booher, 2010; Staffans, 2004; Bäcklund, 2007). Several approaches have been created to involve the public and to mediate uprising conflicts, but so far no successful integration of procedural and content theories of urban planning exists. Manzo and Perkins (2006, 341) claim that ”*While this process may indeed require special management techniques, it has an uncovering of place meanings and values at its core*”. This means that inhabitants` place- based knowledge has not been sufficiently acknowledged in urban planning. Participatory urban planning should mobilize people to bring their own history, the assets of their social relations and dreams of a better future to the content and substance of planning.

Versatile methodological competence is part of a larger capacity to understand urban complexity and to resolve wicked problems. At the same time, it makes urban planning more transparent and more fit for purpose (Wallin and Horelli, 2009). The faculty to combine knowledge, produced through traditional quantitative methods with qualitative knowledge and modelling, enriches urban planning and decision making (Anttiroiko, 2012). The key is new knowledge sources, such as the place-based knowledge of inhabitants and other real-time urban informatics (Batty, 2013). Novel data and its application enrich the planning material and enable the understanding and anticipation of complexities (Horelli and Wallin, 2010). The expansion of data produced by the civil society increases the participation of residents and new groups – both in the process and substance of urban planning.

The systemic [1] gathering, and systematic use of planning information, can make the planning system more transparent, reflective and agile than it is today. In practice, this means the adoption of new approaches and new methods, not only during the on-going planning process, but before

[1] Systemic refers here to the systems approach, which means the comprehension of isolated systems as affecting one another and making a whole or a system. (Hummelbrunner & Reynolds, 2010; Reynolds & Holwell, 2010).

the actual planning begins. These contribute to the planning objectives, but also to the implementation of the plans, when the ex-post evaluation of the urban setting takes place. Thus, they produce planning information for initiatives of linear procedure, but also for those of visionary or even disrupted future (Figure 1. Horelli and Wallin, 2010).

The next section seeks to justify Jane Jacobs´ claim about urban complexity. The claim is still valid in Herttoniemi, a Finnish neighbourhood of 45.000 residents, although Jacobs made it 50 years ago in New York. The section comprises an analysis of urban complexity at the neighbourhood level, which was perceived, explained and partly resolved by action research on urban planning and community development.

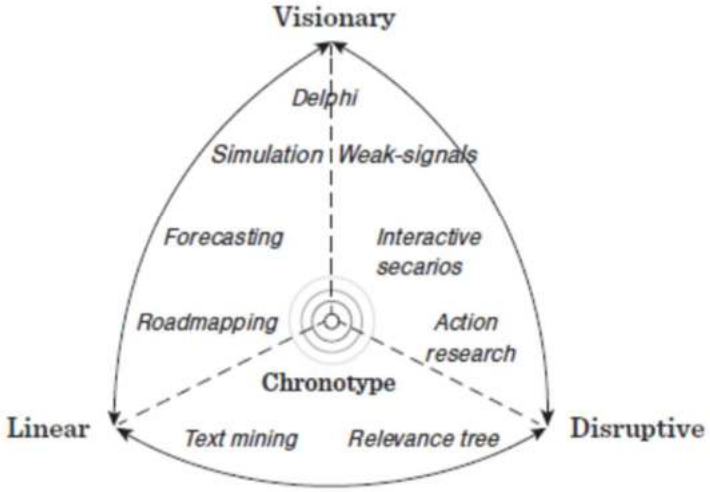

*Figure 1. Examples of urban planning methods suitable for resolving different types of urban complexities (adapted with permission from Aaltonen, 2007 in Horelli and Wallin, 2010).*

## 3. Research on self-organising urban planning and development

Action research is one way to conduct studies on urban change in a systemic way. Action research is an established research approach in social and behavioural studies (Lewin, 1946; Kuula, 1999). Action research is a strategy in which the researcher, together with the subjects in the study, implement various interventions[2]. These comprise simultaneous observation, monitoring and analyses. The process is transparent and co-evolves with the context. Systemic refers here to a trans-disciplinary approach in which, besides the structural and temporal transformation of the context, also the different agents and their rationalities are recognised as part of urban planning interventions.

[2] The dual role of the researcher, the so called ´sitting on two chairs`, poses a dilemma as the research is simultaneously an explanatory and transformatory factor in terms of the research object (Alasuutari, 1993).

In the action research on Herttoniemi, urban planning and community development interventions were entwined in order to study the different actors and their activities in the neighbourhood. The adapted action research approach was called LENA, *A Learning-based network approach to urban planning and action research*. LENA expanded formal urban planning that traditionally deals with specific zoning and building projects to comprise multi-stakeholder processes. It transcended administrative and areal borders and explored new ways to gather inhabitants` place-based knowledge.

In the light of the action research, the neighbourhood is no longer seen as an object of the town fathers or professional town planners. Herttoniemi unfolded as a self-organising, co-evolving system in which all actors had some meaning, even if the roles were not similar or comparable (Boolens and Boonstra, 2011). The prior actors had been officials, land owners and construction companies, who wanted to engage local actors in planning, but only in the role of the end user.
The self-organization in urban planning means that residents, civil society organisations and the workers of local associations, even passive actors who do not come to planning events and gatherings, carry weight in terms of shaping the environment. The urban transformation can take place by conscious, self-made development interventions or just by having an impact on the setting through everyday practices, such as walking (Kuoppa, 2013). Not only active involvement in a workshop or writing a statement, but even the chosen route or service, and a lived moment can be part of the evolving urban texture.

This kind of urban development might seem chaotic, when diverse interventions and research are simultaneously taken forward. However, in practice it is clear that the redesigning of the location of children´s afternoon care, building of a community yard and the changing of local bus routes are tasks for urban planning, yet initiated and completed by others than urban planners. These acts together make the neighbourhood a better place to live. The co-planning, timing and taking forward of the locally identified activities through action research enabled the description and even certain steering of the transformations in the neighbourhood.

## 4. Urban complexity in Herttoniemi: simple solutions and the identification of non-solvable challenges

The neighbourhood of Herttoniemi has been a functional part of Helsinki since the 1950s. Industrial activities found their place there, and offered to the whole city harbour and warehouse services. Right after the Second World War Herttoniemi turned into one of Finland´s first suburbs, which attracted people who wanted better housing conditions. Thus, Herttoniemi became a classic neighbourhood unit that provided its inhabitants all public and commercial services in addition to work places. Gradually its identity as a neighbourhood got stronger. It was divided into two residential areas: West-Herttoniemi and Roihuvuori, which were separated from one another by an industrial and harbour area, and later by the eastern motorway and the Metrorail towards East-Helsinki and the South-East Region (Packalén, 2008).

By the beginning of the Third Millennium the urban structure of Herttoniemi is decisively different from the Post-War one. In practice, the neighbourhood has been rebuilt in terms of its functions, population, image and position in the central hierarchy of the metropolitan area. Herttoniemi has always been the transport node of South-East Helsinki. Consequently, it is scaling up to a new level, while it is simultaneously being internally changed. Once a labour-class neighbourhood has now become a concentration of green urban activists. Its architecture underlines the change, as the point-access block houses and slab blocks are being complemented by new buildings of latest architecture. A completely new neighbourhood, called Kruunuvuorenranta, is being built South-East of Herttoniemi.

Urban functions have changed even more drasticly. The old suburban structure is dissolving. The former harbor area has been replaced by a new high density housing area, called Herttoniemenranta. Its services are provided around the metro station, and the former industrial area has evolved into an office and retail district. The old shopping centres in the West-Herttoniemi and Roihuvuori have been emptied of commercial services, except for small grocery stores. All the public services, such as the library, youth house and the local parish have been suggested to move to the commercial centre around the metro or even further to the city center or to other neighbourhoods, such as Kalasatama.

The above described factors have transformed the urban landscape and the role of Herttoniemi in the region. The original aim of action research was to examine this transformation and to find out, how to support people´s everyday life and opportunities to participate in urban planning. The action research comprised several distinctive development projects with different foci.

In each phase, data was gathered from the area. Two large surveys covering the residents of the neighbourhood, as well as focus group and individual interviews were conducted, in addition to observing the meetings of administrators and associations in Herttoniemi. The objective of the data gathering was twofold: first of all, to collect views of different actors concerning the ways to develop the neighbourhood and to disseminate information for deliberation. Secondly, the data enabled the monitoring of the evolving context. The planning solutions and interventions have been described in several PALCO-publications (https://wiki.aalto.fi/display/Palco/Publications).

The planning targets and needs that came up during the action research have been gathered in Table 1. They have been analysed from the perspective of urban complexity and the role that participation had in the problem solving.

*Table 1. Urban complexity recognised by action research at the neighbourhood level.*

| **Problems of urban complexity** | **Target of planning/action research** | **Role of participation** |
|---|---|---|
| Simple problems | New timetables and routes for the bus, common yards, local websites | Speeded up the finding of problems and their solutions<br>Enabled the implementation of solutions even through the means of co-production<br>Increased the fit of the solution and its sustainability |
| Problems of disorganised complexity | Uncertainty brought about by a multitude of service providers and a lack of planning data, such as childcare in the afternoon and the mobility for hobbies of young people | Produced information about phenomena, events and trends that cannot be found in statistics or via surveys to particular groups<br>Enabled the comprehension and deliberation of different perspectives |
| Problems of organized complexity | The chaos brought forth by different administrative systems, their varying ´temporal windows`, and the evolving context in general, for example the raising of real rents and the urban development of the new Herttoniemi Centre. | Brought forth new active user groups as producers of planning knowledge – some of which might change the future direction<br>Enabled the use of digital data (e-planning) and time planning for foresight and anticipation, providing opportunities to envision solutions in the changing urban context |

From the perspective of urban complexity, described at the beginning of this paper, the first result was the recognition of the disorganised complexity of the neighbourhood (see Table 1.).

The action research took place in collaboration with the Department of Urban Planning and the Social Department of the City of Helsinki. The former was interested in Herttoniemi due to the need to find novel places for housing, as well as due to the many zoning and transport projects in the new centre of Herttoniemi, which was the consequence of the future Kruunuvuori neighbourhood. The Social department of Helsinki was worried about the lacking services of the 20.000 residents in Herttoniemenranta. They had not been built due to the financial recession in early 1990s. The Social Department also lacked local data on services. The social services were planned at that time according to age groups for the whole city in general and no longer according to local needs, as before. The principle meant, for example that the services of members in the same family were planned in different administrative units. The problems of children did not relate

to the problems of their parents, even if their connection was indisputable. This also hid the fact that social problems were concentrated in certain neighbourhoods, even in particular blocks.

Despite officials, there were many activists in the area, who had resources and the motivation to organise services or to take part in the planning and financing of spaces in the neighbourhood. These were members of local associations or private service providers, who offer spaces for activities. The neighbourhood had also traditional residential activities among better off people who lived in the owner occupied area. The new residents of Herttoniemenranta and the tenants of social housing did not participate in the residential activities. The ways and instruments to increase social interaction were scarce, especially between the residents in different parts of the neighbourhood. The surveys disclosed that even if the different residential groups appreciated the neighbourhood for the same reasons, they could not find shared goals, except for the need of a public swimming pool. The location of the services became a conflict between the different subareas, especially as the newest one was almost totally without services. On the other hand, the centralisation of services around the metro station worsened the services of West-Herttoniemi, known for its activism. These were examples of problems in disorganised complexity that cannot be solved as such. However, they can be described which means that they can be divided into smaller controllable units (Table 1.).

These smaller units were not easy problems but it was possible to solve them. The simple complexities, which were separately solved, were found through surveys and participatory observation. Some of the solutions were strategic, such as the creation of participatory arenas and instruments for local co-governance and the founding of the local websites. Others were operative, for example, the hiring of a community worker. All of them were ground stones for the participatory structures that enabled residents to resolve the provision of child care in the afternoon based on different partnership models, to reconfigure the transportation system and to plan, build and turn the unsafe area of Roihuvuori into a multi-generational community yard (Saad-Sulonen and Horelli, 2010; Wallin and Horelli, 2010; Wallin, 2015).

Participatory planning proved to be essential for dealing with ‘simple urban complexity’. The precondition for solving the complexity was the collaboration between the residents, associations, entrepreneurs and the administrators. The solution turned out to be successful, if the official responsible for the planning collaborated with the service provider and the users. The transition from participatory planning to participatory co-production speeded up and enabled a satisfactory outcome, for example, in the case of the Roihuvuori yard.

Participatory planning was also fundamental in the controlling of disorganised complexity. The participatory means produced new knowledge about the current and future situation of the neighbourhood. Besides statistics and expert surveys, a variety of co-planning methods was applied, ranging from informal events to structured workshops and charrettes. Thus, it was possible to approach the complex situation from different perspectives, to plumb the background of problems and to find common denominators, which made it easier than before to understand varying causal relationships. Although complexity as such was not decreased, the Lena approach

of the action research enhanced the finding and creation of shared means and arenas for the neighbourhood actors, which in turn, enabled to make complex, even conflicting issues visible.

The recognition of the two types of complexity did not, however, solve all the challenges of the Herttoniemi neighbourhood. The solving of specific planning problems, or revealing different perspectives and creating shared understanding, are not enough to bring responses to the situation that will emerge from the unknown future of the larger contextual transformations. The disruptive future cannot be completely coped with, even if the anticipation of and preparation for changes are the purpose of different administrative departments, especially that of the Department of Urban Planning.

In Hertoniemi, the administrative and decision-making machinery was not capable of controlling the urban organism, especially as the timescale seemed to extend to years or decades. Thus, the planning system and city government could not steer, not even together with the neighbourhood activists or associations, the most important activities and events related to urban spaces.

One example of organised complexity that is difficult to steer, was the raise of real estate taxes. The city decided to triple the rent of the old housing areas, although these needed desperately renovation. This, in turn, increased the dwelling costs to a level that was unbearable, at a time when housing and living had become extremely costly in the metropolitan region in general. The raised rent endangered the possibilities of the residents and real estate owners to maintain their houses and even to live there. On the one hand, not increasing the rent was inconceivable. Old rental agreements were ending and new ones had to be made. According to legislation and good governance, lower rents were not possible due to the equality of citizens.

Another, similar problem of organised complexity was the structural and functional challenge of Herttoniemi. It is 10 years, since the statutory plan of Herttoniemi metro station was made, but its implementation has not yet begun. The old suburban structure dissolves and services escape from housing units, not only to the metro station, but even further away from the everyday life of the residents. It is impossible to prevent the development during the times of current economic priorities. Services will be produced less expensively to larger groups of people, which means that the services will no longer be situated in the near environments of residents, like before. Urban planning fails to guarantee the benefits of urban densification due to the policies of other administrative sectors.

How should urban planning relate to organised complexity that is emerging from the established administrative and planning practices, especially if the challenges cannot be solved through planning? The action research on Herttoniemi discloses that urban planning should be seen both as techno-rational problem solving and as part of a larger understanding and anticipation of the socio-political development of society.

It is not suggested, that action research should be applied as a planning device. However, urban planning could profit from the applied methods and the understanding of the meaning of

participatory planning in different planning cases. With the aid of multiple methods and sufficiently long term research, it is possible to understand the neighbourhood and to solve its challenges. Expanded urban knowledge that participation brings forth might enable the anticipation of the future and the understanding of plausible continuities or loose trends which organised complexity will be made of.

In sum, the new approaches to urban planning, which are based on localities and local actors instead of administrative sectors, can identify and split different types of complex urban problems and resolve many of them. This is, in fact, what urban planning has always been about. However, the contribution of the approach presented here implies that the limits of planning have to be understood. The city is a living organism, a co-evolving adaptive system that transforms space and time. The steering through straight forward urban planning processes do not work in each case. The contributions of incremental and rationalistic planning approaches have to be understood with their limitations in the context of the changing, multi-actor and even disruptive urban reality in which planning takes place.

## 5. Conclusions

This paper has described urban complexity in Herttoniemi from the perspective of action research at the neighbourhood level. It has asked and answered three questions, concerning what urban complexity means, how one can be prepared for it in urban planning and what the role of public participation is in the complex urban development. Consequently, all of them are also relevant in urban development and policy-making at the metropolitan level.

The action research described here supports the outcomes of classic studies on urban planning. Complexity is an urban characteristic that emerges as a result of different activities, polymorphous structures and varying features of different people. In addition, both internal and external pressure affects the changing context. The pressure comprises, among others, urbanisation and the increase of population, the technological change and the transformation of everyday life. Worth naming are the new consumption patterns, the changing governance style and the rise of self-organisation, as well as the events and networks in different spatio- temporal dimensions which can be examined in the context of urban planning. So, what are the lessons?

The first lesson concerns the comprehension of complexity in urban planning. It means that instead of turning the watchful eye of planning and governance to future urban structures and fragmented planning processes, it should be turned to the ways people live, especially to the curbing of consumption and mobility and to the development of the existing urban structure and its functions. The objective of planning interest should thus be human communities, not the implementation of specific activities or certain urban structures.

In the light of systems-based urban research and the action research on participatory planning in Herttoniemi it can be claimed that it is possible to solve wicked urban problems, if the understanding of urban functions takes place locally, comprising the acknowledgement of the

special characteristics of local actors. The local perspective is frequently missing in the metropolitan context.

Secondly, it is important to understand that the urban planning solves best simple problems. These are well- defined, often techno-rational planning objects and single cases in which building or reorganisation can change the neighbourhood and consequently improve the inhabitants´ daily lives. The action research indicated that participatory planning and even co-production can have a significant role in this respect. Collaboration with local actors succeeded in implementing some construction projects (the common yard of Roihuvuori) and in organising participatory structures for deliberation (Local committee and Herttoniemi website).

In order to be able to solve simple problems, they have to be distinguished from the group of situations and systems that represent disorganised and organised complexity. This is where urban planning can contribute by producing diverse planning information. The knowledge creation in urban planning can support other sectors of administration, as long as it is based on high quality knowledge production. This means in practice that traditional data gathering modes, such as statistics and surveys, are complemented by data and methods of urban informatics comprising e-planning instruments and new deliberative models of action which engage self-organised resident activism.

The third lesson is that, due to a multitude of planning information about the complex situation, it is possible to distinguish the different types of complexity-related problems, but not always to resolve them. Sufficient knowledge production can make urban complexity understandable. It is also possible to distinguish simple problems whose solving might decrease disorganisation. However, it becomes clear which issues are caused by organised complexity. Neither urban planning, nor the means of participatory planning, can manage this type of complexity. Yet, the anticipatory knowledge production illustrates the situation for all parties. Thus, it is possible to change the urban policies and to affect the causes of organised complexity in the future.

In sum, the City is not only a problem in organised complexity, as Jane Jacobs claimed many years ago, but that of different types of complexity. It is not possible to solve all forms of complexity, but it is evident that the planning policy in Finland and the production of planning should be renovated by increasing the recognition of new urban knowledge brought about by participatory planning, urban informatics and the self- organisation of citizens. Currently, this is not the case in the Helsinki Metropolitan Region.

Key words: housing, housing market, strategic planning, boundaries, England

## Abstract

Following the recovery from the global financial downturn, the underlying policy issues of house price inflation, a high demand for owner occupation, restricted land supply, and a relatively small social sector new build programme are resurfacing again in the UK. The boom and bust housing cycles have long been a major challenge to successive governments. The way the Coalition Government managed the economic downturn was to dismantle regional planning and strategic planning in England and replaced it with an open source, local-oriented style of neighbourhood planning. This paper examines the spatial patterns of recovery in different housing markets and provides a critical review of the policy experiments and fragmented institutional framework in house planning. It argues that strategic coordination of spatial development has to be part of the policy package to tackle the major housing crisis.

## Introduction

The nature of the housing issues facing Britain has changed markedly over the last twenty years. There are now less physical problems with housing stock, but more concerns over housing affordability and the external environment that goes with housing consumption (Barker, 2004). Following the recent recovery from the global financial downturn, the underlying policy issues of house price inflation, a high demand for owner occupation, restricted land supply, and a relatively small social sector new build programme are resurfacing again. The boom and bust housing cycles have long been a major challenge to successive governments. There is thus a need of providing a comprehensive package with different policy levers and instruments that will help to make a step change to deliver the right type of housing in the right location. The way the Coalition Government managed the economic downturn was to dismantle regional planning and strategic planning in England and replaced it with an open source, local-oriented style of neighbourhood planning. This paper provides a critique of the fragmented institutional framework and lack of political leadership in house planning and argues that strategic coordination of spatial development has to be part of the policy package to tackle the major housing crisis.

## Variegated spatial patterns of housing market recovery

As the UK emerges from the recession, housing market conditions are spatially varied, with some areas experiencing a dramatic oversupply of housing stock and others a lack of supply due to the reluctance of the private sector to commit to new build activities. This has had strong implications for house prices, creating affordability issues in some areas as well as negative equity concerns in others. The Joseph Rowntree Foundation (JRF) commissioned study (Wong et al, 2011) suggests that

recession did bring a degree of convergence between the regions, but that this has been diminishing as the South pulls away fastest as the economy recovers. Nonetheless, rapidly growing regions such as London and the South East can be strongly segmented with considerable social and housing problems found in the inner areas of the capital.

The JFR study shows that average English neighbourhood standardised house prices decreased by 10.4% between 2007 and 2009. However, different neighbourhoods had very different patterns of change, with the greatest decrease found in a Birmingham neighbourhood (-40.3%) and the greatest increase in the London borough of Camden (+81.4%). Despite the overall drop in house price levels, house prices remain high resulting in continued housing affordability issues, particularly in Southern England where the house price to household income ratio is particularly high. In 2009, the ratio between prices to income for Great Britain was 7 times, only slightly down from 7.7 in 2008. Repossessions and mortgage arrears also increased significantly during the recession.

The recession has significantly impacted upon housing supply as private and social house building decreased, resulting in a decline in both prosperous areas such as Southern England and more industrial areas. The number of new housing starts in the UK decreased by 50.8% between 2007 and 2009. In 2009 there was a closely matched balance between housing supply and demand. There has been a 48% increase in new social housing starts in England between 2007/08 and 2009/10, though the picture was highly variable geographically.

The ratio of households to dwellings is an important indicator in the long-run models of housing supply and affordability. In 2009, the England average of 0.98 suggests that there was a reasonably close balance between housing supply and household number. The areas with the highest levels of pressure are in London where the boroughs of Camden (1.15) and Westminster (1.13) have the highest ratios. Housing supply will be further pressurised when taking into account of the potential demand from projected household growth.

The Coalition government s commitment since 2010 to reducing public spending in key areas of housing, welfare benefits, and regeneration has inevitably produced variable spatial impacts. The JRF analysis suggests that socio-economic conditions and economic growth dynamics vary considerably across different areas. Most of Greater London, South East and the East Midlands saw a rise in new enterprises despite an overall UK decline between 2007 and 2008, which mirrors the patterns of high levels of employment rate and the stronger housing market performance in these areas. The recovery period has seen areas that are more market-orientated emerge better positioned in socio-economic terms, while those areas that are more dependent on public sector support will most likely be worse off as the impacts of funding and public sector job cuts manifest themselves spatially.

The strong recovery of southern England was supported by the statistics from the National Housebuilding Council (2014). Increasing number of new home registrations was found across all regions in England. Greater London had the strongest growth through 2013, with a 60% rise on 2012. The Midlands also enjoyed strong regional growth. Figures from the second quarter of 2014 show that the average UK house price is around £186,000, but over £400,000 in London; which represents an 11.5% annual increase for the country and an even bigger leap of over 25% in London. Considering the average starting salary for graduates is around £20,000 and slightly more in London, it is not a surprise that there is a major housing affordability crisis in the UK.

**Successive planning policy regimes: fuzzy responsibilities**

The main cause of the poor supply responsiveness has been long recognised as an issue. The challenges associated with the land-use planning system have been widely debated and successive

governments have introduced different reforms and experiments to make the system more effective and efficient, though the outcomes tend to receive mixed reception.

*The PPG/PPS and RPG/RSS regime*

During the first term of the last Labour government, the allocation of additional housing land was largely the outcome of a top-down approach that began at the national/regional interface with the preparation of Regional Planning Guidance (RPG), which was then being replaced by Regional Spatial Strategies (RSS). Following the publication of Planning for the Communities of the Future White Paper (1998) and Planning Policy Guidance Note 3: Housing (2000), the Labour Government introduced a revised notion of plan, monitor and manage as a means of handli allocation process. Further elaboration was made in the White Paper (1998) of the need to have housing provision indicators such as house and land prices, housing standards and local housing needs in RPGs. This signified a departure from the government s long-standing practice, allow de-standardisation and de-institutionalisation of national household projection figures from local and regional housing provision policy.

The technically-driven assumptions on household projections were usually supple based considerations, although the nature and extent of these appeared to vary rather mo region-by-region basis. In broadest terms, economic factors or environmental constraints were particularly common, and the relationship between metropolitan areas and the adjacent shires in terms or urban regeneration and housing capacities was also evident. An examination of the annual housing requirement figures in the RPGs for 1996-2016 and the 1996-based DETR household projection figures covering the same time period clearly revealed the north-south division over housing land policy.

The differential between housing requirements and projected growth can be broadly classified into three groups: (1) areas which have housing allocation requirements similar to their projected growth (e.g. areas around the eastern side of England and the South West and they tend to be in more rural areas); (2) areas that had a lower housing allocation than the projected growth (e.g. areas in the South East and London and the shire counties of the North West); and areas with an above projected growth housing requirement (e.g. areas in the northern regions and many had significant amount of brownfield land). The relative differentials between policy allocation and projected growth were most remarkable in the North East (an over-supply of nearly 55%), followed by the West Midlands (39%) and Yorkshire and the Humber (20%). At the other end of the spectrum, there are potential problems of under-provision in the South East (by 15%) and London (by 11%).

The introduction of the Planning and Compulsory Purchase Act 2004 continued to reaffirm a plan-led approach to development control and replaced land-use planning with a spatial planning approach via RSS and Local Development Frameworks (LDFs). However, by 2011, seven years after the 2004 planning reforms, 70% of local planning authorities still had not adopted a core strategy of their LDFs. In order to encourage the release of more housing land, the Labour Government also introduced growth areas and growth points, eco towns, the establishment of the NHPAU and explicit reference to affordability criteria in PPS. However, this policy had limited success as c when the financial crisis struck.

The Government s Sustainable Communities Plan (2003) had focussed thinking on linkages and strategy-making with its identification of four major growth areas that mostly straddled regional boundaries (Milton Keynes / Northampton; Stansted / Cambridge; Thames Gateway) and nine Housing Market Renewal Pathfinders in areas with failing housing markets in the north and midlands.

The latter were incorporated into the Northern Way (2004) strategy documents that represented collaborative working between the three northern RDAs.

The Labour Government also announced a more ambitious brownfield land target in 1998, specifying that at least 60% of all new built housing in England would be on brownfield land by 2008. This target was subsequently achieved eight years ahead of schedule. While the government s target was met, the actual amount of brownfield land for residential use during 2000/06 (2,774 ha per annum) was only marginally higher than that throughout the period in 1989/98 (2,644 ha per annum). There had actually been a decline in the total amount of land used for residential development from 5,660 ha per annum in 1989/98 to 4,765 ha in 2000/06. The meeting of the brownfield target was therefore a function of a parallel decrease in the use of greenfield land (Wong and Schulze Baing, 2010). Schulze Baing and Wong (2012) found that high levels of brownfield reuse activities had successfully accomplished the objective of injecting dynamics into the housing markets in the most deprived areas, particularly the market for flats, since the mid-2000s. This shift was related to the spatially targeted activities of the National Neighbourhood Renewal Initiatives and the Housing Market Renewal Pathfinder programmes. In terms of economic impacts, the outcomes were mixed - significant change in population growth and the improvement in economic deprivation were associated with the process of social upgrading by the incoming new residents of b developments.

*NPPF and Localism*

The Coalition Government heralded a wholesale dismantling of inherited regional strategies and institutions in 2010. The publication of the Localism and Decentralisation Bill (2010) placed the emphasis squarely at the local level. The National Planning Policy Framework (NPPF), introduced in 2012, has subsequently replaced all previous planning policy statements with a single planning document. Under the NPPF local planning authorities are required to have in place an evidence-based, up-to-date Local Plan, which includes a five year land supply.

In order to drive the pro-growth agenda, the NPPF introduces the presumption in favour of sustainable development, which means that when a local authority does not have an up-to-date Local Plan, then planning permission should be granted unless there would be significant adverse impacts or specific breaches of the NPPF. This has created an incentive for LPAs to complete and update their local plan core strategy. Nevertheless, only 55% (185) of local authorities had adopted local plans by May 2014, according to the figures of the Planning Inspectorate (PINS). There proportion of local authorities with plans that fully comply with the NPPF is much lower. This system heavily relied on the judgement of the PINS to assess the soundness of the evidence base underlying core strategies in local plans.

The Localism Act stipulates that all local authorities have a Duty to Cooperate with other government bodies (e.g. Environment Agency) on issues that are beyond their sphere of responsibility. This cross-authority working is seen as important for large-scale developments. However, this bottom-up approach offers relatively weak incentives for local authorities to collaborate with each other in meeting the so called greater than local housing requirements. This be problematic in authorities in southern England, which reflects the continuation of the entrenched culture of under-supply of housing land in the RPG era. The limitation of the Duty to Cooperate was partly evident in the overall under-provision of housing land allocation. The weakness of this cooperation approach requires further adjustments to allow effective implementation.

The abolition of the RSS has left a gap in strategic spatial planning, especially when the Duty to Cooperate is found to be problematic is some areas. While the RSS targets for house building was not always welcomed by all communities, they did drive the provision of housing by bypassing local

politics. As identified by the Building and Social Housing Foundation (2014), since the abolition of the RSS housing targets, the level of identified housing need has dropped dramatically in some areas, with only the North East of England increasing targets. This has resulted in an overall reduction in the amount of land allocated for housing through the granting of planning permission. However, others such as the Home Builders Federation and the Royal Institute of Chartered Surveyors suggest that the NPPF and the five year land supply are having a positive effect on the supply of land for residential development.

*Issues arising: s106 agreement, CIL and affordable housing*

Planning obligations under Section 106 (s106 agreement) of the Town and Country Planning Act 1990 have been a mechanism which makes a development proposal acceptable in planning terms that would not otherwise be acceptable. S106 agreements are often referred to as 'developer contributions' for site specific mitigation of the impact of development. S106 agreements have been used to secure affordable housing, and to specify the type and timing of this housing; and to secure financial contributions to provide infrastructure or affordable housing. The 2008 Planning Act has introduced a new mechanism, the Community Infrastructure Levy (CIL), for developers to make a contribution for local infrastructure development. Since CIL is not allowed to be used for affordable housing, s106 agreements continue to be the main mechanism for affordable housing provision.

Both s106 agreements and CIL are designed to capture some of the uplift in development values as a result of planning permission for community benefit. However, it is not easy to decide the level of payment - if such payments are too high, development can become unviable. This has been a particular problem since the depreciation of land following the global financial crisis. Payments negotiated on the basis of previous land values are still required of developers, even when current land values are significantly lower. Unrealistic s106 agreements negotiated in differing economic conditions can be an obstacle to house building.

According to the Joseph Rowntree Foundation (2014), about a quarter of affordable units delivered through s106 agreements with no grant are delivered in London (12%) and the South East (13.9%), whilst the West Midlands (17%), the South West (16%) and the Eastern Region (14%) show higher proportions of delivery in general (2004Q2-2013Q1). This variation can be a result of skills and political will in negotiating for affordable housing. JRF commissioned research suggests that even among some of the London case studies where neighbouring boroughs with very similar housing market conditions have wide variations in units negotiated (15-20% as opposed to 35-40%) via s106 agreements. This variation suggests that in some areas planning obligations are not as effective in delivering affordable housing.

The NPPF introduced a viability test of development that To ensure viabilit
requirements likely to be applied to development, such as requirements for affordable housing, standards, infrastructure contributions or other requirements should, when taking account of the normal cost of development and mitigation, provide competitive returns to a willing land owner and willing developer to enable the development to be deliverable . The test aims t of unrealistic planning obligations to thwart housing developments. However, viability assessments only capture a snapshot of assumed land value and property sales, which are su

The introduction of new permitted development rights in 2013 to allow office buildings (B1(a)) to be changed to residential use (C3) without the need for a planning application has created some side effects (London Borough of Lambeth, 2014). Local authorities are unable to control where these new homes are located, or to require compliance with minimum space standards, amenity space standards and other best practice design standards including Lifetime Homes and wheelchair accessibility. The

permitted development rights may also be used by landowners to generate a higher existing use value for a site, with residential rather than office use becoming the baseline. This means the margin between the existing use value and the proposed use value will be lower, which will have an impact on the viability considerations for the proposed scheme and will affect the autho affordable housing from these sites.

**Strategic Housing Market Assessment: fuzzy boundaries**

Policy monitoring often relies on the adoption of spatial boundaries including housing and labour market areas, administrative boundaries, or national territories to frame any analysis. Therefore, how spatial boundaries are drawn, and the spatial resolution that is chosen to frame any spatial analytical exercise, is crucial in the construction of an understanding of spatial structures and outcomes. Despite the change to the new localism agenda in 2010, the emphasis on the flexible use of functional geographies and the creation of the local enterprise partnerships very much echoes the spirit of spatial planning.

The former Labour government introduced sub-regional Strategic Housing Market Assessments (SHMAs) to the English planning process in 2005. The ODPM then published housing market assessment guidance (DTZ Pieda, 2004) to identify broad approaches to defining sub-regional or local housing market areas (HMAs). HMAs are seen as areas within which people are prepared to search for housing and, related to this, they will contain both the origin and destination of the great majority who move home.

A desk-based analysis (Baker, 2010) of the SHMA across all English regions in a NHPAU commissioned study highlights a number of key challenges. First of all, the methodological approaches adopted to identify sub-regional housing market areas have generally adopted a hybrid approach of house prices, commuting and migration patterns, reflecting the DCLG Advice Note. Secondly, many housing market areas cover more than one local authority, necessitating the creation of effective joint working and partnerships to adequately address shared housing market issues. However, occasionally (e.g. along parts of the south coast of England) political or other issues appear to have prevented strategic housing market assessments of areas that clearly form a single sub-regional housing market area. Thirdly, SHMAs do not generally appear to provide a fine-grained analysis of the issues faced by the more rural parts of the regions, with issues relating to the more rural parts of larger strategic housing market areas often being obscured by the issues and influence of the more urbanised parts of their shared housing market areas. Fourthly, the particular characteristics and issues relating to National Parks in planning policy terms are not generally reflected in the identification and assessment of sub-regional housing markets and different parts of individual National Parks have been split between a number of separate housing market areas.

There was a general consensus from the interviews and workshop discussions with local and regional stakeholders (Jones, Coombes and Wong, 2010) that a consistently defined set of HMAs could facilitate cross-border policy interventions as well as helping local authorities and key stakeholders to think strategically in spatial terms beyond their own administrative boundaries and better recognise the reality of local and sub-regional housing markets. One of the consequences of failing to adequately reflect functional or market areas within measures of the spatial planning system is that policy can unwittingly encourage displacement activity. Differences in local planning regimes and market outcomes can lead to housing-led migration flows between neighbouring local authorities and that these exacerbate local house price differentials (DCLG, 2007).

The Coalition Government s NPPF (DCLG, 2012, para 159) made clear that local pl have to carry out a Strategic Housing Market Assessment (SHMA) to assess their full housing needs.

More importantly, it stipulates that each local authority has to work with neighbouring authorities where housing market areas cross administrative boundaries. However, there is no clear guidance of what constitutes a housing market area and the responsibility is simply placed on the local authorities concerned on the ground of duty to cooperate . On the basis of the SHMA, local have to prepare a Strategic Housing Land Availability Assessment to establish availability, suitability and the likely economic viability of land to meet the identified housing needs. This system has proved to be problematic to enforce.

The benefits of aligning housing market areas with grouping of local authorities include practical, political and administrative issues relating to accountability, delivery, data availability, spatial planning policy (local development framework) preparation and the ease of establishing appropriate partnership working. Nevertheless, there are also clear disadvantages in ignoring evidence that housing market areas often cut across existing local authority boundaries. The nature of sub-regional housing markets does not always easily fit to local authority boundaries and this has been exacerbated in places where recent local government re-organisation has resulted in much larger unitary authorities than the previous pattern of smaller district councils. Although there was evidence of successful collaboration and joint-working on local housing market analysis and policy development since the Labour government, but there are also examples where political or other issues appeared to have prevented the adoption of cross-boundary housing market areas in areas that clearly formed a single sub-regional housing market area from a technical perspective (Baker, 2010).

**The need for a strategic spatial planning approach**

The gravity and spatially diverse problems of housing delivery remain an imperative for strategic thinking even if the region is no longer seen as the optimal spatial focus for this. Spatial planning issues of commuting, migration, pollution and transport flows seldom respect lower-tier administrative boundaries and will still need addressing on a cross-boundary basis. Better understanding and analysis of functional inter-relationships via the use of coherently defined housing market areas, travel-to-work areas and environmentally derived spatial units can be used to underpin collaborative initiatives between neighbouring local authorities and key stakeholders (Hetherington, 2006; Wong et al, 2000; Wong et al, 2006).

The relationship between administrative boundaries and functional areas is highly variable and that no single set of boundaries can fully satisfy the needs of complex spatial policies. Since there is no perfect set of boundaries, rather than arguing and shifting the spatial scales that are deemed as most appropriate to carry out strategic spatial planning, what really matters is that planners and stakeholders can think *spatially* (Jones et al, 2010; Wong et al, 2008); that is, have a good understanding that different planning issues are taking place and interacting at different spatial scales and creating differential spatial impacts.

While the introduction of a duty to co-operate through the Localism Act 2011 r collaboration cross local authority boundaries, the response has been, so far, sporadic. Whatever happens, the need for continued spatial analysis and evidence-based policy development at a strategic scale has not gone away, even under the current drive towards localism (Baker and Wong, 2012). The most effective future collaborative arrangements will probably be a more voluntary approach to sub-regional collaboration, which may mean a greater chance of delivering innovative and visionary outcomes. City regions and newly-formed Local Enterprise Partnerships (LEPs) can be expected to provide a focus for much of this activity, but other initiatives and spatial units may also emerge. Varied and multi-scalar approaches will be needed to best address different issues, so both collaboration and geographical coverage are likely to be fluid.

While the LEPs are clearly charged with the local growth agenda and free to work with partner planning authorities to develop strategic planning frameworks, the Local Growth White Paper did not mention any similar arrangements for the governance structures, or the delivery approaches, of sub-regional spatial planning. There is clearly a serious institutional void between the need for some forms of strategic spatial planning and the government s localised approach to plan-making. O help fill the institutional vacuum outlined above is to introduce an explicit national spatial planning framework for England; the case for which has been made analytically by the Royal Town Planning Institute, the Town and Country Planning Association and the Royal Society for the Protection of Birds (Collingwood Environmental Planning, 2011).

From a strategic planning perspective, it is crucial that policies are sensiti outcomes and able to coordinate and address the impacts and changes brought by the interaction of different policy sectors. The NPPF makes it clear that the government s key housin significantly increase the delivery of new homes, but does not articulate the spatial distribution of future housing supply and demand. Instead, it requires local planning authorities (with neighbouring authorities where housing market areas cross administrative boundaries) to prepare a SHMA and SHLAA to ascertain the spatial requirements of different types of housing within the local plan. A lack of strategic governance and accountability has led to a policy vacuum in the current planning system. The weakness in the bottom-up approach of Duty to Cooperate means that SHMA may not be carried out to reflect the functional Housing Market Areas. A set of nationally derived HMAs should be used as a reference point to identify cross-boundary issues to facilitate the process of Duty to Cooperate. There is a need to develop sub-regional working mechanisms, e.g. city-regions / LEPs to have a strategic role to ensuring that housing needs are fully met and SHMAs are conducted in a robust and holistic manner.

Research commissioned by the RTPI (Wong et al, 2012) clearly illustrates that there is a lack clear long term national overview of the inter-relationship between housing delivery, environmental constraints and other infrastructure delivery across different parts of the country. For example, the study shows that the areas with the highest projected household growth are mainly found in London and the South East, part of the South West, the eastern part of England, and part of West Yorkshire. By overlaying the major planning constraints, the areas that are assessed with high flood risk and water stress (drought risk), it is clear that strategic planning policy framework is required to plan for housing supply rather than just following the market demand. These challenging issues cannot be addressed at even sub-regional level, but the NPPF does not provide such an overarching perspective of long term strategic planning and coordination. The situation is more daunting when the household projection figures are overlapped with proposal for high speed broadband and transport infrastructure proposals there is no major plan for the high growth areas in the eastern part of England.

The broad political interest and support in creating new settlements such as urban extensions, Garden Cities, Eco Towns, and New towns. While these major new development concepts have the potential to deliver win-win solutions by resolving housing shortage as well as injecting economic dynamics and to rebalance regional development when linked to regeneration. However, these proposals are complex, controversial and challenging to deliver. They will require high level strategic, national planning and government commitment, as the private sector has not proved adept at driving these ideas forward alone.

A strategic spatial approach is needed for meeting the challenge of housing planning and delivery:

- *to devise spatially sensitive strategies:*
  There is no a 'one size fits all' solution to the house building challenges in England. The headline housing need figures tend to mask substantial mismatch between supply and demand across the country (Meen et al, 2008; Whitehead et al, 2009) in terms of location, size and dwelling type. The non-spatial housing policy guidance in PPS and NPPF often fails to address the very different housing requirements in different parts of England. Attention tends to focus on the housing pressure in the south. However, great housing pressure is found in parts of northern England such as North Yorkshire and Cheshire; major opportunities for housing-led regeneration are desired in core city-regions such as the Greater Manchester City Region and the Tyne and Wear City Region; and some northern industrial towns continue to suffer from the problem of low demand. With the very different housing markets in England, intervention that works in one location may not be feasible in another. Indeed, it is wrong to assume that there is one single housing market in London as different parts of London have different housing stress and needs.

- *to coordinate infrastructure and local facilities provision*:
  Sustainable housing development has to be coordination with essential physical and social infrastructure and amenities and connected to the wider job market to be liveable. Previous research suggests house prices are highly correlated with low crime rates, good local schools and good access to employment locations (Orford, 2000). This coordination is particularly important for large scale housing development.

- *to deliver quality homes within the wider place-making agenda:*
  Housing delivery is not just about quantity, but also their quality to achieve more balanced and sustainable developments. Quality is seen as critical for large scale urban extension, new settlements and garden cities and strategic coordination will be required across different policy sectors to deliver the place-making agenda.

- *to collect information and monitor policy on a consistent and frequent basis:*
  There is a need to collect information in relation to household projections and housing requirements in a consistent manner rather than a compartmentalized approach. On the whole, there is a lack of an overall national framework for housing development. Initiative-driven delivery framework can be characterised as fragmented and ad hoc, rather than strategic and visionary. The economics of housing development also vary from location to location, depending upon the value base of an area or a site, the requirement of physical infrastructure to bring forward development, and the cost of the associated s106 agreements and affordable housing policies. Information in relation to land ownership and land values and other information should be frequently collected to monitor policy delivering.

# Eco-city planning conditioned by the growth ideology: The case of Copenhagen

Jin Xue

Norwegian University of Life Sciences, Department of Landscape Architecture and Spatial Planning
jin.xue@nmbu.no

Keywords: growth ideology, sustainable urban development, urban planning

**Abstract**
*This paper aims to investigate how the eco-city planning is framed and conditioned by the growth ideology and propose an alternative urban development and planning for long-term sustainability inspired by the degrowth paradigm. Setting well-being, ecological sustainability and social equity as the goals of societal development, the degrowth paradigm differs from the growth paradigm in how to interpret and achieve them. Drawing on this distinction as a conceptual framework, this paper scrutinizes how the current growth-oriented planning for the Copenhagen Eco-metropolis in Denmark functions as a hindrance to the transformation to real sustainability. An agenda for reorienting eco-city planning towards degrowth is laid out by focusing on the purposes of planning and strategies for urban development in the domains of land use, housing and transportation. The paper concludes with pointing out the capitalist economic structure as the fundamental reason for the growth ideology embedded in eco-city planning and suggesting a degrowth alliance with urban planners to confront it.*

## 1. Introduction

Since it is coined in the 1980s, many cities have undergone a transformation to eco-cities. At first glance, literally, the global proliferation of eco-city initiatives in urban policy and planning is a response to the growing concerns on local environmental problems and climate change. However, it is reported that eco-city is transformed in practice where political and economic neoliberalism provides the context conditioning the real interpretation of eco-city practice. Motivated by this critical stance on eco-cities, the aim of the paper is to study how the growth ideology is manifested and influences the development of Copenhagen eco-metropolis and its limitations in delivering long-term social and environmental sustainability, and discuss the potentials of an alternative urban development and planning inspired by the degrowth paradigm.

The paper is structured as follows. In section 2, the degrowth paradigm is contrasted with the current growth paradigm, with the purpose of providing a theoretical understanding of the societal background of urban development and planning and setting out a normative conceptual framework for degrowth planning. The contrast revolves around the distinctive interpretations of and approaches to well-being, ecological sustainability and social equity by the two paradigms. Section 3 analyses how the current urban planning for Copenhagen Eco-metropolis is shaped by the growth ideology, followed by a discussion on the limitations of such a planning paradigm. As a response to the analysis, section 4 lays out an alternative planning paradigm informed by the degrowth paradigm for long-term environmental sustainability and social justice. Finally, the concluding section provides reflections on how the growth imperative derived from the socio-economic

structure shapes the growth-oriented planning and functions as the deep-rooted barrier to degrowth transformation, and argues for the potential proactive role of urban planners in confronting it.

## 2. The contrast between the growth and degrowth paradigms

Faced with multiple crises characterized by ecological deterioration, social injustice, and economic recession, degrowth is put forward as a possible alternative to the economic growth paradigm in response to these crises (Bonaiuti 2012; Schneider et al. 2010). Simply put, degrowth challenges the hegemony of growth and calls for a democratically led redistributive downscaling of production and consumption in industrialised countries as a means to achieve *environmental sustainability, social justice and well-being* (Demaria et al. 2013: 209, emphasis added). By radically confronting the configuration of contemporary socio-economic structures and their associated norms and values, degrowth represents a new paradigm in economic and societal spheres and attempts to construct an alternative sustainable future. The streams of thoughts constituting the degrowth movement are diverse, embracing bioeconomics, quest for deeper democracy, social justice and equity, culturalist critique on development, anti-utilitarianism movement, meaning of life, and environmentalism (Demaria et al. 2013; Muraca 2013; Schneider et al. 2010).

Degrowth is a normative project in the sense that its goal is pursuit of well-being, ecological sustainability and social equity (Schneider et al. 2010: 502). Arguably, these goals are also shared by the growth paradigm. However, the two paradigms differ greatly in how to interpret the connotation of these concepts and through which approaches they can be obtained. Generally speaking, degrowth adherents believe that human prosperity without economic growth is possible (Jackson 2009; Victor 2008), while for growth advocates, economic growth is a necessary pre-condition for the achievement of societal progress.

For the goal of well-being, degrowth dismisses the prevalent utilitarian way of defining quality of life as maximizing individual utility by satisfying preferences. Under the prevailing neoliberal agenda, competitive market mechanism through providing an extensive set of choices of commodities is often claimed to be able to fulfil peoples preferences and enhance happiness (Sen 1993). This creates a life-style trapped in materialism and consumerism wherein people work more in order to get the freedom to consume more. However, the lack of proportionality between increase in purchasing power and happiness, a phenomenon known as the Easterlin Paradox (Easterlin 1974; Inglehart & Klingemann 2000), makes the utilitarian and neoclassical economics approach to well-being rather untenable. In the view of degrowth, modern growth society through unfettered supply of commodities and services forces people to become increasingly dependent on material goods and thus deprives people of the freedom and autonomy to satisfy their own needs (Deriu 2015). Instead, degrowth confronts the meaning of well-being based on possession of material wealth, and believes that people can live meaningfully and happily by maintaining a minimally sufficient material living standard, i.e. voluntary simplicity, in exchange for more time and freedom to pursue non-materialistic sources of satisfaction and meaning (Alexander 2015).

Regarding ecological sustainability, the idea of decoupling economic growth from adverse environmental impacts through technological efficiency strategies dominates the environmental discourse in the growth society (WCED 1987). The belief in green growth is strongly influenced by the ecological modernization theory which portrays a paradigm reconciling economic growth and environmental sustainability within the capitalist organization of production and consumption (Spaargaren 2000). In light of the decoupling idea, continual economic growth is a prerequisite for successfully dealing with environmental problems, a contention partly derived from the so-called

environmental Kuznets curve hypothesis (Barry and Paterson 2003). The possibility of maintaining economic growth through decoupling has been questioned by growth critics who argue that absolute decoupling is implausible and even a delusion (Nørgaard 2009). Empirical evidence investigating the extents of decoupling both at the aggregate economy level and sector level substantiate this critique (Azar et al. 2002; OECD 2002; Tapio 2005; Xue 2012). In addition, as with increasing purchasing power due to economic growth, eco-efficiency improvements are likely to generate rebound effects, offsetting the expected environmental benefits or even making the efficiency strategy counterproductive (Alcott 2005; Schneider 2008). Hence, as argued by the degrowth advocates, the key to reduce the environmental impacts as much as is needed in order to stay within the biophysical limits of the planet consists in the reduction in the scale of the total economic output (Martinez-Alier et al. 2010). The sufficiency strategy seeking to lower the affluence level in the Global North is proposed as the way to cope with unsustainability.

The goal of equity is multi-faceted. It refers to social equity across space, i.e. intragenerational equity, across time, i.e. intergenerational equity, and environmental justice (Arler 2001). It is widely assumed by the growth proponents that economic growth is a necessary pathway to a more equitable society both locally and globally through the trickle-down mechanism, whereby th benefits of growth will spread and eventually benefit the worst-off parties (WCED 1987). In terms of intergenerational equity, although it is admitted that the continuation of current growth rates will result in higher risks of undermining the capacity of succeeding generations to create well-being, the depletion of natural resources may lead to a number of substitutions that defenders of weak sustainability rely on (Beckerman and Pasek 2001). However, degrowth refutes the trickle-dow assumption by pointing out the more pronounced relative poverty during the latest decades of economic growth (OECD 2008; Stutz 2010). Furthermore, the prevalence of neoliberal policies as a global trend will reinforce the inequality tendency of economic growth (Harvey 2005). The viewpoint represented by weak sustainability is criticized to ignore the irreversibility of key and fundamental functionalities of nature once they are destroyed, which makes substitution rather limited (Ekins 2003). In order to save ecological space for following generations and for people living in poor countries where economic growth really makes a difference, degrowth holds an ethical stance of distributive justice achieved by less competition, large scale redistribut sharing and reduction of excessive incomes and wealth (Demaria et al. 2013: 199).

## 3. Growth-oriented urban planning for eco-city and its critiques

### 3.1 The case city and methodology

Employing the discussion above as a conceptual framework, the main task of this section seeks to unfold how the eco-city planning for Greater Copenhagen are framed by the growth ideology and discusses the limitations of it in delivering sustainability and equity. Based on the moral premise that ecological space is to be left for poor nations, transition to sustainable degrowth should take place in wealthy countries and is of necessity and urgency to cities in the developed world. Since Greater Copenhagen represents a typical metropolitan area of the Western Europe, it is illuminating to look at how planning is dominated by the growth ideology and the challenges of implementing a degrowth-oriented planning for such a city region. In light of this, the Copenhagen case can be understood as a *representative* case, the lessons learned from which are assumed to be informative about the experiences of similar city regions (Yin 2009). Furthermore, with Copenhagen being internationally known for its sustainable development agenda and non-motorized urbanism model (e.g. it has recently won the award of European Green Capital 2014), a critical scrutiny will show how limited the growth paradigm is in delivering long-term sustainability and social justiceIn this sense, the presentation of Greater Copenhagen is put forward as a *critical* case.

Defined by The Danish Planning Act 2007, Greater Copenhagen is a cohesive functional metropolitan area across municipal borders, covering an area of 3132 $km^2$ and consisting of 34 municipalities with the municipality of Copenhagen the most populous. It had in the beginning of 2014 about 1.97 million inhabitants. The spatial development of Greater Copenhagen has back to the 1940s been planned into a finger structure and could be characterized as hierarchical polycentric. The downtown Copenhagen has an unchallenged status as the dominating center. The central parts of five towns in the fingers form the second-order centers, along with some major regional retail districts included in the continuous urban area of Copenhagen. The third-order centers are those more local centers in connection with urban rail stations and smaller-size municipal centers.

Greater Copenhagen has a long tradition of spatial planning on the regional scale, which can be traced back to the first finger plan in 1947. The original ideas behind the plan have laid a foundation for succeeding plans at the regional level and strongly impacted the spatial development of the city region. Until the local government structural reform in 2007 in Denmark, the planning authority for the Greater Copenhagen lied in various metropolitan institutions, the last one being the Greater Copenhagen Authority (Hovedstadens Udviklingsråd), who prepared the last regional plan 2005. Since 2007, the metropolitan institution was abolished and planning authority for the Greater Copenhagen was transferred to the Ministry of the Environment, who made the national planning directive titled Fingerplan 2007 for the city region based on regional plan 2005. According to the Planning Act 2007 (Ministry of the Environment 2007b), this directive aims at providing guidance for the spatial development of the metropolitan area and is legally binding for the municipal planning in the city region. According to Olesen and Richardson (2012), the Fingerplan 2007 on one hand represents a conscious ministry attempt to strengthen the spatial framework for the metropolitan area, and on the other hand allows the municipalities to designate areas for local urban development through only regulating designation of urban development of regional character.

The analysis of the case is mainly informed by a critical scrutiny of key official plans published at different governmental levels, including the 2006 National Planning Report, the Danish Transport Infrastructure 2030, Fingerplan 2007, Regional Plan 2005 for the Capital Region, and the 2011 Municipal Plan for Copenhagen. The analysis of the plans seeks answers to three questions: Is economic growth formulated as a goal of urban development and planning? How is the growth ideology embedded in the understanding and pursuit of well-being, environmental sustainability and social equity? And what are the concrete planning strategies for urban development? In so doing, the analytical focus is on the goal-setting and contents of plans instead of how plan-making is carried out. The investigation of planning strategies will concentrate on land use, housing development and transport infrastructure. Although other components of spatial urban development, such as retailing, public facilities and industry, are also important in terms of their consequences on environmental sustainability and social justice, given limited space, I have decided to focus on the three above-mentioned aspects.

### 3.2 The manifestation of growth-oriented planning

#### *A shift in the role of planning from growth management to growth stimulation*

The purposes and agenda of state spatial planning in Denmark has undergone constant reorientation since its genesis in the mid-20$^{th}$ century. Since the late 1980s, following a similar trajectory of many European countries, the Danish national planning has typically shifted from a welfarist approach addressing balanced and equal development across the country to a neoliberal approach in the pursuit of competitiveness by stimulating growth in major cities and regions (Galland 2012; Olesen

& Richardson 2012). The early planning emphasis on equalization across Denmark in the 1950s was a response to the negative socio-spatial consequences from rapid economic growth and imbalanced concentration of economic growth and population in the eastern part of the country and in the capital. The objective of equal development fits well with the idea of spatial Keynesianism that the state seeks to equally distribute welfare services, economic activities, population and investment across the entire country. Throughout the 1960s and 1970s, equal development has remained a central objective in the Danish national planning. These periods were characterized as rapid economic growth and planning can thus be seen as playing the role of *growth management* which aims at distributing economic development in a spatially equal way.

However, the economy in the 1980s and 1990s experienced periods of stagnation and recession. Together with globalization as the main driving force and an emerging neoliberal political climate in Europe, it has promoted a growth-oriented planning in order to strengthen Denmark s competiveness and secure its position in the global economy. Since the 1990s, planning has been gradually advanced as an instrument to *stimulate growth*. The discourse on planning towards economic growth culminated in the 2006 national planning report, wherein the vision of the government for spatial development in Denmark is evidently manifested in the title planning for economic growth (Ministry of the Environment 2006: 10). Spatial planning should play an important role in pursuing growth and enhancing competiveness:

> getting globalization to continue to positively influence Denmark and its
> that Denmark strengthen its ability to create innovation and to develop solutions that add value
> and cannot easily be copied They place demands on spatial planning, which m
> Denmark s special qualities and nature and also create a favourable framework
> actors as companies, knowledge institutions and employees and ensures that they thrive. (*ibid.*: 8)

The consequences of this neoliberal turn on planning are not only confined to the substantive aspect that focuses on creating a spatial environment that can promote economic development, but involves the liberalization of market in providing and allocating goods and services. The role of planning is changed from the provider of welfare to the enabler of development.

The shift of state spatial strategies from equal development to growth and competiveness is of significance to the planning for the Greater Copenhagen. For a long time until the late 1980s, the capital region has suffered from the planning objective of equal development, which attempted to contain growth in workplaces and populations in the Greater Copenhagen (Hansen et al. 2001). When strengthening the international competiveness of the capital became a national interest, the national policy for Greater Copenhagen skewed towards growth stimulation . Th Greater Copenhagen as the locomotive for all of Denmark in the global competition is highly emphasized: A strong and competitive capital city is an important prerequisite spatial development. Denmark must have a capital that can attract companies, jobs and employees in global competition (Ministry of the Environment 2006: 11). This has led the national priority for the Greater Copenhagen to ensure that spatial planning strengthens its international competiveness (*ibid.*: 16).

With the awareness that urban region s physical design is a decisive competiti of the Environment 2007a: 8, author s translation), the Fingerplan 2007 is committed to enhancing the quality of living and working environment in order to attract business, private sectors and entrepreneurs. A similar vision is highlighted in the latest Copenhagen municipal plan, as stated by

the Lord Mayor in the preface that: The City of Copenhagen Municipal Plan 201
economic growth in the entire Øresund Region while at the same time maintaining Copenhagen as a good city to live in and to visit (City of Copenhagen 2011). The Copenhagen municipality even goes further to target an average annual growth rate of 5% up to 2020 (*ibid.*)[1].

***Growth ideology embedded in planning***

Both the national government and local authority of Copenhagen consider the commitment to growth is of importance to the pursuit of well-being and prosperity. The framing of planning at the national level steered by the growth and competiveness rationality is seen as necessary in order to meet the demands set forth by globalization and to secure Denmark s future prospect the Environment 2006). The attainment of growth in the capital region is crucial not only for the development of the region, but also for the whole country s growth prospects Environment 2007a: 8). In the Copenhagen municipality, it is believed that growth and go hand in hand because the sectors which the city lives by support a greener, healthier and more exciting city (City of Copenhagen 2011: 15).

The emphasis on growth in spatial planning goes alongside a concern on nature and environment. Copenhagen has a strong vision of being a green growth metropolis where environment and growth go hand in hand. One one hand, it is believed that Copenhagen municipality can become the first carbon neutral capital by 2025 while increasing employment and spurring growth, reflecting the decoupling notion in planning. On the other hand, the motivation of being green is to further strengthen the region s competitive edge and attract investment and business. Both national and local planning authorities are very aware of how urban competitiveness itself partly relies on the sustainable remaking of urban environments. As stated in the 2006 national planning report: G spaces, recreational areas and attractive urban environments are key prerequisites for attracting companies, jobs and employees. The municipal councils should therefore give high priority to valuable landscape, natural and cultural features (Ministry of the Environment 2006: 17 Municipality of Copenhagen aims to become the green growth hub through attracting clean-tech enterprises and investments that will become the city s new growth engine and generate new jobs (City of Copenhagen 2011). In addition, successful reduction in carbon emissions will become a showcase of Copenhagen and Denmark s leading role in global environmental developmen Interestingly, even green growth *per se* is regarded as a competition field where the world s cities are fighting hard to top the green growth agenda If the city does not have a clear strategy and remain in control, Copenhagen is at risk of becoming marginalized in low-growth Europe (*ibid.*: 26).

At the national and metropolitan levels, this growth-oriented planning has predominantly focused on economic development and environmental sustainability, leaving the social aspects largely in the background. The concern on equal distribution of public resources and welfare, a primary goal of early planning, is almost out of the picture. Only in the Copenhagen municipal plan has the challenge of social and health inequality in the disadvantaged residential areas been briefly mentioned.

***Fragmented planning strategies***

Greater Copenhagen has a long history of spatial urban expansion in the 1960s and 70s, leading to a sharp decline in population densities within the inner city and a low-density residential development characterized by single-family homes in the suburbs. This trend began to reverse in the mid-1980s

[1] Its current GDP growth rate is slightly below 2%.

since when the urban expansion has stagnated with slight increase in population density within the inner part of Copenhagen. However, in the suburbs, and in particular in the parts of the metropolitan area located outside the continuous urban area, development has still predominantly taken place as spatial urban expansion (Xue et al. 2011).

Stipulated in the Fingerplan 2007, new urban zones cannot be designated in the inner part of the metropolitan area where development should take the form of densification and redevelopment of brownfield areas. However, in the outer part of Greater Copenhagen, despite the oversized scattered development and low population density which was around 22 persons per hectare in 2008, densification has not been suggested as a major land use strategy. Instead, municipalities along the five fingers are allowed to convert rural land to urban areas as long as they can justify the development. In the rest of the metropolitan area, new urban development of local nature is still permitted. Locating new developments close to urban rail stations is strictly regulated in the finger plan and a high density near the stations is sought for. According to this plan, urban functions of intensive use should be located less than 1000 m from an urban rail station and preferably within 500 m.

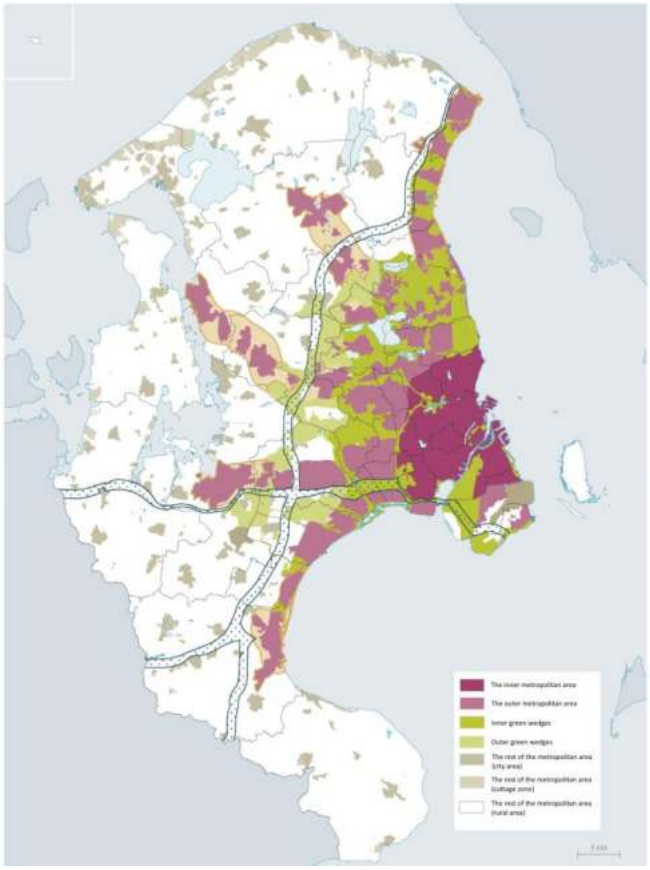

Figure 1. Geographic demarcation of Greater Copenhagen and its finger structure (Source: Ministry of the Environment 2007a).

Planning for transport infrastructure is based on a predicted ever-increasing mobility and traffic volume. In the report The Danish Transport Infrastructure 2030, mobility is considered a element in the competiveness of businesses and thus for the growth conditions of Danish soci (Danish Infrastructure Commission 2008: 306). It is taken for granted that traf

according to our prosperity (*ibid.*: 36). Although there is an awareness that expected increases in traffic volume will strain the environment, channeling large part of the traffic growth to public transport is recommended as the solution. In Greater Copenhagen, traffic flows have been primarily towards the central part of the metropolitan area, accommodated by the five radial transport corridors. Today, it is argued that transport infrastructure should be provided to strengthen the ring connections across the five figures so as to accommodate increased traffic flows from commuting across the region (Ministry of the Environment 2007a). This intention to intensify regional economic activities leads to the approval by government of a new inner-city metro circle (Cityringen), adding to the already extensively networked metros and S-trains (City of Copenhagen 2011). Initiatives enhancing the ring connection also include a light rail (Ringtre) that will connect 11 Copenhagen suburban municipalities, with the expectation of promoting urban development along the rail and easing congestion issues in the region (The Ringby Light Rail Partnership 2013). Although these infrastructures are provided in the form of public transport, they are all aimed at enhancing mobility and economic activities. Arguably, the increase in the aggregate traffic volume may offset any environmental benefits from such strategies.

Already one of the leaders in cycling infrastructure, the municipality of Copenhagen continues its efforts to increase the share of biking for commuting trips through improving physical conditions for accessibility and expanding the bike network. A variety of initiatives have been carried out to support cycling (cf. Nielsen et al. 2013 for an overview), some of which have also been extended to the metropolitan area. In cooperation with the Capital Region and 17 surrounding municipalities, a new initiative called Cycle Super Highways (cykelsuperstier) is established targeting commuters who travel long distances between 5 and 20 km.

On the other hand, increasing road capacity, e.g. the harbor tunnel project, has been part of the transport policy in Greater Copenhagen, with the motivation to eliminate existing or projected future congestion. An economic rationality has underlined this motivation, as motorway and railway capacity is considered a bottleneck for the economic growth in the Øresund region in the longer term (City of Copenhagen 2011). One of the main recommendations proposed by The Danish Infrastructure Commission is to complete the ring connections in the Copenhagen area both on roads and rail (Danish Infrastructure Commission 2008). Moreover, municipalities in the metropolitan area are required to reserve space for future road expansion and extension (Ministry of Environment, 2013).

In Greater Copenhagen, after decades of growth (with stagnation in the 1990s and slight decline in 2010 as a result of economic crisis), the average residential floor area per capita has reached 51 $m^2$, among the highest standards in the world. Seen in a shorter and more recent period, the share of detached single-family dwellings in the total new housing stock has declined from over 30% in the second half of the 1990s to a level of 12% after 2000. Even though the majority of the new dwellings have still been located in the rest of the metropolitan area, the inner city has shown a tendency of increasing its share of the total number of newly completed dwellings.

Housing strategies in the Greater Copenhagen are to ensure that there is a plentiful and varied supply of housing opportunities (Hovedstadens Udviklingsråd 2005). In the regional plan 2005, based on projected population growth, replacement of existing housing and expectation of increasing housing standards, it is estimated that there is a lack of 75,000 dwellings that needs to be built over the period 2005 2017. The guidelines for the densities and types of new housing differ in different parts of the metropolitan area. Residential development in the inner city will take place in the form of densification and urban renewal and the type of housing to be built is confined to

apartment buildings. In the inner parts of the fingers, although concentrated types of housing, such as apartment buildings and compact and low-rise housing are recommended, single-family houses can also be added. Land regulation in the outer parts of the fingers is further relaxed where the designation of new urban zone for housing purposes and the construction of space-consuming types of dwellings are allowed. It can be seen from these strategies that the impacts of housing types on environment and transport are downplayed in the plans of Copenhagen, which do not dare challenge the predominant preference for single-family houses among citizens. Seen from the above examination, under the growth paradigm, the urban development plans of Copenhagen exhibit a feature of fragmentation and even internal confrontation. Growth-oriented planning has the potential to result in fragmented measures with some tilted to growth and others to environmental protection. It tends to confine environmental policies to those that can enhance a ci edge, while constraining other, more radical environmental measures incompatible with growth.

The fragmentation of planning strategies reflects the idea behind urban planning that through creating opportunities in the built environment enlarges citizen s freedom of choices so that different preferences can be satisfied. As formulated in the national planning, spatial planning should ensure diversity and continue to prevent everything from becoming unifo the Environment 2006: 11). Urban planning has done this mainly via two approaches. One is the supply of efficient and reliable infrastructures to enable people to choose residences, workplaces, and functional facilities on a larger geographical scale, such as the proposed ring connection in Greater Copenhagen. The other is to offer a rich variety of products in the built environmen meet different demands, such as infrastructure provision for car, public transport and cycling, and a diverse supply of housing with different types, geographical locations, densities and amenities. From this perspective, the differentiated components in the planning strategies can be viewed as different products provided for diversified market segments (Næss and Vogel 2012).

**3.3 Critiques of growth-oriented planning**

There are several arguments against the belief in and the possibility of decoupling urban economic growth from its negative environmental impacts. The Greater Copenhagen case indicates that the pursuit of economic growth entails the construction of new building stock and expansion of infrastructure (either on brownfield land or new urban area), which both constitutes part of economic growth and accommodates increased economic activities. The growth in the physical elements is heavily reliant on material, energy and land resources, in addition to the energy consumption induced by the use of these physical structures (such as building operation, travel-related energy consumption). Densification and creating a compact urban structure, as illustrated in the planning strategies for the development of Copenhagen, can to some extent prevent rural land from converting to built-up areas and reduce energy consumption of transportation. However, there is a limit to what the densification strategy can fulfil, as the opportunities for densification will sooner or later be taken up and continuous growth will then have to be channelled to undeveloped land. Resource and energy saving benefits from eco-efficiency measures in the field of urban planning represented by high density land use and promotion of public transport tend to be counteracted by growing traffic volume and consumption level in the floor area. Unless the increases of eco-efficiency can catch up with the growth rates of the building stock and traffic volume, the absolute environmental impacts will increase.

As indicated in the Greater Copenhagen case, an overall planning strategy facilitating consumerism and diversity to meet different tastes implies a mixture of sustainable and unsustainable strategies to urban development. People have different preferences and differentiated economic and social capabilities to make free choices. The better-off usually can afford a luxury and environmentally-

unfriendly lifestyle, like spacious dwellings and car driving. Hansen et al. (2001) reported that growth stimulation policy in Copenhagen embraces the housing policy as an instrument to attract a so-called economically sustainable population to reside in the capital reg constructing spacious, expensive and upscale housing. This segment in the planning strategies will largely counteract the overall environmental benefits derived from strategies that adapt the development of land use, housing and transport towards a sustainability direction. Without a consistent and coherent planning strategies, sustainable and unsustainable solutions will end up with competing each other, leading to an inefficient investment in infrastructure and attempts for urban sustainable development.

Having said these, empirical studies on the environmental performances of Greater Copenhagen s urban development reveal that growth in land conversion for urban purposes has been relatively decoupled from metropolitan economic growth during the period 1991-2008, suggesting an expanding urbanized area though at a lower growth rate than the economy (Xue 2014). The same finding applies to the residential energy consumption which despite Denmark s high building energy standard has experienced growth at the aggregate level due to increased aggregate floor space and possession of domestic appliances (*ibid.*). The discussion above points to that attempts to resolve the tension between growth stimulation and environmental sustainability through a green growth approach are subject to limitations and not adequate in leading to reducing absolute environmental impacts from urban development in the long run, in particularly when green strategies are themselves considered as a trigger for further growth.

The social consequences of growth stimulation planning are dependent on the approach through which the growth is allocated. There is a difference in the impacts between a Keynesian approach with strong public intervention to ensure that urban development benefits all societal groups, and a neoliberal approach with market playing the major role in leading urban change and distributing benefits and burdens. As Rydin (2013) notes, planning reliant on the market to generate growth is likely to reinforce socio-spatial inequality through gentrification that displaces local residents and gives more location choice to higher-income groups than those with lower income. As indicated before, the distributive function of Danish spatial planning rooted in Keynesianism is under a neoliberal transformation (Andersen and Pløger; Olesen 2011). The shift to market-led planning does not only take place at the level of strategic spatial planning, but also in urban renewal project, waterfront redevelopment (Galland and Hansen 2012), and housing policies (Vagnby 2008), generating socio-spatial consequences such as gentrification, segregation, ghettoization, and housing unaffordability.

## 4. Reorientation of eco-city planning towards degrowth

The previous discussion shows that planning of Copenhagen Eco-metropolis in its current form is employed as a vehicle for the pursuit of economic growth and underpins the growth-associated norms and values. This section sets out to expound the implications of degrowth for urban development and planning and propose an agenda for eco-city planning that is committed to the degrowth-oriented interpretation of well-being, sustainability and equity.

### 4.1 Socially sustainable degrowth as the purpose of urban planning

Planning informed by the degrowth paradigm should discard some of the taken-for-granted but misconceived assumptions underlying the current planning strategies that are evident in the Greater Copenhagen case. These include the ideas that growth is the primary goal of urban development, ever-increasing mobility is essential for prosperity, planning should satisfy different preferences by

enlarging freedom of choice, and economic growth can be reconciled with environmental sustainability. The degrowth-oriented planning would require to amend the national planning report and finger plan to reflect the central ideas of degrowth. Growth and competiveness as the primary vision of planning should be substituted by societal goals with reference to well-being, sustainability and equity.

Degrowth emphasizes the non-materialistic sources of well-being apart from the achievement of minimally sufficient material living standard, which implies that planning should not prioritize the way of land use and types of infrastructure that fulfil the need for productivity and economic efficiency. Instead, planning will be people-oriented rather than profit-oriented, prioritize use value of land over exchange value, and seek to improve city and neighbourhood liveability (Brenner et al. 2012). The remaking of an attractive urban environment is not for the sake of attracting inward investment and creative class, but aims at enhancing the liveability of local residents.

Although environmental sustainability is already given emphasis in planning, it is framed in the conceptual setting of ecological modernization with a focus on efficiency. A degrowth approach to sustainability would require planning apart from addressing efficiency to draw on the sufficiency in urban development in relation to mobility, land use, residential floor space and infrastructure. It is proposed that planning should purposely and in a socially sustainable manner reduce, first the level of consumption per capita, and then shrink the total volume of urban built environment and decline mobility in order to reduce energy consumption and carbon emissions, protect rural land and the integrity of habitats of other species.

A commitment to social equity which is neglected in current planning should be incorporated as one of the goals explicitly formulated in planning documents. Social equity refers to the pursuit of distributive justice and democracy in urban planning. Here, planning will strive for an equal distribution of environmental hazards and benefits, ensuring the access to affordable housing, public facilities and transportation for the low-income groups (Fainstein 2010). Social issues like social segregation, housing unaffordability, ethnic integration and ghettoization should draw more attention from urban planners.

### 4.2 Degrowth-oriented planning strategies for eco-city development

#### *Planning strategies for land use*

In Greater Copenhagen, principles of land use including densification on brownfield sites has been adopted in the inner part of the metropolitan area, while the peripheral areas are left with rather relaxed land regulation allowing the conversion of rural areas into urban zones. In the context of strong inter-municipal competition, local authorities in suburban municipalities will tend to employ generous supply of vacant land as a vehicle to attract investment, leading to low-density outward urban sprawl. Suburban expansion is more likely to contribute to increased need for transportation due to on average long distances between destinations and to increased need for motorized modes of transport (Næss 2012; Stead and Marshall 2011). Although the latter tendency is meant to be remedied by the principle of station proximity that encourages public transportation, this will only counteract the negative environmental impacts from increased aggregate traffic volume to some degree. Given the fact that the density of the outer part of Greater Copenhagen is already very low which provides opportunities for densification, an amended land regulation banning the conversion of rural areas to urban zones in the finger cities should be favoured in the finger plan.

Locating offices and residential development close to rail stations discourages car travel, but does not contribute to reducing the total amount of traffic. In general, there is a lack of concern in the finger plan on the traffic impact of locating different urban functions relative to the main city centre. Studies have shown that increasing distance from residence to urban centres is associated with increasing travel distance (Næss 2012; Stead and Marshall 2011). In recent two decades, residential development in Greater Copenhagen has shown a trend of concentration. If new dwellings are going to be built in future, an emphasis on proximity to the downtown Copenhagen should be reinforced in the metropolitan plan.

High-density urban development, despite its positive effects on energy saving and preservation of natural land, does not go without negative consequences on certain aspects of well-being (Neuman 2005). Residents living in dense urban areas are exposed to higher levels of noise and air pollution and run higher risk of traffic accidents. In addition, densification may deprive citizens of opportunities for access to city greenery by building on green areas. The lack of greenery, nature and outdoor activities may be compensated for by possessing second homes a rebound effect that undermines the effectiveness of planning strategies for sustainable urban structure (Strandell and Hall 2015). These potential negative impacts suggest the limitations of the densification strategy based on an assumption of ever-growing building stock and infrastructures. Urban development in the degrowth society will therefore aim at non-growth or even shrinkage of the size of built-up area and volume of the building stock, a topic that will be dealt with in the next section.

***Planning strategies for residential development***

As mentioned before, sufficiency in consumption is proposed as an organizing societal principle in the degrowth paradigm in order to reduce absolute consumption. This strategy is apparently highly relevant to the consumption of housing. Considering the high housing standard in Greater Copenhagen, it is pertinent to ask if further growth in per capita floor area is morally acceptable if an equal distribution of natural resources on a global scale is to be achieved. Moreover, a further growth is probably not socially necessary since the contribution of material goods to well-being tends to decline above a certain level. In view of the degrowth planning, the goal of residential development should be non-growth or even shrinkage in residential floor area on per capita basis and avoid inequality in access to housing. Such a view will have implications on the amount, composition and location of future housing supply.

The total amount of new housing measured by floor area therefore should be based on projection of population growth and annual replacement of existing housing. In the regional plan 2005, the prediction of housing growth, apart from these two segments, also took into account an expected rise in the average housing standard. This latter segment should therefore be excluded in planning for residential development in the degrowth paradigm. Stabilization or even shrinkage of per capita floor area also implies that the construction of space-consuming type of housing, i.e. detached single-family dwellings, should be discouraged in future. Therefore, the existing plans that allow the construction of this type of building in the outer areas of Greater Copenhagen should be amended. This requires planning to confront the idea that the supply of housing should be varied so as to meet different tastes and demands. A maximum standard of per capita consumption of residential space can be stipulated in planning documents as a control of the volume of housing supply.

Houses to be demolished annually should be the least environmentally friendly ones, like single-family homes in highly car-dependent suburban areas disconnected from the inner city, and dwellings with poor thermal performance. Suburban brownfields where the o

dismantled can be used for nature regeneration. On the other hand, the replacement of those demolished dwellings should take place as densification with availability of public transport and other city facilities and take the form of concentrated types of dwellings (Næss 2011).

With a ceiling on the consumption of residential space, every increase in floor area per capita among some population groups must be balanced by reduced floor area per capita among some other groups. The poor are usually the losers in such a situation because a limit on the size of the housing stock will induce housing scarcity and push up housing prices. The issue of social inequality can be worsened if no proper policies are in place. Under the neoliberal political climate, urban planning for the Greater Copenhagen area has gradually shifted away from focus on certain social groups, but given way to market to determine how wealth, such as housing, is distributed. Driven by market profits, development aims at meeting the needs of people who have purchasing power and consequently those low-income groups are in face of housing unaffordability. Social justice in the degrowth paradigm calls for the redistribution of wealth and pays more attention to the vulnerable social groups. The interests of the marginalized and vulnerable population should be fully represented by urban planners, who would to some extent need to work as advocates.

First buyers and needy families would demand redistribution measures like subsidies or tax reduction. Tax can be levied on empty owner-occupied dwellings to reduce overconsumption of living space. Some present institutions can be made use of as part of the redistributive strategies. For instance, social housing - traditionally an important part of social welfare in Denmark can be used permanently for renting. In the same vein, the long tradition of rent control in the rental market needs to continue. In addition, economic incentives and planning strategies can be employed to encourage cohousing and reusing empty dwellings (Lietaert 2010).

***Planning strategies for transportation***

In line with the degrowth paradigm, Banister (2008) proposed a sustainable mobility paradigm that focuses on people and accessibility instead of mobility, and aims at slowing movement down rather than speeding up traffic. This represents a departure from the current transportation strategy in Greater Copenhagen based on the idea that increasing mobility is a symbol of prosperity. The implication is that initiatives to expand motorways and increase road capacity in Copenhagen and reserve land for such infrastructure in order to facilitate economic activities with Malmö in Sweden should not be prioritized. Instead, planning strategies will aim at reducing traffic volume through proximity, rather than triggering more traffic by encouraging commuting from a wider area.

Besides aiming at reducing traffic, the degrowth planning will also change the composition of transport infrastructure supply in favour of more transit-oriented development and non-motorized modes of transportation. It requires a significant increase in the environmentally friendly elements such as biking infrastructure, walkable neighbourhoods, and better public transport services, replacing those that facilitate resource-demanding and polluting activities, such as high-speed transport infrastructure.

## 5. Conclusion

This paper has illustrated that eco-city planning for Copenhagen is conditioned by the growth ideology which seeks to reconcile the strategies for dealing with the pressure of environmental degradation with strategies for city competitiveness. Such an eco-modernistic eco-city planning leads to fragmented planning strategies for urban development and abstain the implementation of more radical solutions to urban sustainability transition. With the awareness of the limitations of the

eco-city planning under the growth paradigm, the paper attempted to propose an alternative planning paradigm informed by the degrowth debates which focuses on the pursuit of human prosperity without economic growth.

When asking why the growth ideology is the very essence of urban planning and the dominant driving force of built environment formation, the answer lies in the growth imperative inherent to the capitalist market economy (Gordon and Rosenthal 2003; Harvey 2010). The significant role of cities in perpetuating and expanding capitalist accumulation through the arrangement of built environment has long been discussed (Harvey, 2010; Lefebvre 1974/1991). Land use and built environment are wrought to adapt to the needs of capital, and provide necessary physical conditions to facilitate the capitalist production, consumption and exchange processes. As a consequence, propelled by the growth compulsion from the deep economic structure, promoting local economic growth and enhancing the city s competitive edge have become the most ambitiou local government. It therefore suggests that degrowth transformation necessitates a political movement to establish a new kind of socio-economic structure beyond the capitalist market economy (Fotopoulos 2007; Kallis 2011). In this respect, urban planners can be a mobilizing force through involving widespread public participation in the planning process to catalyse collective critical consciousness on current society, enhance public awareness of sustainable choices, build strategic alliances, and advocate vulnerable people (Rankin 2012; Rydin 2013).

# TRACK 19

# Smart Approaches to Responsible-minded Planning Practice

## Track description

Co-chairs: **Petra Hirschler**, **Roberto Rocco**

There is no single best practice for how to do successful spatial planni process will differ depending on location, society, economy, market pressures, and the size and the particular planning culture. Spatial planning is typically oriented to the legal framework, the institutional circumstances as well as the particular time in its history. In addition, power and responsibility shift and cities and regions are in constant change.

However, the transfer of ideas and practices in urban and regional planning happens all the time around the globe and it is increasing with higher connectivity between individuals, governments and institutions across nations and continents. Furthermore, many adopted in the developed world are transferred to the developing world without necessary critique and adaptation. Successful experiences embedded in very specific contexts are exported as panaceas.

This tracks looks for innovative planning projects and practices on different levels (transnational, national, regional and local) that foster responsible and critical knowledge transfer in the planning practice in both developed and developing countries, and that contemplate common challenges of implementation, understanding of specific contexts and differences in planning cultures. Attention to the local political economy and governance frameworks is essential.

The following issues will be highlighted:

- Attention to context and governance frameworks, power and responsibilities
- Smart approaches and innovative methods, products, processes that rely on an understanding of differences in planning cultures and practices
- Challenges and gaps between formal planning and informal development
- Lessons learned
- Discussion of transferability hurdles
- Accounts of success stories where the transfer of ideas and practices was successful and a discussion of the elements that made success possible.

# WHAT CAN PLANNERS DO ABOUT HARDCORE LAND VACANCY?

Paper presented to AESOP Congress, 13-16 July 2015, Prague, Czech Republic

David Adams
Urban Studies, University of Glasgow, UK
Email: david.adams@glasgow.ac.uk

**Abstract**

Property developers and investors have been at the forefront of urban regeneration in the UK since the 1980s. This has produced an emphasis on prime office space, luxury apartments, shopping centres and leisure attractions, which has been widely criticised on social equity grounds. But there has been only limited interrogation of the failure of property-led regeneration to deliver on the development it promises or on whether it represents good value for public money. Nottingham Eastside is one such example of market failure, where over a 25 year period, property developers and investors have come and gone, none of four masterplans have been implemented, decontamination and infrastructure provision has never been completed, and most of the land is still vacant. By reconstructing the story of Nottingham Eastside and evaluating its experience against Jessop's strategic-relational approach, this paper asks whether it is now time to create an alternative place-based model of urban development, drawing on best practice from continental Europe.

**Keywords**
Property-led urban regeneration, hardcore land vacancy, place-based urban development

## 1. INTRODUCTION

Walk ten minutes from the busy shopping streets of central Nottingham, and you will come across over 10 hectares of urban wasteland. This is Nottingham Eastside, once a thriving hub of industrial activity, but characterised now by waste ground, rough grassland, leftover concrete foundation slabs, and decaying fire-damaged buildings. Significantly, much of the site has been vacant since the late 1980s, when former occupiers began to depart. Since then, four major masterplans have been published for its redevelopment. None have been implemented, although the scattering of small office blocks, a budget hotel and a media centre on the western edge of Eastside bears testimony to the modest progress made on one of those plans.

The purpose of this paper is twofold. First, it is to explain why such a large area close to the centre one of England's eight 'core' cities and the principal business centre of the East Midlands has remained largely vacant for so long, despite significant policy efforts and substantial public resources devoted to securing its redevelopment. Although development on the ground has been limited, the current condition of the land cannot be attributed (as might be the case in some other countries) to policy neglect or disinterest. Instead, the story is one of frustration as a series of developers and investors have come and gone, with the public sector left largely reacting to events, rather than taking charge of them. These events set the scene for the second purpose of the paper, which is to provide a reflective critique on the market failings of that particular response to deindustrialisation and decay known as property-led urban regeneration, which came to dominate policy thinking in the UK from the 1980s onwards. This prompts the paper to consider whether an alternative approach to major urban redevelopment might be more productive and, over time, generate better returns for the public purse.

The next section of the paper explores the concept of property-led regeneration, connecting it to what is known about the critical success factors that may need to be present if hardcore urban vacancy is to be overcome. This highlights the theoretically contentious relationship between structure and agency in urban redevelopment. Here the paper introduces the strategic-relational approach favoured by Jessop, which is later used to help explain the particular course of events taken at Eastside.

Against this broad context, the third section of the paper summarises the Eastside story, concentrating on the years between 1990 and 2015. It documents key events and turning points, and traces those responsible for important decisions and actions. The style in this section is deliberately factual, both to contain its length and to provide a clear basis for subsequent evaluation in the section that follows. The research method employed to build up the case study was akin to much historical research, with a heavy reliance on documentary analysis, but with the benefit of interviews with key actors. These were used to expand and cross-check material, and wherever possible achieve triangulation.[1]

Section 4 of the paper seeks to evaluate what happened at Eastside and, from this, to open up broader debate on how best to achieve such large-scale urban redevelopment. Applying a strategic-relational approach, the section acknowledges that Eastside was never an easy site to redevelop and considers how different strategies deployed by different actors in their attempts to 'break through' structural constraints, achieved varying results. The final section of the paper summarises the main findings of the research and considers its implications. While recognising the particularities of the Eastside story, it seeks to draw out lessons that may have broader applicability in helping to chart an alternative policy direction to property-led urban regeneration.

## 2. PROPERTY-LED URBAN REGENERATION AND HARDCORE VACANCY

As part of the entrepreneurial turn in urban governance, 'property-led urban regeneration' (PLUR) became the primarily thrust of UK urban policy in 1980s (Healey, 1991). Although property development had often formed part of previous renewal strategies (Turok, 1992), PLUR represented a significant shift in the power relations, products and funding of urban regeneration. Whereas in the past, the private sector was seen as subservient to the planning strategies of the public sector, PLUR overturned that balance of power with planning strategies, at least for major redevelopment areas, coming to reflect the priorities of the private development industry. In some places, this was facilitated by the creation of urban development corporations, enterprise zones, and other measures that bypassed the jurisdiction of elected local planning authorities, but in others, planning authorities themselves enthusiastically adopted the new agenda.

The immediate result of such changing power relations was to fundamentally alter regeneration products. Prime office space, luxury apartments, shopping centres and leisure attractions, facilities, for instance, began to appear in places long considered 'off-pitch' by most private-sector developers. To achieve financial return and ensure market appeal, PLUR needed to operate, at least initially, at a large enough scale to create entirely new locations that could be branded as quite separate from their poorer surroundings. This is why PLUR often focused on grandiose or flagship projects (Loftman and Nevin, 1995), creating high value uses in what had previously been low value areas. Market-making on this scale was not simply a private-sector responsibility but became a core component of planning strategies. Indeed, despite political rhetoric, the public sector provided much of the baseline funding for PLUR through land assembly, decontamination, new infrastructure and direct development subsidies. Those who championed PLUR argued that such redirection of public funding was justified by the extent of private funding it subsequently levered into regeneration areas.

Nevertheless, PLUR was widely criticised as socially divisive (Imrie and Thomas, 1993), directing scarce public resources towards the urban rich rather than the urban poor and creating up-market environments intended for incomers, rather than the workplaces and decent homes needed by local people. Although some suggest that PLUR reached its heyday in the UK during the early 1990s, and was replaced by more community-based approaches to regeneration, others argue that its fundamental tenets became entrenched within broader regeneration policy and are still very much alive today (Dillon and Fanning, 2015). There has certainly been strong evidence that PLUR is widely practised internationally, for example in Ireland (McGuirk, 2000), across Europe (Carbonaro and D'Arcy, 1993), in Chile (López-Morales, (2013), and even in China (He and Wu, 2005).

The literature around PLUR is resplendent with case studies and critiques of schemes that were eventually built, but there is remarkably little written on projects that failed and were never implemented. Property market conditions are too often taken for granted in PLUR evaluations (D'Arcy & Keogh, 1999), which means that studies tend to focus on the implications of PLUR for social equity, important as these are, but not directly on the efficiency and effectiveness of PLUR itself. This is where the Nottingham experience, reported in this paper, provides an important new contribution to the literature. As it shows, understanding the management and distribution of development risk between the public and private sectors is crucial in assessing whether PLUR represents good value for public money.

In this context, PLUR can be contrasted with the European experience of place-based regeneration (Hall, 2014), discussed later in the paper, in which municipalities contain risk by acting as direct place-promoters. This rarely happens in the same way in the UK, with the result according to Falk (2011: 38) that "numerous masterplans are often produced for the same site and yet little happens on the ground (over 70 masterplans have been produced for the Royal Docks in London for example)." It has been argued that PLUR is a response to the embedded failure of urban property markets (Jones, 1996) in which "Low demand, dereliction, and risk in development costs prevented new construction" (Larkin and Wilcox, 2011: 3). In the case of land that has been vacant or derelict for more than nine years, it is officially defined as having fallen into semi-permanent or 'hardcore' vacancy (English Partnerships, 2003).

The significance of hardcore vacancy is twofold. First, the overall amount can be expected to be disproportionately weighted towards problematic sites requiring, for example, expensive decontamination. Second, the very fact that hardcore land has remained vacant for so long normally means that it has survived the demand pressures from at least one development boom. In 2001, some 16,523 hectares of all vacant or derelict land in England, representing around 25% of the total, was estimated to be hardcore vacant (English Partnerships, 2003). By 2014, unofficial estimates suggested this total had increased to 17,740 hectares, a 7% rise on the 2001 figure (CPRE, 2014).

Whether PLUR can provide an effective market response to hardcore vacancy will depend on its ability to generate what Dixon *et al*., (2011) call seven 'critical success factors' that enable long-term barriers to redevelopment to be overcome. From their comparative study of 10 hardcore sites in Manchester and Osaka, they consider these to be strong local property markets, developers able to exploit recession by purchasing land cheaply, long-term vision capable of spanning market cycles, strong brands often established through flagship projects, strong partnerships between the public and private sectors, achieving large-scale development, and prioritising infrastructure. The Nottingham experience reported in this paper explores whether the converse of these factors helps account for continued hardcore land vacancy.

The 'critical success factors' identified by Dixon *et al*., (2011) sought to link economic and property market change to the strategies of key stakeholders. If we wish to know whether PLUR is likely to resolve or perpetuate hardcore urban vacancy, it is indeed important to understand how structure and agency are constituted in each specific context and by what means they interact with each other. Applying Giddens' (1984) theory of structuration, Healey and Barratt (1990) suggest that although actors define and pursue their strategies, interests and actions in the context of a structural framework, structure itself is established, re-established or replaced as the resources, rules and ideas by which it is constituted are deployed, acknowledged, challenged and potentially transformed through agency behaviour. However, one of the most prominent critics of this conceptualisation (Ball, 1998), claims that agency behaviour cannot produce significant structural change, and argues that it is conceptually problematic to offer structural explanations of the existence and roles of agencies.

The strategic relational approach developed by Jessop (1996, 2001 and 2007) helps to resolve such criticisms through a more nuanced understanding of the relationship between structure and agency which avoids any theoretical separation between the two. Jessop attributes the weakness of Giddens' structuration approach to its concentration either on structure while temporarily ignoring agency or on

agency while temporarily ignoring structure. He describes this as the 'bracketing' of "structure and agency in a rather mechanical fashion" (Jessop, 2001: 1223) producing what he calls a 'dualism masquerading as a duality'.

Jessop's response is to "to examine structure in relation to action and action in relation to structure, rather than bracketing one of them" (Jessop 2001: 1223). What this means in practice is that the same element of structure may have different impacts on different actors at the same time, or on the same actors at different times. In short "a given structure may privilege some actors, some identities, some strategies, some spatial and temporal horizons, some actions over others" (Jessop 2001: 1223) while, crucially, those actors who realise this through their 'strategic-context analysis' and 'feel for the game' will adopt strategies and tactics that enable them to take advantage of 'conjunctural moments'. These comprise those structural elements that can be modified by a particular actor pursuing a particular strategy at a particular time and contrast with 'structural moments' that cannot be so modified. Of course "the self-same element can operate as a structural constraint for one agent (or set of agents) and as a conjunctural opportunity liable to transformation by another agent (or set of agents). It also implies that a short-term structural constraint for a given agent (or set of agents) could become a conjunctural opportunity over a longer time horizon or even within the same time horizon if there is shift in strategy" (Jessop 2007: 42).

Instead of a 'dualism masquerading as a duality', Jessop claims to have reached a 'dialectical duality' in which structure has been transformed into 'structurally inscribed strategic selectivity' and agency into 'strategically calculated structurally orientated action'. Despite their theoretical relevance, few attempts have been made to test and apply Jessop's ideas to planning and development. The Nottingham experience of changing actor strategies pursued over 25 years within a dynamic and complex structural context, as recounted in the next section, provides a valuable opportunity to attempt this in the subsequent section.

## 3. NOTTINGHAM EASTSIDE: A CASE STUDY

Nottingham Eastside is a 13.9 hectare redevelopment area, located immediately to the south-east of the city centre of Nottingham. By 2015, much of Eastside had lain vacant for at least 25 years, although some 2.8 hectares on its western edge have been redeveloped in recent decades. As shown on Figure 1, Eastside comprises three main parts; namely Boots Island to the north (Site A), Boots Warehouse in the centre (Site B) and the former railways lands to the south (Site C). The Eastside story is best recounted in five acts, each of which is summarised below.

### Act 1: Deindustrialisation, dereliction and departure (Pre-1990)

By the 1980s, the pharmaceutical giant Boots had occupied A & B as its main manufacturing hub for almost a century, while C had been in railway use for even longer. However, during that decade, Boots decided gradually to decant its central Nottingham operations to a modern campus in the west of the city. To the south, the once-busy rail-based activities fell into decline and then disuse. The prospect of significant redevelopment potential on A & C (Site B remained in operational use as a major warehouse for Boots until around 2005) seemed inhibited only by numerous decaying buildings and extensive contamination left behind from decades of heavy industrial use. To accelerate the redevelopment process, in the late 1980s Nottingham City Council threatened to take compulsory purchase action against both Boots and the then nationalised British Rail. It also published planning briefs for A & C, setting out redevelopment options, albeit in quite generalised terms. The council's prime objective was to secure new employment, through the development of new offices and light industry. More ambitious plans, however, were soon tabled by the landowners.

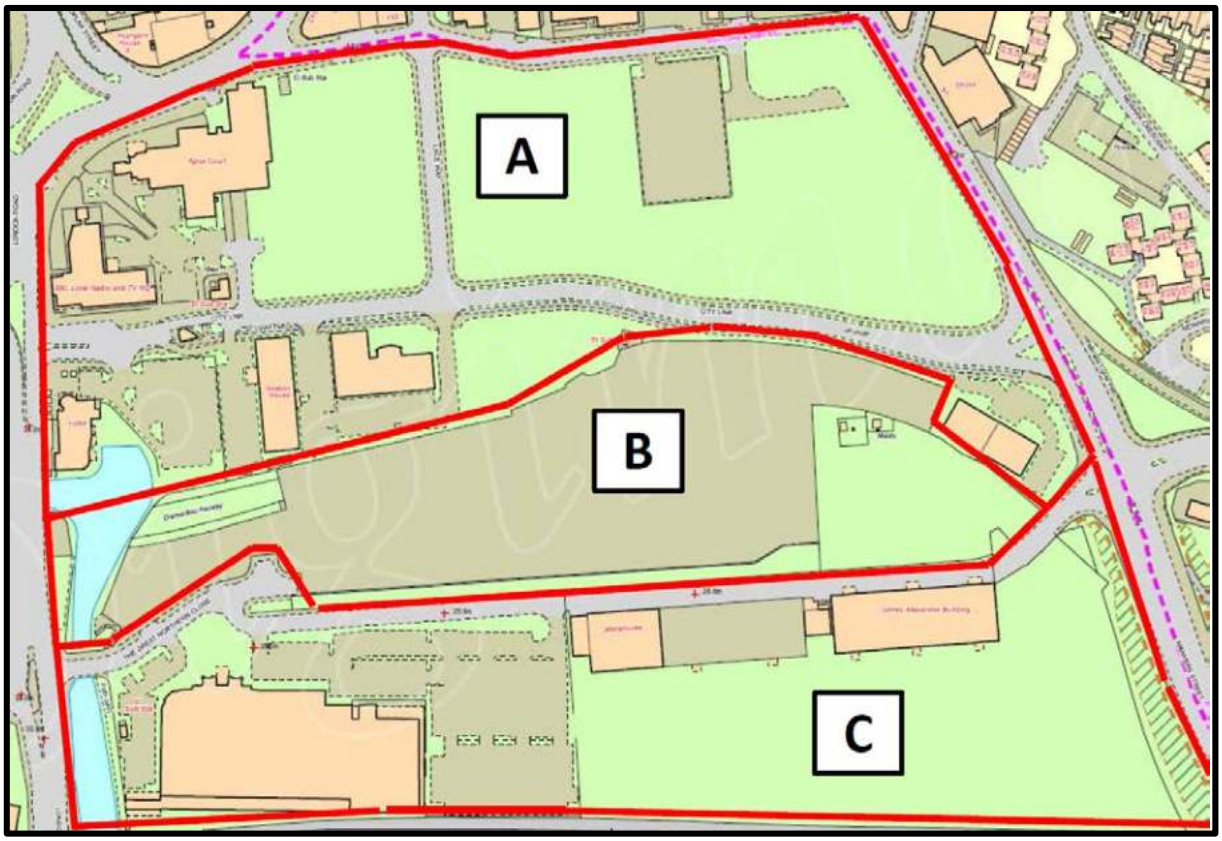

Figure 1: The three component parts of Eastside

**Act 2: Piecemeal property-led redevelopment (1990-98)**

In early 1990, Boots announced proposals for a massive commercial redevelopment of Site A, including 57,000 m² of speculative offices, a 'World Trade Centre' of 13,500 m², an upmarket hotel of 10,300 m², along with luxury apartments, shops, canal marina and 1,100 parking spaces (see Figure 2). This was the first of four major masterplans produced for the site. At an estimated development cost of £150 million, it was said to offer the prospect of 2,500 new jobs for the city. Not to be outdone, in late 1990, British Rail then announced its own plans for comprehensive commercial, retail and residential development on Site C. But had such longstanding industrial landowners really turned into real estate developers? Looking back some 25 years later, one regeneration expert long associated with the area was quite dismissive of the Boots proposal, commenting that "This was all part of a strategy to create some hype and excitement about the site prior to selling it …The notion of having a World Trade Centre was a bit fanciful but it got lots of coverage in the press. Lots of people got excited about it and then the City probably overpaid for it."

While this view may well be correct, the interview conducted earlier with Boots Properties in 1997 revealed another important motive – the desire to access funding from 'City Challenge', the high-profile regeneration competition launched in 1991 by the then Environment Secretary, Michael Heseltine. Nottingham City Council had successfully bid for £37.5 million 'City Challenge' monies over five years to regenerate the deprived inner city neighbourhoods of St Ann's and Sneinton, in which Eastside is located. But once it turned out that the council was unwilling to hand any of the cash to subsidise the Boots scheme, a land sale was agreed, with the council buying Site A from Boots for £2 million in 1994. By this time, the Island site had been designated as a City Challenge 'flagship project' and almost £6 million of public money was allocated for clearance and decontamination work, which subsequently took place between 1995 and 1997. Moreover, even before the land purchase from Boots was finalised, a well-regarded local developer, Simons of Lincoln (partnered by Gulliver Development Property Unit

Trust) had been selected to take forward the development on a 'back-to-back' deal. This meant that shortly after the council paid out the £2 million for the purchase from Boots, it would receive just as much, if not more, from Simons for a 999 year lease of the land.

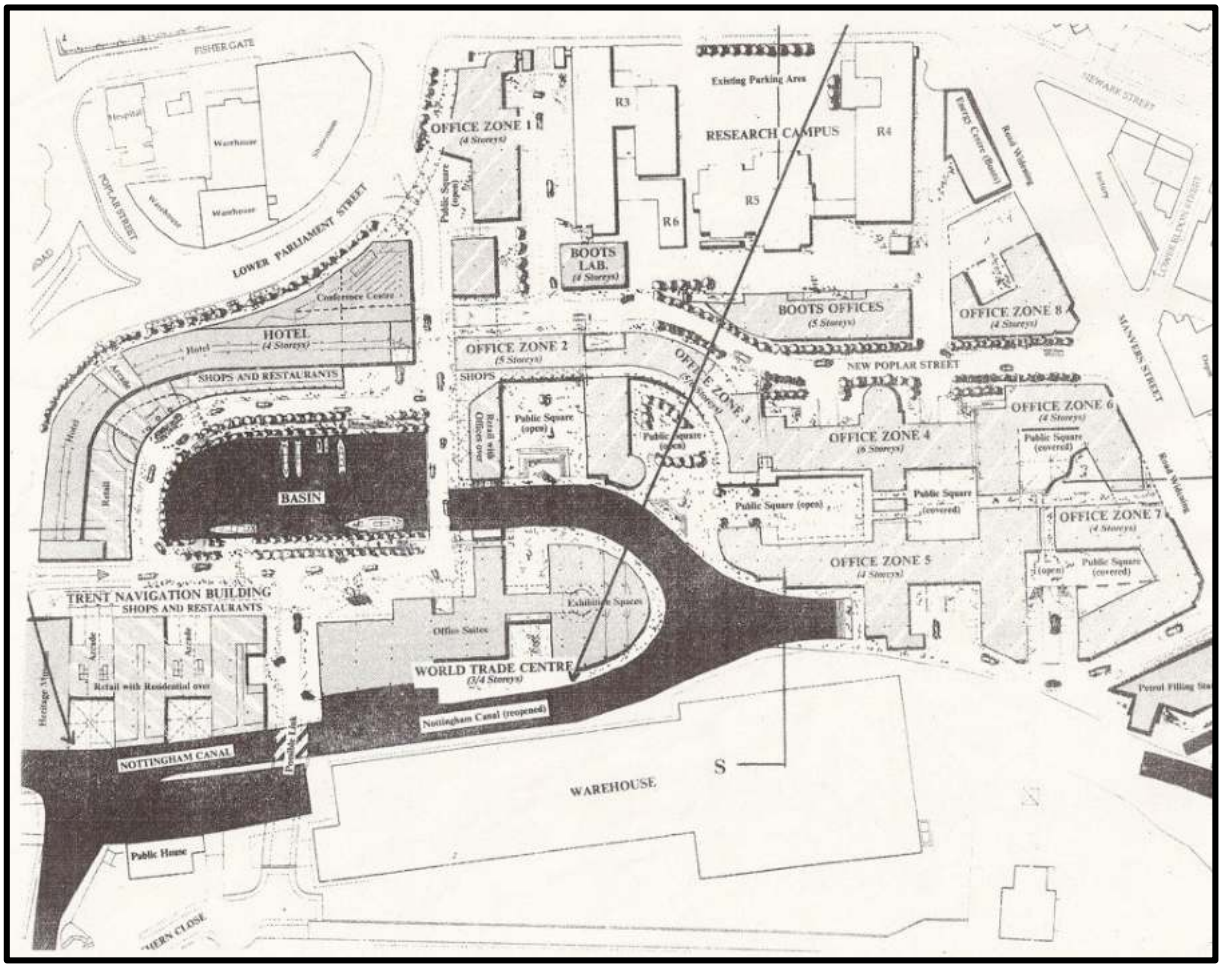

Figure 2: Boots Masterplan (1990)

Simons then launched its own masterplan for the Island site – the second to be produced, but one that was far less ambitious than the earlier Boots scheme. This proposed campus-style office development in central and western parts of the site, with light industrial development to the east. The latter was included at the insistence of the council, even though Simons thought only the office development to be commercially viable. Again jobs were promised – up to 2,000 on completion of the scheme. Yet, by the time Simons exited the development partnership in late 1998, its achievements at Site A were limited to building an east-west link road, constructing a new media centre for the BBC, and securing planning permission for two nearby office blocks. This was modest progress, at best, in comparison with earlier hopes.

To the south, the council had also bought out British Rail in 1993/94, paying around £1.6 million for the railway land and buildings. Initially, the council supported a community-based proposal for a transport museum in the former station, but then pulled out of this proposal. Instead, it again engaged Simons as preferred developer for the whole of C, except two former nineteenth century warehouses. Keen to divest itself as soon as possible of any repair responsibilities for these structures (one of which had been listed in the 1980s), the council quickly sold them to a local antiques dealer.

On the rest of the site, the agreement with Simons remained dependent on obtaining planning permissions and securing occupiers via pre-lets. Ironically then, Simons' first proposal for a cinema and leisure complex was withdrawn after it was 'called in' for a decision by the Secretary of State, while its second proposal for car showrooms and a 'drive-thru' restaurant was again withdrawn, this time after the council threatened to refuse it. Simons did manage to turn the former station and adjacent land into a health club, but after that, its agreement to take on rest of the site lapsed. The council was then left holding a significant chunk of the former railway land without any immediate prospect of development, while subsequently seeing the adjacent listed warehouse it had previously sold to the antiques dealer go up in flames, with the shell soon falling into decay.

By 1997, when City Challenge ended, substantial public funding had generated only limited piecemeal development at Eastside and certainly nothing to match the ambition of the 'World Trade Centre' proposed by Boots at the start of the decade. Disappointing as this was to Nottingham's civic leaders, it was time to take stock and consider what alternative strategy might be pursued.

**Act 3: Emergence of greater ambition (1999-2002)**

The turn of the millennium produced limited on-site change at Eastside. Gulliver Development Property Unit Trust, which assumed had responsibility for Site A after the exit of its partner Simons, was itself taken over by a series of property investment trusts, which then presided over the development of three 'campus-style' office blocks and a Premier Inn Hotel on the western edge of the site. Meanwhile, on the vacant former railway lands to the south, not even the hint of any development was evident. But with the election of a New Labour Government in 1997, the institutional landscape for urban regeneration and economic development in cities such as Nottingham changed markedly. The East Midlands Regional Development Agency was established (one of nine RDAs covering the whole of England) and the role of English Partnerships (the Government's own urban regeneration agency) was much expanded. These two bodies came together with the council and private-sector interests in the city to set up Nottingham Regeneration Limited (NRL), as a non-for-profit urban regeneration company. NRL's focus was "on physical regeneration though spreading the benefits more widely. The company commissions masterplan and regeneration studies and then seeks appropriate partners. They are developer of last resort" (URBED 2002: 33).

NRL was immediately asked by the council to prioritise plans for Boots Island and the wider area within which it sits. As a result, it commissioned a new Eastside Masterplan (the third in our series) from a team led by Latham Architects. This was published in 2002. It covered both the 13.9 hectares of the Eastside site itself and another 42 hectares of fringe city centre neighbourhoods to the north. Although termed a masterplan, it was no architectural blueprint of the kind produced earlier by Boots, but rather an informal development framework intended "to help deliver a vibrant, sustainable, high density and mixed-use urban area in line with national, regional and local policy" (Latham Architects, 2002: 1).

Turning specifically to the 13.9 hectare Eastside site, the Latham report (2002, para 7.2.7) concluded that office development had "faltered in market terms" and that it represented the "wrong product … in this location." Extending the canal basin into the very heart of the site would, it was argued, create the opportunity for higher-value and higher-density commercial, and especially, residential development. The report recognised that as well as private-sector contributions, further public-sector support would be needed to deliver this vision. Since its publication fortuitously coincided with an improving national economy and a rapid upturn in real estate development, the report did not go unnoticed outside Nottingham. Very soon, London-based property developers "came into town, promising to do wonderful things and putting money behind it… They commissioned a crack team and spent proper consultancy money" (Nottingham-based regeneration expert). The fortunes of Eastside were about to experience quite radical change.

**Act 4: Grandiose property-led visioning (2003-09)**

These new entrants to Nottingham were Eastside and City Developments (ECD), a joint-venture development company specifically formed in June 2003 with the intent of promoting one of the biggest single developments ever to take place in Nottingham. ECD was a partnership between Barclays Bank, Laing O'Rourke (one of the UK largest construction companies) and a relatively small firm of project managers and development consultants, called Roxylight. Its public face in Nottingham and beyond was Nigel Brunskill, Roxylight's Managing Director. Up to 2005, ECD spent what Brunskill later described as "tens of million" "painstakingly" assembling the whole of the Eastside site from 15 different landowners. He described this as "the most complicated land assembly I have ever been involved with" (quoted in Cunningham, 2009).

The main purchases were that of Site A from ING Real Estate Management (successors to Simons and Gullivers), Site B from Boots (which finally closed its major warehouse and last operational use on the site in 2005) and Site C from Nottingham City Council and the local antiques dealer who had previously bought the two nineteenth century warehouses from the council. What is remarkable about land assembly of such a scale is that it was undertaken in a relatively short timescale entirely by the private sector and without any threat of compulsory purchase. For the first time, it brought the whole of the Eastside site into single ownership, opening up the real possibility that it could be planned and developed as a single integrated project.

Figure 3: The Hopkins Masterplan

When ECD's masterplan for the whole Eastside was unveiled in 2004 (the fourth in our series: see Figure 3), the scale of ambition for the site was quite staggering. Masterplanned by the international architectural practice of Hopkins Associates, the proposed 270,000m² comprehensive mixed-use redevelopment included 131,000m² of prime office space, 123,000m² of luxury apartments, almost

12,000m² of shops, bars and restaurants and 4,000m² of leisure space, all centred around a major new public space and a new canal basin, first envisaged in the Latham Report. The estimated total development cost was £900 million.

It took four years of detailed negotiations with the council before planning permission was eventually granted and accompanying legal agreements signed. However, by that stage, the Global Financial Crisis (GFC) had produced rapid downturn in investment property values, bringing the long development boom of the 2000s to an end. At around the same time, ECD sold its interest in Eastside to the specially created Guernsey-based investment vehicle called Heathcote Holdings (HH). The reason, according to Nigel Brunskill was that "A project of this size and geographical importance requires substantial equity investment, and the Guernsey structure has the ability to achieve this … Overseas investors, family funds and sovereign wealth funds would expect and often demand ownership through a non-UK entity" (quoted in Cunningham, 2009). HH retained Brunskill as project manager, but the funding required to commence the development never materialised.

It could be argued that, by taking four years to grant planning consent, Nottingham City Council ironically saved ECD and subsequently HH from what might well have been financial disaster had their development commenced in the period immediately before the GFC. Looking back, those interviewed in 2014 and 2015 were firmly of the view that the Hopkins masterplan was just too large and ambitious for a provincial city such as Nottingham. In retrospect, the Chief Executive of Nottingham Regeneration Limited thought that everyone had been "seduced by glorious images of docklands-like development, with a massive amounts of apartments centred around public squares and fancy fountains etc. etc. They were all very seductive." This view was shared by another Nottingham-based regeneration expert who considered that even the council had been "swept up in the hubris of the moment" trying to re-create Kings Cross, London in central Nottingham. He added the proposal "was driven by a London developer who was a bit disconnected from the provincial world … They didn't understand the dynamics of the (local) market." In the end, Nottingham Eastside was no further forward in 2009 than it had been in 1999. Indeed, as one interviewee poignantly suggested, the site had once again been left standing at the altar.

**Act 5: Hard reality dawns (2010-15)**

Despite the demise of the Hopkins masterplan, Heathcote Holdings had one last card to play. Even in the post-GFC recession, the main UK supermarkets continued to expand their store numbers, with Tesco taking prime market position. So in 2010, HH linked up with Tesco to make a joint planning application for an 11,800m² superstore on part of Site A, which would have been one of the largest such developments in the UK. This time, the number of jobs promised by the developers was smaller than before, at only 300 to 500. Yet, it soon became clear that this proposal faced fierce opposition from the council, owing to its perceived negative impact on retail activity in the city centre. The application was therefore withdrawn in 2011, possibly to avoid a formal planning refusal. Ironically, within three years, Tesco itself ran into financial difficulties and made a strategic decision to slim down, rather than expand its estate portfolio, casting doubt on whether the Nottingham store would ever have been built, even if planning permission had been granted. For Heathcote, the end result of this failed venture with Tesco was to undermine any support it may still have had from NRL and the council, making relationships, according to the NRL's Chief Executive "quite confrontational" and "unpleasant" at the end. In his view, the Guernsey-based company was by then perceived as being "very absentee landlordish" and without any long-term investment interest in the city.

By 2012, the council had agreed a new 'City Deal' with central government in which the wider Eastside area was designated as a new Creative Quarter for the city and support was promised for "the redevelopment of Nottingham's prime Eastside Island regeneration site." But with still no proposals coming forward from Heathcote, the council eventually lost patience in December 2014, and resolved to take control of the site itself, either through voluntary acquisition or compulsory purchase. Justifying this decision, Councillor Jon Collins, the Leader of Nottingham City Council said "We have done all we can to encourage and support the site owners to progress with the site's redevelopment but after

years of inaction from them, we have no confidence they have any intention of doing so" (quoted in Nottingham Post, 2014). Ironically, some 20 years earlier, the same Councillor Collins, at that time Chair of the City Challenge Board, had commended the council's decision to sell Site A to Simons of Lincoln on the basis that the number of jobs then promised were "realistic predictions if you look at the balance of the development" (quoted in Bell, 2013).

Figure 4: Nottingham Eastside 2014

Perhaps anticipating the council's move, in October 2014, Heathcote Holdings placed the entire 13.9 hectare site on the market through the international property agents, Savills, seeking expressions of interest from potential purchasers. At the time of writing, it is not known whether any deal has been agreed either with the council or another party, but Eastside remains much as it has been for the last 25 years – an urban wasteland (see Figure 4). That's not to suggest it is wholly unused. Instead, it seems to function well as a location for informal recreation, since "People use it as a running circuit, or commuters who cut through from the station to Sneinton - there's also a lot of dog walkers, cyclists, people who picnic there - there's lots of people using it in lots of different ways" (Griffin, 2013). It has even been informally 'twinned' with another area of wasteland in Indonesia. But, despite some limited redevelopment on its western edge, none of the plans of the last 25 years have produced any substantial transformation in how most of Eastside appears to, and is used by, the people of Nottingham. In the next section, we seek to discover the deeper reasons why it remains vacant after all these years.

## 4. EVALUATION

This section seeks to apply Jessop's strategic-relational approach to understand what really happened at Eastside and to evaluate why a property-led approach failed to transform the area. The section has a twofold focus on both the differential impact of structure upon actors and the differential response of actors to structure. Three main structural elements are identified: locational and site-specific constraints, economic and property market cycles, and the broader policy context. All three made development difficult, although the impact of this varied between actors and over time. Elsewhere, PLUR has delivered major redevelopment in the face of challenging structural circumstances. Why then at Nottingham did no single actor or combination of actors succeed in breaking through the site's inherent structural difficulties?

Locationally, although close to the centre of Nottingham, the site is separated from the commercial and retail hub of the city by major arterial roads and it is only on the fringe of the city centre. It is generally bordered by relatively low-value uses, consistent with its location within a broader regeneration area. Decades of heavy industrial activity meant Eastside was highly contaminated and, within the site itself, deficient in modern roads and sewers. Ownership was fragmented at the start, and became ever more so before ECD eventually pieced it together.

At the start of the 1990s, the council saw this as classic 'employment generating' land, by which it seems to have meant industrial workshops, with some office activities on the edge. This would have provided only limited financial reward for the departing industrial owners, Boots and British Rail. To raise land value expectations and secure significant exit payments from the council, they 'reimagined' the location as one suitable for significant PLUR. This early 1990s vision of major mixed-use redevelopment radically changed structural perceptions of what might be achieved at Eastside, but it did not make actual redevelopment any easier. The conjunctural moment created and exploited by Boots and British Rail allowed them to depart without even paying for the contamination they had created, while leaving other actors to grapple with the consequences. No-one was subsequently able to overcome the locational and site-specific disadvantages of Eastside, apart from at the western edge closest to the city centre. As argued below, to do so would have more required more effective institutional arrangements for the management of risk in the development process.

Broader economic and property market cycles provide the second structural element which served to open up and close down opportunities to act. Developers who can successfully 'read' this structural element and act accordingly by starting development early in a cycle will normally be expected to outperform those who start late. Although Eastside saw its existing uses wind down in the 1980s, the site missed the development boom of that decade and emerged as a real redevelopment opportunity only in the midst of the recession in the early 1990s. Even by 1994, it was still not a fortuitous economic moment for Simons to launch its masterplan and when the company withdrew in 1988, this was because it felt that local market conditions were still "going badly by this stage." Yet, within two years, the long development upturn that lasted until the onset of the GFC in 2008 had begun. Why did no-one take advantage of this upturn to commence major redevelopment at Eastside?

Again, the answer lies in the deficient institutional arrangements at Eastside. PLUR normally requires lengthy preparations to be made over several years. In 1998, it fell to NRL to pick up the pieces and chart a new direction for the site but as an urban regeneration company, rather than an urban development corporation, it had no control over planning policy and never gained ownership control of the site. Its Eastside masterplan, published in 2002, transformed the structural perception of the site's potential with cleverly created visions of high-value commercial and residential development, but was not directly linked to any means of implementation. But it helped create the conjunctural moment that ECD's Hopkins masterplan, produced in 2004, sought to exploit. By then, the development upturn of the 2000s was well underway. ECD's late arrival was exacerbated by the four years it took the council to grant consent for the Hopkins masterplan. Whether the plan would have succeeded if it had been tabled in 2000, gained early planning permission, and started on site in 2002 will never be known and, in many ways, is irrelevant. This is because PLUR, especially when deployed at such a large-scale as

Eastside, creates very significant development risks which cannot easily be managed by individual actors operating alone within a single development cycle and which lessen their ability to challenge and transform difficult structural conditions. The conclusions of the paper highlight alternative ways to manage major urban redevelopment which it is argued can help developers of large sites more easily handle the ups and downs of economic and property market cycles.

The broader policy context, which provides the third structural elements, reinforced site-specific and broader economic constraints. After a decade of neoliberalism, by the 1990s local planning authorities were no longer expected to drive or deliver change, but merely to regulate it. The rapid increase in unemployment experienced during the 1980s also meant that councils were easily swayed by any promises made about future job creation, whether reliable or not. PLUR offered the chance to capture a greater share of central government funding for development projects at a time when mainstream budgets were under severe strain. Early experience from Canary Wharf in London, Salford Quays in Manchester and elsewhere had indicated the apparent potential of ambitious PLUR projects, making other localities keen to attract such up-market development. At the same time, disempowerment and institutional fragmentation increasingly encouraged local authorities to share city leadership with the private sector through relatively short-term programmes such as City Challenge. Although Eastside benefited from almost £6 million of City Challenge money spent on decontamination and infrastructure, this limited subsidy seems not to have been able radically to transform the fortunes of the site

From a private-sector perspective, almost all the uncertainties of planning regulation remained at Eastside. There was much planning controversy, for example, over Simons' various designs on Site A and the company eventually withdrew two major proposals for Site C after planning refusals seemed imminent (despite having already agreed to buy the land from the council). ECD appears to have underestimated the time it would take to secure planning permission for the Hopkins masterplan, while later on Heathcote Holdings badly misunderstood the policy context, even though it recognised the market potential of the supermarket boom.

There is little sense that the council ever wished or even knew how to drive development forward at Eastside. It provided no long term vision for the site and seemed indifferent between the cost minimisation strategy pursued by Simons and the value maximisation strategy favoured by ECD. Published planning documents offered no clear or consistent sense of what the council wanted to achieve but appear to have served merely as a baseline for negotiations. Indeed, the council mainly reacted to proposals from others, not really appreciating local market conditions or its own ability to shape them. Crucially, when it might have taken overall control of the site after those initial purchases from Boots and British Rail, the council appears to have wanted to divest itself of direct ownership responsibility as soon as possible.

Even if its role was intended to be that of mere development facilitation, it seems not to have fulfilled this with any vigour, still less to have challenged and transformed the structural context. Apart from the scattering of development on the western edge of the site, it now has little to show for the £9.6 million spent on land acquisition, decontamination and infrastructure, not to mention all the administrative costs incurred over many years. Although its authority was never usurped by an urban development corporation (as happened elsewhere with other PLUR projects), its largely reactive role created a vacuum in local place leadership which the private sector struggled to fulfil.

In summary, no single actor or combination of actors ever adopted strategies and tactics capable of breaking through the structural constraints at Eastside. It could be said that ECD came closest to this with the Hopkins masterplan, but the view emerged from those interviewed for the research that this proposal was too late, too ambitious and never likely to secure the massive amount of development funding it would have required. Indeed, by unduly raising expectations, in terms of both value and product, ECD's property-led regeneration proposal might well have impeded other less ambitious proposals coming forward.

Of the 'Critical Success Factors' identified by Dixon et al. (2011), only three were actually present at Eastside, and then only partially. The scale of site was certainly large. While substantial monies were spent prioritising infrastructure that enabled some development to go ahead on the western edges, infrastructure provision and decontamination work has yet to start on the former railways land to the south. Although strong markets were experienced during the 2000s, by the time this was widely appreciated, it was too late to promote the Hopkins masterplan. Conversely, Eastside lacked strong partnerships, a strong brand and any real long-term vision, while land assembly, even in the recession, proved expensive not cheap. As this suggests, 'Critical Failure Factors' are recognisable from the converse of those identified by Dixon et al. (2011). In the final section, drawing on European experience of similar sites, the paper thus argues that there is thus much to be learnt from events at Eastside on how best to promote major urban redevelopment at sites of this type.

## 5. CONCLUSIONS

Some 25 years after much of Nottingham Eastside first fell vacant, it remains a major potential redevelopment site close to the centre of one of England's core cities. Its experience offers some insights for similar kind of sites in similar kinds of cities, but the conclusions presented here should not be over-interpreted as necessarily applicable in all circumstances. For despite powerful criticism of PLUR on social equity grounds, it has indeed delivered substantial urban reconstruction in other locations. What this paper argues is that even that should not be taken for granted and that, in particular circumstances, PLUR may be as much an ineffective and inefficient means to deliver major urban change as an inequitable one.

At Nottingham, these circumstances derived from the financial risk posed by three elements of the structural framework identified in the previous section. While the economic and property market cycles provided relatively short windows of opportunity within which development could take place, the particular locational and site-specific characteristics of the site demanded long-term commitment extending beyond a single development cycle. Ironically, the policy context offered no such commitment from the public sector, but instead assumed that the private sector would lead the development of the site over the long-term. At times, there was even no integrated commitment to the site over the short-term, as evident when Simons was encouraged by the council's estates committee to pursue plans for car showrooms and a drive-thru restaurant on Site C, to which the planning committee then took exception.

Specific risks consequently faced by private-sector developers included first, the cost and extent of decontamination, second, the means and timescale for recovery of any infrastructure expenditure, and third, the distinct possibility that development of any scale could not be completed and occupied before the next cyclical downturn. On Site A, the first two of these risks were reduced, but not eliminated, by public subsidy. Simons, for example, claimed the east-west link road it built across the site had detracted from its ability to invest in new office development. Sites B and C received no public similar subsidy, and still remain to be treated for contamination and equipped with infrastructure. The third risk proved to be the major reason why ECD was unable to finance the Hopkins masterplan. As the Nottingham experience demonstrates, when such risks are divided up between development actors, rather than shared among them, it becomes very difficult for any single actor to create that 'breakthrough moment' when a difficult structural context is challenge and transformed, enabling development to move ahead.

There is now much evidence from across continental Europe that a locally-led and place-based approach to regeneration can be equally if not more effective than a property-led one (Hall, 2014). Place-based approaches emphasise the importance of creating new urban quarters, with high quality design and public realm, which are well connected and 'knitted in' to the existing urban fabric, rather than standing apart from it. Masterplans prioritise place creation and infrastructure provision and normally provide the basis for packaging up large development sites into much smaller parcels which can then each be built out by different developers, thus reducing any individual developer's exposure to risk. As phased land sales take place over time according to a parcel map, infrastructure investment is gradually

recouped, with the expectation that later parcels will be worth more than earlier ones, reflecting development that has already taken place.

Crucially, this place-based model requires someone to take on the leadership role of 'place promoter' (Adams and Tiesdell, 2013), providing what Leinberger (2007) calls the 'patient equity' for long-term investment. While there are some good examples of individual landowners or private development consortia acting as place promoter, in most of the classic continental cases such as Hamburg in Germany, IJburg in the Netherlands and Hammarby-Sjöstad in Sweden, a powerful public agency or empowered municipality has fulfilled this role. According to Hall (2014: 35) the single most important conclusion from his study of urban development across Europe was the need for "Strong city planning departments (or city agencies) with real planning powers and a willingness to take a positive lead, particularly in developing overall master plans as a framework for development or regeneration of specific areas."

Until the 1980s, the UK was well used to this type of model. But with the privatisation of urban development widely promoted since then, local authorities have mostly lost the capacity to drive forward development of their areas. The purpose of this paper is not to argue that the property-led approach is always ineffective, even if it may inequitable. In favourable circumstances, it has clearly regenerated parts of many British cities. But in Nottingham, opportunities to transform a difficult structural context were missed, primarily as a result of uncoordinated actor behaviour. Property developers and investors came and went, four masterplans were produced but never really implemented, decontamination and infrastructure provision was partial and most of the land is still vacant after all these years. Perhaps most ironically, the City Council is now trying to buy back, possibly by compulsory purchase, the very land it sold to the private sector all those years ago.

None of this can be defended on grounds of economic efficiency, still less on those of social equity. In places such as Nottingham, is it not therefore time to create an alternative place-based model of urban development, drawing on best practice from continental Europe, in which the risks and rewards of major urban transformation are more effectively assigned and shared between the public and private sectors?

Keywords: Polycentric Compact Mode, Sustainable Development, Shanghai

## Abstract

*This paper discusses issues relating to the urban structure of contemporary megalopolises in China. As the urbanization rate is over 50% in China, the New Mode of Urbanization Planning (2014-2020) specifies new ways for Chinese cities to optimize their urban structure. Many Chinese megalopolises propose to focus future urban development plans on the polycentric and compact urban structure that would address sustainable development concerns. Shanghai is one of the cities taking the lead in adopting this mode.*

*This paper also reviews theories about both urban polycentric structure and compact city in order to identify new ways to integrate them. To understand how this integrated mode of urban development might work, an urban concept model is established to analyze the relationships between inner city, suburbs, new districts and new towns.*

*Taking Shanghai as an example and making reviews of its previous planning, this research explores the reasons and motivations for adopting the integrated mode and examines the effect of the spatial expansion of population and industry, as well as the role of the intervention and organization of* government. This research also shows how Shanghai s urban structure has tra *monocentric system towards a polycentric structure with compact form.*

The paper s final section presents a quantitative and qualitative analysis of *stage of approaching the polycentric and compact urban structure. Preliminary findings indicates that,* for China s megalopolises, this development *mode is both sustainable and particularly well suitea national conditions.*

## 1. Introduction

### *1.1 Research background*

#### *1.1.1 Demand for optimization of urban spatial structure*

Chinese cities have experienced profound changes since the period of reforms in the late 1970s, and in 2011, the urbanization rate reached 50% (Figure 1).Although the speed is so fast the quality is not satisfactory, some big cities spatial structure and urban scale is not reaso Chinese government enacted a New Mode of Urbanization Planning (2014-2020), in which new ways for Chinese cities to optimize their urban structure are specified. It emphasizes that the extensive way of developing should be changed, the scale of built area and the boundary of the city should be reasonably controlled, and the land use efficiency should be promoted.

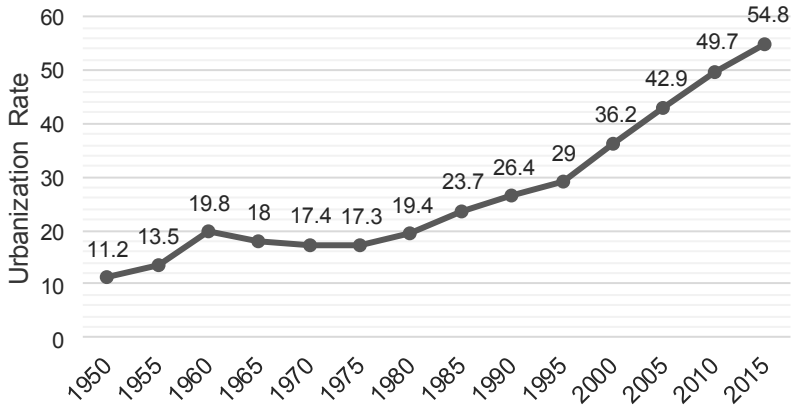

Figure 1. Urbanization Rate of China (Source: National Bureau of Statistics of China)

*1.1.2 Trend of the polycentric structure and compact form*

At present, the number of megalopolises that have fast growing population is still increasing in the process of urbanization in China. In addition, with limited resources, the extensive development approach makes cities sprawl unceasingly and disorderly, leading to many problems like traffic congestion, deterioration of ecological environment, and lack of green space, disease . In order to meet the demands of complex functions and promote the q many cities begin to evacuate pressure from inner city and develop new centers in different levels, thereby gradually changing the urban structure from monocentric to polycentric type. Cities like Beijing, Shanghai, Guangzhou, and Chongqing are proposing to establish a polycentric urban structure and apply the ideas of compact city in their new master plans.

*1.1.3 Concerns for sustainable development*

China is short of many resources though it s a big country, especially arable land because o population. What s more, McKinsey Global Institute (2008) predicted that there will be people living in cities in 2030, which give cities great pressure and a great amount of energy and resources will be wasted as a result of redundant construction unless they apply a sustainable pattern. But luckily, Chinese government has realized the disadvantages of extensive development mode and try to seek a sustainable one, which encourages intensive public transportation oriented development and advocates green traffic system with mixed land use.

*1.2 Research problem and hypotheses*

This study aims to explore the theories and practices about the urban development mode of polycentric structure and compact form, and also identify new ways to integrate them. As nowadays many megalopolises in China are facing great challenges of enormous population, scarce resources and ecological crisis, this mode of development may be a sustainable solution because of low energy consumption and high efficiency of land use.

*1.3 Research objective and scope*

The purpose of this study is to empirically test a polycentric and compact model of sustainable development in whole Shanghai city that comprises 16 districts and 1 county (Figure 2). To understand how this integrated mode of urban development might work, an ideal urban model is

established to analyse relationships between the inner city, new districts and new towns. Making reviews of the previous planning of Shanghai, the research shows how Shanghai s urban structure has transformed from a monocentric system to a polycentric structure with compact form. With a quantitative and qualitative analysis, this research also give an evaluation on stage of approaching this mode.

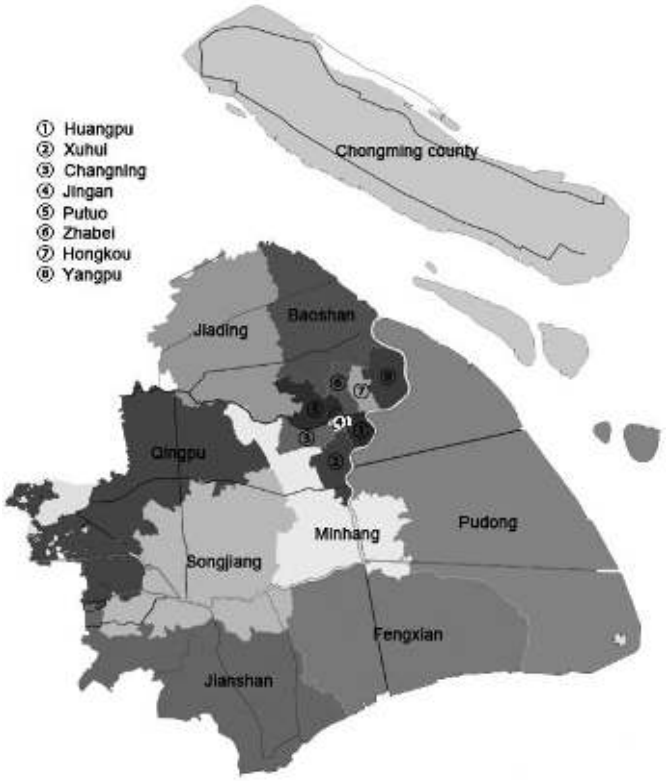

Figure 2. The Administrative Divisions of Shanghai (Source: Self-drawn based on Wikipedia)

## 2. Literature Review

### *2.1 Literature about the urban polycentric structure*

Howard (1898) first suggested an embryonic polycentric urban system garden city , clai city should stop growing when it reaches a certain scale, the excessive part should be joined to adjacent cities to develop a new urban agglomeration. Later, "regional city" put forward by Mumford (1938; 1961) is also a support of polycentric spatial development pattern, which pushed on the ideas of Howard under the background of urban regions. He thought as a geographical presentation, multicenter in terms of spatial form can be measured quantitatively by the method of geography or morphology. Then, the organic decentralization theory proposed by Saarinen (1943) also maintained that population and employment should be decentralized to several districts that have their own characteristics, thereby transferring the disorder concentration to orderly decentralization. In addition, taking Tokyo as a case study, Kawakami (1988) studied how the polycentric structure could form and shape its characteristics, finding that the emergence of polycentric structure has close relation with the size of the city and its change of the transportation means. In regard to the measurement method, Bertaud (2004) proposes the population density, the gradient of the density profile and daily travel mode can reflect the degree of polycentric spatial form. Based on this, Wei Yaping (2006) proposed a quantitative method for spatial structure measurement through density performance, spread

performance, population density gradation performance and OD performance, and extended four modes of the polycentric network structure in the metropolitan area. Finally, taking 8 cities in northwest Europe as examples, Hall (2006), the leader of Sustainable Management of European Polycentric Mega-City Regions (POLYNET), made "grade-scale" analysis on urban functional areas about their degree of self-sufficiency and calculated commuter flows to measure their connection.

*2.2 Literature about the urban compact form*

"Compact city" is one of representative theories of controlling urban sprawl and promoting sustainable development in European countries, which was first put forward in Green pa environment (Commission of the European Communities, 1990). Later, many scholar researches about its mode, objective, strategy and so on. They think "compactness" is a spatial form with high density and mixed function (Glaster, et al., 2001; Mubareka, et al., 2011), is a development mode towards high density (Gaigne and Riou, 2012; Dempsey, et al., 2012). Furthermore, Jenks (1996; 2000) summarized the five aspects of compact city theory and its development in the first 10 years and discussed the sustainable development of urban form and the urban problems in the developing countries. Kaido (2001; 2007) introduced different theories about compact cities in Europe and the United States, finally discussed how to build compact cities in Japan. In 2012, Organization for Economic Cooperation and Development (OECD) made comprehensive assessment and comparison on the implementation and performance of the compact city policy among its member states, providing by far the most comprehensive definition of compact growth and valuable advice for policy makers. On the aspect of measurement and evaluation of compact city, Ma Li and Jin Fengjun (2011) from Chinese Academy of Sciences established a compact degree evaluation system according to Chinese condition and applied it to more than 120 cities, finding that 67.2% of Chinese cities are not compact and compactness has strong links with urban population and economy.

About how to integrate these two theories that may seems contradictory at first, the Network of European Metropolitan Regions and Areas (2010) provided a base that a polycentric metropolitan area can be a compact city if it has the identified characteristics. In addition, only Rogers (1997) roughly proposed a pattern of polycentric and compact urban structure for sustainable development (Figure 3). From the above statement, it can be learned that the integration of polycentric structure and compact form is less researched, in the following sections, we will analyse the case of Shanghai s development mode to understand how these two ideas can be combined for sustainable concerns.

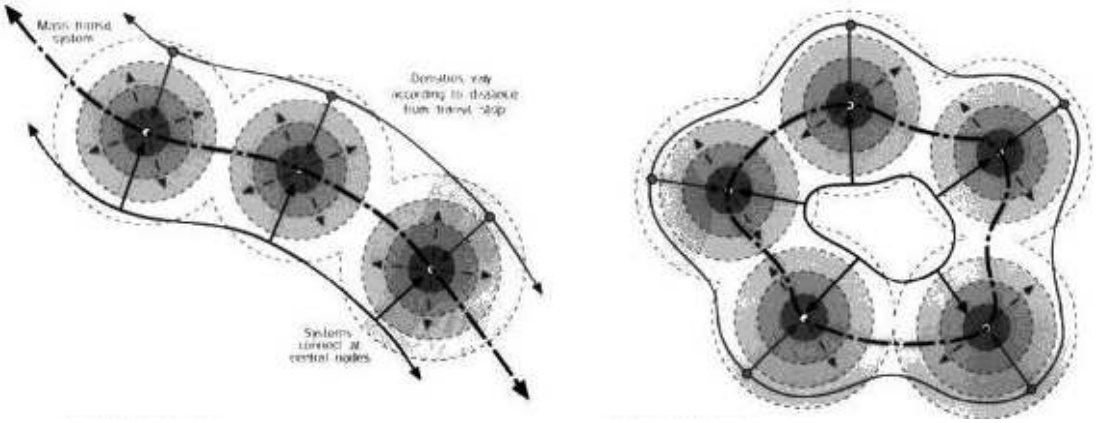

Figure 3. Rogers s Polycentric and Compact Urban Pattern (Source: Cities for a Small Planet, pp.39)

**3. Methodology and Analysis**

*3.1 Polycentric and compact urban concept model*

*3.1.1 The definition of multicenter*

City center is an area of highly concentrated urban functions. As living and working are the two main functions of the city, the residential and employment center can be chosen to analyse the polycentric structure. Residential center refers to a geographical unit in which resident population or residential density is higher than a certain value, so does the employment center (Giuliano and Small, 1991). Furthermore, the essence of employment center is that it is the node of the information flow of economic activity and it can dominate surrounding employment, population and housing prices (McMillen and McDonald, 1998).

*3.1.2 The definition of compactness*

OECD (Organization for Economic Co-operation and Development) has given an authentic interpretation of compact city, they consider that the key characteristics of a compact city are dense and proximate development patterns, urban areas linked by public transport systems and accessibility to local services and jobs (Figure 4).And the report also proposes a set of 18 core compact city indicators that are considered essential for analysing compact city (OECD, 2012, pp.87). The indicators are selected to represent effectively the compact city and compactness as here d

Figure4. Key Characteristics of a Compact City (Source: Compact City Policies: A Comparative Assessment, OECD, 2012, pp.28)

*3.1.3 The integrated model*

In order to integrate these two concept, based on Rogers s pattern this study polycentric and compact urban model as shown in the figure below (Figure 5). As polycentric structure is the best city form for megacities when the population reaches 5 million (Bertaud, 2004), the largest radius of the city with 5 million population is about 12.6 $km^2$ according to indices for land area per capita (about 100 $m^2$/p in China). When the population is over 5 million, the city extends outward to develop new centers. The polycentric structure includes two aspects. First, within the scope of the whole city, the layout of inner city, new districts and new towns that have their own characteristics is polycentric. Second, the inner city even each new districts also have their own polycentric structure. Similarly, compact form also includes two aspects. First, all the centers have a compact distribution with some overlapped suburban areas, and second, the concept of compact city is applied to each center and they will keep appropriate scale of population and space. Thus, the urban agglomerations are not necessarily located contiguously but are not widely dispersed. Last but not the least, they must be linked together by public transport systems as proximity of urban cores is an important notion for a polycentric compact city (OECD, 2012). This mode emphasizes the spatial intensiveness, though the centers are separated with each other, the land use in each new district is compact.

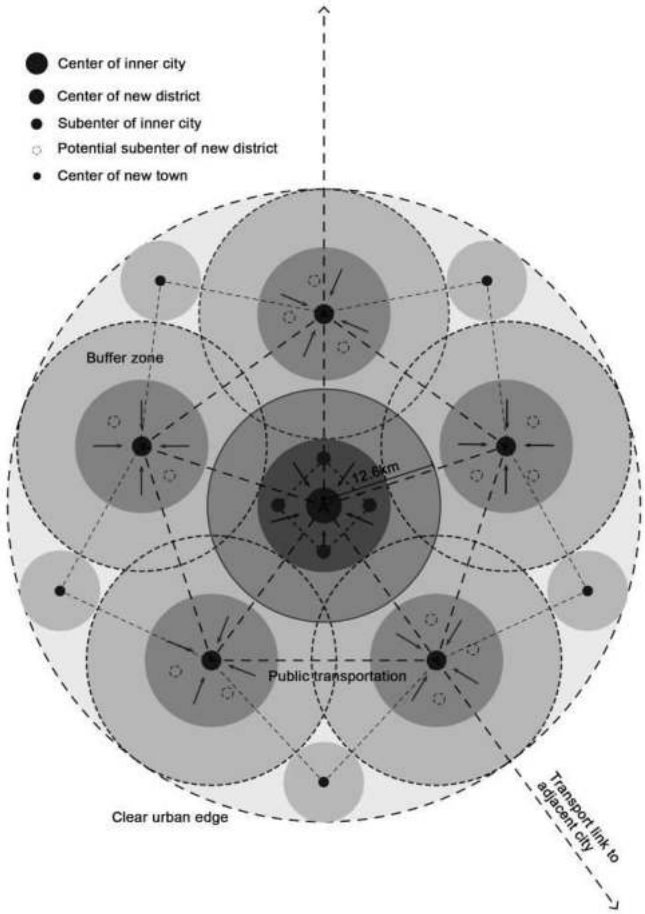

Figure 5. The Polycentric and Compact Urban Concept Model (Source: Self-drawn)

*3.2 Mapping and planning review*

The evolution of Shanghai urban spatial structure are closely related to urban planning and its implementation. From port opening to now, four strategic plans have significantly influenced the urban system of Shanghai, also deeply affected urban development. The four most important plans are City Planning of Grand Shanghai in 1946, Preliminary Views on Master Plan of Shanghai in 1959, Shanghai Master Plan in 1984 and Shanghai Master Plan (1999~2020) in 1999. The implementation of these four plans directly contributed to Shanghai today's urban system. Making a review of the development and evolution of Shanghai s spatial structure, we can easily find t historical periods.

*3.2.1 From the founding of new China to early 1980s: A typical monocentric urban system*

After the victory of Anti-Japanese War in 1945, Shanghai government set up Shanghai Urban Planning Committee, and drew up a "Draft Report of Shanghai Master Plan in December of 1948.A the time, the population and economic activity was concentrated in the downtown area, three million people, 3/4 of the whole, lived in the city center that had just about 80 km$^2$, 9.6% of the total area. The report found that the central city capacity was limited and it was necessary to search a method that can evacuate population, thus proposing to build satellite towns near the city center, which had great influence on the later development of Shanghai city. After the founding of new China, Shanghai government authorized Works Bureau was responsible for the city planning, some architects and

engineers returnees adopted the new urban planning theories like organic decen
planning in the draft of Shanghai master plan (Figure 6).

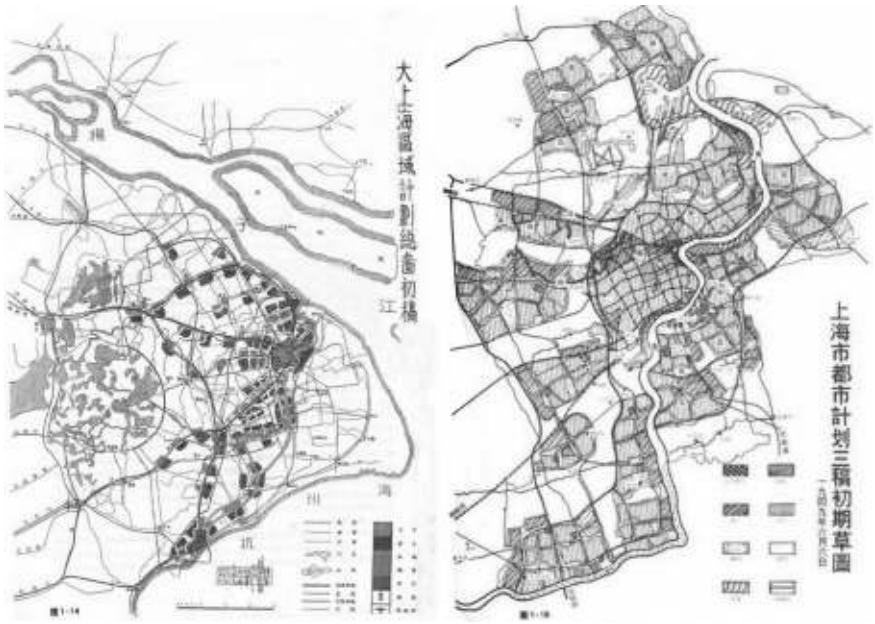

Figure 6. City Planning of Grand Shanghai, 1946~1949(Source: Shanghai Works Bureau)

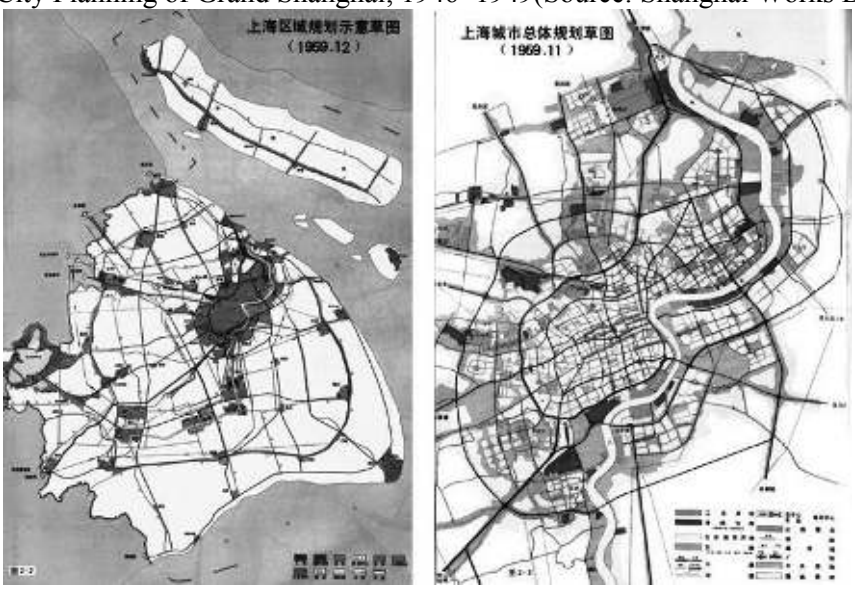

Figure7.Shanghai Master Plan, 1959 (Source: Shanghai Urban Planning and Design Research Institute)

Later, during the time when planned economy was dominated, Shanghai became a single-functional domestic productive center, gradually become China's important industrial base and financial support. In 1959, Shanghai Municipal Council invited the urban planning group of architectural engineering department to work on the Master Plan of Shanghai (Figure 7), which aimed to compress the old town, control the suburbs and develop satellite towns . After 1959, Shanghai st towns, by 1970s seven satellite towns were built, and in 1982, central Shanghai had 10 districts such as Huangpu, Luwan, and Hongkou, whose density was about 28000 hab / km$^2$.

In this period, Shanghai expanded around the inner city as a core, monocentric urban space layout was very obvious, but what cannot be ignored was that the ideas of decentralization was about to appear.

*3.2.2 In late 1980s and 1990s: Transferring from monocentric to polycentric structure*

After the Reform and Opening up, dominated by market economy, Shanghai s urban function had transferred to a multi-functional export-oriented economic center. In 1984, Shanghai Urban Planning Institute began to make a new master plan under the organization of the government (Figure 8). In this plan, urban system were divided into four levels: inner city, satellite towns, suburban towns and rural towns. In inner city, mixed functional districts were established to give people access to work, residence, recreation, social communication in their life. Each districts can be divided by green space, river, and railway but linked by convenient transportation. Then, the satellite towns integrity of urban function was stressed, which insisted that satellite towns should have its own leading industry and a well-developed environment for living and working. In addition, the suburban towns can be the political, economic and cultural center of the locality. Finally, the rural towns can be dispersedly distributed among satellite towns and the rural towns.

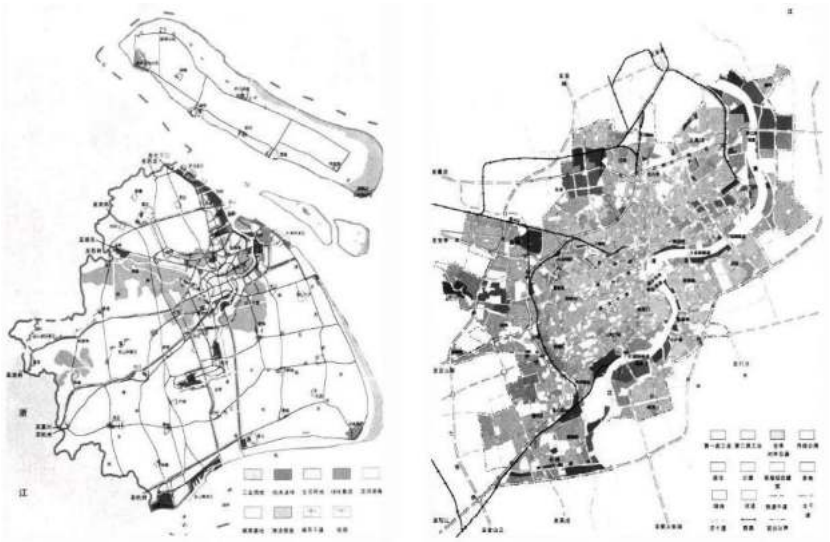

Figure 8. Shanghai Master Plan, 1984 (People's Government of Shanghai Municipality)

This plan strived to change the concentric spatial structure of Shanghai, to integrate the inner city, satellite towns, suburban towns and rural towns and to take the ideas of polycentric city with conglomerate structure as the important guideline for urban construction, thereby making Shanghai spatial structure gradually transfer from monocentric to polycentric type during this time.

*3.2.3 Since the new century: Approaching a polycentric and compact development mode*

In order to adapt to the development of Pudong area and the social and economic development of Shanghai, Shanghai Urban Planning Institute finished making the Master Plan of Shanghai (1999~2020) that was approved by the State Council in 2001(Figure 9). In the whole city level, a multi-axial, multi-level and multi-core urban spatial structure was fixed in this plan, and the urban system changed to inner city, new districts, key towns and common towns. And in the inner city level, the polycentric and open layout was adopted to shape the one center (Lujiazui and The Bund) and four sub enters (Xujiahui, Wujiaochang, Huamu and Zhenru) pattern. Besides, as satellite towns had gradually transferred to new towns that had larger scale and higher independence, urban spatial structure also was gradually developing towards polycentricism.

Shanghai continued to push forward the polycentric urban system in its "11th five-year plan (2006~2010)". A 1966 urban system was put on the table, namely a system comprised o

city, nine new cities, about 60 towns and about 600 villages, to take into full account the issues of population regulation, industrial development, infrastructure construction, resource utilization and environmental protection. The construction of the suburban towns was the key issue of this planning, which first clarified the specific number of them.

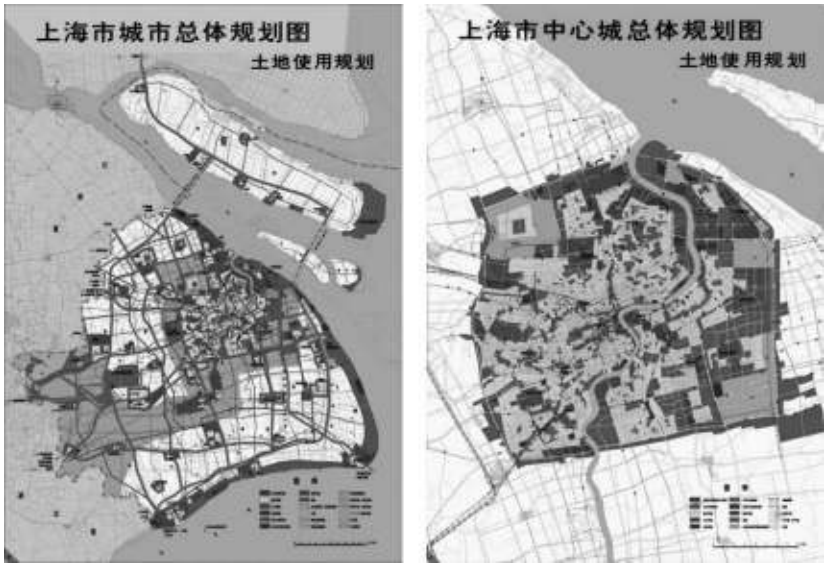

Figure 9. Shanghai Master Plan, 1999~2020 (Source: People's Government of Shanghai Municipality)

At present, government are preparing to make a new master plan for Shanghai 2040, they will take measures to strictly control the scale of the population and the land, for instance, decentralizing population from inner city and accelerating population aggregation in new cities and towns that are well developed, optimizing land use and prohibiting the growth of built area. The urban spatial structure still keeps polycentric and open and establish an intensive and compact network. As a result, Shanghai is approaching a polycentric urban structure with compact form.

### *3.3 Qualitative and quantitative analysis*

#### *3.3.1 Measurement of multicenter in Shanghai*

The measurement of multicenter can be carried out in two ways: form and function. Based on the geographical spatial distribution, morphological multicenter can be described by three elements: average population density of built area, vertical density gradient and daily travel mode (Bertaud, 2004). Functional multicenter emphasizes the information communication of company s ir organization, which generally appears in the urban areas with a high integration of economy. It is only when different urban functions are complementary and specialized that it works (Hall and Pain, 2006). Based on population and employment density, I chose the former way to find out the distribution pattern and evolution characteristics of residential center and employment center respectively.

On the aspect of residential population distribution, most is concentrated in the inner city with a little agglomeration in Minhang, Songjiang, Jiading, and Chuansha in the suburb in 1996. Before 2005, population soared in inner suburbs and was stable in the outer suburbs. But after 2005, the outer suburbs like Jiading, Baoshan, Qingpu and Songjiang also showed a sharp growth of population. Generally, the changes in the population indicated a trend that it decreased in inner city and increased in suburbs. Population density dropped sharply in the central area, and had a rapid growth in the inner suburbs and Jiading, Songjiang and Qingpu in outer suburbs, but inner city was still the main residential center (Figure 10).

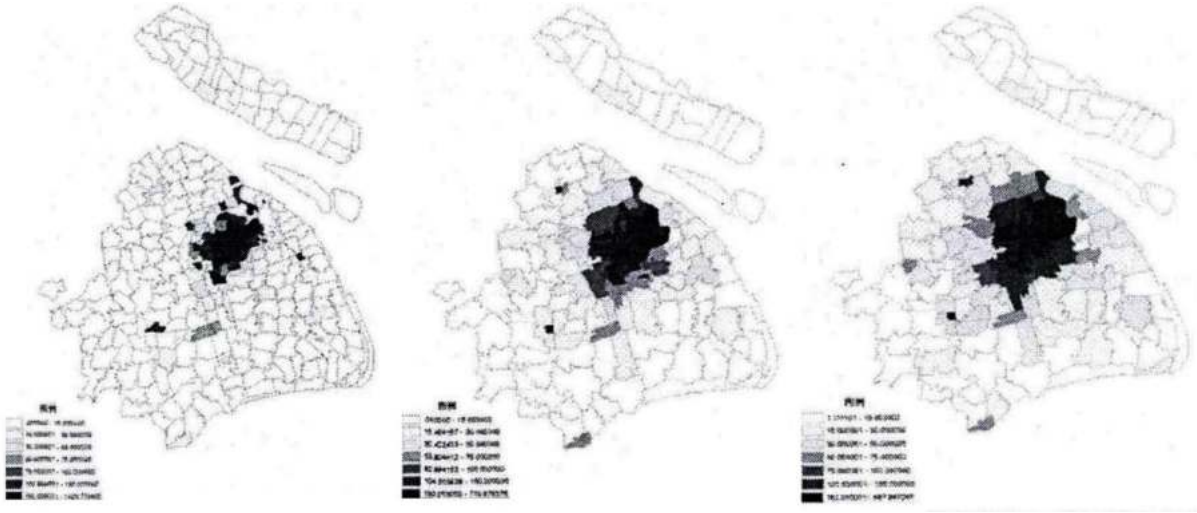

Figure 10. Variation of Residential Population Density in Shanghai 1996, 2005, 2010 (Source: Shanghai Bureau of Statistics)

If we further analyse the change of the employment population since 1996, we can find in different stages, the employment population increased in different ways. Before 2004, we saw the decrease in the core area of inner city and part peripheral area, also most of Chongming County. Meanwhile the employment population showed a trend of rising in suburbs, especially the inner suburbs. After 2004, the main declining area was still the inner city, but suburbs still kept increasing, with the key growth point transferring to some outer suburbs like Songjiang, Jinshan and Fengxian, approaching a trend of polycentricism (Figure 11). Here we found a big difference from residential population is that employment population spread along transportation lines while the residential population sprawled concentrically.

Figure 11. Variation of Employment Population Density in Shanghai 1996, 2004, 2008 (Source: Shanghai Bureau of Statistics)

*3.3.1 Measurement of compactness in Shanghai*

As developing countries have unlike backgrounds and characteristics of urban development, the content of compact city is different. Referring to the indicators of compact city put forward by OECD (2012) and combining with China's national conditions, this research proposed a compact degree

evaluation system from three dimensions: form, structure and efficiency (Figure 12). On the form aspect, it reflects the saving of urban scope, namely having reasonable population capacity and economic activities as much as possible in a limited area, and occupying less arable land and green space. Structure dimension mainly refers to the structure of roads and land use, which should match the growth of population and economy. Efficiency dimension is comprised of the accessibility of transportation, public facilities and infrastructure with efficient use and less energy consumption.

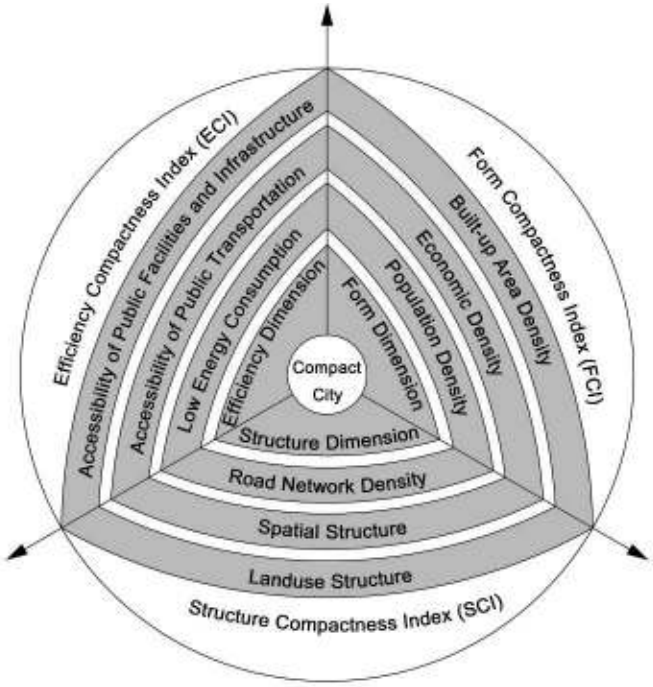

Figure 12. The Compact Degree Evaluation System from Three Dimensions (Source: Self-drawn)

*3.3.2 Measurement of compactness in Shanghai*

This study selected the whole Shanghai city as research object, including 16 districts and 1 county. After zero-mean normalization, data about these 17 zones can be used for factor analysis. Since there are 9 items in this evaluation system, so the scores of each item in each zones should be calculated. But now I only chose the 3 items in form dimension because of the limitation of data collection. Taking the covariance score as the weight of each factors to calculate comprehensive score of each zones, I got the form compactness degree score of these 17 zones after 0-1 normalization (Figure 13).

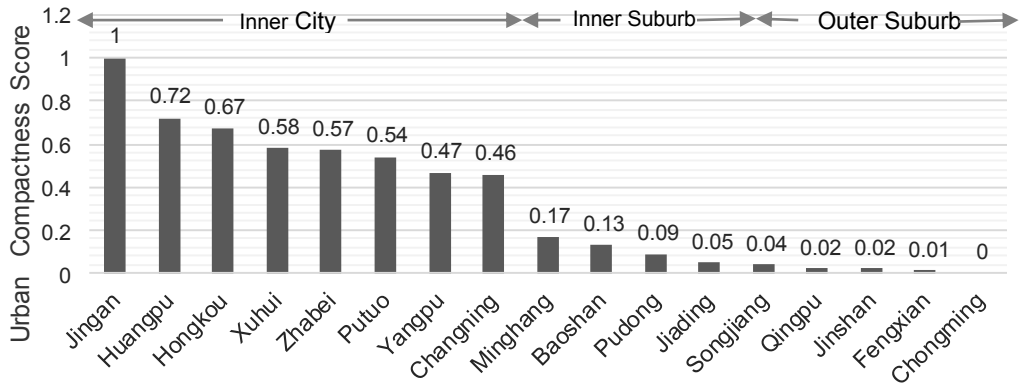

Figure 13. Urban Compactness Score (Source: Self-drawn based on Shanghai Statistical Yearbook)

## 4. Findings and Discussion

### *4.1 The advantages of polycentric compact urban structure*

The model above shows that the most significant advantage of polycentric compact development mode is that it can control urban sprawl efficiently. More precisely, the advantages of this integrated mode are as followings. First, from the perspective of resources consumption, compactness is beneficial to saving resources, including fuels, water, materials, products, manpower and time, it also reduces pollution at the same time. In one word, it saves individual and social cost of travel, which are the negative externalities of environmental pollution and traffic congestion. Second, it helps improve the quality of life. This compact polycentric structure can improve the convenience for social communication, enjoying services and making use of various facilities, which will make people inspire creativity and understand each other better, thus promoting social development and harmony. Third, it increases the density so as to improve the utilization efficiency of urban space. This kind of high density is a suitable high density that does not have negative impacts such as overcrowdings. Compact urban development will first develop the urban land that has not been fully developed and redevelop existing buildings or previously developed areas while subdividing, transferring, consolidating and expanding. Finally, polycentrism means networked, it will neither causes overloads of the inner city, nor creates excessive dispersion. Polycentric compact structure is a basic urban spatial form in information society. Linked by highway network and information network, cities will develop a regional constellation structure for specialization and cooperation (Figure 14).

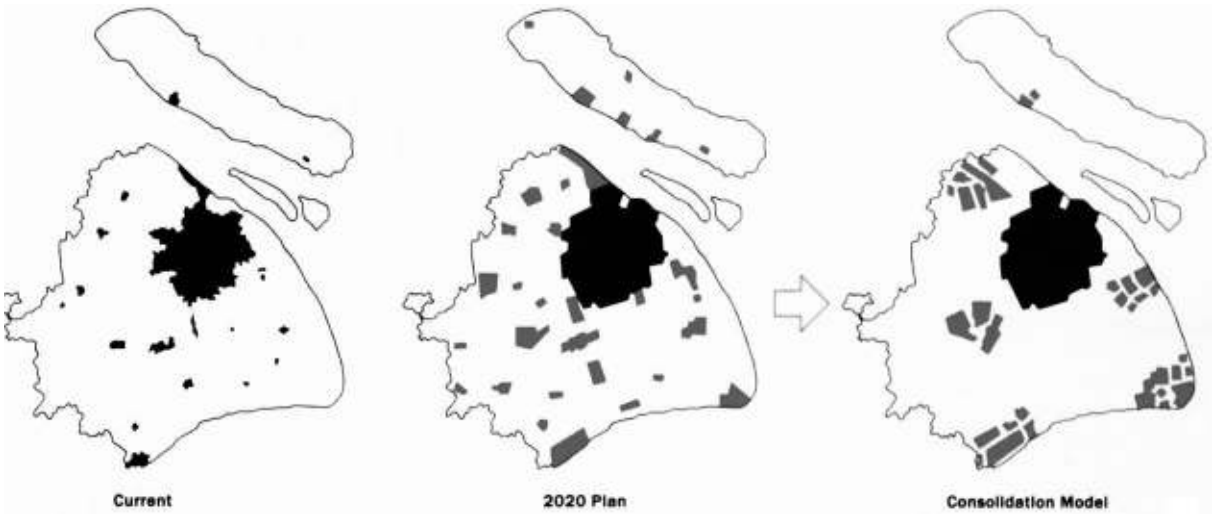

Figure 14. A Regional Constellation Structure (Source: Rem Koolhaas s proposal for future Shan in 2003)

### *4.2 The economic explanation and strategic drive of polycentric compact development mode*

Almost all cities started growing from the center of downtown. The centripetal force brought by agglomeration is the original power of urban development, the game between the centripetal and centrifugal force push on the development of urban system (Fujita, Krugman, and Venables, 2000). The process of urban extension is the result of the scale effect and agglomeration effect of the growth poles, the marginal revenue will increase with the growth of scale, but decline when scale reach to a certain size (Figure 15). When marginal cost equals the marginal revenue for second time (P3), it indicates that all the residents in the city gain the maximum net benefits, in other words, the whole city reaches the best scale with reasonable compactness. When the average cost is equal to the average

revenue for second time (P4), the urban scale reaches maximum. If the city continues growing, the increase of marginal cost caused by long commuting time and traffic congestion will exceed the marginal revenue produced by agglomeration effect, leading to that population and the economic elements will spread to the surrounding areas and develop a new growth pole. Gradually, the city will transfer to a polycentric structure.

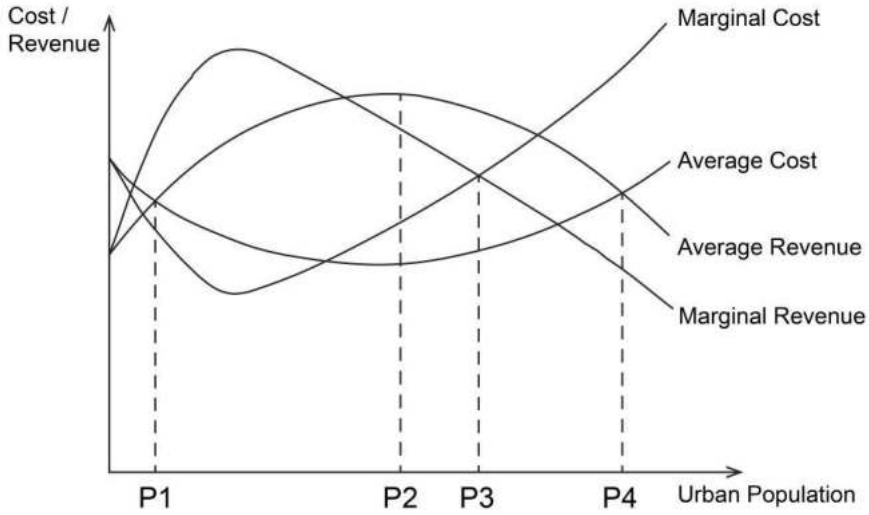

Figure 15. The Economic Explanation of Reasonable Urban Scale (Source: Urban Planning Forum)

On the other hand, the strategy of polycentric compact structure can make maximum urban comprehensive benefit, whose success depends on the effective correction of the external negative effects of the market from the government. In other words, the essence of this strategy is a game between the market and the government behaviour that regards the maximization of urban comprehensive benefit as the value orientation. From the past plans, we can see the intervention of government or even legislation is very essential. Therefore, the development of polycentric compact structure of Shanghai is not a product of the market economy, it needs governm involvement and organizations. As urban planning is a policy instrument to execute the will of the government, it should stand up in new town construction and play a positive role in pushing on the process of polycentric compact structure evolution.

*4.3 Evaluation on* Shanghai s development stage of approaching *the integrated mode*

Based on the spatial evolution of the residential and employment centers in Shanghai, some conclusions can be made. First, suburbanization process has begun in Shanghai, and the residential and employment centers are gradually developing in the suburbs. Second, in term of residential density or employment density, monocentric structure still exists, the polycentric structure is not well developed in the whole city, but as Songjiang and Jiading are becoming two powerful sub enters and several potential residential and employment centers also formed in outer suburbs, the monocentric structure is being broken. Finally, compared the connection between each districts and the inner city with the result of Europe POLYNET program (Hall and Pain, 2006), Shanghai is in a phase of the transition from monocentric to polycentric structure. Besides, with the improvement of road network and subway system, polycentricism is expected to be further improved.

In term of form compactness degree, it is relatively high in the inner city and the inner suburbs and outer suburbs is low, which is almost in line with the model. Specifically, Jingan District shows the highest form compactness degree, which is lowest in Chongming County. It also indicates that the

more the economy is developed, the higher is the intensiveness of the land use, conversely, the intensiveness of the land use is low in where the level of economic development is also low as the result of cheaper land price. Above all, the compactness degree in Shanghai still have space for improvement, especially the suburbs .

## 5. Conclusion

In this paper we have analysed the polycentric and compact development mode of Shanghai. This integrated mode also has been the hot pursuit of many metropolises and areas with limit resources. In this mode, polycentric and compact concept are embodied in both the whole city level and each districts, as it can save resources and promote land use efficiency because of high density, it is particularly well suited to Chinese national conditions for sustainable development under the background of stringent constraint of resources. For instance, restricted by the regulation, the built area of Shanghai cannot increase any more, this mode will become the inevitable choice of Shanghai, which also can give some reference to other metropolises in China.

There also exist some limitations in this paper. The paper used a method of generalization and induction when explaining the model, lacking quantitative detail. The concept model of polycentric and compact structure is abstract and it must be modified if used into practice and it is hard to find what proper high density is. The method of multicenter measurement just takes care of the morphological one, and the method of compactness measurement only gives a relative value from internal comparison, they still needs promotion. Other problems existing in this paper also need improved. In the future, more works can be done around the model this paper proposed, including seeking strong links between this mode and sustainable development, searching better ways to measure multicenter and compactness, and exploring how this integrated mode can provide reference for other cities in different conditions.

# URBAN ENTERPRISE ZONES AND THE BRUSSELS ZONE OF ECONOMIC EXPANSION IN THE CITY (ZEEC)

*Brussels' policy instruments and strategies for mixed-use development in a European context*

Sarah De Boeck, David Bassens, and Michael Ryckewaert

> *When dispassionately evaluated, the evidence suggests policy can in truth do relatively little to change the basic trajectory of underperforming urban areas, but misguided policies can have very bad unintended outcomes on all cities. In other words, governments have limited power to directly improve urban economies and a great deal of capacity to damage them.*
> *(Cheshire et al. 2014:6)*

## 1. Introduction

Urban enterprise zones (UEZs) are part of a toolbox of spatial policy instruments that are used worldwide to stimulate economic development and growth (*Briant et al. 2012, Givord et al. 2012, Green et al. 2001, Ham et al. 2012, IWEPS 2014, and Mayneris 2014)*. The Brussels Capital Region (BCR) will shortly introduce a UEZ along the canal Brussels-Charleroi, named Zone voor Economische Uitbouw in de Stad, or in English, Zone of Economic Expansion in the City (ZEUS-ZEEC). This zone will be used specifically to attract enterprises in deprived neighborhoods (BHG 2013, 2014a). The stimulation of job creation by attracting enterprises with fiscal benefits is used as a strategy to reduce unemployment. The ZEUS-ZEEC was approved by Ordonnance (BHG 2014a) in January 2014 but is not implemented yet, because the authorized Minister is awaiting an evaluation of several policy instruments for economic expansion, including the ZEUS-ZEEC (BHG 2008, 2015).

Researchers are mostly negative to moderately positive about UEZs because they do not reduce unemployment as they are supposed to do, because land prices rise in that particular zone, etc. (Givord et al. 2012, Green et al. 2001, Mayneris 2014, and Rousseau 2010). The underlying question is whether UEZs reduce or reproduce inequality? An analysis of international cases shows us that the *Zone Franche Urbaine* (ZFU) – the French variant of UEZs– of Roubaix, Lille, is an exception and is seen in its beginning period as very successful by researchers (Colomb 2007, Green et al. 2001).

How can we understand the success of Roubaix? Can we trace policy elements that have contributed to Roubaix' success that are transferable to other contexts? Can the BCR learn from the ZFU Roubaix to enhance the ZEEC' succeeding, so that the UEZ can rather reduce inequality instead of reproducing it?

In the first part of this paper we try to qualify territorial policy instruments in a broader political-economic context. Based on the social- and economic geographical insights about uneven development we place these policy instruments within the historical transition from Fordism to post-Fordism (Brenner 2004, Harvey 1989, and Swyngedouw 1997, 2002). We also look at how this transition is reflected in spatial policy instruments (Graham 2010).

In the second part of the paper we zoom in on the case of the ZFU Roubaix and compare it to the ZEEC. We describe the French and Brussels variants of UEZs, we make an inventory of the effects of these spatial policy instruments, as well as of the arguments used to explain the success of the ZFU Roubaix.

Every listed effect and argument related to the ZFU Roubaix will be compared to the ZEEC in Brussels. We make use of policy documents, reports and literature about the functioning and effects of UEZs.

## 2. Territorial policy instruments in a broader political-economic perspective

### 2.1. Rescaling and fragmentation

Until the 1980s, other strategies were used than those we know today by European governments to conquer uneven development on their national soils. The concept of *spatial Keynesianism* describes a body of spatial policy instruments and strategies used on a national scale to influence the geography of capital investments (Brenner 2004, Harvey 1989). These planning strategies can we see as a way to spreading, managing and softening the inequality within the national boundaries.

Brenner (2004) describes a transition of policy making at the national level to policy making at smaller scales (local and regional level) starting in the second half of the 1970s. He depicts this transition as the emergence of *new state spaces* as a result of the use of *urban locational policies* which causes new patterns of geographical uneven development. Policy shifts from a redistributive agenda towards a growth oriented agenda and the enhancement of territorial competitiveness. This fragmentation of policy spaces happened in a context of heavy deindustrialization causing an immense structural unemployment on the one hand, and a weakening of the fiscal revenues of cities by a continuous suburbanization on the other hand (Harvey 1989; Fainstein 1991). We can link these processes of rescaling also to a parallel transition in governmentality, namely of a controlled economy (Fordism, Keynesianism) to a rather *reregulated economy* (post-Fordism) and see a growing importance of the local scale against the backdrop of globalization known as *glocalization* (Brenner 1999, Peck et al. 2002, Swyngedouw 1997). *Urban locational policies* are seen by Brenner (2004) as an attempt to answer to the heavy deindustrialization and the unification of the European market. They are place- and scale-specific regulatory interventions, used to regulate urban development, and include *state spatial projects* and *state special strategies*.

Graham (2000) observes a parallel shift in the realm of urban planning, which he describes as a *splintering* of urban planning. Policy spaces, who before were experienced as coherent and comprehensive spaces, become divided in whether or not contiguous fragments since the 1980s. Examples are cultural, heritage and sporting zones, business improvement districts, enterprise zones, technology zones, shopping malls etc.

We situate UEZs, like the ZEEC and the ZFU Roubaix, within this broader political-economic perspective of rescaling and identify them as forms of a splintered urban planning.

### 2.2. Competition and rivalry

After the 1980s, governments change their strategies to answer to the deindustrialized economy by trying to enhance the supranational competitiveness of their strategic cities and city regions.

Where site- and scale specific interventions were previously oriented on intranational and intraregional redistribution, they are more and more oriented to the strategic positioning of major cities in a broader global and European history (Brenner 2004). To attract investments, local authorities try to put themselves in the spotlight by taking a series of initiatives to revitalize local economies. Where once by

national borders the intercity and interregional competition could be somewhat buffered, this competition just fanned by the unification of the European economic market. This means that cities and regions, more than before, become each other's competitors in attracting investment capital, companies and funds. The fragmentation and competition also takes place on smaller scales, namely –such as Graham (2000) cites above – in terms of zoning within one region or even within one city.

### 2.3. Metropolitan regions

Starting from the 1990s, we see that local authorities try to organize themselves again on a larger scale in the form of metropolitan regions. These are mainly European regions that are already embedded in or connected with European and global circuits of capital and transport networks (Brenner 2004). The parties assume that removing or mitigating the competition within the region, makes them more competitive on a supraregional scale. The ZFU Roubaix works within a metropolitan spatial planning framework – Colomb (2007) speaks of a *metropolitan consensus* – where one has managed within the Lille region to weaken the internal competition between the municipalities.

Some metropolitan regions manage to weaken competition within the region and to achieve a form of territorial cohesion. Below we'll see that implementing a ZFU within a *metropolitan consensus* operation indeed may partly explain the success of the ZFU Roubaix (Colomb 2007). In some cases, UEZs within metropolitan regions, can thus be seen as a tool to combat social and spatial polarization within a region. Today, the BHG is not operating within a metropolitan spatial planning framework. However, it is important to mention the competition-weakening operation within metropolitan regions. The competition arising from the relocation of jobs and businesses to a UEZ, is accepted to some extent because local governments are cooperating. The *affected* areas within the region can then rely on accompanying measures such as investment in urban renewal, building a network of public transport with extra stops, etc. (Colomb 2007).

Areas outside the metropolitan region are less fortunate. Brenner (2004) describes the formation of metropolitan regions as a particularly aggressive form of rescaling. While they weaken the interregional competition, the metropolitan levels increase instability on interregional scale. This is partly because inequality is going to (re)organize according to principles of connectivity and disconnectivity. Who is not or less well connected and thus has difficult access to services, training, work etc. starts from a weaker position to connect to society.

## 3. Comparative case study between the ZFU Roubaix and the ZEEC of Brussels

Since many years, both the BCR and the region of Lille are confronted with the challenge to deal with a vast and structural unemployment. The ZFU Roubaix is considered as a pretty successful territorial policy tool to address unemployment (Colomb 2007, Green et al. 2001). The numbers used to legitimate this success are among others an increase of 5.000 jobs between 1997 and 2001 in the ZFU (60% business transfers and 40% new businesses), primarily in the service sector and in construction. Hereof, a little more than 20% or approximately 400 jobs went to local inhabitants[1]. In *table 1* we give an

[1] Despite this success, one speaks of *the paradox of Roubaix* (Colomb 2007). This paradox is similar to the paradox of the BCR, namely a parallel presence of a big amount of jobs and a vast unemployment.

overview of the important characteristics of the ZFU Roubaix and the ZEEC. Subsequently, we discuss the effects of UEZs and the arguments that are used to explain the success of the ZFU Roubaix.

**Table 1 – Overview of the important characteristics of the ZFU Roubaix and the ZEEC Brussels.**

| | **Zone Franche Urbaine Roubaix, France** | **Zone of Economic Development of the City, Brussels** |
|---|---|---|
| **Objective** | Job creation for residents of the zone.<br>Attracting economic activity as leverage of city renewal. | Job creation for residents of the zone.<br>Attracting economic activity as leverage of city renewal. |
| **Actors** | The central government allots zones based on criteria of 'deprivation' and a system of auction. | The Brussels regional government allots zones based of criteria of 'deprivation'.<br>Authority of the regional administration Brussels Economy & Employment[2] (BEE). |
| **Zoning allocation criteria** | 5 criteria:<br>> 10.000 residents.<br>Unemployment of 25% lower than the national average.<br>The share of youngsters <25 years is higher than 36%.<br>The share of youngsters >15 years without qualifications is higher than the national average of 29%.<br>A local tax potential lower than 3.800FF per resident. | 3 criteria, of which the average has to be lower than the average of the BCR:<br>Unemployment.<br>The share of unemployed people with the profile of worker.<br>Income per tax return. |
| **Location** | 1 of the 44 'Quartiers en difficultés' spread over France, and part of the metropolitan region of Euralille.<br>Roubaix is the only ZFU that is located in the city center. | 1 Zone of 'deprivation', located on both banks of the canal Brussels-Charleroi, from Vorst to just past the site of Tour & Taxi (*see figure 1 & 2 below*). |
| **Size** | 525ha.[3] | Estimation between 550ha and 650ha.[4] |
| **Which companies are eligible to be chosen?** | Small companies of max. 5 employees. | Micro, small, medium and large companies with a place of business in the zone.<br>A minimum of 3 employees.<br>No account is taken of the amount of jobs per m². |

[2] The Brussels regional administration in Dutch: Brussel Economie & Werkgelegenheid.
[3] The average surface of a French ZFU is 189ha. Only 4 ZFUs are bigger than 300ha, among which the ZFU Roubaix (Green ea. 2001:58). This shows that also the Brussels ZEEC has a big size in comparison with the average French ZFU.
[4] For now, we haven't found any numbers of the exact size of the ZEEC, so we made an estimation to be able to compare the size of the ZEEC with the ZFU Roubaix. The canal area of the BCR covers 9,2% of the territory and has a surface of 161,4km² (ATO-ADT 2013). The ZEEC is a little bit smaller than half of the canal area. Therefore, we estimate the ZEEC covers 4% of the surface of the BCR.

| | | |
|---|---|---|
| | No account is taken of the amount of jobs per m². | |
| **Company benefits** | Most important benefits:<br>Exemption of municipality tax for 5 years.<br>Exemption of surface tax for 5 years.<br>Partial exemption of employee tax (social security, work accident insurance) for 5 years. | Benefits:<br>Partial takeover by the government of the annual salary and social contribution of staff who live in the zone: 30% in year 1, 15% in year 2.<br>Partial exemption of surface tax: unlimited in time as long as the criteria and constraints are respected. |
| **Conditions for companies to get involved?** | 20% local recruitment. | 30% local recruitment of residents living at least 6 months at the moment of recruitment. |

### 3.1. How do urban enterprise zones work?

Below, we give an overview of the effects of urban enterprise zones. The size of this paper keeps us from giving a complete overview. The high costs per job created[5], processes of gentrification (Rousseau 2010), and short-term effects (Green et al. 2001, Mayneris 2014) will not be addressed for now.

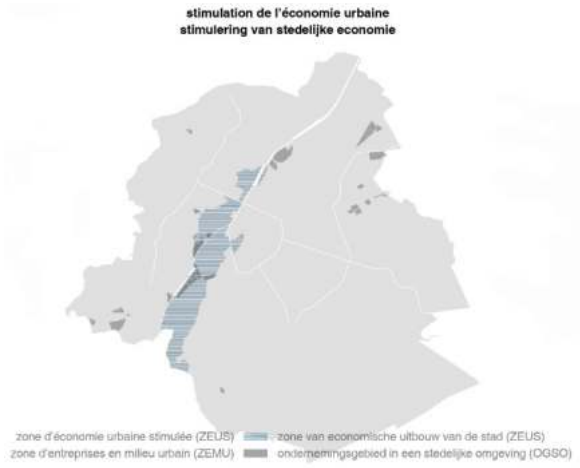
**Rising land prices who price away businesses:** Green et al. (2001) notifies the increase of price of buildings and available parcels within the ZFU Roubaix. He warns that this markup can have a negative effect on the attraction of new enterprises. Not only new enterprises might no longer be attracted by rising land prices, but also the existing companies can be priced away through mixed-use development (Wolf-Powers 2005), with a risk of relocation or even disappearance of jobs. Real estate agents probably will start speculating to maximize the benefits of their properties (Smith 1987, Swyngedouw 2002). Companies in for example the construction sector – one of the growing sectors in the ZFU Roubaix – pay lower rent and land fees than offices or lofts. Rousseau (2010) counts at the end of 2009 400 lofts in Roubaix and describes the rise of forthcoming loft development since a change of the political majority who's policy switched from countering inequality to maximizing benefits by closing the rent gap;

We can describe this as competition on a micro level, namely on the scale of a parcel. With the splintering of space by private property we see mechanisms of competition arise who are placed in time, namely between the actual and the future use of the parcel. The pricing away of functions who are less profitable is described in literature as *speculation*, *closing the rent gap* and *property-led development* (Smith 1987, Swyngedouw et al. 2003, Wolf-Powers 2005). We wonder whether this mechanism happens systematically in UEZs or even, whether it is inherent in their functioning. If so, we have to ask ourselves to what extent it is desirable? If one wants to preserve the companies within the zone then the government should take accompanying and support measures to keep the land prices for economic activities under control (Wolf-Powers 2005).

[5] Green et al (2001) counts more or less 27.000 US Dollar per job created.

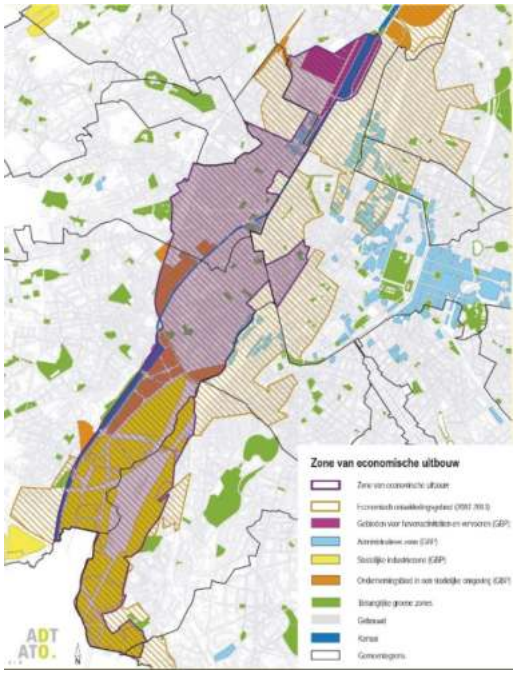
Mechanisms of speculation are already taking place at some parts of the future ZEEC along the canal Brussels-Charleroi, especially in those parts where the BCR changed zoning plans from monofunctional development to mixed-use development by adding a residential function to the existing industrial function. These areas are called *Ondernemingsgebied voor Stedelijke Ontwikkeling* (OGSO) or *Enterprise Area for City Development* (EACD). Private developers and investors, like for example Atenor in the EACD Biestebroek area in Anderlecht, are buying land and clearly prefer residential and other profitable development over industrial development. That means that the amount of affordable land for industrial development is already shrinking and that land prices in some parts of the future ZEEC become too expensive for industrial activities. Here we see that the policy of the EACDs is conflicting with the policy of the ZEEC: the upzoning to mixed-use development actually increases speculation and prevents the ZEEC to achieve its objective of attracting enterprises that create jobs for low-skilled people because of the disappearance of affordable land.

**Fig. 1 – Location of the Brussels Zone of Economic Expansion (ZEEC)**



*Source: GPDO 2014 – map 6 Economic Development*

**Fig. 2 – Zoom on the Zone of Economic Expansion (ZEEC)**



*Source: GPDO 2014:91*

**Effects of displacement**: Research of Mayneris (2014) shows that when we see a growth of the establishment of companies and an increase of the amount of local jobs, effects of displacement are involved. Effects of displacement or business transfers can be qualified as mechanisms of competition on a local scale whereby the periphery of the zone is forced to compete with the zone itself. During the first 3 years of the ZFU Roubaix, between 1997 and 1999, already 40% of the companies in the zone were transfers and came from another area within the metropolitan region of Lille (Green et al. 2001). Colomb (2007) mentions that only 2 years later, in 2001, already 60% of the companies in the zone were transfers.

Where Mayneris (2014) describes business transfers as a negative effect, Colomb (2007) writes how in the ZFU Roubaix those transfers were part of a deliberate strategy to attract decentralized enterprises to

the city center of Roubaix. This is confirmed by Green et al. (2001). Colomb therefore concludes that an urban enterprise zone is a suitable policy tool to strengthen polycentric cores and to counteract the suburbanization of enterprises.

In the Brussels ZEEC it is likely that a significant proportion of companies will come from the surrounding areas of the zone. These already existing but relocated companies will probably not create new jobs, but will merely be attracted by the fiscal and other benefits. Our hypothesis is that competition will take place between the company locations in and around the zone. Important for the BCR is to consider whether it is desirable to instigate such a mechanism of competition in the surrounding area of the ZEEC.

**Few or no benefits for local residents:** Green et al. (2001) notifies a significant increase of companies in the ZFU Roubaix. Data between 1997 and 1999 show an increase of 544 companies. Unfortunately, there are no numbers available about the permanency of the created jobs. Mayneris (2014) disputes the permanency of jobs. He concludes for all French ZFUs that residents of the enterprise zone might come out of unemployment a little bit faster than non-residents of the zone, but only to a small degree and only for a short time. Further research is needed to determine the permanency of the jobs and the settlement of enterprises, because also Green et al. (2001) can't find any positive long-term effects for the whole of all the French ZFUs.

Following these conclusions, this might imply for the Brussels ZEUS that the jobs created for local residents could not be permanent, but will only be there for the duration of the fiscal and other benefits.

Nevertheless, it's difficult to trace demographic data that can bring possible long-term success to the surface, because local residents climbing on the social ladder tend to move out of the neighborhood (Mayneris 2014). We haven't found any research until now[6] that took data from out of the urban enterprise zone into consideration. Especially in neighborhoods that function as an *arrival city*, there is a strong correlation between social and residential mobility (Oosterlynck et al. 2012, Saunders 2011). In *arrival city neighborhoods* the data about unemployment, income etc. often stay the same or even become worse. This makes people often think that no effort is worth its cause, because it seems that nothing is changing. Saunders' (2011) identifies this way of looking as a static way of looking at those places. His research shows that if we continue to look at those neighborhoods only as static spaces of miserable living conditions, we miss a big deal of what is really going on. He introduces a dynamic perspective demonstrating a continuous passage of people coming and going. Migrants moving in, climbing on the social ladder, and moving out of the neighborhood. In some cases we could say that the people moving out are taking their success with them.

Linking social to residential mobility has big implications for measuring the success of this policy tool in neighborhoods that function as an arrival city, which is the case for large parts of the Brussels ZEEC. We estimate that few or no changes will be detected in the social-economic living circumstances of its local residents, as long as the residential mobility is not taken into account. Further research could clarify if and to what extent UEZs function as social mobility machines in arrival city neighborhoods.

[6] We continue to look for it.

**Mainly small and mobile companies:** Mainly small and mobile companies are attracted by the fiscal benefits of UEZs (Givord et al. 2012, Green et al. 2001, IWEPS 2014, Mayneris 2014). This is also the case with the ZFU Roubaix (Green et al. 2001). The question is whether these small companies – in France there is a limit of 5 employees – are able to solve any structural unemployment of an area?

In the Brussels ZEEC there is no such limit and all enterprises with a minimum of 3 employees can make use of the benefits. Nonetheless, if we examine the degree of participation of enterprises of the existing policy[7] of economic expansion in the BCR, we see that micro enterprises[8] are represented the most. Their degree of participation balances between 57% and 74% depending on the type of subsidies to be granted, for the year 2013 (BHG 2014c). This might indicate that also with the ZEEC, which is seen as a measure of economic expansion, especially micro enterprises will make use of the support measure. We wonder if and to what extent micro enterprises are really able to create enough volume of new jobs to help conquering the vast and structural unemployment of residents within the ZEEC? Beside it, there is a considerable risk that a significant part of the companies will move out of the ZEEC from the moment the support measures end.

### 3.2. Circumstances that enhance the succeeding of a UEZ

Some researchers pinpoint the ZFU Roubaix as a successful exception (Green et al. 2001, Colomb 2007). Therefore, we will pay extra attention to the circumstances that are used by the researchers as arguments to explain this success. We also try to put these circumstances within a broader political-economic perspective.

**Metropolitan consensus or collaboration on a bigger scale, a strong leader:** Under the impulse of Pierre Mauroy[9] the four municipalities of the Euralille region – Lille, Roubaix, Tourcoing and Villeneuve d'Asq – came to a *metropolitan consensus*. This consensus, the making of which was a process of 25 years (!), made it possible to implement the ZFU Roubaix (Colomb 2007). The municipalities started working together on a bigger scale. Together, they made a strategic plan about what spatial interventions were needed in what zone of the region with the objective of transforming the deindustrialized economy. According to Colomb (2007), this collaboration through consensus on a metropolitan scale plays a crucial role in the improvement of the social-economic circumstances of the residents of Roubaix. Brenner (2004) describes how the social-economic circumstances of an area can improve by weakening the mechanisms of competition between local governments. In that sense, the collaboration of a metropolitan region is indeed a way to counteract inequality in certain areas.

In the BCR there is no such collaboration on a metropolitan scale and we do only detect some informal collaboration on an interregional scale. This means that inevitable mechanisms of competition will play on different levels the day the ZEEC is implemented. On a local level there will be competition within the municipalities themselves (the ZEEC never overlaps totally with one municipality). There will also

[7] The support measures of economic expansion exist in many ways: subsidies for research by research bureaus, subsidies for travel to international trade fairs, investment subsidies etc.
[8] A micro enterprise in the BCR is a company with less than 10 employees.
[9] Some elements of the biography of Pierre Mauroy (1928-2013) which shows his knowledge of and his access to the highest political networks and administrative functioning on different government levels in France: Prime Minister of France from 1981 until 1984, Mayor of Lille from 1973 to 2001, President of Lille Métropole Communauté Urbaine (LMCU) from 1989 until 2008 (Wikipedia 2015).

be competition between the Brussels municipalities on a regional level, and an interregional competition will arise with the municipalities on the border with Flanders.

**Degree of physical isolation:** Briant et al. (2012) writes that the success of French ZFUs depend on the degree of their physical isolation. He defines the degree of isolation as the connection of the zone to principal lines of public transport, the centrality of the zone (proximity to services for example, and the presence of urban ruptures who make it impossible for commuters to go to work. This is confirmed by Green et al. (2001) and Mayneris (2014), who add an extra dimension, namely the availability of land. If the needed competences for the job profiles are not present with the local residents, managers need to be secured that they will able to attract commuters with the needed profile.

The ZFU Roubaix is the only French UEZ of the first round (1996) that covers a city center. Green et al. (2001) sees this central position of the zone as an explanation of its success. In the city center of Roubaix we can find all kinds of public services and it was already well connected to public transport in the 1990s.

In the ZEEC we find areas that are well connected and areas that are not well connected to public transport. There is no public transport along the canal. Neighborhoods like Kuregem and Birmingham are very accessible. Main thoroughfares, like for example Sainctelette, might function as barriers. As we have seen in the chapter about *Rising land prices who prize away companies* speculation on land is already going on in some parts of the ZEEC, especially in the EACD mixed-use development zones. Further research is needed to make an inventory of available and affordable land and buildings for companies. Further research is also needed about how the different parts of the ZEEC will function according to their degree of accessibility/isolation and the proximity of the city center.

**Comprehensive approach combining different policy tools:** The ZFU Roubaix is part of a comprehensive approach of the city center of Roubaix, combining urban renewal and spatial interventions with a whole package of measures to improve the social-economic circumstances of the local inhabitants (Colomb 2007). Colomb describes how economic development and investments are linked to training, integration and insertion programs for unemployed people. This policy of insertion obliges projects funded by public money to recruit jobs for local residents. This rule is explicitly stipulated in the open tendering procedures of construction projects financed by public investments. Training programs focus on skills of reception and communication, because these competences were not present with the local residents after a long career of factory work. Also Green et al. (2001) and Mayneris (2014) point to the importance of combining spatial interventions with training programs to align the supply and demand of competences.

The researchers mentioned above, all point to the enormous importance of a comprehensive approach where training, integration and insertion programs are combined with spatial policy measures. This implies for Brussels that the succeeding of the ZEUS can be enhanced, if the fiscal and other benefits for companies are combined with training, integration and insertion programs.

**Awareness of cultural/discriminating barriers:** The municipality of Roubaix was aware of the fact that CEOs are not always fond of recruiting local residents. CEOs were not only concerned about the lack of competences in the area, but also had a cultural reserve (Colomb 2007). A special team of the municipality negotiated with companies to recruit local residents in exchange for public investment

(Colomb 2007). Next to this special team, the municipality has put other means into operation to stimulate the recruitment of local residents such as available land, management agreements, surveillance, cleaning services etc.

Following the actual debate in Belgium about the recruitment of immigrants or people from neighborhoods 'to avoid', such as 1080 Sint-Jans-Molenbeek, we see that also in the Brussels ZEEC cultural and discriminating barriers will play a role in the attraction of new companies. A lot of persuasion, consisting of extra support measures next to the benefits of the ZEEC, is needed to convince companies to recruit locally. On the one hand, we can ask ourselves whether the BCR is willing and able to go so far as to – what Colomb (2007) calls – a win-win arrangement for companies and the government? On the other hand, we can also question whether extra costs must be added next to the already high costs per job created in an UEZ?

**Located in a European Zone of Development:** Research about the functioning of UEZs in Wallonia (IWEPS 2014) can't find any significant results of improvement of the unemployment rates between 2006 and 2011. UEZs who are located in a Zone of Development, give slightly better results than UEZs not located in a development zone. The IWEPS report (2014) tries to make a difference between new companies who made use of the benefits of UEZs and companies who made use of the support measures of the development zone. The use of support of the development zone was significantly higher and the report states a positive effect of this policy, where it doesn't find any positive impact of the measures of the UEZs. Following these results, the report questions whether the benefits of UEZs are large enough to be really interesting for companies. This is a question about the costs that governments are willing to pay to attract companies to their territories. We also wonder if a territorial approach is well suited here. How do the budgets invested per job created relate to the budgets invested in policies of empowerment (for example training programs)? Fact is, that the ZEEC will overlap with the Development Zone 2014-2019 [10] which will be implemented in the BCR via the European Commission and the Federal Government. This means that, almost certainly, we can expect some positive results on a short term because the subsidies of the Development Zone will reinforce the functioning of the ZEEC.

## 4. Conclusion

Using the theoretical framework of Brenner (1999, 2004) about *new state spaces*, and the concept of *splintered urban planning* of Graham (2000), we start from the hypothesis that UEZs are part of a *post-Fordist-Keynesian* policy tool box that apprehends space as a collection of fragmented pieces of land whereby each piece of land has its specific problems, challenges and needs, and where we see a policy shift from a redistributive agenda towards a more growth-oriented agenda. We recognize this movement not only in the planning instrumentation in Brussels but also in other regions of Europe, including the *Zone Franche Urbaine* (ZFU) of Roubaix, Lille. Together with other comparable conditions between the two regions like a history of labor migration, labor market changes, deindustrialization etc. the introduction of a logic of growth in the planning instruments, makes the ZFU Roubaix an interesting case for a comparative analysis with Brussels. Next to the recognition of growth-oriented agendas of deprived areas as well in Brussels as in Lille, we would like to understand the possible socio-spatial consequences of this policy shift and thus see whether UEZs rather reduce or reproduce inequality. The *Zone of Economic Expansion of the City* (ZEEC) of Brussels is a special case, because it is not operative

[10] The European Structural Fund EFRO-FEDER.

yet. In that way, this research tries to grasp the functioning of UEZs who are used by governments of deindustrialized cities and regions desperately looking for solutions to deal with structural unemployment. Thereby, we use the Brussels ZEEC as a test case.

Where growth is stimulated, processes of competition are unavoidable – in the case of UEZs as well on a local (intermunicipality) as on a regional (between municipalities) scale (Green et al. 2001, Colomb 2007, Mayneris 2014). An UEZ is thereby understood as a solution to conquer structural unemployment by making that zone grow through the attraction of enterprises, often to the cost of other zones through transfers of enterprises (Mayneris 2014). Looking at the costs that governments are willing to pay to attract these enterprises, the creation of jobs for low-skilled people can be conceived as a happy byproduct.

In our research to understand how UEZs work, we are not convinced whether they are able to reduce inequality, since they generate also perverse effects that function as hindrances to attain the objective of job creation for low-skilled people like mechanisms of speculation (Rousseau 2010, Wolf-Powers 2005), effects of displacement (Green et al. 2001, Colomb 2007, Mayneris 2014), only short-term effects because of the attraction of small and mobile companies (Givord et al. 2012, Green et al. 2001, IWEPS 2014, Mayneris 2014), and few or no benefits for local residents (Green et al. 2001, Mayneris 2014).

We see that in some cases, like in Roubaix, an UEZ creates local jobs, but under very specific circumstances. An UEZ doesn't work as a policy format, nor as a miraculous solution, that can be implemented by governments in any part of their cities to conquer unemployment. Research from a manifold of perspectives shows that an UEZ cannot function as an isolated policy measure, but it needs to be part of a comprehensive approach. Although this call for combining *soft* measures, like training programs, with a spatial policy measure like an UEZ, we can still question the fact whether we have to use policy measures to adjust habitants to specific needs of enterprises in a zone instead of doing it the way around and adjust the space around habitants to fulfill their needs and longings (Berardi 2011).

We would like to end this paper with a reflection on what happens if we look at the UEZ in Brussels from a more Keynesian perspective? Can we understand it as an attempt to soften the inequality, which was strengthened by former and current urban developments in areas such as the North Station or the European Quarters? Investing in the Brussels Canal Zone, which is situated in the west, could be interpreted then, as a way to restore a certain balance of government investment and policy between the richer south-east and the poorer west part of Brussels. The development of a growth pole along the Canal Zone, of which the implementation of an UEZ can be seen as a symptom, can be interpreted as a strategy to deal with inequality. Following this Keynesian perspective, space is indeed seen as a more coherent whole, but the mechanisms of dealing with inequality are fundamentally different from those of thirty years ago. We think that the territorial approach of the UEZ zoning policy stays manifestly fragmented, in the sense that the Brussels region wants to solve problems of inequality *in situ* and doesn't acknowledge that the origin of problems lay partly elsewhere (1) and that the region is not able to change its administrative/fiscal borders (2). Two examples to clarify this: (1) The increasing socio-spatial inequalities of Brussels with a big concentration of poverty and structural unemployment in the Brussels Canal Zone is not only caused in and through the Canal Zone itself. Although this is not the case, this view is implied by the policy instrument of the UEZ used as a way to resolve an unemployment problem within limited borders. The socio-spatial inequalities are the result of historical processes of labor market restructuring, and office and housing market dynamics at the scale of the Brussels region (Van

Criekingen 2012), combined with a discrepancy between the political delimitation of the Brussels Region (a member state of the federal state of Belgium) and the geographical urban region, and the administrative fragmentation of the Brussels Capital Region (Kesteloot et al. 2002). A more even spreading of affordable housing (social housing as well as rental housing on the private market) throughout the region would for example stop to push poorer people towards the Canal Zone. (2) This discrepancy and administrative fragmentation brings us to the second example which shows us that the Brussels region is bound by fiscal restraints. Although the economic flourishing of the Brussels region has positive agglomeration effects which do not respect the regional borders, these benefits are not reflected in a fiscal solidarity between the region and its periphery. The suburbanized municipalities around Brussels receive the agglomeration benefits through the Belgian fiscal system which makes commuters pay taxes in their home towns and not in their working towns. This leaves the Brussels region – and especially the west part – in continuous financial problems that forces the regional and local governments to continue to look for partial (and thus, splintered) solutions.

# Interconnecting Urban Planning with Multi-Scale Urban Quality: Review of Macro Scale Urban Redevelopment Project on Micro Scale Urban Quality in Shenzhen

Xiaofan Deng

Delft University of Technology, the Netherlands, dengxiaofan@gmail.com

## Abstract:

*The Shenzhen planning system has been effective in promoting economic growth through the prodigious urbanization of land. It has given priority to the macro-level pla growth through physical development. Questions can be raised about the physical and social outcomes from the development process at the micro-level , not least in the l physical environment at the micro scale and the creation of a place identity (Chen, 2010; Hang, 2006; Wu, 2012). This paper examines these questions in the redevelopment of the metropolitan area, drawing a case study of the Sungang-Qingshuihe (SQ) district in Shenzhen. We have established criteria for evaluation of the planning and implementation of redevelopment, with reference to both macro-level economic goals and micro-level urban spatial quality objectives. We exp approach taken and the reasons, outline its strengths and weaknesses in relation to the criteria, and define the apparent limitations.*

*The findings point to critical features of planning and development practice in Shenzhen which make a significant contribution to the creation (or destruction) of micro-level spatial quality and place identity, including the lack of an independent quality control authority and the close processes of decision-making. This paper concludes by examining the problems of transferring practice from elsewhere and challenges the priority given to national economic growth over the local public interest . It recommends strengthening the role of coordinator, to balar and micro-level objectives, to expose the interests of all affected parties.*

Keywords: Urban redevelopment, Local Quality, Planning Tool

## 1. Introduction

Urban development and planning of cities in China has made a fundamental contribution to meeting national economic and social policy goals at the macro-level and with signific urbanization rate in China reached 53.73% in 2013, achieving the fastest urban growth worldwide (UN, 2014; UN Habitat, 2014). More recently, increasing attention has been given to transformation of existing urban areas and urban redevelopment, since peripheral expansion of cities has become more difficult, as well as the ageing of urban development schemes from the 1980s and the need for renewal. The commodification of housing and land, since 1980, helped to initiate large-scale urban redevelopment. Within the interaction between the state and the market, the rationale of urban redevelopment in China has changed from the alleviation of dilapidated housing estates as a means of social welfare provision, to state-sponsored property development as a means of growth promotion (He, 2009).

Questions have been raised about the physical and social outcomes from the redevelopment process at the micro-level , not least in the level of quality of the physical environment and maintenance of a sense of place or place identity (Chen, 2010; Hang, 2006; Wu, 2012). of the performance of urban development have concluded that, whilst standardized planning and

design has enabled rapid urban development and achieved huge economic growth, it has also contributed to poor spatial and environmental quality - meaning for example, the do mono-functional urban neighborhoods and the loss of street vitality, the erosion of cultural heritage, local distinctiveness and place identity, poor accessibility to services and widespread negative externality effects such as noise and pollution.

This paper contributes to the debate of urban redevelopment and evaluates the impact of macro-scale urban redevelopment project and planning policy on the micro-scale urban quality and place identity. It draws the regeneration of the Sungang-Qingshuihe (SQ) district in Shenzhen as a study case, to evaluate its plan and implementation process, and provides recommendations on integration of different scales of urban quality through urban planning.

## 2. Theoretical Framework

Many developed countries have had similar problems. For example, in her seminal text, Jane Jacobs (Jacobs, 1961) criticized urban planning practice in the USA, which she argued was creating characterless, and mono-functional neighborhoods and undermining the livability and attractiveness of cities. She helped to define the essential ingredients for the vitality and viability of cities and called for urban planning to recognize and promote their importance. Charles Landry (Landry, 2008) explains how in Europe, planning has often achieved qualities of mix of functions, diversity of uses and cultural identity of cities. However, these qualities have been under threats from planning approaches that prioritize macro-level objectives with insufficient attention to the local micro-level effects. While there is great variety in planning systems and cultures in Europe (Nadin, 2008), there is a general trend towards 1) more strategic approaches that integrate the objectives of competing policy sectors and levels of government in territorial governance (Nadin, 2007, Zonneveld, 2012); 2) adaptive and locally responsive planning tools that can reconcile both macro- and micro-level objectives in urban planning (Halleux, 2012; Rauws, 2014); and 3) collaborative planning processes that engage with stakeholders in an inclusive way (Healey, 2006).

There is potential for China to learn from the experiences of integrating macro and micro concerns in territorial management and urban planning in other countries. This study brings this knowledge into the Chinese context, and sets up an analytical framework to review the redevelopment case of the SQ district. The study considers urban redevelopment as a dynamic and collaborative process, and thus the social, spatial and political context, the involved actors, and the planning and implementation process of the redevelopment project are given great attention.

## 3. Urban context Shenzhen

### 3.1 Context and trends

Shenzhen is located in the Pearl River Delta (PRD) region adjacent to Hong Kong. Prior to 1979, it was a small fishing village with a population of only 20,000 people (Zacharias, 2010). This all changed in 1978 with the creation of China s first Special Economic Zone (SEZ) l part of the Opening up policy . The SEZ is an area of relaxed financial regula government autonomy (Ng, 1999). The creation of the SEZ led to staggering economic and population growth. From 1980 to 2001, the annual GDP growth rate was 38.9% per capita (Ng, 2003), while the population has grown to 10.47 million as of 2011 (Shenzhen Information Network Center, 2012).

Shenzhen has grown through a land-based economic development model. The planning system of Shenzhen has been very successful in promoting economic growth, where the urbanization of land and

the redevelopment of existing areas has been used by the Municipality as a means to gain capital for regional development (Lin, 2011). In 1987, the paid leasing of land use rights began in Chinese cities with the leasing of land quickly becoming a significant source of income for local governments. This new land policy has changed the form of urban areas leading to land speculation, price increases and a land rent gradient that had previously not existed in Chinese cities (Yeh, 1996). Combined with pressure for economic growth, this system of land leasing encourages development projects that will achieve high economic returns in well located urban areas, often pushing out the existing residents (Yeh, 1996).

Shenzhen now is undergoing a new wave of economic restructuring. Due to the cheaper labor in many inland cities and other countries, Shenzhen has lost the competitive advantage it once had and much of the light manufacturing and industry has now moved away (Zacharias, 2010). To promote the economic growth of the city during its development, urban planning focused on the development of large land parcels (Zacharias, 2010). However, as industry relocates, the previous focus on large urban parcels means large areas of the city are now vacant.

In addition to economic restructuring, Shenzhen is being defined by new urban scales, rising levels of competition and increasing regionalization. The Pearl River Delta Region, encompassing the cities of Guangzhou, Dongguan, Foshan, Huizhou, Hong Kong and Macau, has an estimated population of 27 million people (Woetzel, 2009). The delta cities are becoming increasingly more connected through the development of major new infrastructure projects (Ye, 2012), driven by the National and Municipal governments. At the same time, competition between the cities in the PRD, as well as intra-urban competition between the city districts, intensifies (Zacharias, 2010; Bruton, 2005) as areas seek investment and connection to the international, national and regional networks.

Driven by the departure of industry, rising land price, political and economic pressure to attract foreign direct investment, high-profile redevelopment projects which are often designed through international competitions are becoming a common development response. As a result of the fast urban construction, the city also is outdating extremely fast. However, more attention is given to the new development, instead of regeneration. There are a number of recent examples in Shenzhen of new business districts (Shenzhen bay Super city - 2014), new towns (Guangming Gateway), science (NFU and SZU Advanced Technology Park - 2010) and large new urban areas (Qianhai water city - 2010). The regeneration of SQ is one of the few and the biggest regeneration projects in the city. However, the ambition and planning procedure for this area is not much different than building a new district, as the paid leasing of land use rights encourages development that achieve high economic returns to ensure profitability. The brief for the SQ reflects the international aspirations of the local and municipal government calling for an international consumer center .

## 3.2 Challenges of local scale pressures

The current planning approach has, however, not effectively reached to local scale urban environments and many workers and migrants are left feeling that they are not seeing their share of the economic benefits. While cities have been developing, the provision of adequate public services has not kept up with this economic growth. According to Ye (2012), this lack of public service provision, together with income gaps, social stratification and housing price spikes, leads to widespread social unrest in Chinese cities .

## 4. Regeneration Case Study of SQ District, Shenzhen

### 4.1 Site

SQ district is a 540-hectare outdated logistic center in Shenzhen. It represented the manufacturing history of the city, and witnessed the dramatic urbanization of Shenzhen in the past 30 years. The site is centrally located in the Luohu district, the first city center, and is well connected to the city infrastructure and transportation networks as shown in Figure 1. The former North station in the site connects Hong Kong and Mainland China, making the site a gateway of Shenzhen.

Figure 1: Location of SQ in Shenzhen. Source: A. Reynolds based on Open Streetmap data

Compared to other parts of Shenzhen, where high-rise towers play a dominant role in the city image, SQ presents unique character and quality due to its diverse urban structure and lively social lives. Warehouses, urban villages, modern residential communities and office buildings are mixed in the site. Several major infrastructure runs through the site, including urban highways, large areas of disused railway and railway yards. In addition, a city park, Honghu Park, is situated on the east of the site, and a significant green corridor, Honggang Mountain, is running east west dividing the site into half. Densities, uses, nature and infrastructure are mixed into what could be understood as an unpolished paradigm of the ultimate contemporary urban condition shown in Figure 2.

Now the site sits functionally obsolete, as the warehouses and urban facilities cannot fulfil the contemporary usages, and the pressure of transforming this area increases due to its central location. In addition, the road and traffic system on the site is disorganized, making the site fragmented and segregated from other parts of the city. Therefore, the Luohu District Government (District Government) and the Urban Planning, Land and Resources Commission of Shenzhen Municipality (SZPL, Municipal Government) have initiated the regeneration project for the SQ area in 2010. The plan aims to turn the site into a new international commercial center and creative hub, with housing capacity for 20,000 people (Sasin, 2012).

Figure 2: Three dimensional visualization of the existing urban conditions. Source: sz.chachaba.com

## 4.2 Project Process

The redevelopment of SQ has experienced conceptualization, legalization, and implementation phases since 2010.

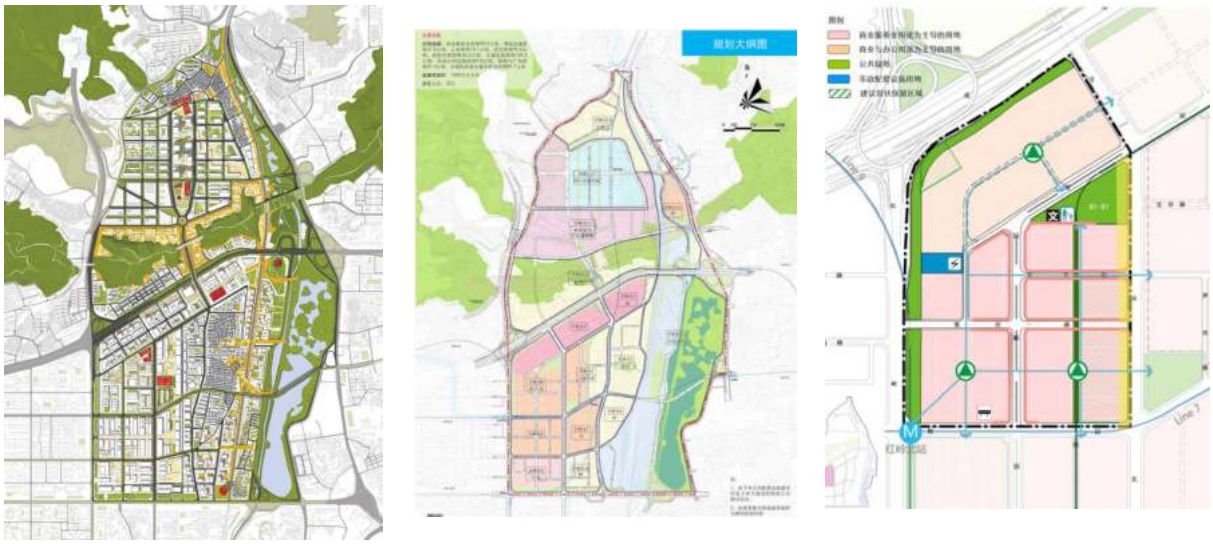
**International masterplan competition**

Luohu government and SZPL organized an international competition for the regeneration masterplan of SQ in 2010. The winning proposal from a Dutch planning company, named KCAP (Kees Christiaanse Architects and Planners), is progressive in terms of urban development in Shenzhen as it seeks to create a framework to facilitate an incremental development process and to upgrade the site by working on the existing urban fabric. The approach of the masterplan derived from European experience is socially and contextually sensitive. The new interventions are based on the acceptance of the current urban condition, in order to continue the urban history of the site, as well as that of Shenzhen. It has defined the primary principles for the regeneration, such as fine-grain and walkable urban fabric, intermodal public transport for seamless transition, connective and multi-scale public space, mixed use program, characteristic urban typology by keeping building footprint, sustainability and low carbon city, as well as collaborative implementation through phasing. It also proposed a series of planning strategies for different topics, following the above principles. Some may criticize the winning masterplan not ambitious enough for a city like Shenzhen, where the spirit is to look forward instead of backward and where magic is made daily to achieve the prosperity of the city. However, this plan has brought tremendous quality for the regeneration of SQ and more importantly, a new mindset to the development of Shenzhen, to value its own physical and social structure, and to turn the seemingly outdated into unique identity.

While the masterplan unfolded great potentials and drew desired perspective of the site, the reality is much more complicated when regenerating this 540 ha area. The site is currently leased to more than a dozen of companies, who can be considered as the temporary landowners of the site. Many of them also become the developers during the regeneration. In order to maximize their profit, they started to approach the local government even before the masterplan was launched, with grand projects of super high density and ambitious commercial program. When mutual benefits are reached, some projects had been approved and signed off by the government before the masterplan was finished. However, the approved proposal for some of the key areas did not fit in the planning vision of incremental development. Consequently, instead of being proactive to guide the site s re masterplanner has to modify their plan in order to integrate those already-designed plots.

**Statutory plan**

In August 2012, based on the refined masterplan, a statutory plan was created by the municipal government and announced to the public. This document abstracted the factorial information of urban planning to control the subsequent urban and architecture developments on the site. It touched different elements of urban planning, including land use, the main road network, public transportation, municipal facilities, as well as the green structure and density. Although the information provided by the statutory plan was highly abstract, it had a dominant impact on the site because it defined the most important factors of the plan, such as property line, municipal road and infrastructure, density for every sub-district, public facility, some big public spaces and so on as shown in Figure 3.



(1) (2) (3)

Figure 3: The three phases of the redevelopment process. (1) Masterplan prepared by KCAP, (2) Statutory Plan and Subunit Division, (3) Detailed subunit control plan.

Following the Shenzhen planning regulation, the draft of statutory plan had to be shown to the public for 30 days. During this period, anyone could deliver a written feedback to it. The planning department in the municipality would review the feedback, and decide if there were any necessary modifications. After that, the final statutory plan would be approval by the city as a legal document, which in principle, must be followed by all the subsequent developments.

Although the statutory plan included a number of elements from the original masterplan, there were essential differences between these two. Instead of regenerating the site based on the existing spatial and social context, the statutory plan put economic benefit and practical feasibility as a priority, making some major modifications on the masterplan due to practical concerns. Consequently, the spatial qualities provided by the original plan were lost in the translation to the legal document.

**Overall urban design guideline and sub-unit design**

As the statutory plan provided new conditions to the plan of SQ, Luohu district government initiated another round of design tenders, in order to develop more comprehensive urban designs for SQ, and to make planning guidelines for the entire site and its sub-units. The project brief stated:

*We hope that a unique and charming city image, and forward-looking, implementable sub-unit planning schemes for SQ and its construction can be plotted with international visions and innovative ideas, so as to drive it to take the first try and become a demonstration area for building Luohu into the international consumer center (People's Government of Luohu District, Shenzhen & Urban Planning, Land and Resource Commission of Shenzhen Municipality 2012).*

The tenders consisted of two packages - one was urban design guidelines for the entire site, and the other was sub-unit planning for the first phase. Both documents were supposed to be developed under the framework of the statutory plan, and used by the district government to control the developments on the sites. The urban design guidelines for the whole site were asked to enrich and improve the statutory plan, producing detailed and feasible planning guidelines and referential spatial results to guide the future plan implementation.

The sub-unit design would be assigned to different design entities. It was expected to serve as an intermediate level between the overall urban design guidelines (upper plan) and development for each plot. It should provide a more detailed urban design following the guidance of the overall masterplan, and more importantly, tackle the practical issues, like land ownership, compensation policy, and to coordinate the ambition between the upper plan and the developers' vision on the

While the original masterplan for Sungang-Qingshuihe district did develop a framework that could allow for incremental growth, the plan was unable to realize its ambition when it was transformed into the statutory planning system. The following overall urban design and sub-unit design guidelines were not given space to improve upon the statutory plan. When comparing the plan of the SQ district between the conceptual competition phase and the overall design guideline phase, although one may still recognize the urban structure from the two dimensional map, it is difficult to find coherence in the three-dimensional bird-eyes view as shown in Figure 4.

(1)

(2)

### 4.3 Challenge for planners and limitations for the current planning practice

During the process from design to implementation in the past four years, several problems regarding the current planning practice emerged, challenging the planners:

**Time pressure and inefficient planning process**

Similar to most of the urban projects in China, the redevelopment of SQ district is planned into a very tight schedule. Both the government and the developers would like to reach a prosperous result overnight. The planning process has been largely condensed, therefore creating a number of problems. For example, the overall urban design guidelines were supposed to guide the sub-unit design. However, in the case of SQ project, the overall guideline and first phase in the sub-unit design are being implemented simultaneously. This means the sub-unit designers started out without an overall picture of the entire site, making the overall design guideline powerless to control the development of the sub-units. Furthermore, this cost extra time and energy in coordination among the designers of the guidelines and sub-units, which in the end slowed down the process of the entire project.

**Striving for economic benefit and sacrificing socio-spatial qualities**

There are complicated partnerships in the project among the different levels of government, developers, local residents and landowners. Each group is seeking to maximize their economic benefit during the process of regeneration while not considering socio-spatial qualities, creating a dilemma for the guideline and sub-unit planners.

**Rigid statutory planning based on technical indices**

The statutory plan for the SQ district is the most powerful document to control the development of the site. However, as discussed previously, it sacrificed a great deal of spatial quality for the so-called economical and technical feasibility. For example, the statutory planning has defined the density for every sub-unit. However, the density was not defined based on the desirable city image or planning rationale; instead, it was defined according to the extent of difficulties of implementing

transformation. As a result, the urban villages are given the highest density, since the village owners are not willing to transform their homes unless the government gives them a very large amount of extra square meters. Furthermore, as the statutory plan has been already approved by the Municipal Government and published to the public, it was nearly impossible for the guideline and sub-unit designers to make any necessary changes.

**No formal system for the local government to enforce the guidelines**

The overall urban design guideline provides detailed, refined and thoughtful rules that should guide the development of the entire site. However, the legal power of the guideline is much less than the statutory plan s legal power. In addition to the items that already appeared in statutory plan, m contents in guideline are indicative and referential. There is not a formal system to ensure the execution of the guideline.

**Unclear or little benefits to socioeconomically weaker groups and local residents and workers**

The redevelopment of the SQ district is focused on international visions: it was to become an international business and retail center for the regionShenzhen Information Network Center, 2012). While the current development approach may achieve such objective of boosting the regional economic competitiveness as the process of development is focused on regional ambitions, it is unclear how it can benefit the existing local actors if the needs of the local residents and the socioeconomically weaker groups are excluded from the process.

## 4.4 Evaluation

To evaluate the effect of the redevelopment on macro- and micro-levels, the study categorizes the development of the site into XL, L, M, S, XS scales. They represent respectively:

XL (eXtra Large) Shenzhen
L (Large) overall site of SQ
M (Medium) sub-units within SQ
S (Small) individual plot
XS (eXtra Small) individuals

The planning and intervention of redeveloping SQ happens at L, M and S scales, while the influence covers from XL to XS scales. From the macro-level, which is at XL, L and M scale, the redevelopment of SQ has largely improved the competitiveness of Luohu district in the city. It turned a brownfield into lively and prosperous urban quarters, with its creative program and atmosphere that complement the whole city s urban landscape.

At the micro-level, however, the redevelopment has not given sufficient consideration to the local environment and residence. For example, the introduction of public space, especially those at the neighborhood scale are lacking; the plot division is also relatively big without having enough local road; the street prioritize automobile use instead of being pedestrian-friendly, so on and so forth. Although the government is supposed to represent and fight for the public s interest on balancing the financial interests of stakeholders, instead of prioritizing social needs.

## 5. Conclusion: How to interconnect urban planning with multi-scale urban quality?

As outlined in the paper, with competing interests and spatial demands, as well as time pressures, it is no easy task to bring together urban planning and multi-scale urban quality. However, some key lessons can be learned from the redevelopment of the Sungang-Qingshuihe district and the method proposed in this paper.

**Creation of an independent quality control authority**

To enable the approach proposed in the case study, the creation of an independent quality control authority by the Municipality is proposed. This authority would coordinate and oversee the negotiation and implementation process. As there are many internal competing interests within the Municipality e.g., the Planning, Infrastructure, Environment and Economic Departments, it is considered that a separate authority could deal with these competing interests better, provide a more transparent process and gain trust from all actors, allowing for the formalization of the negotiation process.

**Early involvement of planners and designers with a proactive coordinating role**

The involvement of designers and planners from the initial stages of the process and brief would allow the designers to contribute to defining the brief, providing a more strategic and broader vision from the beginning of the process. This could also help the planning and organization, allowing for a better understanding between the clients and the designers in terms of planning and coordinating timelines. There is also a need for the planner to move towards a new role as key coordinators to find a better balance between the interests of the various parties. This puts the planner, with their professional knowledge and ability to cross sectors in a unique position which should be recognized and encouraged.

**Change of focus from short term economic and political impact to long term quality**

The development focus of the National, Municipal and Local Governments must shift from seeking short term financial and political gain to promoting long term socio-spatial quality. Therefore, it is important not to start with a quantitative goal, i.e. amount of financial investment, but instead begin with processes that aim to achieve certain agreed qualities and principles that result in qualitative and quantitative improvements.

**Accept a broader range of development possibilities moving from a single render to layered stories**

The process for large-scale planning project is highly dynamic and a fixed masterplan can never be fully implemented. Therefore, it is important to provide a planning framework which can guide the plan and promote key qualities as well as have the flexibility to adapt potential changes in the future. The approach requires the National, Municipal and Local Governments, as well as developers, not to focus on a fixed vision, but on principles, qualities and a broader range of development possibilities. This will require the National, Municipal and Local Governments and individuals to sacrifice some of the current control they have on the final image of the project, and focus on the process. If all the actors, including residents and those directly affected by the development are confident in the process, have the basic trust on one another, then a project can achieve the agreed-upon goals and can be more inclusive of local needs.

Keywords: Masterplan, Change, Resilience, Sustainability, Principles

## Abstract

*Unprecedented worldwide urbanisation, financial instability, climate change and emerging new lifestyles are challenging the capacity of cities to attract and retain people and activities. Particularly, as many masterplan-driven developments realised from the second half of last Century have been criticised for their inability to cope with changing needs and uncertainty of future outcomes and for their incongruity with native physical, socio-economic and environmental contexts, the need to reform conventional approaches to masterplanning is now pressing. As cities competitiveness and success depends on their capacity to meet these manifold challenges, a new generation of masterplans has emerged over the recent years to respond more clearly to the sustainability agenda.*

*However as we become increasingly aware that cities are inherently unstable and prone to unpredictable change over time, to complement the concern for sustainability, resilience as applied in the field of system-ecology needs now consideration.*

*The paper argues that re-evaluating masterplanning against the theoretical framework of resilience would help defining a reformed approach, referred to as "*Masterplan for Change", *more openly aimed at giving strategic direction and spatial quality to places, while accommodating modification over time. However the role of resilience in guiding urban design and masterplanning is still marginal. Hence, the fundamental link between sustainability and resilience is clarified and a preliminary list of guiding principles of* "Masterplan for Change"*, emerged from combination between urban design sustainability and socio-ecological resilience principles, suggested.*

## 1. Introduction and Background

Over the last half-century, urban and population growth were largely managed through centralised control in the implementation and coordination of transformations in the built environment. This reflected the need to give rational foundation to urban planning and management and the belief that acquisition of complete and certain knowledge on future outcomes would allow to scientifically pursue the public interest (Alexander, 1984, Thwaites et al., 2007, Batty, 2013b). Masterplans were seen elective tools capable to translate this knowledge into space through detailed and prescriptive spatial visions on the future asset of an area over a long period of time (Firley and Grön, 2014). Once implemented, they would bring about wealth, civic uplift and physical order into society (Hall, 1988). However increasingly from the 1960s these top-down masterplans were systematically accused of physical determinism and short-sightedness as they advocated an ideal final state that was often unrealistic (Jacobs, 1961, Bullivant, 2012) and underestimated the irrational, unpredictable and complex dynamics taking place once the masterplan was realised (Portugali, 2011, Verebes, 2013).

Today, the unprecedented changes the world is facing are uncovering even more the shortcomings of this approach to designing cities (Tachieva, 2010, Verebes, 2013, Mehaffy et al., 2011). In a world inhabited by 7 billion people, 50% now live in cities. By 2050, this number will spike to 70%, and 87% of these new urbanites will live in today's developing countries (UN-HABITAT, 2012). The impact of human activities has, for the first time in history, reached global dimension, ushering a new geologic epoch earth scientists referred to as *"Anthropocene"* (Ellis et al., 2013). The disproportionate detrimental role cities carry on the global ecosystem is most visible in the sharp increase in frequency and severity of natural disasters (Adger et al., 2013). These, far from being merely environmental issues, have major social-economic implications, affecting people's livelihoods and health (UN-HABITAT, 2009).

The 2008 global recession radically reduced financial availability and government effectiveness (Collier et al., 2013), highlighting the frailty of our urban development strategies to economic instability (Tachieva, 2010), with masterplans, acting as inflexible, overly prescriptive and static tool of spatial planning (UN-HABITAT, 2009). On one hand many large-scale state-led projects realized across Europe in the post-war years are endemically affected by economic inactivity, lack of community cohesion and social stigmatization (Rudlin and Falk, 2009). On the other, the neo-liberal urban planning model practised in the height of market-led development of early 1990s and relying on the private sector did not manage to better stand the recent collapse of the property market (Watson, 2009). In both cases repair strategies are economically demanding, as the overly-rigid structure of their form and pattern of ownership make them unable to recover quickly after unexpected shocks (Tachieva, 2010, Dunham-Jones and Williamson, 2011). This apparent inability of recent additions to our cities to cope with changing conditions is particularly worrying considering that over the next 100 years much of the buildings and infrastructure of the developed world will need to be reconfigured, replaced or even rebuilt, while even more will be needed to host and service the rapidly expanding cities of the developing world (Novotny et al., 2010).

Simultaneously, the socio-economic profile of urban population is also changing. Particularly in more developed countries, living, working, socialising and consuming patterns do not longer comply with the traditional models of nuclear family that drove urban planning over the last 100 years (Rudlin and Falk, 2009, Dunham-Jones and Williamson, 2011). Today's ascending generation, the so-called Millennials[1], is drastically reshaping housing trends and requirements of the built environment. Enabled by new forms of communication and powered by technological innovation, they move frequently location and occupation, rent rather than owning, chase opportunities that better respond to career aspiration or to employment instability and engage in flexible and mobile forms of work. At the same time the increasingly ageing population is challenging the services cities are able to offer in terms of accessibility, mobility, housing, facilities and healthcare. Shrinking, diversified and unconventional household types are further diversifying housing demand. This all calls for greater flexibility and quality in living and working environments and fairer access to opportunities within cities (Bernheimer et al., 2014, Litman, 2012). Matching these demands is the key for many cities competiveness and equity and opens up new largely unforeseen scenarios to urban development (Rudlin and Falk, 2009).

Aware of these manifold issues, over the last 20 years many countries are experiencing important reforms in their planning systems to deregulate land development and stimulate economic growth (Davoudi and Madanipour, 2015). This often implies decentralising governance, devolving responsibilities locally, implementing cross-tier collaborations, bottom-up participatory approaches and engaging innovatively with private sector actors (Bentley and Pugalis, 2013). In England, the Localism Act 2011 (House of Commons, 2011) introduced Neighbourhood Development Plans and Neighbourhood Development Orders, granting communities the right to pursue development they deemed desirable. This shift marks, at the very least and despite shortcomings (Davoudi and Madanipour, 2015, Ludwig and Ludwig, 2014) the trend of a retrenching State that envisions a more directly involved civil society and acknowledges the right of citizens to shape their own future. The Netherland, where traditionally municipalities hold a degree of autonomy in creating and implementing policy, is becoming an exemplar case of innovation in small-scale and bottom-up strategies to urban development, particularly in relation to the self-build agenda and the active involvement of municipalities (Lloyd et al., 2015). While the economic recession has slowed down construction everywhere, the legal power of Dutch municipalities in supplying land, providing for basic urban infrastructure and serviced land is playing a major role in ensuring architectural quality, social equity and economic viability in urban development during this transitional period (Tarbatt, 2013).

[1] *individuals aged between18-34 (Bernheimer et al., 2014)*

The need to update approaches also extended to masterplanning, whose role re-emerged in professional practice and academic research (Tarbatt, 2012, Firley and Grön, 2014, Bullivant, 2012). As a matter of fact, despite the growing criticism for conventional masterplanning approaches, masterplans remain central in many parts of the world as "*one of the principal urban design activities engaged in by urban designers and architects alike"* (Tarbatt, 2012: p. 20), both in public and private sectors (Watson, 2009, Bullivant, 2012). They are embedded in legislation and urban design guidance in many countries where they enable local authorities to turn policy, aspirations and objectives in three-dimension through an established range of mechanisms for commissioning, negotiation and delivery (Watson, 2009). Masterplans are by no means modern urban planning. Some of the most loved, successful and sought after parts of our cities, were built centuries ago through the implementation of clear, well-conceived masterplans which achieved character, coherence and flexibility, as in 1760's Edinburgh of James Craig, 1850's Paris of Haussmann and Barcelona of Ildefons Cerdà. Despite their ability to continuously and seamlessly regenerate over time these are generated very much by design, codes and regulations (Kostof, 1991, Hakim, 2014).

Hence, driven by the desire to address changing and new urban needs and rediscover the timeless quality of responsive and flexible urban structures, many experimental urban design projects are underway, particularly across Europe (Bullivant, 2012, Rudlin and Falk, 2009), supported by innovative commissioning, implementation and management methods and by new evidence-base knowledge of urban dynamics (Batty, 2013a, Bettencourt, 2013).

The possibility to assess the different performance and success over time of both recent masterplan and *historical* masterplans provides a real opportunity to systematically re-evaluate the role of masterplanning in dealing with change and uncertainty and in delivering more resilient and sustainable urban environments. This consideration is at the basis of the current research work, carried out at the Urban Design Studies Unit at the University of Strathclyde.

## 1.2 Urban design, sustainability and resilience

Since the issue of the report *"Our Common Future*" (Burton, 1987), the concept of sustainability gained momentum in different disciplinary fields, particularly in architecture and urban design. However, in the last decade, something has changed in how scholars and scientists look at sustainability (Batty, 2013b). Unpredictable disturbances as natural and artificial catastrophes (i.e. flooding, fires, building crises, economic booms and crashes) prevent any attempt to achieve long-term stability (Ahern, 2011), as future outcomes are largely beyond our ability to make predictions and, consequently, to make plans (Schön, 1987). Accordingly, sustainability must embed a transitional dimension and be interpreted as an on-going process rather than an ultimate goal (Novotny et al., 2010, Wu and Wu, 2013).

In the field of system ecology the property of a system to persist in the face of future change is called *resilience* (Holling, 1973). In natural ecosystems, it is described as the capacity of a system to respond to disturbance without changing its basic states and relationships, even when change is sudden and unexpected (Walker and Salt, 2012). Work in complexity theory (Batty, 2013b) and system ecology (Walker and Salt, 2012, Marcus and Colding, 2014) advanced the idea, now largely accepted, that not unlike natural ecosystems, cities are complex adaptive systems (Garcia, 2013), constantly unstable, inherently variable and prone to change over time. Therefore the adoption of the theoretical framework of resilience seems particularly powerful in addressing to uncertainty, variability and change in the urban environment. Indeed, according to Anderies (2014) resilience theory *"can provide some theoretical perspectives for addressing design challenges for built environment* […] *in the extremely challenging design environment of the Anthropocene"* (p. 130).

In particular, two concepts integral to resilience appear important in relation to cities (Novotny et al., 2010, Sharifi and Yamagata, 2014, Godschalk, 2003):

- *Robustness,* or the ability to withstand stress without significant structural or functional change, and

- *Adaptability,* or the ability to adjust to changing external conditions without radically departing from previous conditions

In cities, the ability to persist during periods of turbulence and preserve core identity, character and fundamental morphological structure (i.e. plots, blocks, streets and public spaces) are trademarks of most successful and memorable places (Carmona, 2010). Simultaneously such places also have the ability to change gradually and incrementally (i.e. through land-use conversion, small alteration in layout and arrangement of buildings and spaces, re-organisation of activities) though a self-organising mechanism that prevents them from getting *'locked-in'* in inefficient paths (Novotny et al., 2010) and spares them from the need of more radical interventions (Tachieva, 2010). Applied to masterplanning, resilience theory would stress the importance of conceiving, designing and assessing urban form in terms of its probabilities of maintaining its basic identity while continuously and gradually evolving.

However, the current debate on urban resilience mainly focuses on post-disaster emergency planning and on vulnerability to sudden and catastrophic events at the expense of smaller, progressive and incremental change (Davoudi et al., 2012). Additionally, whilst few system ecologists tried to translate the theoretical framework of resilience into spatial form (Marcus and Colding, 2014), in the vocabulary of urban designers the term is still a buzzword (Stumpp, 2013). Therefore its potential to operatively inform urban design practice remains largely untapped, a rather important gap given that design intervention on the urban environment are always mediated via the spatial form.

Within this broader framework, the current paper takes on the argument that embedding a resilience framework into urban design may help designers and policy makers to create places able to endure culturally, socially and environmentally as well as to dynamically adapt to contextual conditions and evolve. Accordingly, it is advocated the role of a reformed approach to masterplanning, referred to as *"Masterplan for Change"*, in giving strategic direction and spatial quality to places, by building in them enough resilience to accommodate modification over time. Recent masterplanning experiences and models have been driven by sustainability principles in shaping the form of new urban development. At the same time, literature has suggested for a number of years (Wu and Wu, 2013, Marcus and Colding, 2014) how the framework of socio-ecological resilience shares many commonalities with the sustainability agenda. Hence, to set the grounds for the hypothesis here presented, following pages clarify the fundamental link between sustainability and resilience and distil fundamental principles of *"Masterplanning for Change",* achieved by integrating and combining urban design sustainability principles with principles of socio-ecological resilience.

## 2. Method for reviewing and combining principles of urban design sustainability and socio-ecological resilience

As the current paper aims to stress the appropriateness of a resilience framework in guiding the conception and assessment of masterplans, literature on urban design sustainability and socio-ecological resilience are used to generalize principles of *resilient* masterplanning or "*Masterplanning for Change"*. The two-stepped methodology presented in this paper consists in: 1) the identification of key principles of urban design sustainability and socio-ecological resilience and 2) the integration of the principles emerging from the two fields into principles of *"Masterplanning for Change";*

Review of key principles of socio-ecological resilience was conducted using the SCOPUS search engine including all publications in English[2] dating between 1978 and March 2015 referring to principles, characteristics or proprieties of resilient systems. After applying additional thematic restrictions to target the search, including the wider body of publications of the top 10 most active investigators reported and scanning the references section of most relevant publications, a total of 50 publications were selected to distil resilience-related criteria, from an initial of 758 documents.

Regarding urban design sustainability principles, much of the literature is summarized in the work of Carmona (2010) and Luederitz et al. (2013). To ensure the comprehensiveness of the list and a degree

[2] Since English publications accounted for 95.7% of all entries, this was considered acceptable.

of agreement upon it, this was integrated with other academic and non-academic publications as planning guidance (The Scottish Government, 2008, DETR, 2000), consultancy agencies statements (Roger Evans Associates Ltd, 2013), tested on textual statements associated with recent examples of masterplans randomly sampled from journals, books and websites and discussed with selected urban design practitioners, academics and policy makers (i.e. Glasgow Housing Association, Academy of Urbanism, Prince's Foundation). Although the list seemed to adequately reflect academic literature and professional practice, given the open-ended nature of this search, omissions, additions or modification are possible. These principles appear in the majority of cases described as physical properties having social-economic and environmental repercussions, hence their specification across these three aspects in the table below

13 principles were derived from literature on socio-ecological resilience (Table 1) and 10 from literature on urban design sustainability (Table 2).

Table 2. Thirteen principles of socio-ecological resilience

| Principle | Definition |
|---|---|
| Self-organisation | Small-scales interaction and bottom-up rules produce macro-scale patterns at larger scales. |
| Autonomy | Ability of systems and subsystems to maintain some independence from outside control. |
| Coherence | Ability to function as unitary structures while composed by various elements and sub-systems by virtue of connectedness and integration at higher scale. |
| Interdependency | Reliance on mutual support and synergy within systems (components, sub-systems) and across different systems. |
| Flexibility | Ability to enact small, gradual adjustments in component and subsystem to respond to changing conditions and evolve. |
| Responsiveness/ Resourcefulness | Ability to timely identify problems, establish priorities act and re-organize function, structure, and basic order ahead and following disruptive events or failures maintaining key functions fit for purpose or minimising disruptions |
| Feedback | dynamic continuous process of trial and error that relies on experience, knowledge and memory of previous failure or success to effectively respond to context |
| Creativity/ Innovation | Ability to transform change into the opportunity to achieve a more advanced state by gradually tested and eventually mainstreaming innovative strategies |
| Diversity | Coexistence of many functionally different components providing a variety of services combined and distributed within and across scales/time, in a way that is efficient spatially and economically and thus avoiding reliance on a single solution. |
| Redundancy | Coexistence of many functionally similar components fulfilling the same, similar or backup function in several different ways, implying functional replication, internal variation and a degree of buffer capacity, so that failure of one component does not stall the whole system. |
| Modularity | Presence of small-scale, relatively autonomous and poorly-specialised modules. Whilst highly distributed and decentralized, modules can aggregate to form higher-level coherent systems, enabling contextual responses and decreasing spread of failure |
| Scale-free connectivity/ Scale hierarchy | Networks organised via few long-range connections and many tight short-range connections, with focal nodes connecting lower and higher scales together, where every scale is simultaneously connected to the others and all systems are mutually interactive, with no connective scale dominating the others. Hence, failure of a substantial number of links rarely affecting the network as a whole. |
| Balance/ efficiency | Capacity to guarantee performances in resource-limited settings, in the short and in the medium-to-long term by balancing inputs and outputs of resources and energy. |

*Adapted from, among others, Sharifi and Yamagata, 2014; Dovey, 2012; Galderisi, 2014; Novotny et al., 2010; Moench, 2014; Collier et al., 2013; Ahern, 2011; Cloete, 2012; Da Silva et al., 2012; Wu and Wu, 2013.*

Table 2. Ten principles of Urban design Sustainability

| Principle | Definition |
|---|---|
| Diversity | **Urban form:** mix of uses within buildings, blocks, streets; variety of buildings appearance, age and type; provision of a wide choice in mobility;<br>**Socio-economic**: mix household types, age groups, income bases; variety of tenure options and employment and entrepreneurial opportunities.<br>**Biological:** sustenance and enhancement of fertile and self-supporting habitats and a diversity of plants and animals through provision of diverse green spaces. |
| Connectivity | **Urban form:** permeable street and transport networks; fine-grain and accessible street layout and uses; physical and visual integration with their surroundings.<br>**Socio-economic:** support and socialisation networks; face-to-face interaction opportunities.<br>**Landscape:** interconnected ecological network, accessible for both people and wildlife. |
| Concentration | **Urban form:** efficient match between density, building typology, land use distribution, street and transport network and focal nodes and public spaces.<br>**Socio-economic:** support of urban living, economic viability of transport and facilities.<br>**Landscape:** reduction of land intake and ecological footprint; preservation of greenfield. |
| Distinctiveness | **Urban form and environment:** character result of unique geographic, morphologic and cultural circumstances; preservation and valorisation of built and natural heritage against pressures towards homogenisation; integration and response to setting and context.<br>**Socio-economic:** awareness of local assets and economies; sense of pride and ownership; sense of identity and belonging. |
| Human needs | **Urban form:** facilities, services and spaces scaled to the needs of individuals and community and locally accessible; legible and well maintained places and buildings.<br>**Socio-economic:** enhancement of psychological and physical health; sense of safety; comfortable human-scale environment; psychologically restorative connection with nature<br>**Landscape:** Integration of natural resources within the built environment; balance between natural and man-made environment. |
| Efficiency | **Urban form:** efficient and innovative building design; reuse of existing fabric and infrastructure; integration of transport options; efficient land-use and street layout.<br>**Socio-economic:** reduced incidence of cost of fuel; equitable distribution of costs and benefits of development.<br>**Environment:** minimisation of energy deployed in building life-cycle; use of; reduction of waste emissions; use of services provided by ecosystem and renewable natural resources |
| Adaptability and Durability. | **Urban form:** places, buildings and infrastructure capable to upgrade, cater for overlapping functions, overcome obsolescence and adapt to technology, lifestyles, demography, uses.<br>**Socio-economic:** places able to follow and adapt to people's life-cycle; flexible grass-roots management of properties and public spaces; preservation and reuse of community asset to foster sense of belonging and identity;<br>**Environment:** long-term view on energy and environment; focus on non-environmental destructive uses, materials, resources. |
| Self-sufficiency. | **Urban form:** provision of basic needs locally and means local access to mobility options; reduced need for commuting; locally available community infrastructure.<br>**Socio-economic:** self-sustaining and viable local economy; availability of local employment options; strong social capital; locally managed public spaces.<br>**Environment:** local production of food, energy generation and waste disposal. |
| Stewardship | **Urban form and environment:** well-maintained public and green spaces; fine grained and diversified land division to enable different forms of management.<br>**Socio-economic**: long-term commitment of community, stake-holders and local authority in management and governance; |

*Adapted from, among others, Carmona, 2010; Tarbatt, 2012; Barton et al., 2010; Luederitz et al., 2013; Thwaites et al., 22005.013; Farr, 201; Roger Evans Associates Ltd, 2013; Bullen, 2007; DETR, 2000; Rudlin and Falk, 200; Porta and Romice 2013; Thwaites et al. 2005.*

The following section combines the two sets of principles based on evident agreement/analogy in literature into 12 principles of *"Masterplanning for Change"*. Eventually, this list will be functional to the selection of compatible masterplanning case studies and of relevant metrics to analyse them. Analysis of case studies will help verifying whether masterplans responding - or conceived according to - urban design sustainability principles and compatible with principles of resilient systems, display themselves resilience in their resulting urban form and use. This, however, is not the object of the current paper as is currently being investigated.

## 3. Defining principles of Masterplan for Change: linking urban design sustainability and socio-ecological resilience.

During both reviews it was noted that identified principles of urban design sustainability and socio-ecological resilience bear no distinction between structural characteristics and (i.e. modularity, diversity) and behaviours (i.e. self-sufficiency, distinctiveness) of the system/place. This, however, becomes particularly important in urban design and masterplanning, as clearly some of these properties (i.e. modularity) can be embedded from the outset in the physical design of a space (i.e. through fine-grained division of ownership into small plots) while others cannot be produced by design (i.e. self-organisation) and can only be indirectly encouraged or potentially enabled to evolve over time by many factors, forms being one (i.e. through setting looser frameworks and rules and leaving room for institutions to emerge and consolidate). Therefore in combining the two sets of principles these where structured in a) behaviours of resilient cities (i.e. how a resilient urban system operates) and b) structural characteristics (what structure is associated with these behaviours).

The final list includes 12 principles, 5 of which related to the *structural characteristics*, 7 to the *behaviours* of resilient urban systems (fig.1). The division in structural characteristics and behaviours is reflected in the structure of the next section. Each principle starts with a general definition. Structural characteristics focus on geometric and physical properties of the urban fabric and landscape. Behaviours, on the other hand, focus on capabilities and how, whenever possible, these are declined in the physical, socio-economic and environmental dimensions. For these, a link with the underlying urban structure is presented.

### 3.1 Structural characteristics of resilient urban systems

*Diversity.* Diversity has many dimensions - physical socio-economic and biological (Ahern, 2011).
Spatially, density entails presence of a variety of functions simultaneously or hourly/daily/weekly intertwiningly, both horizontally (i.e. in different buildings in close proximity) and vertically (i.e. in one same building) (Ahern 2010; Tarbatt, 2012) in a cost-effective way. Hence it requires intensification of uses, services and densities at focal points of the urban spatial network (i.e. transit hubs, main streets) in order to maximise accessibility and reach. Diversity also refers to modal variety (i.e. use of public transport and other non-motorized commuting such as cycling and walking).
Up to some extent socio-cultural diversity plays a role in establishing building a coherent identity and is related to generation and exchange of knowledge and diffusion of innovation and creativity (Wood and Dovey, 2015). Biological diversity, whilst contributing to sustain and enhance wildlife also caters for a variety of human needs and produces psychological wellbeing (Ahern, 2011)

*Redundancy.* In urban systems redundancy focuses on the multiplicity options to choose from (Folke, 2006) and the multiple paths that can be taken to perform or get access to the same function or to fulfil the same need (Salat and Bourdic, 2012). Redundant transport networks offer the possibility to choose between overlapping modal options to move across a same area or across the city. Similarly in a redundant street network people have plenty of option to choose from in selecting a preferred path. In the built fabric, redundancy complements diversity, by increasing and combining the range of small, medium, sized uses (i.e. houses, business activities, and shops), boosting user's choice. In all cases, local damage or failure can be overcome easily as flow can be re-routed and individual components easily substituted. In biological systems, the presence of a great number of species performing a similar function but responding differently to disturbance (i.e. natural predators, climatic

variation, pollution levels) ensures continuity of the services provided by the ecosystem and preservation of habitat integrity and richness over a wider range of conditions (Ahern, 2011).

*Modularity*. Urban systems possessing a modular structure are spatially and organizationally conceived as progressive assemblages of smaller independent but interacting units aggregating at different scales (Batty, 2013b). In the urban fabric, the plot is the smallest and most basic land-use unit (Panerai et al., 2004). Indeed plots are individually independent (each driven by the development and management strategy of its owner) with roughly similar in size, non-specialised but, within certain limits, able to accommodate a wide range of functions. Plots can aggregate into wholes to form higher-order element (blocks, districts, settlements) or to disaggregate according to needs. Scale is also crucial as the larger are the units at the outset (i.e. blocks, super-blocks), the harder is for them to be modified or downscaled (Panerai et al., 2004). Additionally, in a fine-grained plot-based spatial structure, failure (i.e. demolition) has reduced impact and is more easily amendable. Hence, plot-based parcelling of land works with diversity and redundancy to increase complexity of the urban system, increasing its capacity to adapt to context, to test diverse strategies and to gradually change (Porta and Romice, 2010, Panerai et al., 2004, Tarbatt, 2012). Finally, modularity is a fundamental landscape property, particularly in their integration in the urban structure, where every small coherent unit or *patch*, can create a system of smaller spaces that can aggregate into larger wholes (Novotny et al., 2010). When woven into the fabric of cities to its ecological value is added an important restorative role for people (Thwaites et al., 2013).

*Scale-free connectivity and scale hierarchy*. Resilient urban systems many geometric and functional connections structured in a scale-free manner, following a scale hierarchy (Batty, 2013b, Salat and Bourdic, 2012), that implies the presence of a large pool of ordinary, frequently interspersed uses/elements countered by progressively less frequent, rarer and larger ones. Networks lacking connectivity at a given scale, as for strictly hierarchically organised street layouts, remain poorly connected and vulnerable to component failure despite spatial closeness of their elements, as they require upward and downward mobility to be navigated and only one or few paths (Salat and Bourdic, 2012). Cross-scale connectivity is fundamental for the emergence of focal points where different scales meet (i.e. transport hubs, busy street intersections) and where interaction and activity are most intense. This property is linked together with the three previous ones (diversity, redundancy, modularity), and together they help responding to a more diversified demand at many scales. This property extends to different aspect of the urban structure. In terms of mobility, networks structured so to include few fast links outreaching the wider metropolitan or regional context and many human-scale walkable and dense local streets are better connected both internally and across scales. In the ecological network, the presence of many small-scale frequent green areas (i.e. small private gardens), less frequent medium-scale green areas (i.e. neighbourhood parks) and occasional large portions of green space (i.e. county parks, natural reserves) highly interconnected at different scales via corridors (i.e. linear parks, tree-lined boulevards, rivers basins), cater for multi-habitat species and represent valuable basins of biodiversity, and offer important restorative benefits and services (Thwaites et al., 2013).

*Balance/efficiency*. The concept of efficiency it is rather controversial in resilience. While it is listed as important by many (da Silva et al., 2012), others (Novotny et al., 2010) state that resilience and efficiency are often incompatible. Indeed, when efficiency is framed in a short-term perspective, it tends to focus on optimization or maximization/minimization, at the expenses of redundancy (ibid.). Yet, as in a complex system there is no optimal state (Holling, 1973), efficiency must be framed into a long-term perspective of dynamic balance between energy and resources supplied and delivered (Godschalk, 2003). Hence efficiency describes an urban system, its places and buildings which provide means for human needs satisfaction, in a resource-limited setting, minimising negative impacts on the economy, the people and the environment (Cloete, 2012).

Spatially, according to Salat and Bourdic (2012) efficiency relates to structural properties of the urban system, as scale hierarchy, modularity, redundancy and interconnectedness of uses, networks, in that they fair distribution and access to places, resources and services. Efficiency does not rely only on

energetic performance but refers to the appropriateness of strategies to fulfil people needs (i.e. food, shelter) and provide fundamental services (i.e. public transport), in a way that is environmentally sound, socially equitable and economically viable.

### 3.2 Behaviours of a resilient urban system

*Coherence/Identity.* In the urban form, the concept of coherence refers to the capacity of various individually distinguished urban elements to achieve a sense of large-scale consistency and to behave as a whole (i, streets organise into a street network etc.).
Coherence does not entail a *"general plan"* or any particular form of spatial regularity and cannot be deterministically achieved. However, the spatial configuration of places and landscapes has an important role in supporting the formation of a complex form of order, an own identity and properties. More specifically, it relies, both in the built environment and in the ecological network, on fine-grained diversity, concentration and variability of complementary but not identical elements (i.e. plots, patches) tightly interacting at many different levels of scale both within and outwith the system (i.e. connected through network of streets or landscape corridors), similar in scale and size but progressively aggregating to higher scales (i.e. plots organise on street to shape urban blocks, patches connect to form continuous habitats) (Salingaros, 2000). Hence, coherence is strongly related to diversity, redundancy, scale-free connectivity, modularity and scale hierarchy.
Coherence in urban form is a trademark of the most cherished and successful cities and places (Salingaros, 2000, Barton et al., 2010) as adds distinctiveness and uniqueness (Salat and Bourdic, 2012). In ecological terms, coherence ensures habitat integrity, fundamental for the protection of and enhancement of biodiversity (Thwaites et al., 2005). Finally, coherence intended as identity is also an important social construct essential to create vital, liveable, well-loved human environments able to bring people together (Carmona, 2010).

*Interdependency/Synergy.* In the urban context interdependency involves stimulating synergy between spatial elements, agents and uses so that they are more than simply compatible but mutually enhancing (Sharifi and Yamagata, 2014). In the urban this implies, among other things, matching infrastructure and transport nodes with higher concentration of uses (i.e. increasing mix) and densities (i.e. through more compact building types), to support economic activity and urban living, to extend accessibility across different parts of the city, to reduce overall energy consumption and ecological footprint and to provide more opportunities for social interactions. From an environmental perspective, the synergistic relationship between different elements and functions of the ecosystem helps delivering a series of service within the urban environment to the advantage of urban communities and wildlife (Novotny et al., 2010). From a social perspective, collaboration between individuals, households, community groups, stakeholders and local authorities improves decision-making and governance (Godschalk, 2003), increases the possibility to access resources in a variety of circumstances, gather knowledge and learn.

*Autonomy/Self-sufficiency.* Self-sufficiency is the capacity of urban systems to exercise greater local control over essential assets (Carmona, 2010, Galderisi, 2014) hence reducing vulnerability to economic fluctuations and resource scarcity (Galderisi, 2014). As it requires addressing locally a range of functions associated to urban living (from community infrastructure, shops and businesses to public transport), diversity becomes crucial. From an ecological perspective, achieving self-sufficiency implies managing locally urban processes and resources and decentralising energy systems (Novotny et al., 2010). Socially it stimulates commitment to places, social capital formation, pro-active involvement and empowerment of local communities in urban management, ultimately fostering higher quality of life, and local knowledge (Crabtree, 2006, Roger Evans Associates Ltd, 2013).

*Flexibility/Adaptability.* Flexibility refers to the potential of the urban system and its components to accommodate foreseeable or unforeseeable future environmental, social, economic and technological requirements, through gradual and non-traumatic adjustments. Spatially, a diverse and modular urban structure enables quick, relatively inexpensive and immediate adaptations or replacement (i.e. improvements, upgrades and conversion, plot subdivision/aggregations). Building flexibility requires

a shift from a short-term mind-set that privileges specialised single-use buildings to a long-term strategy focused on durability and adaptability (Carmona, 2010) and allowing for easy re-organisation, conversion and reuse (Moench, 2014). Socially, flexible places and buildings are more inclusive and more likely to accommodate various lifestyles, households types (i.e. families, empty-nesters, cohabiting students), income bases, tenure/ownership models, employment preferences (i.e. live-work units, flexible working). They are less economically demanding are positively perceived by local communities. From an ecological perspective, flexibility prevents wasteful processes and lowers the load of the built environment on the ecosystem. (Carmona, 2010, Bullen, 2007)

*Self-organisation.* Resilient urban systems evolve from countless actions and decisions taken routinely by independent agents (i.e. individuals, households, communities), without awareness on cross-scale consequences (Portugali, 2000, Anderies, 2014) but that, nevertheless, have important cumulative effects on the overall system (Cloete, 2012). Natural ecosystems are prime examples of self-organizing systems, whereas independent elements at local scales interact through generative behaviours. While cities are also shaped by decisions taken by centralised institutions and top-down rules (i.e. building regulations, religious codes) (Kostof, 1991, Davoudi et al., 2012), vibrant and liveable cities have developed in large part through progressive self-organising processes (Anderies, 2012; Hakim, 2014). In fact, the built fabric is a significant enabler or impediment to self-organisation. Porta et al. 2013 reflects on how patterns of use, control and ownership of places affects processes of self-organisation in the built environment. The more people have unified control over these aspects, the higher their freedom to implement flexible and responsive changes (Liao). Hence fine-grained modular urban structures seem better suited to promote self-organisation because they are highly decentralised and autonomous. In turn, places that can be managed locally without need of central control, report higher overall maintenance (Porta). From a social perspective, Ostrom (xx in xx, xx) reported how people, given the possibility, can effectively organise and mobilise to deal with complex issues without any centralised governance structure. Additionally, demanding local management to locals promotes cooperation and stewardship (Sanoff, 2000), favours emergence of local distinctiveness against homogenising trends (Carmona, 2010). With this regard, Folke (2006) stressed how non-prescriptive management and regulation characterised by a degree of openness empowers people, according them greater margin of control and negotiation.

*Resourcefulness/Responsiveness.* Resourcefulness and responsiveness in urban environments are related to the ability of people and institution to mobilise effectively assets (financial, environmental, human, technological) and to meet established priorities (da Silva et al., 2012) to better and faster respond to stress and to achieve durable recovery (Moench, 2014). The availability and accessibility of tangible resources – physical, natural, social, human and cultural - is fundamental as it is the capacity to learn from experience, self-organise and establish networks (i.e. information and support), cooperate and innovate (Galderisi, 2014, da Silva et al., 2012).
Resourcefulness and responsiveness stress the role of the local scale to take action on the basis of a realistic understanding of priories and resources, as opposed to meet imposed requirements and externally set standards (Collier et al., 2013) and addresses local issues of inequality in distribution of resources, access to knowledge and material infrastructure that tend to penalise low-income and marginal groups. As resourcefulness is also an organisational capacity, it also requires establishing and maintaining relational links across space and scales. Therefore, in cities, the capacity of organizations (i.e. community groups) and public authorities (i.e. municipality, the State) are also crucial for coordinating local efforts.

*Learning and innovation capacity.* Resilient cities internalise and operationalize information, memory and experience as fundamental learning mechanism that enables them to avoid repeated failures and to innovate and improve performance (Galderisi, 2014).
Learning capacity is key for improving ability to anticipate, foresee and cope with change (Folke, 2006). Spatial effects of learning processes are generally context specific and tailored to local challenges and resources. Hence they contribute to distinctiveness and character.
Capacity to innovate helps transforming external pressures into opportunities betterment (Galderisi, 2014). Also the urban form learns through adaptation that also depends on the flexibility and

organisational capacity of its physical structure (Porta and Romice, 2010). Innovation implies failure, urban system that have enough autonomy at the smaller scales make it possible to initially test innovation through minor, gradual and fail-safe experiments. Then, in case of success, innovation can be more safely spread across wider urban system (Ahern, 2011). Socially, community learning is a basic ingredient of resourcefulness and responsiveness, and is further enabled synergy at different scales between people with different experiences, skills, and knowledge.

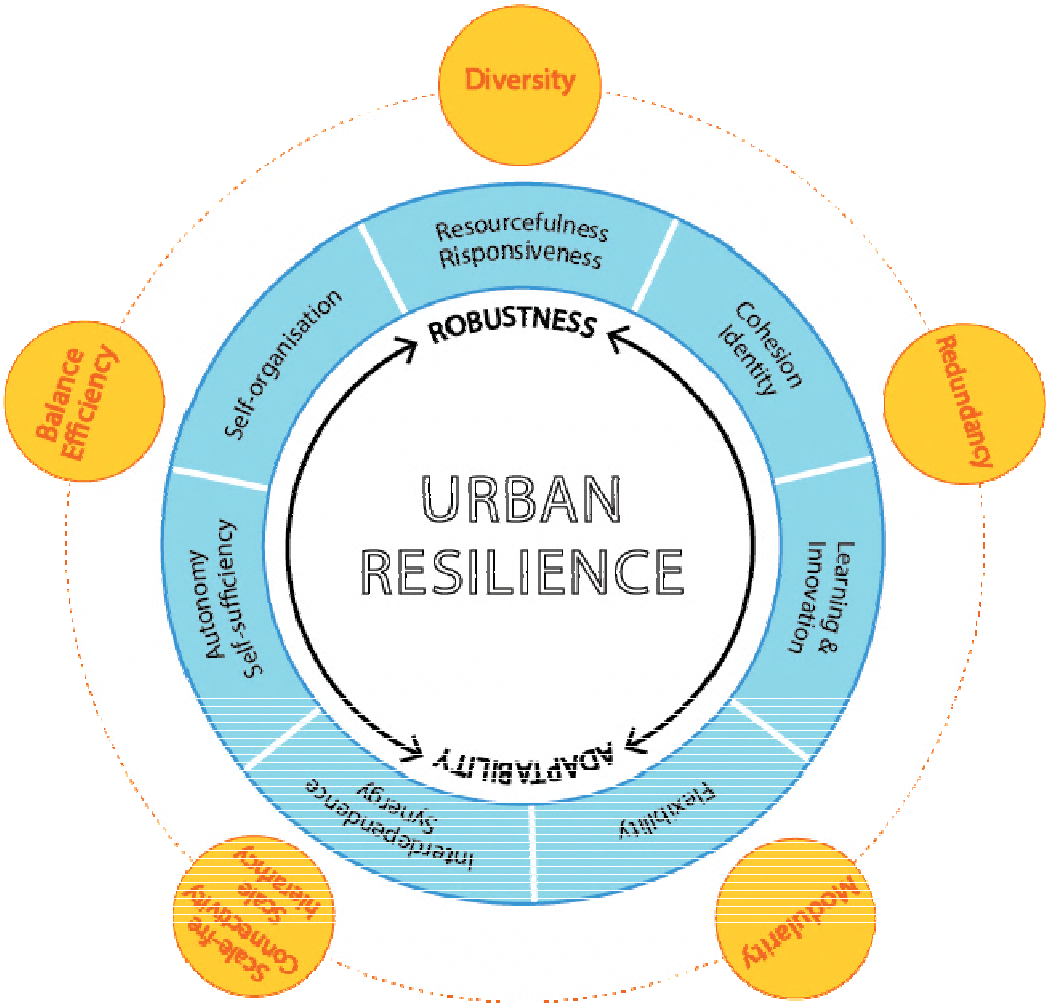

Figure 1. Urban resilience principles for Masterplan for Change, divided in structural properties (the outer circle) and behaviours (the inner circle).

## 5. Conclusions

In the face of future challenges, embedding a resilience framework into urban design and masterplanning can potentially help designers and policy makers create places able to perform culturally, socially and environmentally as well as to adapt to dynamic contextual conditions and evolve over time (Verebes, 2013). The current work preliminarily explored the possibility to reform masterplanning in a way that makes it fit to give strategic direction and spatial quality to places, by building in them enough resilience to accommodate change, even when unforeseen. Over the last 15-20 years, masterplanning experiences have sought to embed, with varied degree of success, sustainability principles in shaping the form of new urban development. The framework of socio-ecological resilience shares many commonalities with the sustainability agenda, as recognised in much literature (Wu and Wu, 2013, Marcus and Colding, 2014). Hence integrating and combining urban design sustainability principles with principles of socio-ecological resilience, made possible to list a series of structural characteristics and behaviours that any resilient urban system should possess

and that urban design and masterplanning should aim to achieve. This work, while still at an early stage, is also meant to give further definition to the very concept of *"Masterplanning for Change*", in parallel carried out by the Urban Design Studies Unit at Strathclyde as an operative and practical approach to masterplanning. The identified principles are intended as complementary and mutually reinforcing. Their aim is to illustrate general properties of resilience as manifested in the urban form across several socio-economic and environmental processes. However they do not provide technical specifications. No claim is made, particularly at this stage, about the possibility exhaustively determine all possible interrelations driving resilient urban systems, as this would mean incurring in the same form of over-simplification and determinism that we seek to overcome.

As the discourse on resilience of complex adaptive systems shows, the practice of urban design is not free from producing unintended and unattended consequences on form, society and the environment, nor should it try to be. Nonetheless, taking on the challenge of uncertainty and designing places capable respond to it and evolve remains crucial. Innovation brings inherent potential of failure. By learning from past and recent failures and successes of masterplans, the chance is to shift more deeply the focus of place-making on durability and adaptability and find again the quality of our most successful cities so deeply cherished.

What will be the final shape of this *"Masterplan for Change"* is still under development by UDSU. It will consist in "*planning without deciding too much"* (Hamdi, 2013, p.117), addressing to physical change integrating long-term goals and short term initiatives, thinking smaller and at smaller scales and linking these to wider and progressive large-scale change in a way which is self-adjusting, harnessing potential of innovation and creativity while remaining place-based and locally relevant, being flexible, open and inclusive and embedding community involvement and political will.

## 6. Next Steps

The list of principles of "Masterplanning for Change" is functional to the selection of masterplan case studies; this is based on compatibility with the principles and on observations on the ground of achieved spatial, environmental and socio-economic performance as suggested in literature. Analysis of case studies seeks to verify if masterplans complying with principles associated with resilient systems display themselves resilience in their resulting urban form.

At the current stage, two sets of masterplan case studies have been considered. The first set includes masterplans dating from the early 1990s, selected as illustrating innovative approaches to commissioning, implementation and governance. The second set, dating back to 1800s, provides some lessons on long-term adaptive quality and identity, visible in their formal spatial outcomes. Jointly they provide a cross-section of different masterplanning approaches and outcomes. Currently 10 case studies from the first and 3 from the second set have been shortlisted for further analysis. The geographic focus of the selection is international, but concentrated, with few exceptions, in Northern Europe and the United Kingdom. A pilot case study, the masterplan for Homeruskwartier in Almere, (Netherland) was selected to perform initial analysis. At the time of writing, analysis on the pilot is not at a stage where results can be presented, but hopefully will be object of discussion in occasion of the forthcoming AESOP Conference in July 2015.

## 7. Outcomes for planning and design

The current research seeks to inform scholars, professionals, users and policy-makers, locally and internationally, with the results of the research. The work presented should be taken as a work in progress and will be constantly revised, tested and refined. As part of a larger PhD research that stems and benefits from on-going work carried out by the Urban Design Studies Unit at the University of Strathclyde, the current work contributes to the creation of a more comprehensive urban design manual that embeds the result of research on *"Masterplanning for Change"*. This manual will be made available to practitioners, students, and community groups to guide design, delivery, management and monitoring of urban developments, as well as to assess proposed or implemented plans.

# A TALE OF TWO CITIES: COMPARATIVE STUDIES OF URBAN-RURAL COHESION DEVELOPMENT POLICIES BETWEEN CHENGDU AND CHONGQING IN CHINA

Xinyue Gan[1], Jianbin Chen[2]

[1]College of Architecture and Urban Planning, Tongji University,ganxinyue@outlook.com
[2]College of Architecture and Urban Planning, Tongji University,chenjianbin1989@hotmail.com

**ABSTRACT**: *Separate developments of Chinese urban and rural areas were caused by urban-rural dualistic system, which seriously impeded urbanization process in China. Chengdu and Chongqing were two pioneer cities of promoting urban-rural cohesion. They have adjacent location and similar background, while their policies were not exactly the same.*

*This article had a review of the urban-rural cohesion policies and their consequences in this two cities and pointed out the main features of them. Comparative analysis of the reasons for the different polices in Chengdu and Chongqing is presented in the end.*

*According to the analysis, Chengdu adopted integrated management which put rural elements like the land, capital and the labor force into market to promote urban-rural cohesion. Market played a more significant role than the government in Chengdu case. However there was an opposite situation in Chongqing where the government relied on the power to dragged rural elements into market circulation. Government dominated the whole process in Chongqing case. The urbanization rate change indicated that polices in Chengdu which rested on market are more efficient and more sustainable than those in Chongqing.*

*The conclusion is that although it will take a longtime to establish the order of the market, it will have a steadier, more reasonable, efficient and sustainable processes and results than a strong government-led transformation which can get instant results. If there is no orderly market, once the pressure of government has been taken away, the transformation will cease. Therefor market should lead the urban-rural cohesion with the support of government s authority. Both of them are indispensable.*

## 1. Introduction

In the third convention of the 18th plenary session in China, the government of China paid high attention to the urbanization of China. The holding of *Central Urbanization Meeting of China* in 2013, marking the arrival of transition session of urbanization in China. Urbanization has become one of the core topics of the whole people of China. Urbanization, is a process in which rural inhabitants transform to urban residents. The appearances of this process are the increasing of urban population, the expansion of the scale of urban land and the formation of urban social life-style. In terms of urban connotation, the vigorous promotion of urbanization means that the free movement of land resources, capital resources

and labor force resources between urban and rural area. However, the urban-rural dualistic system which implemented from the planned economy era has impeded the free movement of the resources. Therefore, the key point to solve Chinese urbanization problem is to break urban-rural barriers by urban-rural cohesion.

*1.1. The urban-rural dualistic system in China*

Since the founding of new China, the heavy industry road heading to industrialization caused the foundation of the urban-rural dualistic system in China which absorbed the fruit of rural agricultural production into the urban to supply industry. Urban grew rapidly while the development of rural was constrained. Since the reform and opening-up, Chinese government have tried to reform this system whilst the urban-rural dualistic system remains and restricts the vigorous development of urbanization in China.

*1.1.1. What is the urban-rural dualistic system?*

The urban-rural dualistic system means that urban and rural developed separately. The key point of this system is the barrier between urban and rural which restrict the free movement of their resource. Because this barrier, the government use better policies on urban to make it develop much faster than the rural area. In this process, the industry of China developed rapidly and the citizen who had urban household registration got rich, while the farmers who had rural household registration endured terrible life.

*1.1.2. Why the government adopted this system*

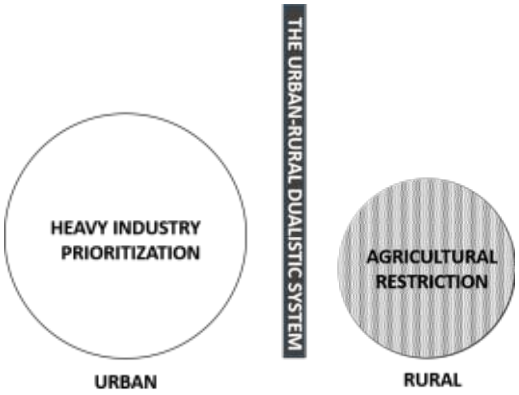

Figure 1. The Urban-rural Dualistic System of China

At the beginning of the new China, the main economic form in China is small-scale agriculture without any heavy industry. The government believe that the urban area of China must start developing industry while they all know this county cannot give up agriculture since they need the money for industrial development. Consequently, the government established this dualistic system between urban and rural. In rural area, the farmer went on with farming work and must hand most of their fruit over to the government. In urban area, the government make use of the benefit get from rural area to develop industry. That is to say, in a certain long time after the foundation of the state, government got most of their income from rural area while invested most of them in urban area. That s why the rural area fell so muc

*1.1.3. The features of urban-rural dualistic system*

The basic feature of this system is the household registration, and it have three appearance.

*Land resource*

Urban and rural area have different land use police. In rural area, lands belong to collectives instead of farmers. Farmers rent the land and just have the right to use so that they cannot sell their land. And if their collective decide to sell the land, the benefit belong to collective. In this system, the farmers have two things they can use. The first one is the contracted land which they use to produce to get food, the second one is homestead which they use to live. However, since neither of their ownership belong to farmers, farmers cannot sell them in the market. In urban area, lands belong to country. Country have quota for city construction. So if the government want promote urbanization, they need to transform rural land to urban land. Therefore they need to buy lands from rural area. At this time, the urban-rural dualistic system restrict the process.

*Capital resource*

Since the government want to use the fruit of rural area to develop urban area, the price of agriculture products were undervalued while the price of industrial products were overestimated in the market. One result is that the income of farmers are extremely low so that they endured a terrible life, and another result is that no one want to invest in agriculture. Consequently, the capital flow just have one direction: rural to urban, just little capital came back.

*Labour force resource*

The government use the capital from rural area to support different kinds of social services and security for the people who have urban household registration so that they have retirement insurance security, medicine security, education security and other securities. However these security will not support to farmers who have rural household registration. As the development of science and technology, rural area don t need that much young person to work on agriculture and meanwhile, the co need more labor. With this back ground, many surplus labor of countryside go to work in cities with their rural household registration. They work for the construction of cities while the city would not support any security for them since they don t have urban household.

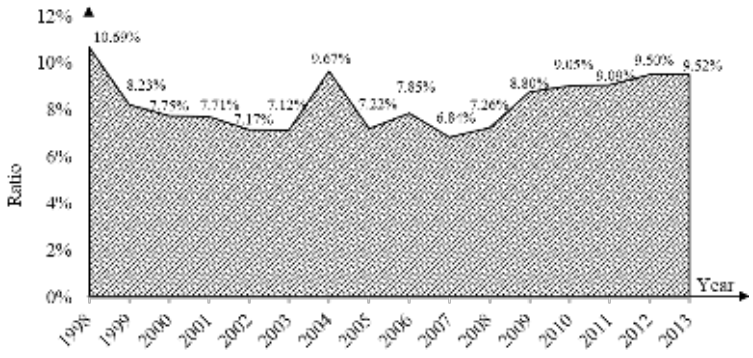

Figure 2. National Agricultural Expenditure Ratio from 1998 to 2013
Source: Chines National Bureau of Statistics, 2006;2007;2008;2009;2010;2011;2012;2013;2014

*1.1.4. The problems created by the urban-rural dualistic system*

There are five main problems caused by the urban-rural dualistic system. Firstly, the collective ownership of land prevented land scale management. Chinese country adopt collective ownership system. Farmers only have the right to use the land instead of own it. However the owner of land including towns, villages, and unincorporated villages and other stakeholders don t have

clear boundaries of the distribution of land revenue share. Which means if a piece of land will be sold to someone in the market, nobody knows that the how to allocate incomes to its owners. Therefore the land cannot be exchanged freely in the market. That s why nobody can own a large scale management agriculture. Secondly, since the income distribution system biased to urban, the agricultural, rural infrastructure and public services cannot get adequate investment. Before 2007, although the number of national rural spending seems increased annually, while total state revenues also increased, so that the proportion of agricultural spending is actually declining (Figure 2). The truly present situations are rural public service facilities are fell behind, agricultural developed slowly and modern agricultural science and technology are also still in its infancy stage. The national government was aware of this problem and began to increase investment in agriculture in recent years. Thirdly, price "scissors difference" underpriced the agricultural products so that the farmers have the lack of expansion capital which increased the gap between urban and rural areas (Xin Yan, Kun Tian and Jie Gao, 2011). During the initial period of founding the state, agriculture must support industry and hence agricultural products have been undervalued while industrial products have been overvalued for a long time. City had surplus funds for its development while countryside is short of expansion capital. Rural-urban gap expanded. This situation still exist today. Fourthly, financial industries suck more capital than lend loans in rural areas caused the significant outflows of rural capital (Xin Yan, Kun Tian and Jie Gao, 2011). Rural enterprises are small with low credit. They are difficult to secure loans from the financial sector so that most of the money flows to big enterprises and big projects in the city, rural enterprise development difficultly. Finally, the household registration system restricted the free movement of labor force. The household registration system created by urban-rural dualistic system caused that the migrant workers with rural accounts cannot enjoy pension, education, health care and other safeguards which are enjoyed only by urban residents who have urban accounts. It seriously impedes the freedom of rural surplus labor flowing into city.

These five aspects seriously hampered urbanization of China. Therefore, solving the urban-rural dualistic problem should focus on these five issues.

*1.2. Analysis of the comparability of the Chengdu and Chongqing urban-rural cohesion*

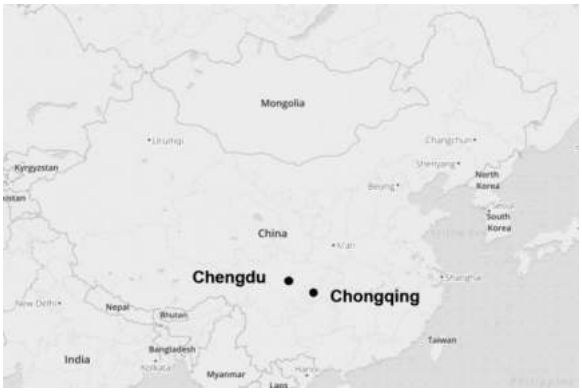

Figure 3. The Location of Chengdu and Chongqing

Chengdu and Chongqing have always been compared by scholars in different aspects since they do have comparability. Both of them are located in the western part of China with just 340km distance between them and are the leader cities of Chengdu-Chongqing economic zone (Figure 3). They also have many things in common on the topic of this article: urban-rural cohesion strategies. Both of them emerged serious rural-urban polarization so that they both have necessary to develop urban-rural cohesion planning. In 2007, both of them are

approved by the National Development and Reform Commission for the national urban-rural cohesion reform testing area, and did a lot of research in urban and rural cohesion planning with some outcomes. However they are totally different with their geographical, social and political environment. Therefore, comparing their measures and achievements in urban and rural cohesion planning can be used as a reference for research on urban-rural cohesion planning in China.

## 2. Methodology

### *2.1. Research strategy*

The mail method of this article is comparative study. Since the main features of the urban-rural dualistic system are mainly on three aspects (land resource, capital resource and labor force resource), this article will analysis the strategies adopted by both cities to see if their strategies is useful to change these features. Then in order to see the general system of their strategies, the article analyzed the strategy structure of both cities. Finally, the article introduced some special strategy in both cities.

### *2.2. Methods of data collection*

The data of this article is mainly come from the *CHINA STATISTICAL YEARBOOK*, *CHONGQING STATISTICAL YEARBOOK*, and *CHENGDU STATISTICAL YEARBOOK* from 2003 to 2012. In order to do the comparative study, the author wants to use the data from the same number of years for both cities. That is to use the data from 2003 to 2008 for Chengdu and 2007 to 2012 for Chongqing which is 6 years since the stating of reformation.

Because of the main purpose for urban-rural cohesion strategy for china is to promote urbanization, the urbanization rate is one of the main indicators adopted in this article. The other indicator is the income gap between urban and rural areas which is used to evaluate the effect of urban-rural cohesion development.

## 3. Research on urban-rural cohesion planning in Chengdu

### *3.1. The review of urban-rural cohesion planning process in Chengdu (using 6 years information since the starting of reformation)*

Chengdu urban-rural cohesion planning began in 2003. During 6 years from 2003 to 2008, this process mainly consists of 2 stages (Jiuli Zeng and Peng Tang, 2013).

The first stage was 2003 to 2006, this was is the exploration phase of urban-rural cohesion planning. During this period, Chengdu has implemented the four-in-one and three concentrations politics, began to explore to bring the rural planning into of whole territory planning system which means transform the planning system from urban planning" to "urban and rural planning".

The second stage started from 2006 until 2008. In this phase, Chengdu have implemented the project , giving back the determined ownership to farmers and other means to integration target. In this process, Chengdu have practiced a comprehensive urban and rural plan system, and formed a more perfect system of urban and rural cohesion planning.

### *3.2. The innovation exploration of Chengdu urban-rural cohesion reformation*

#### *3.2.1. Innovation policies promoting free movement of resources*

*Land resources*

Land use system are the key points of urban-rural cohesion development. As it was described in the previous article, the ambiguity rural land ownership and the ambiguous benefits distribution leaded the problems like it was difficult for land ownership circulation and the loss of arable land after circulation. These are key problems to solving the land circulation issues. Chengdu has three main steps. Firstly, Chengdu have conferred land ownership certificate for all the rural land. In other word all the owners of the land can get a certificate to identify their benefit of the land. From January 2008 the government have conferred 33800 certificates for collective land ownership, 1.66milion certificates for collective land-use right, 1.8milion Rural Land Contract Management Certificate involving 10milio Secondly, found land transaction platforms. Chengdu found the first rural property rights exchange of china to support platform for transaction of land in the market. Thirdly, Chengdu established arable land protection fund firstly in China. The criteria is about: 360 yuan per acre per year for primary farmland and 270 yuan per acre per year for general farmland. This is to say if someone own 3 acres primary farmland and he keeps cultivating on it, he can get 1080 yuan from government. That is an excellent policy to encourage to protect farmland.

*Capital resource*

Chengdu have adopted three policies to overcome the difficulties the rural enterprises and agricultural face when they want to obtain capital from market. Firstly, settings up investment companies. Chengdu have organized *Modern Agricultural Investment Company*, *Small Town Construction Investment Company* and *Agricultural Logistics Investment Company* to investment in rural construction directly. Secondly, perfecting the guarantee mechanism by established financial investment rural guarantee company, and the rural land ownership circulation guarantee corporation to improve the guarantee system. Thirdly, banks pilot plan. Testing on some village banks, microcredit banks, as well as agricultural insurance as pilot program to gradually explore the mechanisms of financial reform.

*Labour force resource*

Household registration system restricts urban-rural cohesion development, affecting the free movement of labor force. Chengdu started from household registration reform to promote free labor flows. Firstly, unified household registration and break barriers of urban and rural. Chengdu introduced a government document in October 2006 to further promote the integration of urban and rural which stipulate that if farmers were domiciled in the cities, they can have urban household registration to enjoy old-age pension,

education and health care secure of city. Secondly, establish integrated urban-rural labor market. Improve situation of farmer workers by job training, employment policy, employment assistance, employment work responsibility system and employment services network. Thirdly, enhance protection system for persons who change from agricultural to non-agricultural status.

*3.2.2. Urban-rural integral policy structure*

Chengdu have carried out a series of reformation and innovation on planning structure of the city, financial structure and management structures which mainly in the three integration.

Figure 4. The Planning Integration of Chengdu

*Planning integration*

Firstly, planning area integration. Chengdu proposed an overall layout concept named whole area Chengdu, looks urban centers, surrounding towns and rural settlements as a whole area to plan (Jiuli Zeng and Peng Tang, 2013). Secondly, the special planning integration. Originally separated national economic and social development planning, urban master planning and land use planning have been unified to ensure that different urban and rural planning department can be highly linked up and regulated.

*Urban-rural service system integration*

Firstly, the integration of urban and rural public finance system. Chengdu reformed the rural financial management systems and implemented a new way which utilize county government to manage the finance of villages under it. Secondly, municipal finance directly invest into county. For the situation that the finance power of some basic layers government are too weak to guarantee equal accessibility to public service, the municipal finance invested directly in standard basic public services such as rural middle and primary schools, county (village) health centers (stations) and multi-use culture station. Thirdly, the reformation of basic layers management system. The economic function of sub-district administrative office have been abolished and its level of public services and social management capacity have been enhanced.

*Management system Integration*

Chengdu streamlined the existing administrative system. During the reform period, 758 political examinations have been reduced, which have been cut 66% compare with original amount. More than 30 departments have been dismantled and restructured, including planning, agriculture, transport, water supply, forestry and gardening for the integrated management of urban and rural departments. Simultaneously, 30% countries and 47% villages have been dismantled and restructured as well as more than 5000 official staffs have been reduced.

*3.2.3. Exploring of intensive development mechanisms* Three Aggregations

Reply to the situation that the serious contradiction between people and land, scarce resources and fragile

ecology, Chengdu has explored intensive development mechanism with Three Aggregations as the core idea (Guangyue Li, Min Wang and Jianzhong Wu, 2010). Firstly, industries assemble to the industry aggregation zone. Chengdu centralized 116 original separated small-scale industrial development zones into 20 industry aggregation zone to achieve the goal which develop industry intensively. Secondly, land use assemble to large scale aggregation. The government try to adopt methods like subcontract, lease, and buy a share to transform the existing dispersed small plots land created by land contract responsibility system into agricultural leading enterprises, rural collective economic organizations, professional farmer cooperative organizations or large planter in order to achieve scale management. Thirdly, farmers assemble to towns. Follow the principles like considering local conditions, respecting the will of farmers, paying according to law, promoting steadily , the government built town and rural new communities and guide farmers to transfer from primary industries to the second and third industries.

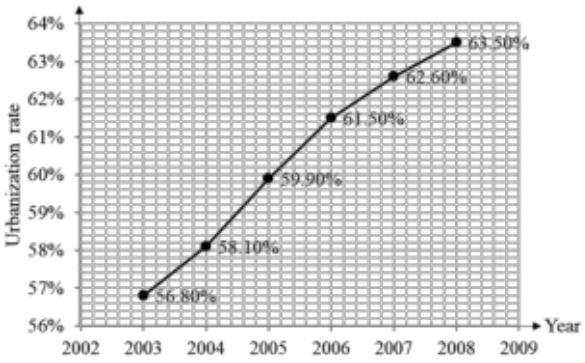

Figure 5. The Urbanization Rate of Chengdu from 2003 to 2008
Source: Chengdu Bureau of Statistics 2009

### *3.3. The outcomes of Chengdu urban-rural cohesion planning. (Using 6 years data since the starting of reformation)*

#### *3.3.1. Outcome 1: urbanization rate raised quickly, reaching the degree higher than standard level of urbanization*

One of the most important indicator used to measure the level of urbanization is urbanization rate count by urban resident population. From 2003 to 2008, the urbanization rate of Chengdu increased 6.7%, with a fast growth rate of 1.34% annual.

Table 1. The Standard Structure of World Development Model About Urbanization Capita Built by Hollis B. Chenery

| GDP per capita dollar in 1964 | <100 | 100 | 200 | 300 | 400 | 500 | 800 | 1000 | >1000 |
|---|---|---|---|---|---|---|---|---|---|
| Urbanization % | 12.8 mid-value | 22 | 36.2 | 43.9 | 49 | 52.7 | 60.1 | 63.4 | 68.5 mid-value |

Source: Zhang Ying and Zhao Min, 2003 cited in Yan Xing, Tian Kun and Gao Jie, 2011

Table 2. The Standard Structure of Urbanization and GDP per Capita According Chinese Situation

| GDP per capita dollar in 1964 | 100 | 200 | 300 | 400 | 500 | 600 | 700 | 800 | 900 |
|---|---|---|---|---|---|---|---|---|---|
| GDP per capita dollar in 2001 | 500 | 1000 | 1500 | 2000 | 2499 | 2999 | 3499 | 3999 | 4499 |
| Urbanization % | 22.1 | 36.4 | 44.1 | 49.2 | 53 | 56 | 58.4 | 60.4 | 62.2 |

Source: Zhang Ying and Zhao Min, 2003 cited in Yan Xing, Tian Kun and Gao Jie, 2011

According to the general law of urban development, the higher level of economic development a country have, higher level of urbanization it will have, and vice versa. Urbanization rate and GDP per capita has a correspondence relation (Table 1).

In 2008, GDP per capita of Chengdu has reached $ 4213.4 (according to the dollar convert from 2001), and its corresponding population urbanization rate should exceed 60.4% and actual urbanization rate of Chengdu was 63.15% which is higher than the standard level of urbanization (Table 2).

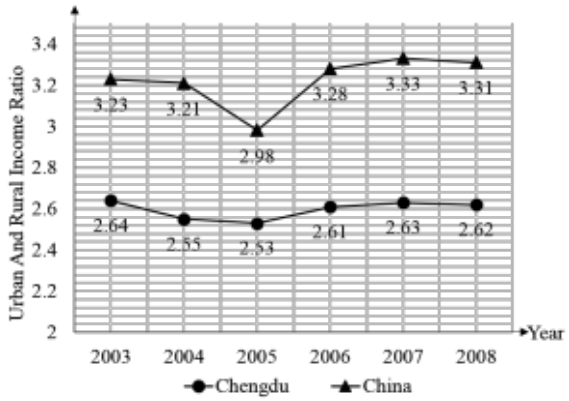

Figure 6. Urban-Rural Income Ratio of Chengdu and China
Source: Chengdu Bureau of Statistics 2009; Chines National Bureau of Statistics 2009

*3.3.2. Outcome 2: the balance urban spatial* `expansion mode create by` *three* `aggregations .`

In 2003 and 2007, non-agricultural population annual growth rate of suburban districts and exurban counties of Chengdu have reached 18.1% and 15.11%, respectively, which is much higher than 7.14% in the Center-City. The non-agricultural population increased fast continuously, especially in suburban areas. This rate in 2007 was 21.15% higher than that in 2003.

*3.3.3. Outcome 3: the income gap between urban and rural areas kept stable and low*

Chengdu urban-rural income gap remained the level below the national average, and maintained stability without widening trend.

Table 3. Urban-Rural Income Gap of Chengdu and China

| Year | | | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
|---|---|---|---|---|---|---|---|---|
| Chengdu | Urban per capita Disposable income | yuan | 9641 | 10394 | 11359 | 12789 | 14849 | 16943 |
| | Rural per capita Disposable income | yuan | 3655 | 4072 | 4485 | 4905 | 5642 | 6481 |
| | Urban-Rural Income Ratio | | 2.64:1 | 2.55:1 | 2.53:1 | 2.61:1 | 2.63:1 | 2.62:1 |

## 4. Research on urban-rural cohesion planning in Chongqing

*4.1. The review of urban-rural cohesion planning process in Chongqing (using 6 years information since the starting of reformation)*

Chongqing urban-rural cohesion planning began in June 2007, after been for the national urban-rural cohesion reform testing area which was approved by the National Development and Reform

Commission. In July 2007, Chongqing founded a leadership group and institution for urban-rural cohesion planning. On September 8th, 2007, Chongqing Municipal Government issued an office document on overall urban-rural cohesion reform which created a better legal environment for the reforms and innovations done by government. On April 28th, 2009, the State Council approved urban-rural cohesion reform program of Chongqing. Since then Chongqing entered a period of urban-rural cohesion reform practice (Yingying Lv and Hongxing Lan, 2011).

*4.2. The innovation exploration of Chongqing urban-rural cohesion reformation*

*4.2.1. Innovation policies promoting free movement of resources*

*Land resources*

Facing the similar problems brought by land ownership system as Chengdu, Chongqing adopted two approaches. Firstly, as similar as Chengdu, Chongqing have also conferred land ownership certificate for all the rural land, which including land contract certificate, forest ownership certificate, homestead certificate and collective-owned construction land certificate etc. Second, *Dipiao* system. Get planning quotas by the reclamation of idle rural construction land and then transform these quotas into *Dipiao* for selling. Other traders can by these *Dipiao* to change them to urban construction quotas which can be used to construct in urban area. In the process, urban got legal quotas for construction, farmers got benefits from selling *Dpiao* and the arable land had been protected.

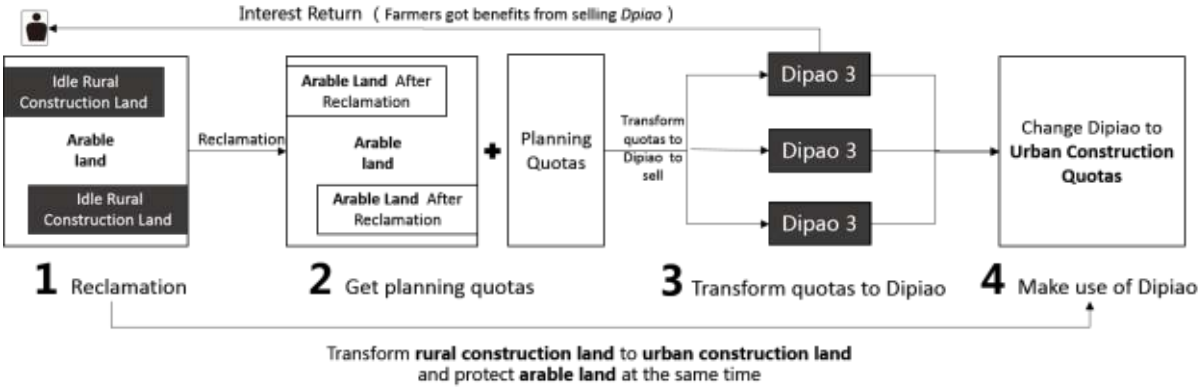

Figure 7. Dipiao system of Chongqing

*Capital resource*

Firstly, promote bank restructuring. Commercial Bank Wanzhou successful reorganized to Chongqing Three Gorges Bank, Municipal Rural Credit Cooperatives reorganized to Chongqing Rural Commercial Bank, and Chongqing Financial Leasing Companies have been approved. Secondly, develop innovative financial products. Mainly introduce unsecured microcredit to promote development of rural enterprises. Thirdly, the financial policy tilted toward agriculture. Use the services network and financial terminals of rural bank to provide loans, payment, withdrawal, settlement, and other financial services to farmers, cooperatives and agricultural leading enterprises. Finally, experiments on agricultural insurance. Mainly promote agricultural insurance pilot project on three kind of agricultural products including pigs, cows

and oranges.

*Labour force resource*

Government provided public services for migrant workers in a variety of ways. Firstly, housing security. Improving the living conditions of migrant workers, which was regarded as an important measure to solve the housing difficulties of urban low-income families, has been mentioned in an official housing document in 2008. Secondly, social security. A system to support retirement insurance and serious disease medical insurance and a series of methods to do 26 necessary things in 7 categories have been established for migrant workers. Thirdly, legal right security. A campaign named defending right in hundred days started for migrant workers. Finally, children education security. An official document which titled the children of migrant workers can have the same educational treatment as their urban peers. These polices have supported security for the migrant workers as well as attracted the surplus labors which are still in countryside to go work in cities so that these policies promoting the free movement of labor force.

Figure 8. One Circle and Two Wings Structure

*4.2.2. Policy structure: One Circle and Two Wings and urban-rural cooperation in pairs*

The main urban area of Chongqing half an hour economic circle regards as the one circ Northeast of Chongqing including Three Gorges area with the center of Wanzhou regards as the north wing. Southeast of Chongqing including the ethnic minorities impoverished mountainous area regards as the south wing. Every district of the main urban area will have a brother country to help with in pairs. The main contents of helping include eight aspects: industry collaborate, employment transfer, educational assistance, scientific and technological cooperation, health resources sharing, personnel exchanges, finance support, poverty alleviation and development etc. Supporting measures include: financial support, building standard rooms, arrange temporary posts for staffs, teacher exchanges, medical training and research consulting etc. Government asked the districts in main urban area must use at least 1% of their financial budget to help their county counterparts, and evaluate their achievement together.

*4.2.3. Pilot experiments to explore a variety of suitable models according to local conditions.*

Because of the complex situation with wide area and high mountains, countries of Chongqing had some pilot project to explore a variety of suitable models according to local conditions. typical projects are Jiulongpo District, Liangping County, Dianjiang County.

Jiulongpo District promoted farmers use contracted land to exchange for social insurance and homestead

for house. The core policies are to transforming farmers to urban residents with their own resources and support excellent migrant workers going into the city. They also focused on comprehensive industrial development on rural collective construction land and the construction of new rural communities which aim to improve the living conditions of migrant workers.

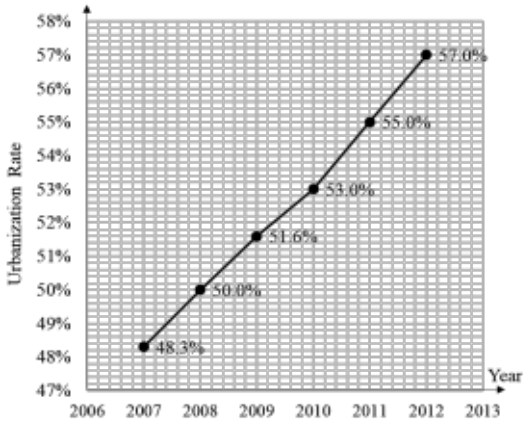

Figure 9. The Urbanization Rate of Chongqing from 2007 to 2012
Source: Chongqing Bureau of Statistics 2013

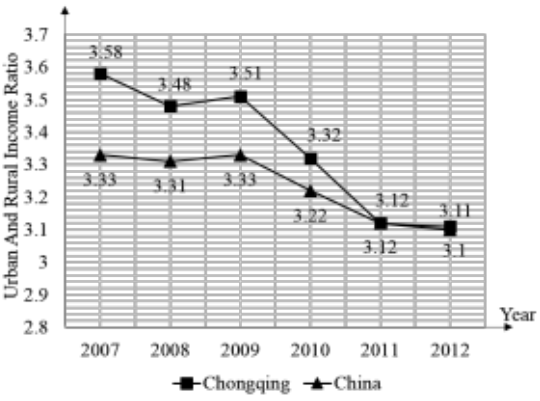

Figure 10. Urban-Rural Income Ratio of Chongqing and China
Source: Chengdu Bureau of Statistics 2013; Chines National Bureau of Statistics

Liangping County developed specialized farmer cooperatives which organized specialized farmers who plant same agriculture products together, so that to solve the contradiction between decentralized planting and the overall market demand.

Dianjiang County chose 50 village to exploring conditional mode to reform step by step with the principles which are smaller units, multiple mo low risks.

### *4.3. The outcomes of Chongqing urban-rural cohesion planning. (Using 6 years data since the starting of reformation)*

#### *4.3.1. Outcome 1: urbanization rate raised quickly, while still have gap with standard level of urbanization*

During 6 years reform period from 2007 to 2012, the urbanization rate of Chongqing increased 8.7%, with a rapid average annual rate of 1.74%. However, according to the standard rates of urbanization level mentioned above, in 2012, GDP per capita of Chongqing has reached $ 6191, which is $ 4472.5 converted from 2001. With this situation the urbanization rate should be above 60% in theory while the fact is just 57% in Chongqing. Therefor the urbanization rate level falls far behind the standard level.

#### *4.3.2. Outcome 2: the income gap between urban and rural areas reduced and reached the national level*

Urban-rural income gap of Chongqing have been larger and far above the national average. After the implementation of urban-rural cohesion reform, the income gap has declined markedly. In 2011 and 2012, it reached the national average level.

Table 4. Urban-Rural Income Gap of Chongqing and China

| | Year | | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 |
|---|---|---|---|---|---|---|---|---|
| Chongqing | Urban per capita Disposable income | yuan | 12591 | 14368 | 15749 | 17532 | 20250 | 22968 |

| **Conclusion** | Same | Similar | Similar | **Totally different** | **Totally different** |

Chengdu and Chongqing adapted similar politics to promote the free movement of resources in urban and rural area. Both of them focused on break the barriers between urban and rural. Because of the similar situation of them, both of them concentrated on three kinds of resources which are land, capital and labor resources. These three kinds of resources problems are caused by the urban-rural dualistic system in China. Therefore the universal methods to the urban-rural dualistic system problem is to try the break the barriers of this three resources between urban and rural.

Nevertheless, Chengdu and Chongqing have absolutely different policy structure for urban-rural cohesion planning. This policy structure of Chengdu is a kind of all-in-one integratio means that organize all the resources and materials of urban and rural together to put them into a same market. The key tool here is market. In other words, Chengdu want to found a market for all these resources to promote urbanization. The situation in Chongqing is completely changed. This policy

structure of Chongqing is try to use urban area to assist rural area in urbanization to reach urban-rural cohesion. The key tool here is government power.

*5.2. Reason analyses*

*5.2.1. Apparent causes: Geography and city scale differences*

Chengdu is located on the plains, with a total area of 12,400 km ², central city and the surrounding countryside contact closely make it is more easily for urban area to radiate the area around the it. The gap between center city and the surrounding countryside was relatively small. Therefore integration planning and the three aggregations can be better implemented. However, Chongqing is located in the mountains, with a total area of 82,000 km ², center city and the surrounding countryside are separated by mountains so that their connections are weak that makes it is more difficult for the center city to radiate the surrounding. Therefore, urban-rural cooperation in pairs is easier to imply. And because the complex situation each district and country should to explore the suitable mode for their local conditions.

Urban and rural areas of Chengdu have equal size. Chengdu had 6 million urban population, the rural population was also 6 million, that means it is big city lead big country which makes it easy to develop integration urban-rural cohesion planning policy structure. However, Chongqing had 7 million urban population, to lead 25 million rural population. Leading power of the center city is obviously insufficient. Therefore the government make use of gathering-diffusion effects of main urban areas to promote urban-rural cohesion planning process.

*5.2.2. Root causes: Political background differences*

The apparent causes seems reasonable, while in the author s opinion political b of this two city should be the root causes. We all know that a health market need a series of long-term policies to establish that means it will take a longtime. The data of Chengdu also proved this idea. Thus facing the problems which were not that much serious, the government chose to give the power to the market even though it will take a longtime. However, the government of Chongqi much patient, they want something faster to solve this tricky problem with serious situation. The leader of Chongqing want to see the outcome in short time (most of them just have 5 years term). In other words, if Chongqing have more patient, they can also try to establish a healthy market while the leader don t have that much time to see the achievement. Therefore they chose to rely instead of market order.

*5.3. Conjecture*

From the current data we may believe that Chongqing have better outcomes, since its income gap between urban and rural fell faster and the margin of decrease are bigger than that in Chengdu. However we can imagine that if the leaders of the government changed and the new comers d power which means the government pressure disappeared and they didn t have an ordered ma this outstanding outcome been maintain? The answer is no. Nevertheless, not all the cities can take up

with the method adopted by Chengdu for not all the cities have condition to wait. So efficiency and durability are both important. Therefore both government and market should be responsible for urban-rural cohesion planning.

## 6. Conclusion

Urban-rural dualistic system is the production of primary stage of social development in China. It is not suitable to remain in the way to urbanization. The aim of urban-rural dualistic system reformation is to break the barriers which restrict the free movement of resources. Chengdu and Chongqing have tried many different policies for urban-rural cohesion while they adopted completely contradict methods according their own situation. Chengdu relied on market and Chengdu relied on government power. The former will takes a long time and the later cannot stable. In author s opinion, the market should lea urban-rural cohesion with the support of government s authority. After all efficiency is jus relying on just government power and ignore the order of market is just like somebody couldn t see beyond the end of his nose. However, both of them are indispensable.

| | | |
|---|---|---|
| # $ | % | & |
| | | ' |
| ! | " | ( ( & |
| | | ( & |
| ) | * | ( |

Out of 192 maps, 79 maps (41.1% of total) has depicted path. There were 48 maps depicted train lines, and only 5 maps depicted roads. The total number of 219. Out of which, 209 were train lines and 10 were roads. In Japan, high sch have driver license. Therefore, it is natural to assume that these students do image of road network or road structure, however, the fact that just only 5 m strikingly different from Lynch s study of Los Angeles. Out of 77 maps that c 65 maps (84%) depicted Yamanote-line. Yamanote-line was most depicted paths. 58 Yamanote-line as circular, however 7 maps indicated only a partial part of Yam comes Chuo-line with 46 maps, followed by Yurakucho-line (12), Sobu-line(11), (9).

From the result of this survey, one can understand that the high school stude spatial structure of Tokyo by two distinguished paths, Yamanote-line and Chuo- it is easier for them to perceive spatial image by train lines that runs over ground. The interesting nding is that despite the huge number of maps depic the shape of Yamanote-line was not represented in a correct shape. Yamanote-lin east-west, 14.8km width in north-south. So, it is much more oval than circle. M maps drew Yamanote-line in circle shape. Yamanote-line supported many students image of Tokyo, however, the actual image they have with Yamanote-line is very reality it is quite oval.

## 3) Edges

Kevin Lynch has de ned Edges as follows (Lynch, 1960).

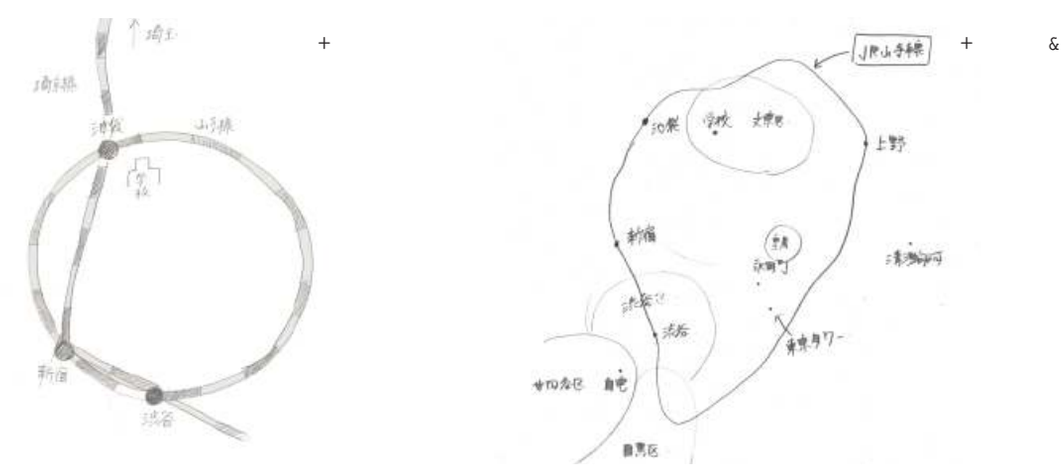

Figure 2. A Map that depicted Yamanote-line in circle (#146) and a map in verti

## 8) Results

Figure 7 is a diagrammatic representation of its major elements excluding d
from the image map study. Yamanote-Line and some major stations along it st
gure articulates that the image of Tokyo is constructed by Yamanote-Line an
stations as a trunk with the support of Chuo Line and other secondary stations
branches. Landmarks have not played an important role to construct the image
school students with the exception of Tokyo Tower, Skytree Tower and Emperor Pa
Airport. This result may indicate that Tokyo lacks landmarks that identify the

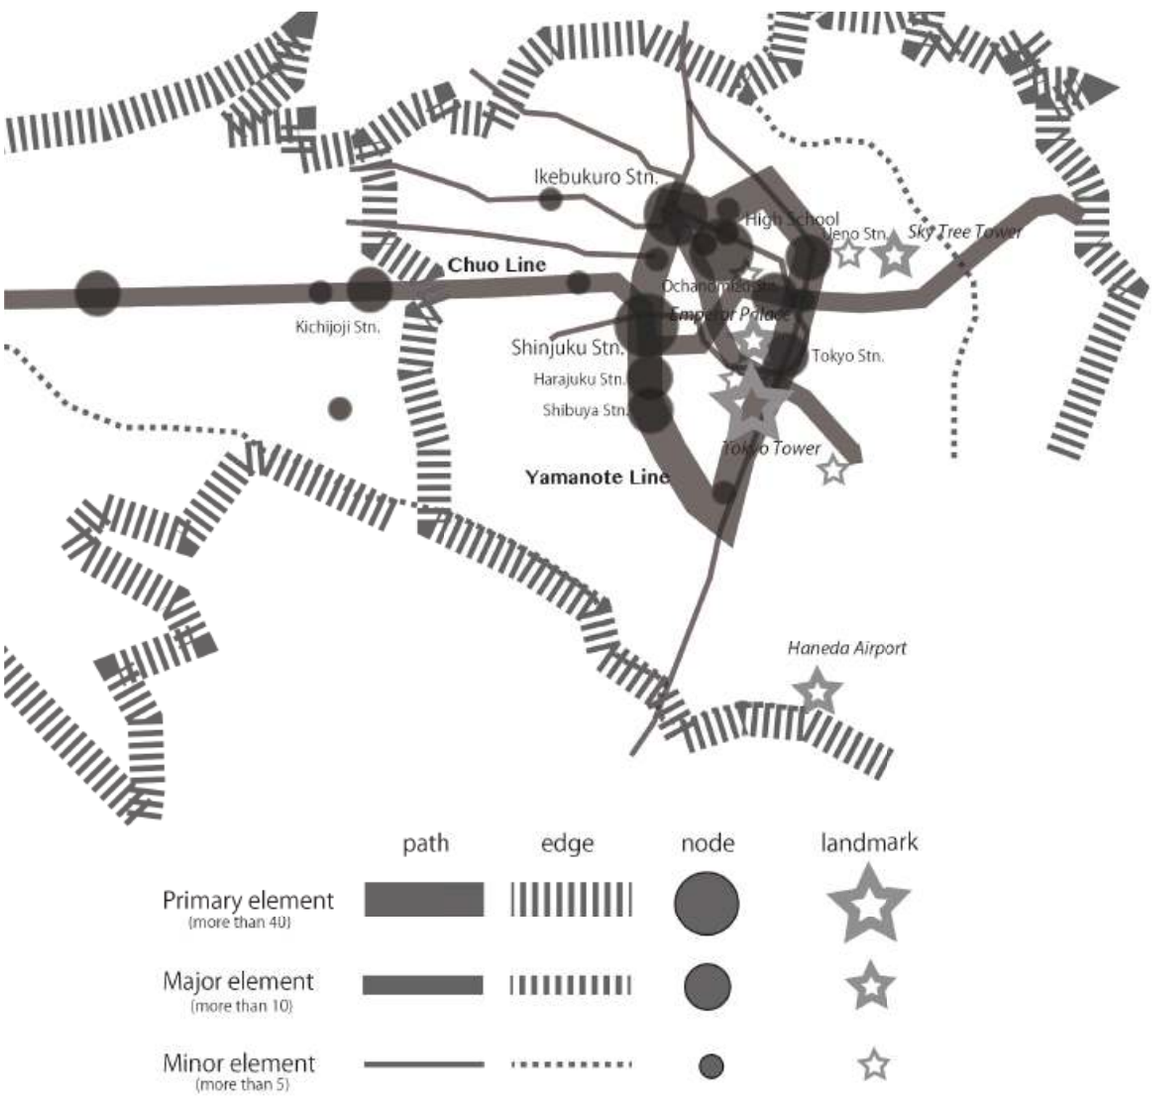

Figure 7. Diagrammatic representation of its major elements excluding district

Findings of the research are as follow.
A) Most of high-school students perceived spatial structure of Tokyo with train lines.
B) Most important train line for high school students to image Tokyo is Yama line that connects important nodes of Tokyo.
C) 142 students (74%) drew the municipal boundary of Tokyo Metropolitan Many maps had the correct shape of Tokyo Metropolitan Area.
D) Many maps did not have landmarks. Comparing to the number of maps tha stations, the number of maps that drew landmarks were much less. One can assum have not supported to comprise the spatial image of Tokyo for high-school stude

## 4. Conclusion

The study result suggests that high-school students have a strong tendency to spatial structure with train nodes and train paths. It has shown that Yamano framework to image the city. Some major stations also contributed in constr notably Ikebukuro, Shinjuku, Shibuya, and Tokyo. These are all terminal station On contrary, road network s role to construct the image of Tokyo is insigni students. In addition, the research found out that there is the lack of landma in Tokyo. Tokyo Tower was the sole landmark that had the lots of indications.

Therefore, in order to make Tokyo more legible, and with higher sense of p generations, it is recommended to improve accessibility to train stations and considered more seriously in enhancing its spatial structure. The landmarks sh and creating post-card city view should be considered. When there is an op some new buildings or parks that have a potential to become new landmarks, e colosseum, their design and vistas for them should be considered from urban des

Kevin Lynch conducted his innovative methodology of image study survey for r area. The application of his image study to the large city like Tokyo may hav for understanding the respondents real image of Tokyo.

# CRAFTING NEW URBAN ASSEMBLAGES AND STEERING NEIGHBOURHOOD TRANSITION: ACTORS AND ROLES IN ECOURBAN NEIGHBOURHOOD DEVELOPMENT

Meg Holden[1], Charling Li[2], and Ana Molina[3]

[1]Associate Professor of Urban Studies and Geography (Simon Fraser University), mholden@sfu.ca.
[2] P.Eng., Candidate, Master in Urban Studies (Simon Fraser University), charling_li@sfu.ca
[3]Candidate, Master of Public Policy (Simon Fraser University), ajm15@sfu.ca

***Abstract:*** *New sustainable neighbourhood developments are multiplying worldwide. Embedded in these model neighbourhoods are not only particular ideas about better urban form, but also particular ideas about better organization of urban life and social development. Frameworks, certifications, and labels to organize the practice of sustainable neighbourhood development are proliferating almost as rapidly as the developments themselves, and each holds a different mix of such ideas. Beginning from a typology of seven extreme types of ecourbanism, we consider the implications of pursuing each extreme for the key actors who assume different roles in planning, building, and living in these new neighbourhoods. We then consider two different ecourban neighbourhood frameworks, the Living Community Challenge and EcoDistricts Protocol. We examine these frameworks in terms of our seven extreme types of ecourbanism, as technologies of ecourbanism that have emerged in order to facilitate the mainstreaming and generalization of experimental ecourban development practices.*

*Building upon a conceptual framework of transition theory and urban assemblages, we see the emergence of such new frameworks as mobilizing different assemblages of actors, via the crucial work of intermediary institutions, in order to move ecourban neighbourhood development from a niche practice to the mainstream. Better understanding the mixtures of actors' roles and responsibilities, and expectations and practices promoted in different frameworks, will help us better understand the prospects of ecourban developments under different frameworks, in different urban contexts, at different stages of development, and different scales of experimentation and standardization.*

**Keywords:** eco-urbanism; green building; sustainable neighbourhood development

## 1. Introduction

Ecodistricts, écoquartiers, eco-cities, zero, low-carbon and carbon-positive cities, ecourbanismo, ecopolises (Downton, 2009), ecobarrios, ecovillages, One Planet Communities and solar cities, are on the rise worldwide. More than 100 municipal governments in China are proposing to build eco-cities, many of them on greenfield sites on the urban fringe (Baeumler et al. 2009); 32 projects in France have achieved the French government's écoquartiers label, with an additional 78 projects working towards this label at the end of 2014 (MLETR, 2015). As of 2015, 79 LEED-ND, 4 BREEAM Communities, 3 CASBEE Urban Development and 2 One-Planet Communities, amongst many other neighbourhoods following different local frameworks, demonstrate the rise of neighbourhood and city-scale ecourbanism around the world. Our own ongoing research has revealed 420 ecourban neighbourhood projects which fit our selection criteria (74 in the US; 27 in Canada; 195 in the EU; 95 in Asia and the Middle East; 8 in Australia and New Zealand; and 15 in South America). Roughly 10% of these projects are completed, with the other 90% at various stages of planning or construction. Currently, we estimate that we have located perhaps 80% of these initiatives around the world.

Manuel Ruano claims to have coined the term ecourbanismo or ecourbanism in 1999, defined as "the development of multi-dimensional sustainable human communities within harmonious and balanced

built environments" (1999). The term 'écoquartier' was first defined in a policy context in 2008 by the French Environment Round Table, as "a sustainable neighbourhood which responds to considerations relating to transport, urban density and layout, green building, social diversity, mixed-use development and the involvement of the local population" (MEDDE, 2014). Research by Criterion Planners documented 54 different tools being used in a total of 22 countries to assess the sustainability of sustainable built environment projects (Criterion Planners, 2014). The first such tool appeared in 2004 (e.g. CEEQUAL, China's EcoCity) and the latest one (AARP Livability Index) was launched in April 2015.

As a set of planning, design, and technological arrangements for living in particular newly-developed and revitalized neighbourhoods, and as a new ideal for urbane, green and healthy living, ecourban developments are at present demonstrating rapid growth in popularity. Their development has also launched a veritable race to establish development frameworks that will successfully guide the experiments into the mainstream. At this time of flux, it is a useful moment to examine what goals are being pursued, in different ecourban experiments and different frameworks, and what the implications are for the roles played by the different actors involved. In so doing, we will be able to better assess the prospects for the standardization as well as fragmentation of new ecourban development practices and approaches.

## 2. Research Questions and Methods

Within the rapidly expanding area of ecourban neighbourhood development, this paper aims to establish a classification typology for the principles that drive them, and to assess the intentions of ecourban frameworks based on these criteria. We do this using an original seven-part typology of extreme types of ecourban neighbourhood development. Recognizing that an integrative urge underlies ecourbanism, we created a framework that identifies the extremes to which any expressed ecourban principle can lead, and that recognizes the need for an integrative approach that combines principles. This approach is used to identify the mix of roles entailed for different actors under different principled priorities. While there are many different ways to categorize and sub-categorize actor types within a model sustainable neighbourhood development project, and there will often be overlap between the groups, we will use three simplified actor categories as follows:

> Public: those employed by or working in partnership with the government, to envision, design, craft policy and governance for, and plan the neighbourhood.
>
> Private: the builders and financiers of the development and implementers of plans.
>
> Civic: the local non-expert populace that makes use of the neighbourhood's built form because they live in, work in, or visit the neighbourhood.

Following this, using the same typology, we consider the implications of applying one of two new sustainable neighbourhood development frameworks, the EcoDistricts Protocol and the Living Community Challenge, for the relative emphasis likely placed on each extreme type, and for the mix of roles and responsibilities likely in bringing ecourban neighbourhood developments from experimentation toward the mainstream.

To create our typology, we engaged in an abductive process of theoretical engagement with literatures of urban sustainable development, community planning, and neighbourhood development dynamics, alongside consideration of published materials about cases of ecourban neighbourhoods. As a set, the seven principles in our typology constitute an integrative framing of ecourban neighbourhoods, including their built form, transportation and other engineered systems, land uses, public spaces, local

institutions, social make-up and governance. Individually, these extreme types are expressed in different combinations in ecourban neighbourhood development practices. In practice, each principle is tempered by reference to others; and numerous principles are related to one another. Each of our extreme types, by nature of being an extreme criterion within a multi-criteria framework, delineates a boundary of practice in one dimension that can help clarify the limits of ecourbanism globally. Considering each principle in the extreme case in which it would be implemented to the exclusion of other principles permits a clear delineation of the conceptual space within which integrated ecourban neighbourhood development is bounded. Our typology appears in Table 1 and can be expressed graphically in Figure 1 (Holden et al., in revisions).

Table 1. Seven Extreme Types of Ecourban Neighbourhood Developments, with Key Principles

| Extreme Type | Key Principle |
|---|---|
| Econ-urban | Shifts economic growth in cities toward greener products and forms; pursuit of green capitalism. |
| Ecol-urban | Lighter footprint living with energy and materials efficiency built into design and technology, as well as the ability to directly experience wild nature. |
| Living-urban | Complete community development with a view toward wellbeing, liveability, and resilience to shocks from outside the neighbourhood. |
| Local-urban | Offers a sense of self-determination and active participation in all aspects of local life within the circumscribed neighbourhood; orients daily life toward proximity. |
| Democ-urban | Reformulates citizenship at the local scale, and offers deliberative, community-based decision-making, with a suggestion about how this will assist in changing values and behaviours. |
| Diverse-urban | Accentuates and generates value from the mixing of diverse social, economic, and cultural offerings of urban life. |
| Equi-urban | Prioritizes redressing inequalities and injustices via attention to targeted needs. |

## 3. Literature Review

Ecourban neighbourhood projects represent a growing diversity of practices, underlain by different motivations, understandings, expertise, and relationships. Ecourban plans and results are often presented as "packaged examples that are ready for export" without considering the politics of urban transformation, and the range of agendas that these projects serve (Bradley et al, 2013 p.190). A growing number of case studies point to the existence of competing agendas, and in particular to the existence of an underlying capitalist development agenda, which stands in contrast to certain ecourban goals. Masdar Eco-City in Abu Dhabi and Tianjin Eco-City in China are examples of a larger trend that has eco-cities reproducing "often neoliberal and potentially inequitable visions of socio-technical transition" (Caprotti, 2014 p.1290). Indeed, a primary battle line emerges in ecourban practice between the modernist urge within the econ-urban camp and the ecological preservationist urge among the ecol-urbanists. These battle lines can sometimes be seen as conflicts between different actors on the same project. Writ large, few policy and planning efforts toward realizing urban sustainable development explicitly question the need for continued economic growth (Hajer, 1995). Also rarely addressed are the continuing community development demands within neighbourhoods where people live, work and play. However, ecourbanism is a political movement, and it has potentially exclusionary, inequitable, over-consuming, stultifying, and unsustainable outcomes. On the more optimistic side, a small number of case studies in cities such as Civano, Arizona (Nichols & Laros, 2010), Orestad, Denmark (Book et al. 2010) and Stockholm (Metzger & Olsson, 2013), Freiburg and Graz (Rohracher & Spath, 2014), suggest the conflict between the econ- and ecol-urban models may

not be insurmountable. These cases are not immune to the forces of ecological modernization, by which efforts to create ecourban districts in the name of environmental and social goals become merged with attempts to use a sustainability edge to attract new growth capital. At the same time, they evidence deeper institutional change, an ecological restructuring of cities to a political agenda that seeks to move 'beyond growth' along the way (Daly, 1997).

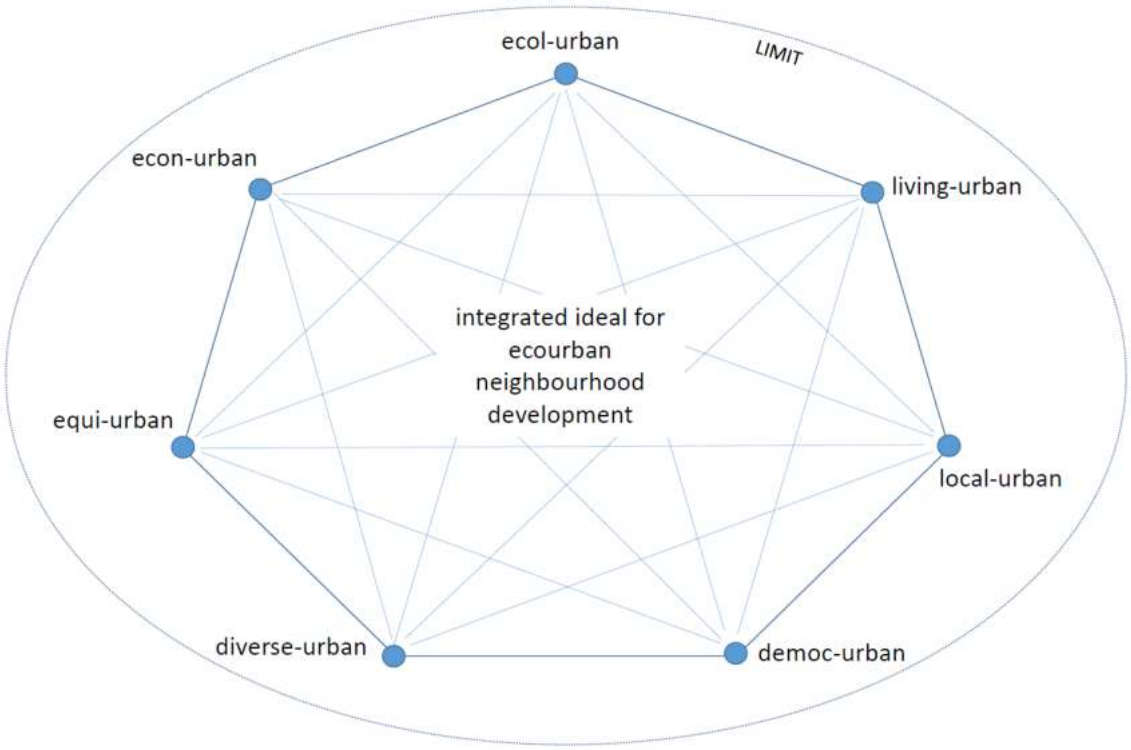

Figure 1: Ecourban neighbourhood development within integrated conceptual space, as circumscribed by seven extreme types.

From a social and political perspective, the prospect for change within ecourbanism comes from an idea about this new form and lifestyle context making space for a sustainability transition in society and governance. The field of research and policy known as transition management has emerged from this idea. Beginning from a socio-technical understanding of past societal transitions, the transition management approach aims to translate ecourbanism into the active management of a widescale transition toward sustainability (Smith & Kern, 2009). Smith et al. (2005) articulate the preconditions for such a transition in terms of societal pressure for change and adaptive capacity. Transitions can be generated from within or from external structures and resources, although they will happen in a different way and at a different rate depending upon their motivation. Hodson and Marvin (2009, p.477) in their research in some of the world's most powerful cities, found "strong evidence of expectations, aspirations and plans to undertake purposive socio-technical transitions," in line with sustainability and climate change adaptation and mitigation goals.

Transition theorists identify a number of factors that increase the potential for a system of governance to undergo an effective transition, in line with their adaptive capacity (Smith et al., 2005). Importantly for our purposes, they identify the volume and actions of 'intermediaries,' actors who are not formal

members of government but who work in partnership with others to bridge the gap between policies and practices, as a crucial leverage point. It is these intermediaries, equipped with a wide range of necessary knowledge types, effective presence in local networks, and communication skills and credibility, that do the key work of developing and coordinating capacities for regime change at the urban level.

In a separate but related literature on enabling social innovation in the non-profit sector, Kania and Kramer refer to "collective impact" as "the commitment of a group of important actors from different sectors to a common agenda for solving a specific social problem" (2011, p36). Collective impact is understood to be a more effective means to achieve large-scale systemic changes than uncoordinated action by organizations across different sectors, with similar goals, competing for the same pool of available financial, political or talent resources. Kania and Kramer highlight the importance of 'backbone organizations' in collective impact actions. These organizations are responsible for providing support to create a shared vision, coordinating initiatives, establishing shared assessment practices as well as advancing policy (Turner et al., 2012).

By examining the frameworks being created to guide ecourban neighbourhood development across cities, we are assessing the degree to which these frameworks, and the nonprofit organizations that create and promote them, are playing or could play such an intermediary or 'backbone' role, in building towards collective impact in the realm of ecourbanism. The forces of standardization, codification, and regularization apply to the practices of ecourbanism and part of the race to develop these neighbourhoods is a race to establish new standard processes and outcomes. Within a process of sociotechnical transition toward sustainable development, we can expect these forces to apply when niche-level experiments deliver on some of their expected values and demonstrate potential for scaling up. In the context of furthering and mainstreaming practices of ecourban neighbourhood development, the technological innovation that has emerged is the neighbourhood development framework. Over 50 such frameworks currently exist around the world. In this paper, we will examine two such frameworks – the EcoDistricts Protocol and the Living Community Challenge.

Our focus here on the mix of actors and intermediaries involved in a range of different roles within ecourban practice also is conceptualized by our understanding of assemblage theory in urban studies. Assemblage urbanism, as presented by McFarlane (2010) and adapted into the urban studies literature by Blok (2014), entails careful thinking about the range of actors engaged in particular experiments in given local contexts. It is these particular urban spaces, inhabited at given political moments by particular constellations of actors, that define the meaningful aspects of efforts to intervene in existing urban dynamics and achieve change. Blok (2014, p.260) explains: "I understand world-conjuring projects as situated experiments of engagement with 'the global', whereby a range of urban actors – policymakers, professionals, activists and others – take the problem … as a site for exploring new questions, initiatives and critical procedures." Collective experimentation, social learning, and the testing and forging of new relationships between people, organizations, the built environment, technologies, and natures, are activities and outcomes of assemblage urbanism as an approach to urban change in the service of sustainability. In the particular instance of building new sustainable neighbourhoods, a crucial role may be played by intermediaries in framing new practices and establishing new expectations of planning and development actors, and even end-users.

Intermediaries are necessary to advance practice because none of the key actor groups, while they are necessary and instrumental to bringing particular ecourban neighbourhoods into being, are invested with any particular role, responsibility or power to spread the practice of ecourbanism more broadly. A new kind of key actor is required to orchestrate this transition. The key actors designing, crafting, and promoting these frameworks may be leaders of government, industry, or non-government organizations, but the role they play is shared: we can generally refer to them here as visionaries. In

crafting particular certification systems, standards, frameworks, protocols, membership groups and challenges, these visionaries are all attempting to promote and advance the practice of a new technology of urban development. Not all visions, nor all visionaries, are created equal. Differences exist in the way in which these visionaries see ecourbanism as being best pursued; the priorities and roles for different actors vary. In order to better understand the difference that these differences can make, we will consider two technologies created by ecourban visionaries, the Living Community Challenge, and the EcoDistrict Protocol. After a brief description of each, we will consider the degree to which each of these model frameworks prioritizes our seven different extreme types, and what each model implies for the role to be played by different actors.

## 4. Case Studies

### *4.1 The Living Community Challenge (LCC)*

The International Living Future Institute (ILFI) grew from the Cascadia Green Building Council, the branch of the green building industry association that spans the western US states and British Columbia in Canada. Its intention is to accelerate the ambitions of the green building industry. It is the home of what it calls the world's most ambitious green building certification system, the Living Building Challenge (LBC), and now a comparably ambitious Living Community Challenge. The ILFI describes its 'challenge approach' as "a philosophy of design masquerading as a certification system."

The LCC is described as "a cohesive standard, pulling together the most progressive thinking from the worlds of architecture, engineering, planning, landscape design and policy" (ILFI, 2014, p.7). The question posed to all these groups is: "How do we create communities that are good for all people through time?" The move to create the LCC out of the LBC is recognition of a need for much more sweeping change to the relationship between people and natural systems than what can be achieved by individual green buildings alone: "we must remake our cities, towns, neighbourhooods, homes and offices, and all the spaces and infrastructure in between" (ILFI, 2014, p.9).

The Living Community Challenge is currently being pursued by four development projects. Their diversity demonstrates the intent for the tool to be applicable across a range of neighbourhood types and densities: a project in Uptown Normal, Illinois, adjacent to an existing LEED-ND development; a resort hotel project in Belize on a mangrove island; a housing development on the outskirts of Mexico City; and a mixed-use redevelopment project in New Orleans. The ILFI is currently "in conversation" with 15-20 other potential LCC projects. The LCC pursues transformation of development practice in seven topical themes known as 'petals,' 20 imperatives and pursuant to 12 'patterns' that cross the various petal themes, as seen in Table 2 below.

Table 2. The Living Community Challenge: Petals and Imperatives (ILFI, 2014)

| **Petal** | **Imperatives** |
|---|---|
| Place | 1) Limits to Growth<br>2) Urban Agriculture<br>3) Habitat Exchange<br>4) Human Powered Living |

### *4.2 EcoDistricts Protocol*

EcoDistricts, or its precursor, the Portland Sustainability Institute (PoSI), was founded in 2009 in Portland, Oregon, to support the City of Portland's urban sustainability efforts. PoSI worked in collaboration with the City of Portland Mayor's Office, Portland Development Commission and the Bureau of Planning and Sustainability to pursue their first initiative, based on then-mayor Sam Adam's request to explore integrated neighbourhood-level solutions for sustainability that combined community development benefits and local economic returns (PDC, 2010; EcoDistricts, 2015). Throughout 2009-2012, five pilot districts within Portland implemented the newly-developed EcoDistricts Framework via collaboration on neighbourhood-level projects (EcoDistricts, 2014).

The EcoDistricts Framework took a different approach from other neighbourhood scale sustainability tools such as LEED for Neighborhood Development or BREEAM Communities, by focusing on the processes and actors around local action for sustainability. The EcoDistricts Framework contains no prescriptive strategies or metrics that must be demonstrated through the certification process. Rob Bennett, CEO of EcoDistricts, describes the framework as "loose-fitting", and states that "EcoDistricts isn't a place – it's a movement" towards collaborative governance (Schuler, 2014). An 'EcoDistrict' does have geographical boundaries at the neighbourhood level, but the outcomes attributed to applying the framework are more related to neighbourhood identity and collaborative decision-making, rather than any particular built-environment features. In justifying the focus on neighbourhood-scale processes, Bennett calls EcoDistricts "a model [that is] about sharing power and sharing decision making…these are things that cities don't do particularly well" (Schuler, 2014).

EcoDistricts launched a draft Ecodistricts Global Protocol in 2014, in partnership with the Target Cities pilot program of the Clinton Global Initiative. This program invites city leaders, urban planners and designers, community members, policy makers, community developers and other stakeholders to set new agendas and visions for district-scale sustainability work in 8 cities in the US and Canada (CGI, 2014). The formal EcoDistricts Global Protocol is slated for release mid-2015. Our discussion is based on the draft version released in Fall 2014. Whereas the LCC organizes its topical themes as seven 'petals', the EcoDistricts Protocol points to eight performance areas, shown in Table 3 below. EcoDistricts additionally articulates four phases at which different actions are taken toward these goals, and a set of six organizational values that encompass ecourban as well as accountability and transparency principles.

Table 3. The EcoDistricts Protocol: 8 performance areas and goals (EcoDistricts, 2014)

| **Performance Area** | **Goal** |
|---|---|
| Equitable Development | Promote equity and opportunity and ensure fair distribution of benefits and burdens of investment and development. |

| | |
|---|---|
| Health & Wellbeing | Promote human health and community wellbeing. |
| Community Identity | Create cohesive neighborhood identity through the built environment and a culture of community. |
| Access & Mobility | Provide access to clean and affordable transportation options |
| Energy | Achieve net zero energy usage annually |
| Water | Meet both human and natural needs through reliable and affordable water management. |
| Habitat & Ecosystem Function | Achieve healthy urban ecosystems that protect and regenerate habitat and ecosystem function. |
| Materials Management | Zero waste and optimized materials management. |

## 5. Discussion: How the LCC and EcoDistricts advance Ecourbanism

At face value, both LCC and EcoDistricts address the gamut of ecourban principles in our typology – with the notable absence of explicit reference to the *econ-urban* principle. The breadth and principle-based nature of both EcoDistricts and the LCC suggests the aspiration of both frameworks to act as catalysts of transformation that runs the gamut of integrated sustainable urban development practice. The Living Community Challenge, in being presented as a "challenge" rather than a "standard," captures this intention to challenge and propel the evolution of thinking in the development sector toward greater sustainability. EcoDistricts, in advancing a process "protocol" rather than a set of specific standards, articulates the notion of process as product, when it comes to transforming neighbourhoods toward sustainability. Both organizations, and both technologies of ecourban neighbourhood development, are positioned as agents of transformation at the institutional level as well as the level of urban design and infrastructure, recognizing the need for an active and visionary intermediary in order to move pragmatically toward a sustainable neighbourhood transformation "end game." Both are signaling, through their products and organizational development strategies, the intent to act in an advocacy role to promote learning and experimentation amongst development and planning actors as well as the public at large, toward this transformation of practice.

### *5.1 How do the LCC and EcoDistricts models value different ecourban principles?*

The *ecol-urban* principle is privileged in the LCC framework because of the intent to expand the notion of community beyond the human monoculture, to include biophilic design principles that rely more on natural than engineered systems, more on natural than manufactured products, and that work toward eliminating toxins and carbon combustion in development. An *ecol-urban* principle of "living off the flow," or no net extraction of natural resource or energy stocks, is expressed in terms of the ban on any combustion-derived fuel as energy source, limiting water use to within the recharge rate of local aquifers, and requiring local waste water and sewage treatment and energy storage. In EcoDistricts, the *ecol-urban* principle is served by the Energy, Water, Habitat & Ecosystem Function, and Materials Management performance areas. The objectives within these performance areas relate to the conservation of energy, water and materials, and optimizing their associated infrastructure systems to reduce negative environmental impacts through the implementation of technologies such as renewable energy, stormwater management, and recycling of water, waste and other materials. Furthermore, the objectives of the Habitat and Ecosystem Function performance are to enhance and regenerate urban natural environments.

The *living-urban* principle within the LCC is expressed in Imperative 7, Civilized Environment, which emphasizes the creation of opportunities for social interaction in public space, and Imperative 8 Healthy Neighbourhood Design. More basically, the living principle is expressed in the LCC as a new

norm of community extending beyond the human community to include other forms of life. The human community and the urban infrastructure and design which typically have supported it are considered a 'monoculture' approach; whereas the effort within the LCC is to design for biophilic ecological urbanism. The metaphor used to describe the "living community" is a forest, with a complex ecosystem structure able to support many different functions and species and multiple evolutionary paths, as opposed to a monoculture of single purpose structures and infrastructures, built for modern, adult, able-bodied humans alone. The question of transforming practice toward revaluing life and living for people in more human-centric community development terms is less clear. Limits to density in the form of strict limits to buildings that create shade for neighbours, and through the first principle, Limits to Growth, suggest an implicit position on limiting population growth to within local ecological capacity. This has negative implications for human development and equity, which go unacknowledged. In EcoDistricts, the *living-urban* principle is highlighted by the Health & Wellbeing, Access & Mobility, and to a lesser extent the Community Identity performance areas. Livability and wellbeing in the EcoDistricts framework is about providing access to recreational and natural areas, healthy and affordable foods, good air quality, and beautiful and safe places that promote interaction. This framework, however, places the onus on local stakeholders to determine, collaboratively, how much and what qualities of livability can be achieved.

The *local-urban* principle is devalued in LCC because it conflicts with the ILFI's stance to "drive work and thinking toward universal solutions to the extent possible." The *local-urban* principle enters into ILFI framework development through the back door to the degree that local developers and local planners (and potentially, although not obviously, the local public) are invited to work directly with the ILFI in order to craft locally-specific solutions to problems that occur when the "universal" principles come in conflict with local conditions and priorities. This puts the onus of responsibility on proactive local actors, whether developers or planners, to argue persuasively for an effective local solution against the baseline scenario of a universal standard. By contrast, the *local-urban* principle is highly privileged by the local process-oriented nature of EcoDistricts, which implies significant onus on all three of the local actor groups involved to adapt to new roles and responsibilities relating to goal-setting at the local scale. More specifically, the Community Identity performance area, with its goal of creating a neighbourhood community identity, reinforces the EcoDistricts approach as a core community identity formation tool.

The *democ-urban* principle is valued by EcoDistricts for similar process-oriented reasons. The EcoDistrict approach in and of itself favours a local democratic structure, as it moves all actor groups through an engaged, participatory process of determining visions, priorities and actions to reinvent the district in question. Value placed upon the *democ-urban* principle within the LCC is evidenced by the use of the charrette as a key means of generating progress in determining the approach to the imperatives, particularly the more subjective ones such as Equity and Beauty. Locating key decision making stages within a democratic forum like a charrette is a marker of the value the LCC places on democratic interaction among actor types, although certainly with a higher degree of emphasis on directly engaging expert actor types compared to non-expert civic ones. At the same time, the LCC recognizes that the charrette process is suited for integration of the different actor types needed to implement better buildings, but that a charrette that engages and allows effective communication across the greater spread of diverse actors involved in neighbourhood development is a bigger challenge. Current practices situate problem-solving and decision-making on crucial points in segmented realms of expertise and authority. This situation poses barriers to integrative thinking, capable of tackling challenges of infrastructure, interactive effects, adapting to change and changing use over time at the neighbourhood. Developing a level of comfort with charrette-style thinking, and incorporating decision-making elements into this process, is no golden key to improved democratic process per se, but may still improve the chances that better processes will emerge.

The *diverse-urban* principle comes through in several EcoDistrict performance areas with objectives such as fostering inclusive, flexible and cohesive networks; expanding economic opportunities to a socially and economically diverse population; and ensuring diverse stakeholder involvement in EcoDistrict activities and decision making. Some recognition of the value of the *diverse-urban* principle is offered in the Beauty petal of the LCC, and components 19 Beauty + Spirit and 20 Inspiration + Education. However, the path to implementation of these objectives is unclear in both frameworks. In the case of the LCC in particular, the recognition of the value of diversity is tempered by the notion of urgency in addressing ecological limits driven, to the ILFI, by an excess of humanity – "a world with seven billion people and counting" (2014, p.9).

The *equi-urban* principle makes an appearance in EcoDistricts under Equitable Development, where objectives aim for equitable distribution of benefits and burdens of development, and for reducing forced displacement of existing residents. In the LCC, recognition of the value of the *equi-urban* principle is found in the Equity component and Imperatives 14-18, namely: Human Scale + Humane Places, Universal Access to Nature and Place, Universal Access to Community Services, Equitable Investment and Just Organizations. The Equity petal strives for more and better public spaces that are accessible regardless of economic wealth, as well as physical ability and age. The value of equity is expressed in specifically ecocentric terms: "A society that embraces all sectors of humanity and allows the dignity of equal access is a civilization that is in the best position to make decisions that protect and restore the natural environment." (ILFI, 2014, p.45)

Regarding the one remaining extreme type in the typology, despite the lack of explicit reference to an *econ-urban* principle, we cannot conclude that this principle is not embraced. Instead, what we see is a silent consent of both the LCC and EcoDistricts to the *econ-urban* principle. Examples of building transformative living spaces into neighbourhoods, such as Manhattan's High Line Park, are heralded by LCC for their success not only on *ecol-urban* and *living-urban* principles but also because this relatively low-cost intervention in the neighbourhood has brought about a tripling of property values surrounding the linear park. With market transformation envisaged, the ILFI sees no conflict in its desire to attract a maximum of capital to zones of living community transformation, in the pursuit of better, greener capitalism. Similarly, none of the eight EcoDistricts performance areas have a strong *econ-urban* emphasis that pinpoints the pursuit of green capitalism, but the early goals of the EcoDistricts initiative highlight local economic development as a driver for district-scale sustainability projects. According to EcoDistricts, these early goals were to: 1) create an integrated sustainability innovation strategy that linked local neighbourhood economic and community development with the region's clean technology and green development cluster; 2) launch catalytic district-scale projects that maximized community benefits and local green job creation; and 3) build robust neighbourhood governance to guide implementation and monitor progress over time to advance community and city objectives (EcoDistricts, 2015a). While 'community and city objectives' likely incorporate other concepts of ecourbanism, the focus of the first two goals clearly articulate an *econ-urban* bias for leveraging existing economic development practices for sustainability outcomes.

### *5.2 How do the LCC and EcoDistricts engage multiple actor groups?*

The LCC is a set of three challenges issued explicitly by the ILFI to a comparable set of actors to those we identified in Section 2 of this paper, namely:

1. All developers, urban planners, architects, landscape architects and contractors to create the foundation for a sustainable future in the fabric of our communities
2. Local, state and federal politicians and government officials to remove barriers to systemic change, and to realign incentives and market signals that truly protect the health, safety and welfare of people and all beings; and

3. All of humanity to reconcile the built environment with the natural environment, into a global civilization comprised of individual communities that create greater biodiversity, resilience and opportunities for life with each adaptation and development. (ILFI, 2014, 5)

As stated above, LCC promotes a cycle of charrette processes as the project moves through addressing the different imperatives of community creation, engaging in common space in order to come to agreement about how to proceed and then actually proceeding in teams that work more independently of one another. However, beyond promoting a charrette process and advancing a negotiated approach to finding context-specific solutions to meeting its various imperatives, the LCC does not address explicitly how each actor type is to contribute to meeting the challenge together. It should also be noted that while both LCC and EcoDistricts are designed for implementation in a range of different neighbourhood types, the 'base case' LCC is a new master-planned neighbourhood, whereas the 'base case' for an EcoDistrict is an existing neighbourhood. This creates very different starting points for the assumption of direct involvement of local actors. The EcoDistrict Protocol, by contrast, attacks the question of shared and differentiated roles for different actors in a much more structured and sequential manner.

The four sequential phases of the EcoDistricts Framework are: district organization, assessment, development and management. At the district organization stage, local stakeholders create a shared sustainability vision and a governance structure to implement that vision, through community engagement and citizen participation. A governance structure is defined, often with a new or existing governance entity being endowed with the explicit goal of leading the district's sustainability projects. In pilot EcoDistricts projects, lead governance organizations have ranged from newly-formed neighbourhood entities, to a university's existing planning department, to new working groups led by planning students, to an existing transportation demand management association, and in one case, PoSI staff assigned to the initiative (EcoDistricts, 2015b). This stage requires significant negotiation and collaboration efforts among all three groups – the public sector, private sector, and civic actors.

At the assessment stage, a performance-based neighborhood sustainability roadmap is constructed to address the eight performance areas. This stage includes identifying and assessing district-level priorities, and establishing baselines and target metrics for these priorities. At the project development stage, stakeholders work together on new district-scale projects that pursue their performance goals. The types of projects can range from the built to the conceptual to the educational and include: green buildings, social housing, urban agricultural space (EcoDistricts, 2015a), community solar programs, arts-focused homes, and community-based energy awareness programs (Capitol Hill EcoDistricts, n.d.). Finally, at the management stage, implemented projects are monitored to gain a long-term understanding of their social, economic and environmental impacts, in order to understand the value of the intervention made. When reflecting on the experience of the five Portland pilot projects, EcoDistricts noted that the engaged actors suffered from a lack of direction in how to create a sustainability roadmap at the assessment stage, and challenges in collecting data for baseline reporting and monitoring at the management stage (EcoDistricts, 2015b). This suggests a lack of knowledge and governance capacity within at least these assembled actor groups.

## 6. Discussion

While both the LCC and EcoDistrict models embrace a multi-actor, collaborative approach, and are committed to the difference that creating these new configurations of actors will make to the results in ecourban neighbourhoods, neither has fully worked out a means to address the different constraints and interests that each actor group brings into the process. Table 4, below, illustrates the different hierarchies of actor groups and intended roles in each of the seven extreme types of ecourbanism in our typology. Depending not just on the stage of development, nor just the specific design issue at

hand, but also upon the principle being pursued by the neighbourhood development, each actor group will be faced with a particular landscape of positions, recognized expertise, and power. These dynamics have bearings on the outcomes of their interplay in ecourban neighbourhood development.

Table 4. Interplay of key actors and their roles in each extreme type of ecourbanism

| **Extreme Type** | **Key actors and roles** |
|---|---|
| Econ-urban | Private sector actors play a key role as the owners of capital, attracted to new investment opportunities. Other actors work within the private sector's understanding of limits to profitability. |
| Ecol-urban | Public sector actors lead by integrating new science, technology, and concepts into the conventional patterns and built form, through regulations and incentives. Private and civic sectors are expected to take up new responsibilities to learn, build and engage in these naturalized landscapes. |
| Living-urban | Public sector actors play a key role in negotiating between the private sector's notions of sound development and those of the civic sector, typically as represented in theories and practices of community development. |
| Local-urban | The civic sector, residents in particular, expresses competency and sustained effort in self-determination and grassroots control and organization. The public and private sectors share responsibility to relinquish control over local affairs that they would typically run. |
| Democ-urban | Public and civic sectors share the responsibility here to reorient activities of citizenship and governance toward community-based decision making. Private sector is invited to the table. |
| Diverse-urban | The public sector, and sometimes the civic sector, assumes a primary role here in offering concepts, mechanisms, and supports for the emergence of a sense of community and belonging within a context of new interactions and diversity. The civic sector must assume a responsibility to take on the risk of these new interactions and connections. |
| Equi-urban | The public sector assumes a primary role in orienting the development process toward specific forms of equity. The private sector must be willing to take up the adjustments to practice in order to implement these equity measures. |

Recognizing that the primary rift in ecourbanism practice worldwide is that between the modernist drive for profit and capital growth, on the one hand, and the humanist need for socially- and ecologically-authentic lifestyles and places to live, on the other, we nonetheless find this more multifaceted, seven-point typology to have significant utility in understanding the full gamut of efforts in ecourban practice as these gather speed. Moreover, Table 4 demonstrates that the mix of extreme type principles that are adhered to in different developments and the frameworks that are advancing practice has implications not only for the project priorities that are pursued, but also for the roles played by the different key actor groups.

Overlaid on this mix of actor groups and their shifting hierarchies is the superstructure of the new actor group in ecourban neighbourhood development represented by the toolmakers themselves, such as ILFI and EcoDistricts. As these organizations create and advance the emergent technologies of ecourban neighbourhood formation, they advance a particular solution set for designing, developing, and inhabiting ecourban neighbourhoods. There are a number of concepts and components that these technologies and their intermediary organizations share. Both are making important and distinctive efforts toward more integrative practice, in terms of the components of development considered within a district-scale planning and development approach and the perspectives needed at the table to advance them. They share a common, understated yet pervasive, agreement with the *econ-urban* principle. This is paired with a common, foregrounded and more explicit, *ecol-urban* commitment, and specification of the key and necessary components of improving ecological outcomes in our neighbourhoods. The frameworks have an equal and expansive focus on the *living-urban* principle, with ambitious goals to expand people's sense of community and their own well-being beyond those elements that conventionally figure into such sensations and calculations: health through design, biodiversity as health. Both frameworks, however, neglect the work needed to integrate this new understanding of liveability with the contemporary sense of the determinants of liveability: opportunity for household improvement in a capital sense; safety and improvement in a social sense; jobs, health care and education in a human development sense. In this oversight, they sideline subsets of public, civic, and private actors committed to these more traditional neighbourhood goals rather than bringing them into the collaborative fold.

In terms of other extreme types of ecourbanism, LCC and the EcoDistrict Protocol conflict. Whereas the EcoDistrict Protocol leverages the *local-urban* principle as its key contribution as an intermediary organization, the LCC has set its sights on universal aspirations toward which all localities ought to be morally compelled to agree. Aligned with this difference, the EcoDistrict Protocol is more forthright in embodying the *democ-urban* principle, which runs through all four phases of collaborative district creation. LCC embraces the *democ-urban* principle to a lesser degree, recognizing the value of a charrette process as key to determining approaches to the most subjective imperatives in the framework, but stopping short of articulating a governance framework overall, and staying more focused on urban design. Moreover, neither framework is explicit in putting upper or lower limits on inclusion, as this affects *democ-urban*, *diverse-urban*, and *equi-urban* principles. Language exists about the importance of a number of dimensions of diversity, but how this importance stacks up against other demands remains unclear, and perhaps untested. Nor, by the same token, is the EcoDistrict Protocol strong on articulating how to move toward attainment of the *equi-urban* principle. LCC is even more hesitant here, citing the limits of what it can undertake within the context of a primarily built-environment approach.

## 7. Conclusion

A neighbourhood development is more than a built environment, and any offering of a fully-integrated framework for ecourban neighbourhood development needs a manner to address the human, social, and community development requirements of effective and successful neighbourhoods. A great deal of wisdom exists in these requirements, but this wisdom is typically found in different books, areas of research and practice than where the keys to sustainable design can be found. More integration within the visionary actor category is thus needed, in order to settle such important questions about what integrative ecourban neighbourhood development practice looks like, who it involves, and how. Our ongoing Ecourbanism Worldwide research project seeks to uncover some of this critical questions, through investigating the overall global landscape of model sustainable neighbourhood developments as well as individual case studies, from the basis of a multipronged typology of ecourban principles.

rather the unbroken dominance of decades of social democratic politics and th
local governments and five counties represent a complex political environment
long established regional authority, the Regionalverband Ruhr could not turn
regional economic development agency. Or is rather the influence of a few lar
corporations, which, supported by political networks they have not much inter
dominance. There are many other reasons, why the Ruhr has lost out in the fie
competition among city regions. One reason is that that it has been a working
strong unions for more than a century, where, in contrast to other German cit
Hamburg, Cologne of Munich, the bourgeois middle class has never evolved from
status. Hence involvement in regional political arenas was left to vey conser
working class union and party leaders. This also explains the fact that the r
developed an open, outward looking international mind-set. There has never be
to sell coal, steel and energy. Public subsidies made it easy for the energy
from the demand of 5 million people in the region and from the export of stee
water. And the fact that the state of North Rhine Westphalia lost its privile
Germany s capital city and the shift of public interest and funds to regions
did also hit the Ruhr.

In the end it may be the lack of urbanity, the lack of entrepreneurial spirit
lifestyle narratives, praising the immense potential of the region in interna
(Kunzmann 2014). It seems the polycentric region has to accept its diminishi
competitive urban region, very much like similar traditional industrial regio

Smart City paradigm to accelerate structural change, not even as marketing we
The paper aims to give some first answers to this question.

## 2. Smart cities: A new paradigm of urban development?

Since the beginning of the 21st century the Smart City concept is receiving c
and attention among media and local governments, searching for popular vision
development However, research on the importance and on the implications of sm
on city planning and development is still scarce (Kunzmann 2014) .

The convergence of information and communication technologies and the applicat
technologies by industries and citizens is changing cities and regions quite
anything experienced in the past. It is second wave of industrial revolution.

Cities are becoming smart not only in terms of the way we can automate routin
individual persons, buildings, traffic systems but in ways that enable us to
analyse and plan the city to improve the efficiency, equity and quality of li
time. This is changing the way we are able to plan across multiple time scale
prospect that cities can be made smarter in the long term by continuous refle
term (Batty et. al 2012 , 482)

Very much promoted by industries, like IBM, Cisco or Siemens, that are eager
sell their high tech and ICT products and services, the new paradigm of the S
emerged, based on GPS, I-phone, I-pad and similar technologies. Being smart i
agenda, on the agenda of city mayors, city planners, and city builders, in ci
Vienna or Berlin, and in China, were more than 80 cities have recently been s
cities for Smart City development.

The interest in Smart City development tells that in the beginning of the 21st century, the
infrastructure development is evolving and a new group of professionals made
communication specialists is entering the stage of urban development, similar
developments a century ago. They are the new urban engineers, designing and i
urban communication networks, without which the cities would not any longer b
organize e-shopping and mobility for young citizens, and public services for
rural areas. The technology driven products and services will certainly chang
will force local governments to act. So far, it seems, only very few cities h
hardly prepared to deal with the new challenge and to provide the expertise t
with the economic drivers of the new technology.

The emerging Smart City paradigm will add another dimension to urban developm
this paradigm a new type of urban planner will enter the stage, the Smart Cit
planner. While traditional planners are discussing with citizens about how fu
should look like, the new planners, together with powerful global ICT corpora
working behind the stage to develop a totally new urban infrastructure for sm
the future city.  The brains behind all that reside in Silicon Valley; and, i
Zhongguancun in China.

The Smart City paradigm is in a process to conquer the minds of architects, a
policy advisors, politicians and CEOs of large international corporations, as

promise and a temptation. Whether they are young or old, citizens can expect
accessible technologies can increase their individual quality of life, make th
enjoyable. The Smart City paradigm, clearly, has both a good and a dark side.

Smart City promoters argue that they aim to make life more convenient for all
they are rich or poor, old or young, privileged or underprivileged. Over long
Smart City s paradigm claim, all citizens will be equipped with i-Phones and
will have ubiquitous access to a plethora of related public and private servic
improving application software. Such software will allow them to get, whereve
hours a day, all the information they require to use public transport, to fin
or a car-sharing location; to find a doctor or a nurse, to make business, to
old and new partners, to find reasonably prized or designer hotels, to get ac
apartments, to sell whatever they wish to sell or buy consumer products they
cheaper price or in another quality, now or later. The new technologies offer
applications. The promoters of the Smart City promise that using smart techno
life in the city better and more enjoyable. They can easily convince mayors a
that (only) smart technologies guarantee human survival in a complex world, i
cities.

The term smart technologies covers a wide field of applications, from big dat
broad range of  i-phone applications., from intelligent energy production  an
mobility Smart technologies offer an endless range of applications, which eas
whether they are young or old to go for it. In everyday life there are manifo
improve quality of life, to solve problems, to overcome constraints, to save t
for information and locations, for partners and help, to save money, to econo
The community of Smart City developers argues that smart technologies can

- Improve individual mobility and orientation in cities and regions
- Create access to any kind of information
- Make consumers independent from opening times and locations (e-shopping)
- Raise personal security at home and safety on the road
- Save energy by numerous systems of controlling consumption
- Facilitate education and training ( e-learning)
- Improve access to public services
- Make it easier for tourists and visitors to enjoy cities and city life
- Assist elderly and physically handicapped to get all kind of personal medi
- Help people to find a partner

Obviously, saving time in finding information and facilitating communication
motive for applying smart technologies, though even smart technologies can ra
stress at work and at home.

The areas of smart technologies vary from interest group to interest group. Ge
following fields are addressed: Smart mobility , smart energy, smart communic
governance, e-health, public safety, e-learning and public information.

The fascination, the smart technologies receive from customers a, clients, fr
professionals in many disciplines, is easy to understand and there is no reas
technologies should not be applied. Arguments that the individual application
technologies will eliminate privacy are mostly accepted or just pushed aside.

!

that smart technologies in the end depend upon a few global corporations only
impress citizens and to alarm cities.

So far, however, not much research is done on the spatial impacts of smart te
development and on planning for city development (Streich 2014, Exner 2014) C
media do hardly report about negative implications and users are not alarmed.

## 3. Smart City Development Drivers

The Smart City excitement is driven by many, who consider the movement to be
instrument to address present and future urban challenges, to improve quality
just to benefit from developing and selling smart technologies to cities. Giv
no common understanding of the fuzzy Smart City paradigm, the approaches to t
considerably.

> Large and globally active corporations (such as Apple, Google, Siemens,
> or, Cisco have realized that smart technologies are the drivers of innov
> economic development in the 21st century, and that applying smart techno
> development is meeting global demand and support from a broad spectrum

> Governments at all tiers of decision-making and planning in Europe have
> Smart City development as a much valued policy field of public policies
> economic environments. The European Community stands not aside, when it

> involved with this transformation. (CEC 2015)

!

To speed up the deployment of these solutions, the Commission initiated European Innovation Partnership (EIP) on Smart Cities and Communities that European cities, industry leaders, and representatives of civil society to urban areas.

.So far, the EIP on Smart Cities and Communities has received some 370 commitments to fund and develop Smart City solutions in the areas of en transport. These commitments involve more than 3,000 partners from acro create a huge potential for making our cities more attractive, and create opportunities. (Laurila 2015)

Research institutions and researchers in a broad spectrum knowledge inc supported by industries, governments and research foundations are offeri competence to carry out basic and applied research in the field.

Encouraged by global success stories, and often supported by speculativ funds university graduates, young entrepreneurs and start-ups have reali cities are a fascinating field to start a business and make a fortune.

The community of architects and urbanists, continuously seeking innovat to make cities more liveable, and more beautiful, has discovered the Sma as an action field, which receives positive response from both politici

City governments, forced by globalisation and experiencing budgetary li addressing urban challenges, providing security and for the provision o to all citizens, expect that using the Smart City label will raise their i competitiveness , and allow them to offer better services to citizens.

Smart cities have become a favourite theme of the media. They are fasci images, Smart City promoters and smart technology developers can provid is easy to communicate and to sell to producing industries for placing advertisements.

The seemingly insatiable interest of consumers in smart technologies dr and encourages industries. Start-ups and public institutions to develop support smart products and services Young consumers, not just young fre cosmopolitan techno-affine generation, have welcomed the I-phone dominat which has changed information and communication modes of the 21st century.

It is a large group of people, enterprises and institutions, driving Smart Ci train is moving on, accelerated by software developers, hard ware producers a Two drivers deserve special attention: The internationally active German Frau and IBM, the influential US corporation.

Worldwide, the Fraunhofer-Gesellschaft employs a staff of nearly 24,000 scien and support staff, who work with an annual research budget totaling more than this sum, around 1.7 billion euros is generated through contract research fro and publicly financed research projects.
On their website the instituion is introduced as follows:

Europe s largest application-oriented research organization. Our resea geared entirely to people s needs: health, security, communication, energy and As a result, the work undertaken by our researchers and developers has a sign people s lives. We are creative. We shape technology. We design products. We

!

and techniques. We open up new vistas. In short, we forge the future . (www.
retrieved 26.05.2015)

Four of the 66 institutes and research units of the Fraunhofergesellschaft, a
Ruhr.( https://www.fraunhofer.de/en/fields-of-research/science-year- 2015-cit
) .Already in 1994 the Fraunhofer Institute for Applied Photovoltaic had been
Gelsenkirchen, in the centre of the Ruhr,. Since 2007 the city hosts the Frau
Solar Energy. The other three focus on material flows and logistics, on micro
software and systems technology (RVR 2012, 53).

The German Fraunhofer Institute for Open Communication Systems in Berlin, spe
movement to turn cities smart, is selling the message as follows

> WE MAKE CITIES SMART : Smart cities have a lot to pull off.
> to be able to get from A to B at all hours, by car or public
> and telecommunications 24 / 7. They should even be able to ge
> at midnight, not to mention apply for a new driver s license
> arrival. Emergency rooms and hospitals can never sleep, and r
> Life in the city no longer comes to a halt when the sun goes
> isn t enough for nocturnal city-dwellers. The city should be
> adapt to the needs of everyone, offering the right thing at t
> efficiently, sustainably and ecologically. And yet, the city
> What s private should stay private, and it should be protecte
> want a digital garden fence so they can feel safe and secure.
> and the ability to lose oneself in the city s undergrowth are
> jungle. Ultimately, the success of the Smart City will be det
> reliability of critical infrastructures and the efficient use
> between freedom and control.

(Focus 2014,11)

The job of the Smart City is to help its inhabitants use scarce resources as
sustainably as possible. It should also enable its citizens to lead a good, s
them the freedom for creativity and innovation. The researchers at Fraunhofer
working on projects which aim to continually improve the everyday lives of re
of the future despite rising population numbers, more traffic, growing envi
many other challenges.

The Centre in Berlin presents their mission as follows:

Urbanization, globalization, demographic and climate changes are putti
demands on our cities. At the same time, however, greater opportunities to ma
material and human resources efficiently are also being created. It is the go
to seize these opportunities. An important basis for this process is the inte
and communication systems into the various technical systems and infrastructu
enables the flexible control of supply and disposal networks, especially for
gas as well as goods, and makes novel solutions for mobility, administration
the city possible. Citizens, businesses, institutions and government are in c
increase the quality of life and work of all parties through efficient and in
flows. The city becomes more of a service provider for its citizens and busin

!

things keep running smoothly through seamless and transparent administration
optimally networked city not only makes everyday life easier in all aspects o
provides environmentally sustainable solutions. The Smart City is an informed
mobile, safe and sustainable city.
(Fokus 2014).

The IBM message is not much different. They sell the application of smartness
fields: Planning and Management, People, and Infrastructure. ( IBM 2015):

The objective of ICT.NRW is the sustained promotion of the region as an impo
productive hub for IT and communication technology. Inspired by the motto In
Integrated. Innovative , the organisation focuses on using intelligent ICT to
generation of solutions for North Rhine-Westphalia s strong and long-establis
industries. Intelligent energy systems and government project Industrie 4.0,
key role in two of the biggest challenges facing Germany: the fourth industr
the country s wide-scale transition to renewable energy.

Drawn from the world of economics, academia and politics, its members are w
transform the ICT market in the state. ICT.NRW focuses on the early identific
strengths, its synergy potential and its forward-looking ideas, and on provid
the ongoing process of innovation. Raising awareness of North Rhine- Westphal
for the ICT sector is another important objective at ICT.NRW. As part of its
activities, ICT.NRW hosts cooperative and networking events, assists companie
fair exhibits and business trips, and also publishes sector and trend analyse
(IKT 2015)..

Efficient and Green Logistics

In 2010 the Fraunhofer Institute for Material Flows and Logistics in Dortmund
NRW EffizienzCluster Logistics upon initiative of the German Federal Ministry
Research, and supported by the Initiativkreis Ruhr, the agiplan GmbH, the Fra
Gesellschaft, PwC, Stute Logistics, the Business Development Agency of the Ci
as well as the Last Mile Logistics Network Herne. Around 170 companies and 28
facilities participate in the unique network, including the port authority of
biggest inland port. The Effizienz Cluster is well established as the leadin
innovation cluster for logistics in Europe! Now, the companies are invited to
potential of the Cluster and to transfer the ideas and concepts into innovati

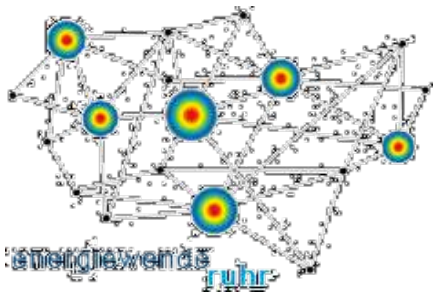
IHK 2013), Following mainstream hype the region has impressively contribution
industries to the regional economy is marginal. The region

A related comprehensive and interdisciplinary initiative supported by the reg
foundation is the ambitious energy turn research programme (Energiewende Ruhr
promote the energy turn in the region by developing elemnts of a regional imp
strategy (Schule et al, 2015) .



Innovation City Bottrop

In 2010, upon initiative of the "Initiativkreis Ruhr", an ambitious competiti
development project had been launched in the region. The city of Bottrop, a c

!

population of around 80.000  won the fierce competition. The aim of the proje
complete urban district into an example for energy efficiency. The concrete a
emissions of a city district by half and thus to increase the quality of life

The pilot area of the InnovationCity Ruhr covers the inner city of Bottrop an
urban districts. 67,000 people live and 22.000 work in the pilot area in more
The area represents all well-known facets of the Ruhr region. The pilot area
function mix of uses (housing, shopping, offices, industries), grown over dec
incremental, semi-planned mode. The urban fabric is not spectacular. It refle
tradition of the region. Like most other urban districts in the Ruhr area is
pressure.

To carry out the project the Innovation City Management GmbH has been establi
private partnership. The City Management GmbH is a company borne by five shar
supporting the company as well as the project with staff and know how. The co
coordinates and controls an coordinates the InnovationCity Ruhr project. The
innovation process and offers expertise in climate-optimised urban redevelopm
energy transition to other cities and companies as a consulting service. In c
several partners, InnovationCity Ruhr | Model City Bottrop is run by an inter
engineers, urban planners, scientists and further experts in order to realise
redevelopment of the pilot area.

The project is developed along five integrated action areas: Housing, Industr
and urban development.

Housing:  Reducing energy consumption of about 60 percent of the more t
privately owned single family houses.
Industry: Optimizing industrial production processes under energy reduc
perspective, and improving energy efficiency in about 2000 private
public buildings.
Mobility: A mix of actions to promote energy saving mobility in the pil
Energy: Decentralizing and optimizing and energy production and intelli
of energy production and energy consumption.
Urban development: Additional action to integrate the sectoral action f
supporting measures (lightning, greening, action research etc.), and
urban design.

To guide the work in the five action fields and to transfer the experience of
implementation to other cities. disseminate the experience of the project, a
handbook has been produced by a consortium of private consultants, who had al
the master plan (Innovation City Ruhr, 2015).

The project is still ongoing. So far no assessment has been made which could
achievements and transferability. No figures are available how much the proje

5. Can smart technologies contribute to a turn-around the Ruhr and what are
spatial impacts of smart technologies

Whether and where can smart technologies contribute to revitalize the region,
old industrial structure of the Ruhr. What kind of smart technologies may ha
impact the regional economy in a polycentric old industrial region? Which fac
which obstacles and limits will constrain the region-wide introduction of sma
What will be the spatial implications of the worldwide smart technology hype
will be the likely consequences for urban and regional development in the reg
bunch of questions can only be scratched on the surface.

The brief explorations above into the potential of the Ruhr in the field of s
shown that the region does not lag behind, when it comes to participate in th
and economic revolution. Obviously given the path dependency of its industria
are that are leading the smart innovation movement. Energy is the one of the
region is demonstrating its strength. Despite the traditional power of the tr
stakeholders, who were always hesitant to act on the forefront of innovation
traditional competence, and heavily supported by policies of the state govern
other drivers smart energy smart energy has become the most promising action
development in Ruhr. Numerous projects are undertaken in this field to demons
energy production and application, together wit smart building technologies c
efficiency and , together with intelligent transport systems, can contribute
reduction of CO2 emissions.

The number of projects in a second field of competence is evolving is smart m

long run are an indispensable action field in city regions, where optimizing
developments will challenge the existing transport system and physical urban
design.

Other areas, such as smart communication and information, e-medicine , e-gov
learning, smart safety or smart water management are not neglected, though in
these fields is less visible in the Ruhr and receives less political and publ
region is not in the forefront, when it comes to develop smart products, proc
applications This does not mean that the five million consumers in the Ruhr,
critical mass, would not welcome and not use smart technologies to earn their
their quality of life and enjoy convenient access to information.

Regional challenges constraining development in the arena of Smart City are t
always constrained innovation in the region, such as the power and the influe
industrial corporations and the related worker and public sector unions, a lo

!

spirit, regional complacency, the tradition of state subsidies, a weak intern
but not least, the limited attractiveness of the region for inward investment
working on strategies to overcome such constraints, it will take a few more d
a change.

The Ruhr is known for its political pragmatism, but also for its lack of regi
second rate local media, a comparatively low profile of the universities, exce
disciplines. The region is always floating between, pragmatism, scepticism an
new media driven development hype. Moreover, the Ruhr is not the German Silic
offering an attractive job market for creative talents. When comparing with B
Cologne the region cannot offer trendy life style environments. Offering chea
not a key-attracting facet for talents and entrepreneurs. So far, such factor
caused the regional stakeholders, to abstain from marketing the region as a S

## 6. Spatial impacts of smart technologies in the Ruhr

Not much empirical research has been done so far to study the spatial implica
technologies in the Ruhr, the change of life spaces in neighbourhoods, urban
of urban production in the region. This is similarly true for other city regi
for Berlin, the city region, which claims to be the hub of smart technology d
Germany.

When exploring the possible impacts of smart technologies on the future spati
the Ruhr, it becomes soon evident that not much will change in the region. Sm
can neither influence the spatial system nor the transportation network, whic
more than 100 years.

The Ruhr is in a process to design a new regional master plan (RVR 2013). Wit
efforts to involve citizens and regional enterprises as well as a great numbe
and semi-public authorities, the Regionalverband Ruhr aims to develop a new s
the polycentric region. Given partial demographic decline in the region, econ
the weak tax base of all local governments in the Ruhr, the new regional plan
become a concept for turning around the region, a road map for change. Despit
its aim is not to develop a new vision for the Ruhr economy, it is rather an
citizen participation., aiming to legitimize the new regional planning author
Smart City dimension, neither its positive nor its negative feature is not a
planners.

There are only few dimensions of the regional urban system on which smart tec
have a positive as well as a negative spatial impact:

> Despite the significant theoretical decentralization potentials of sma
> a further concentration of economic activities in a few places in the R
> unavoidably happen. City centres of the four big cities (Dortmund, Duis
> Bochum) will certainly benefit, places around universities, established
> and other easy accessible locations with a certain urban quality, will
> appealing to IKT firms and businesses, as well as for real estate devel
> smart citizens, smart enterprises and creative talents working in the f
> segment of the regional economy. The much-favoured regional polycentris
> remain a planners dream. The North of the Ruhr will certainly remain an
> laggard.
>
> With smart technologies the chronically congested transit system in th
> optimized without building new roads and tracks. Such measures, which w
> be accepted by citizens and environmental watchdogs, nor financed by th

!

government. To which extent the existing transport network, by applying technologies for both roads and metro-tracks, could absorb more and how traffic, has to be investigated.

Smart energy technologies contributing to energy efficiency will hardl impact, apart from revitalizing or stabilizing declining urban district projects as the Innovation Ruhr Project, would serve as models for othe in the region, they would just raise the quality and value for housing, modest gentrification processes. Undoubtedly the region-wide use of sma can reduce CO2 emissions and improve the ecological footprint of the Ru contribute to reduce some dependency on a few regional energy corporati the expected success of energy efficient urban design could raise the i and make the new competence a more innovative regional export product.

Growing e-shopping in the region will certainly have an impact on exis shopping landscape. Spatial concentration of shopping will further grow city centres will cope with the likely impacts by turning shopping stre fair grounds of international brands, combining visual excitements and access to e-shopping, the number of second and third tier shopping cent will further decline. Niche enterprises in the e-shopping field will fi locations all over the region to operate in and from the region .

Smart technologies will continue to change information and communicati habits of residents, businesses and visitors. The smarter access to inf locations, on attractions, on events, or on regionally available produc make it easier to look beyond local boundaries and discover the Ruhr as living space. This in turn can support building-up a new regional ident contribute to new regional communication networks, beyond and independe traditional political or corporate connections.

There is still another dimension: The Ruhr is not a place, like Paris Vienna, Milan or Florence, where business is always linked with some fo tourism and cultural entertainment. The new information technology allo communication without travelling to the Ruhr. This may facilitate busin support the regional economy in the Ruhr. Tourists, visitors and footba by the much-praised industrial heritage flagship projects and cultural Emscher Park, or by top football matches, will certainly have it much e dispersed locations in the Ruhr. This in turn could raise the profile o

The gradually changing regional economy is supported by a new generati labour. The demand for housing of this new labour force differs from th corporate or affordable (social) housing of the labour force employed i steel production. To avoid long commuting and to enjoy urban life, this labour force, the much sought after creative talents is searching for housing. Their demand could trigger off new developments at more appeal locations in the larger cities of the Ruhr.

With an emerging new middle class working in smart IKT segments of the economy, social polarisation in the Ruhr will further increase. Social will unavoidably bring about spatial polarisation, where the districts spine of the Ruhr and around the universities and technology parks will while the districts in the North, with the exception of a few gentrifyin former mining cities and ethnic communities with their own IKT milieus, or even marginalize

These were just a few assumptions, which positive and negative impacts smart have on cities in the Ruhr. More explorative and empirical research would cer better identify and assess the likely spatial implications.

!

## 7. Conclusion

There is not doubt. Smart technologies cannot save the Ruhr. They cannot turn
economy of a region, certainly not one that has been dominated for more than
vested interests of a few large corporations and heavy industries. The reason
above: The dominance of powerful and politically influential coal and energy
together with the conservative social-democratic political milieus lacked mor
visionary perspectives, the lack of entrepreneurial spirit, the dearth of int
personalities, inward looking media and the difficult love-hate relationship
state of North Rhine-Westphalia.

Apart from technological innovations in the remaining industries and despite
the existence of numerous universities in the Ruhr, and five million consumer
technologies will not become a  new export-oriented territorial capital of th
regions. Hence the Ruhr is not furnished to become a smart city region, a reg
producing smart technologies, not just using products and applying services,
produced and developed elsewhere in Germany and beyond. There are a few hidde
the region, such as Materna, though there are not enough innovative enterpris

Only in two areas of smart applications and benefitting from experience in th
the innovation city project in Bottrop, the Ruhr can excel and compete, and d
leadership, in energy efficiency and logistics. In these two fields, the Ruhr
certain renommØe. In all other fields the region as whole will rather apply w
developed in other regions have developed.

Nevertheless smart technologies will create sufficient jobs for the sons and daught
grandchildren of coal miners and steelworkers, graduating from the regional u
wish to remain in the Ruhr.

# The Gap of Climate Adaptation Development of the Spatial Planning System in Taiwa
# Multilevel Planning Agencies Respond to Climate Risk

Yu-Tzu Lin

Department of Urbanism, Faculty of Architecture and Built Environment, Delft Unive
keats0704@gmail.com

Keywords: climate change adaptation, spatial planning, risk

Abstract

Recognizing that climate risk is a real threat to the environment and society, spa
role in developing adaptation policy responses as well as in integrating the terri
governmental sectoral policies. Planning for adaptation through policy interventio
implementation of climate risk management. Taiwan is situated in a region in
population living in more than three natural disaster impact zones. How to cope
more locally and increase national adaptive capacity becomes an important issue
sectors and actors to incorporate the concept of risk management into the supportive
making, and procedures at different spatial levels across a range of time scales i
in spatial planning. This paper uses a framework to elaborate how and what types of
in planning institution has been adopted or adjusted with case study in Taiwan. Tw
of planned adaptation are multilevel governance and land use management. These ba
existed problems in spatial planning system and affect the effectiveness, efficiency, e
embedded in adaptation decision-making.

## 1 Introduction

IPCC s Fifth Assessment Report (WGII AR5) indicates impacts from climate-relate
significant vulnerabilities and exposures of many human systems to current clima
impacts induce risk to our society, economy and environment due to the interaction
hazardous climate events occurring and the vulnerability of an expose system. Cli
disasters, as in larger and/or more frequent floods, or more intense and/or freque
or less direct, as climate change negatively affects food supplies, or access to w
It results from the interaction of vulnerability, exposure, and hazard (see Figure

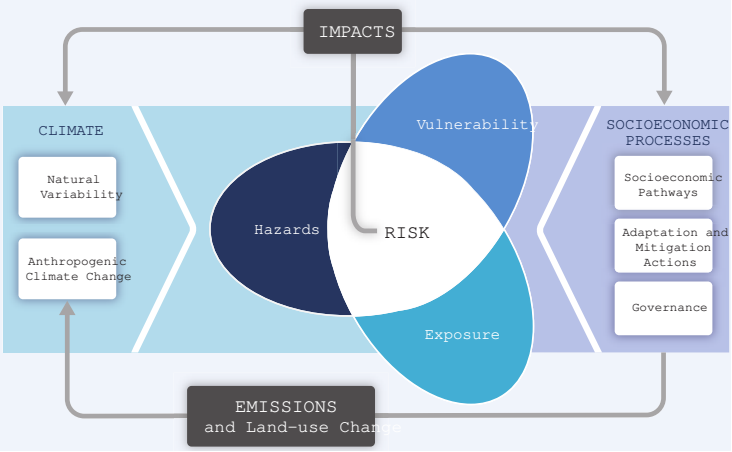

Figure 1 Illustration of the risk of climate-related impacts results from the interac

vulnerability and exposure of human and natural systems. (Source: IPCC WGII AR5 Technical S

## 2 Background about climate adaptation policy context

### 2.1 Research background

Spatial planning has been identified as a critical mechanism through which climate
be facilitated (Hurlimann & March 2012; Serrao-Neumann et al. 2015; Davoudi et al
argues that planning provides a critical approach to climate adaptation by four di
spatial plan making, which are spatial, temporal, coordinative, and multilevel dime

The research question is how has the process and tools of spatial planning system
needs in the governance structure in Taiwan s case. The framework that are based
plans is developed on the article of Simin Davoudi (2013) and Moser & Ekstrom (20
analysis including the interaction of planning actors and the policy documents
involvement, interviewing governmental officials and focus group discussion from 20

By the empirical analysis by the framework, the intervention, tools and resource
adjusted in planning system are assessed and the barriers of planning toward the
planning are identified.

### 2.2 The important aspects of planning for climate adaptation

There is an complex interaction between changing climate and spatial development c
process drivers and impacts, i.e. spatial strategies and its effect (human activi
from urbanisation, land use and planning policies on the climate; and the impact of the
hazards on different levels of space scale. All of these are complicated and req
spatial planning in the light of climate risk management as essential components f
Although it is one of the key messages in the adaptation chapters of IPCC Assessme
planning policies and strategies can trigger adaptation action across all sectors a

#### 2.2.1 Defining adaptation

IPCC Assessment defines adaptation as "Adjustment in natural or human systems in r
expected climatic stimuli or their effects, which moderates harm or exploits beneficial
involves reducing risk and vulnerability; seeking opportunities; and building th
regions, cities, the private sector, communities, individuals, and natural syste
impacts, as well as mobilizing that capacity by implementing decisions and actions
Adaptation requires adequate information on risks and vulnerabilities in order
appropriate adaptation options to reduce risks and build capacity. In this paper
need/and or gaps focuses on the adverse effects that natural hazards and other clim
a given location(F ssel & Klein 2006).

To achieve adaptation objectives and respond to climate risk at different spatial
necessary to clarify that the purpose and outcome of adaptation is a continuous str
decisions and awareness that reflect existing social norms and processes. Linking
adaptation is a series of actions to reduce the vulnerability of a system (e.g. a
population group (e.g. a vulnerable population in some areas) or an individual or
climate risk. It can take the form of autonomous, reactive or anticipatory ad
adaptation is essentially an unconscious process of system-wide coping, e.g. e
Reactive adaptation involves a deliberate response to a climatic shock or impact, r

prevent similar damage in the future. Anticipatory adaptation involves planned
prepare for adverse impacts and attempt to minimize those risks.

2.2.2 Risk-hazard oriented adaptation and adaptation options

The risk-hazard framework, drawn primarily from risk and disaster management, foc
effects that natural hazards and other climate impacts can have on a given locatio
Klein 2006). Although adaptation needs are specific to particular groups and place
more general categories as summarized as five perspectives that are biophysical an
social needs, institutional needs, need for engagement of the private sector, and
resources needs(Noble et al. 2014).

There are many different ways that the range of adaptation options available could
et al. 2005). Three categories of adaptation options are summarized in IPCC AR5
structural and physical, social, and institutional options. Among them, two main meas
options are most related with planning. One is laws, regulations, and planning mea
areas, building codes, and re-zoning are institutional measures that can improve th
communities by designating land use to support resilience.

2.2.3 Characteristics linking planning with climate change adaptation

The general/fundamental principles/characters/capacity underpin spatial planning
climate change adaption strategies. Stead et al. (2008) identify six key principle
spatial planning as democratic, subsidiarity, participation, integration, proportion
principles. Many literatures have noted the role of planning in climate change ad
March (2012) build five common planning tool types associated with planning for
content analysis and the emerging concepts of betterment and post-disaster planni
phase, Serrao-Neumann et al. (2015) propose a typology of enablers to maximise
disaster risk reduction and climate change adaptation by planning systems.

As mentioned above, planning intervene climate risk management by the way to (1)
interests of different stakeholders in different spatial scale in policymaking proc
Crawford 2009; Bulkeley et al. 2009) , (2)reduce vulnerability and by building t
to climate by mainstreaming adaptation into spatial plans(Wilson 2006; Leary et al
2009; Brown 2011; Kumar & Geneletti 2015). Being possessed of these character
important aspects for climate change adaptation. Through surveying the terms used
and adaptation, common characteristics link spatial planning with climate change adaptation (see Table 1).

Table 1 Key terms show the common characteristics linking spatial planning with climate chang

| Terms used in Concerned | Spatial planning | Climate change adaptation |
|---|---|---|
| Time scale | Present to 20 years normally | Present to future (20 years) |
| Spatial concern | Building site to inter-national | Building site to international |
| Disaster preparedness | Precautionary principle | Hazard-risk approach |
| Coordinative governance | Horizontal and vertical coordination | Multilevel governance |
| Benefitted system | Society, economics, environment | Society, economics, environment |

2.3 Operational definition

### 2.3.1 Clarifying adaptation planning and planning for adaptation

Aadaptation planning and planning for adaptation are defined as with diffe procedures, and objectives. Adaptation planning comprises a whole process to unde manage for climate change impact (see Figure 2). Planning for adaptation is like puzzle of adaptation planning . However, planning for adaptation shares comm adaptation planning , but also exerts its own instruments, tools, methods, and provided depending on the different planning system and practicing purpose.

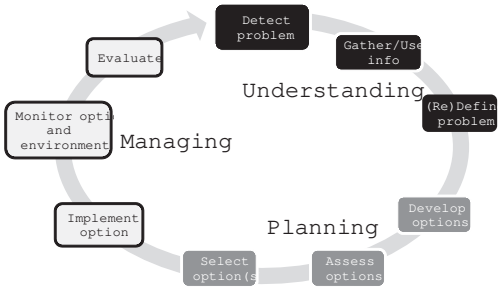

Figure 2 Phase throughout the process of climate adaptation planning (source: Moser &

This study focused on planned adaptation with the approach of risk management. Adaptation strategy is meant shared strategic vision and established priority outcomes through unambiguo with the overarching objective of reducing the vulnerability across sectors or f sectors or locality(qtd. in Biesbroek et al. 2010: 441). Planning for adaptation r risk at all spatial scale by spatial development and increasing the flexibility o system with multilevel governance. Spatial planning system in this paper denotes the actors in multi-level governance and the action related spatial development other. It is involved in the scope and scale of adaptation to climate change (see F

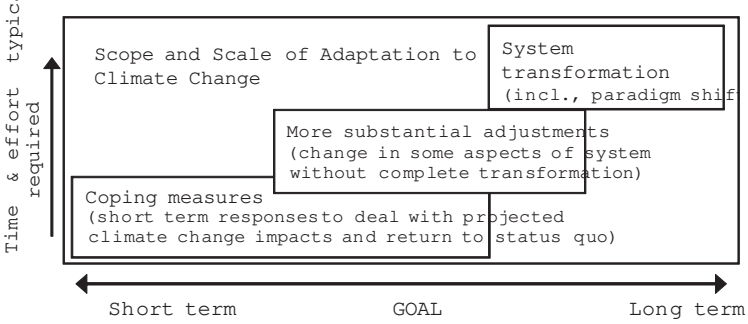

Figure 3 Scope and scale of adaptation to climate change (source: Moser & Ekstrom

### 2.4 Study context

Taiwan is very sensitive to the changing climate and is a high-risk natural di followed by severe floods and slope disasters is one of the major natural hazard death and economic losses, which might be up to US$ 2 billion for a single typh research on the simulation of the impact of future climate change on Taiwan (Lu e concerns of climate change include sea-level rise, extreme weather events, prec temperature. The magnitude and frequency of disasters associated with extreme events have increased in recent years.

About 70% of the population lives in areas that occupy less than 20% of the total The interaction between its natural-social condition and climate changes exacerb

water soil compound disasters caused by extreme weather and land development, water resulting from uneven rainfall and increasing water demands, coastal changes cause sea level rise, and increasing storm surges (see Table 2). The spatial distributi includes river basins (water-soil-bridge-road compound disasters), urban areas vulnerable and environmentally sensitive), and coastal and land subsidence areas disasters).

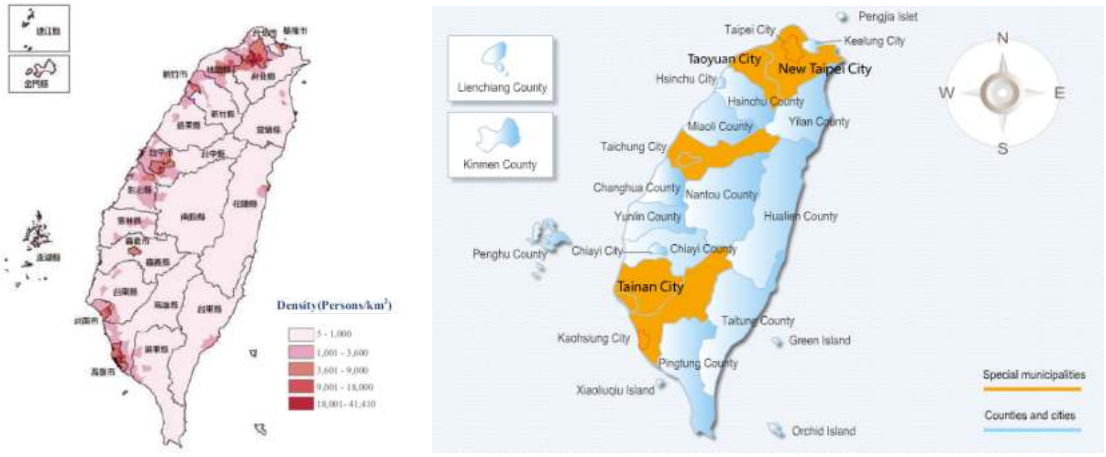

Figure 4 Population density and local jurisdictional territories

Table 2 Main disasters caused by climate and environmental change

| Factors of climate and environmental change | Impacts on floods | Impacts on slopeland disasters | Impacts on compound disasters |
|---|---|---|---|
| Increase in extreme precipitation intensity | Intense precipitation exceeding the carrying capacity of regional drainage systems or dike protection standards will increase flood risk. | Increasing precipitation intensity will raise the risk of slope disasters, which affects the safety of mountainous routes, communities, tourism industries, and minorities without resources to manage disasters. | The effects of compound sediment and flood disasters will increase, affecting government emergency response planning and long-term disaster prevention or reduction policies.<br>Aspects affected include the following:<br>Disaster prevention and emergency response capabilities in high-risk disaster areas;<br>Safety of infrastructure (such as reservoirs, bridges, dikes, and electricity towers);<br>Stability of water quality, reservoir operations, and droughts;<br>River channel erosion, sediment transport, riverbed deposition, and repeated disasters; and<br>Driftwood and landslide dam problems. |
| Increase in frequency of intense typhoons | Successive large-scale disasters will affect the emergency response and recovery capabilities of disaster prevention systems. | The increase in typhoons will cause more recovery and reconstruction problems for slopeland disasters than flood disasters. Successive disasters will increase the risk of repeated disasters and threaten the emergency response and recovery capabilities of disaster prevention systems. | |
| Uneven distribution of precipitation in wet and dry seasons | Uneven precipitation will affect reservoir storage capacity, water quality stability, reservoir operation safety, and downstream flood risks. | Uneven distribution of precipitation will affect soil water retention capacity, which threatens the sustainability and safety of the soil and water environment. | |
| Sea level rise and land subsidence | Sea level rise will make flood discharge more difficult when heavy precipitation events occur, increasing flood risk in low-lying coastal and land subsidence areas. | | |
| Environmental impacts of frequent earthquakes and devastating disasters (such as Morakot) | Increased environmental vulnerability after disasters and the recovery and reconstruction of public construction will increase the probability and risk of subsequent disasters occurring. | | |

## 2.5 The transition of Taiwan s planning system in climate policy context

Following the international trend of responding to climate change, the national started by setting up a cross-sectoral task force namely Working Group of Global E in 1992. This group then has been promoted as National Council for Sustainable Executive Yuan in 1997, which are composed of academics, governmental dec representative of NPOs and NGOs. Most of the policies and strategies associated change for the country were integrated and reviewed by the council. By the 199 environmentally sensitive areas and the delineation of protected areas triggered a spatial planning via a perceived need to incorporate resource conservation(Kuo & planning has been expected to play an important role in resource conservation by th of natural disasters at the beginning of the twenty-first century also led the governme emphasis on national land conservation and restoration.

After the 921 Earthquake in 1999, the already vulnerability of much of central T more fragile. Every typhoon or extreme precipitation event would cause large-scale disasters. Besides being beset by natural constraints, illegal logging and land sensitive areas generally worsened the already bleak state of the natural environm of flood prevention works had increased steadily and the safety of many of the communities was under threat. The central government therefore drafted bills and p existing national land conservation policies. The core principle is the hazards were overdevelopment. Attention therefore shifted from using engineering methods to pre limiting human activity and development in mountain areas, especially in those vu Huang 2010).

The first governmental policy action related with the term climate change adaptati plan of river basin management initiated by water management sector in 2006 for s as well as subsidence in south-western coastal area. Structural and institutiona firstly integrated into flood prevention work by central governmental as an integ climate variability issue.

In 2009, Typhoon Morakot brought high flood discharge, long duration rainfall that hours with max 1623 mm daily rainfall and caused 623 deaths. It triggered the natio develop national climate adaptation policy guidelines as a form of intervention in agency, the Council of Economic Planning and Development (CEPD), is responsible f plans for national economic development, carrying out its advisory functions by w integrate the views of different government agencies, and facilitating decisi government. Following policy guidelines, adaptation action plans and programm management thinking across ministries were fragmentally integrated in 2011. The lo a clear and explicit guidance with the form of national statements from the centra of climate adaptation (Wilson and Piper, 2010). For promoting climate adaptation p top-down approach, the central planning authority assists two local governments of planning for local climate adaptation strategy (LCCAS) by commissioning the acade the representatives from the municipalities as well as to build up the standard op of initiating LCCAS (see Table 4).

Referring to the categorization of Biesbroek et al. (2010) article, key drivers national adaptation strategies in Taiwan have extreme weather events, examples fro

scientific research. Key facilitating factors are political will and active people
Over the past decade, the role of planning in national and local level has expande
mitigation to ensuring climate adaptation policy delivery.

## 3 Planning intervention for climate adaptation needs in Taiwan

This paper proposes a framework to evaluating how has Taiwan s planning system re
change adaption needs? Here, this study adopts the approach of disaster risk redu
through spatial plans initiated by multilevel governments. Through the framewor
existed planning and successful planning toward climate adaptation is identified.

### 3.1 Relationship between planning and adaptation needs

The academic literature using framework to analyze adaptation can be divided into
to analyzing purposes: the first is to provide a systematic analysis of what is and how
itself, the second is to explain adaptation policy or strategies, and the third
capacity of a system. For example, Moser & Luers (2008) propose a framework fo
adaptive capacity of specific resource managers prepare for climate risk with thr
awareness of climate-related risks, analytic capacity to translate such climate
specific planning and management activities, and the extent of actions taken to
illustrate the application of this framework in their work through preliminary
coastal managers where we identify limited awareness of climate-change related r
capacity, and significant constraints on the abilities of institutions and indi
actions. The other literature providing frameworks to elaborate adaptation planning are
et al. (1999), Gallop n (2006), Moser & Ekstrom (2010), and Kumar & Geneletti (2015

Venton & Trobe Sarah La (2008), Hurlimann & March (2012), and Serrao-Neumann et a
demonstrated that planning is widely acknowledged to have a potentially significa
climate change or namely disaster risk reduction. Davoudi (2013) addresses the ext
has influence in tackling climate change depends largely on how broadly it is defi
types of interventions, tools and resources are available to it.

For analysing the response of planning for climate adaptation, in line with the
multilevel planning agencies in Taiwan s case. Here, planning approaches to climate
with disaster risk reduction through two dimension/tools: strategic planning and
management as the following and Figure 5:

> Strategic planning and integration is a rational process to formulate fro
> strategy; to coordinate cross sector policies horizontally as well as to i
> of jurisdiction vertically. Adaptation measures are increasing and becomi
> within wider policy frameworks. Integration streamlines the adaptation

> can be categorized into four groups land use planning and zoning, buildi
> management and natural resource management (Lin & Chen 2010). In land u
> process, public participation will be involved to let stakeholders aware of

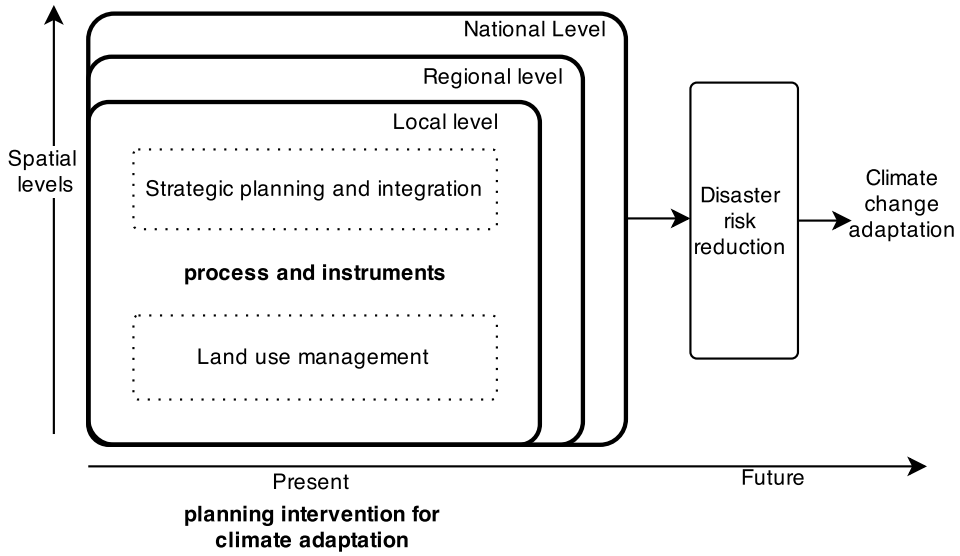

Figure 5 Planning intervention for climate adaptation in Taiwan

3.2 Explaining Taiwan s planning response and its relationship with other policy s

3.2.1 Briefing planning system composition and its transition characteristics

The administration of planning in Taiwan is in two tiers, central and local. The re
government is limited formally to the provision of legislation and the final app
urban and non-urban areas, which are all formulated by the Construction and Plan
Ministry of Interior (CPA). The special municipalities, counties and cities (w
authorities, also see the right map in Figure) are regarded as local government
drafting regional plans, urban plans of municipalities and special district plans

However, the territory of planning hierarchy is divided into three levels: nationa
the top is the National Land Comprehensive Development Plan that is a goal-orient
national spatial development and will be replaced by the future legislation of t
Planning Law. At the middle is the Regional Planning Law enacted in 1974 to contro
regulating the use of non-urban area (occupying more than two third of whole area of the
paralleled planning jurisdiction is National Park Law that is followed to the conse
Four regional plans designated by CPA are the reference of responsible for, but

| Regional | Regional Planning Law<br>National Regional Plan (draft), Regional plans of Special Municipalities, counties and cities | Special Municipality, County and City governments |
| Local | Urban Planning Law (Master Plan and Detail Plan)<br>Rules of Non-urban Area Land Use Control | Special Municipality, County and City governments |

[1] NDC is the main policy-planning agency of the Executive Yuan, charged with the tasks of planning coordinating, reviewing and evaluating the nation s overall development. It coordinates the implementation policies for economic, social, industrial, manpower, land and political governance. CEPD merged other the NDC after organization restructuring of the Executive Yuan in 2014.

### 3.2.2 Strategic planning and coordination in multilevel governance as the planning climate adaptation

Multi-level governance is a conceptual framework, which is needed to capture the v tiers of actors. It originated from the effect of the formulation after EU polity c initiating spatial development policies. The development of planned climate ada government in Taiwan starts from the policy initiative in 2010 and trickling down and the control of development at the national and local levels across spatial sc funding is the way central government exert to trigger local response. In 2011, a Local Climate Change Adaptation Strategy (LCCAS) and two LCCAS pilot projects have by NDC to assist other local governments to promulgate LCCAS. In the planning projects, local and central officials, experts, and NGOs jointly organized a p adaptation options for one year. Till now, eighteen cities or counties completed t funding of NDC (see Table 4).

There are four official regional plans respectively covering the northern, middle parts of the island. Each plans is thick in description of past trends and the current si responsible for the regional plans and empowered to act as a regional planning au formal implementation mechanism to make these plan effect. Decisions regarding majo public projects have seldom referred to any of the four regional plans. Driven by the planning hierarchy and threat of climate impact, in 2010, CPA propose a policy dr Regional Plan which integrates the principle of climate risk management with the land use planning vulnerable coastal, mountain, and hot spot areas across administrative boundar regulation in non-urban to direct local governments to incorporate climate investment in their regional pl regional planning in particular. CPA commissioned a planning guidebook, emphasizin anticipatory adaptation, and subsidized those cities/counties with territory of non-urban lan their regional plan so as to bridge the future enforcing of the National Land Pla the objectives of adaptation strategies in the draft plan, planning intervention c categories: to reduce the sensitivity of the effected system occurs, to alter the c increase the resilience of social and ecological system, urban green management, river basin governance, reservation of agricultural land, etc.

The planned adaptation action in local level is trigger by national level, NDC, thr
in formulating the LCCAS for two pilot areas, Taipei City and in PingDong County
accumulated mitigation effort, the cooperating willingness of municipality, and the

3.2.3 Land use management as the planning intervention for climate adaptation

Taiwan is and cannot avoid of experiencing frequent disastrous weather event e
rainfall, drought, and heat weaves. Frequent typhoons or heavy rains in one year,
in the mountains and floods on the plains, may be followed by drought the next yea
climate risk are river basins (water-soil-bridge-road compound disasters), urban a
(highly vulnerable to debris flow and environmentally sensitive), and southwe
subsidence and coastal erosion).

Adapting to part of these inevitable climate impacts with planning tools as adapta
implemented in various laws, acts, regulations and decrees, which can be categoriz
land use planning and zoning, disaster management and natural resource managemen
Urban Planning Law explicitly states that safety is one of the major concerns wh
central government announced a Disaster Response and Prevention Plan that calle
evacuation routs, open spaces for defensive purpose and refugee sites during th
process, These considerations were further incorporated into amended articles of
for the Periodic Comprehensive Review of Urban Plans, 2002, a subsidiary set of
Urban Planning Law(Lin & Chen 2010).

As for the regional spatial level, Regional Planning Law and Rules of Non-urban Ar
regulate Taiwan s non-urban areas. Although the boundaries of urban planning are
approved according to the Regional Planning Law, the compatibility of land uses be
and non-urban areas is seldom checked. The drafting of National Land Planning Law

for improving such compatibility. The current or proposed land use planning and already considered new requirements for hazard reduction. In addition, land use co in many natural resource management laws, such as the Tap Water Act, drinking w statutes, the Soil and Water Conservation Act, the Slope Land Conservation and Forest Law and the Environmental Impact Assessment Act. The administrative organ natural resource management laws belongs to different ministries with requesting r reduce hazard risk jointly. Land use management/panning for disaster risk reduc governance to make it. For achieving this, development projects smaller than ten reviewed and determined by local governments. Projects with larger areas must be Committee of Regional Planning of the Ministry of Interior. The review work will f project site but also its surrounding area, which may have intense environmenta project site. In practice, however, It takes time to check the completeness and acc developers provide. For a fast growing area many projects may be sent in for re becomes a pressure for the local governments to finish all the review process in a

## 4 Discussion

Assessing planning for climate adaptation has tended to lag behind mitigation effo in the climate negotiations. In part this is because adaptation and development s NGOs, and international agencies have found it difficult to clearly define and constitutes adaptation, how to track its implementation and effectiveness, and how effective development (Burton et al., 2002; Arnell, 2009; Doria et al., 2009). regarded as important approach to climate adaptation, in Taiwan s case it faces son adaptation. Adger et al. (2005) argue an action that is successful for one organizati governmental agency level may not be classed as successful by another. Success t scale of implementation and the criteria used to evaluate it at each scale. They e evaluative criteria for judging the success of adaptations at different scales in t development pathways into an uncertain future. These elements: effectiveness, ef legitimacy, reflect these principles embedded in adaptation decision-making, s trade-offs, and win-win strategy, are used to examine adaptation actions of Taiw planning institution, this paper discusses the barriers of the planning interven dimensions: governance dimension and land-use regulation dimension.

### 4.1 Governance barrier to planning for adaptation

The term governance refers to the sum of the many ways individuals and institutions manage their common affairs. It is a continuing process through which conflicting c be accommodated and co-operative action may be taken and includes formal (e.g. lega well as informal arrangements (e.g. social norms). A key role that institutions and facilitating adaptation is through legal and regulatory responsibilities and author

Bulkeley and Kern (2006) discern four governing modes for local authorities climat self-governing, governing through enabling, governing by provision, and governing b matter through which governing mode, as city governments devise to initiate LCCAS, formalize and institutionalize their work in order to facilitate implementation and legitimacy, coordination, and support for such policies across departments. One asp the establishment of dedicated climate units, either within a relevant department o crosscutting office. In Taiwan s case, the environmental department of Taipei city charge of the coordination of the Panel on LCCAS, since linking the adaptation with

In Taiwan, the way of the planning authorities at national level influence other land use control and coordination at the same level and intervene in the governa top-down mode. The mechanism reflects the tradition of centralized planning syste of the instruments of spatial planning in policymaking. The central government dominate the spatial development by framing national policy and direct public inve of institutions, the actors in national and local governments are borrowing what th domain or experimenting with different approaches to planning for identifying the climate governance. The interaction of actors at multilevel pushes the climate appeared in the planning process of LCCAS driven by the national government. Th private sectors or stakeholders follows the procedures of traditional land use involvement is still on the stage of information awareness. But some local goverr join international alliance to learn best practice from other cities.

There is no regional planning authority between national and local level to integ The task of developing the National Land Planning Law handed down from the Executiv drafting a new NLPL implies the merger of urban and rural planning, but it has a considering that national land use planning must call for coordination and negotiat is far beyond the capacity of the CPA alone(Hua 2010). Besides, the CPA, which is planning at national level, it only has the land regulation and reviewing power. and organizational level, it is regarded as regulating land use but doesn t have t coordinate department plans or without the capacity to affect the policy of other struggle between the expectation of its role and real public administration.

### 4.2 Land-use regulation & other barriers to planning for adaptation

Laws, regulations, and planning measures such as protected areas, building code adaptation measures that can improve the safety of hazard-prone communities by des support resilience. While zoning can be used to procure sites for low-income pop 2014). However, the framework for spatial development in Taiwan has already been d applying rigidly earlier zoning plans. This lack of flexibility and incentive f difficult to adjust when current comprehensive reviews of resource conservation ar growing emphasis on mainstreaming adaptation strategies, spatial planning measures domain to reduce climate impacts are often not linked to the impacts of these mea policy domain(Biesbroek et al. 2009). The phenomenon is also observed in t implementation of policy formulation in national government. In adaptation poli consistent in strategies and actions while it is divided into different sectors, ir point of view to integrate policies of different sectors for concerning the conv distribution.

According to the empirical case in Taiwan, the national policy planning and spatia adaptation action by the way of policy guiding and funding for initiating adapta governments aware the climate risk and the importance to adapt, but has often n process of implementation of adaptation options. The reason for the gap between can be summarized as: (1) adaptation is not viewed as the mainstream of responsibi (2) adaptation is regarded as high importance, but low priority in local and natio for thinking it as an isolated task.

## 5 Conclusion

Adapting to the climate impacts is a significant challenge at all relevant admi spatial scales (Adger et al. 2005; Urwin & Jordan 2008). Flexibility and integratio

characteristics of climate adaptation that emerge from the process of institution
respective political system where planning can contribute as well as is embedded wi

The adaptation literature and this case study provide evidence that institutional
the process of planning for climate risk. Planning institution can also either ena
scale of adaptation to climate change. These barriers or enablers of planning for
countries addressed in IPCC AR5 as well as in this case study are: (1) multilevel
between different political and administrative levels; (2) key actors, advocates,
mainstreaming, and sustaining momentum for climate adaptation; (3) horizontal inter
actors, and policies operating at similar administrative levels; (4) political d
implementation; and (5) coordination between formal governmental, administrative a
sectors and stakeholders to increase efficiency, representation, and support
measures ((Noble et al. 2014). In Taiwan s case, institutional challenges as prepa
from the existed planning jurisdiction and governing modes.

This paper concludes with the barriers facing the planning system and with how to t
of spatial planning to respond with institutional complexity and uncertainty in
adaptation trend. Faced with the gap of planning instruments/process toward climat
different spatial levels, institutional, or jurisdictional dimensions based on this
research about planning for adaptation in short term as well as for long term
multilevel governments increase adaptive capacity to respond to the trend of
challenging the planner to rethink his role in the policy making process. (2)
principles can be mainstreamed into local government plan as well as daily res
cost-benefit, no-regret, low-regret, win-win strategy, learning by doing, and keeping
planning for adaptation, considering to offer development benefits in the relative
reductions of vulnerabilities in the longer term, that can strengthen the role of p
tool.

# SEARCHING FOR SPATIAL SUSTAINABILITY: ONE GOAL, MULTIPLE PATHS

Daniel E. Orenstein[1], Dalit Shach-Pinsly[2]

[1]Faculty of Architecture and Town Planning, Technion Israel Institute of Technology, DanielO@ar.technion.ac.il

[2]Faculty of Architecture and Town Planning, Technion Israel Institute of Technology, dalitsp@tx.technion.ac.il

Keywords: regional development, spatial planning models, sustainability

## Abstract

Sustainability has been a prominent goal in environmental planning over t
*especially in rural regions. Planning scholars and practitioners have contributed to this trend by proposing, developing and implementing frameworks for spatial development that aim to facilitate human economic and social development, while mitigating or even reversing the environmental damage associated to development. A broad diversity of frameworks has been developed, and they have both unique and overlapping features.*

*This work explores the myriad ways in which planners understand sustainability and how they implement it at various spatial scales. Drawing from the theoretical and professional literature and from case studies around the world, we develop a classification system for spatial sustainability frameworks based on three scales of aggregation: typologies (the most general category), models and individual case studies. We develop five axes that define the prominent differences in* characteristics of spatial sustainability framework typologies. These are: *bottom-*up axis, defining who initiates and maintains the initiative; 2) the economic axis, defining the disciplinary approach that *determines relative importan* various priorities; 3) the subject-*specific* holistic axis, defining the fo *initiative;* 4) the local regional axis, defining the spatial scale of the initi *open space orientation.*

*We suggest that the axes of comparison can assist communities to define and implement their spatial planning goals, while addressing diverse and sometimes competing interests, and conclude by discussing implications for planners. In particular, sustainability planning can be tailored according to the particularities of the socio-ecological system.*

## 1. Introduction

For the past half century, one of the prominent trends in global environmental planning and policy has been the quest for sustainability at the local, regional and global scales. It has been widely posited that exponentially growing populations, rapid loss of open spaces, habitat fragmentation and destruction, sprawling human settlement and associated infrastructures all pose growing social, economic and ecological challenges that threaten the long-term wellbeing of human society. Growing recognition of these challenges culminated in such events in the 1980s and 1990s as the publication of the Bruntdland Report and the Stockholm Earth Summit (Conca and Dabelko, 1998). Simultaneously, local communities began experimenting with policy and planning to realize

comprehensive sustainability principles and goals. Planning scholars and practitioners joined the global effort to address these societal challenges proposing, developing and implementing frameworks for spatial development that strive to achieve sustainability development can continue, while the environmental damage is mitigated and even reversed (Jabareen, 2006). Multiple and diverse frameworks have been developed with both unique and overlapping features.

In this paper, we explore the diverse ways in which communities, policy makers and land use managers understand sustainability and how they implement sustainability at the regional sca With such a broad diversity of understanding, interpretation and implementation, we are also interested in finding commonalities between sundry approaches. We review, characterize and categorize a broad range of frameworks for sustainable regional spatial planning. We begin with a literature review of documents pertaining to regional sustainable development from the past decade. We characterize sustainability frameworks using common themes across planning frameworks. Next, we identify the critical differences between the frameworks, and define the underlying values and disciplinary biases that influence each model and define their differences. We conclude by offering lessons for planners and communities embarking on sustainability initiatives at the regional scale.

***What is sustainability in the regional development literature?***

Sustainable development has been a common, though oft maligned, development catchphrase since popularized by the Bruntland Report ( Our Common Future ; World Commission on Environment and Development, 1987), which defined the term as development that meets the needs of the present without compromising the ability of future generations to meet their own needs. Inherent in the definition is the assumption that the earth s capac resources and to absorb waste is limited (Meadows et al., 1972). The combined pressures of increased human population growth and material consumption are considered unsustainable in that they lower the resilience of the planet and its ability to provide resources and absorb waste, thus threatening future generations. Rising from these assumptions, the first definitions and applications of sustainable development were focused on environmental issues, such as sustainable resource use.

While the report and the definition itself have been criticized from multiple perspectives (Wall, 1997; Miller, 2014), the term and the idea it represents have not only endured, but they have promulgated into every discipline and profession that deals with environment, resources and land use. The concept definition has been refined and various frameworks for assessing and monitoring sustainability have been proposed, most focusing on three aspects (or pillars) of human development: social, economic and environmental. The underlying assumption is that only if all three realms of human wellbeing are addressed can true sustainability be achieved. So, while sustainable resource use was and remains a common starting point for sustainability initiatives, the emphasis has shifted from purely environmental reasons to communities that rely on the resource for their social, cultural and economic well-being (Kearney et al., 2007). Weaver (2005) recounts that early definitions of sustainability (with regard to ecotourism) were particularly environment-focused, but this was superseded by the inclusion of social, cultural and economic sustainability considerations.

The literature on sustainable regional development analyzes and advocates the application of the concept via land use planning at the regional scale. Most of this work recognizes the three pillars of sustainability (Wiber et al., 2004; Weaver, 2005; Kearney et al., 2007; Donald, 2008; Wheeler,

2009; Schädler et al., 2011; Reyer et al., 2012), which have also been canonized in government policy documents such as Agenda 21 (United Nations, 1992; Council of the European Union, 2006; Organization for Economic Cooperation and Development, 2006). This three pillars definition has been challenged by some, such as Miller (2014), who suggests that such categorization locks the users into a limited discourse of compromise between the three components. He suggests replacing the paradigmatic definition with a pursuit of quality of life and sustainable livelihoods suggested by others, e.g. Stoll-Kleemann and O'Riordan, 2002; Horlings and Padt, 2013). Wall (1997) simultaneously touts the potentially beneficial definitions and goals of sustainable development while dismissing it alternatively as a political slogan or an imprecise catch phrase (which may also act as a catalyst for community discussion).

Table 1 summarizes the definitions of sustainable development applied in various works on the topic over the past decade.

| Source | Research focus | Definition of sustainable development |
|---|---|---|
| Wiber et al., 2004 | Community-based fishery management | Referred to in **ecological and economic** terms; **sustainable livelihoods** . |
| Weaver, 2005 | Ecotourism | Contentious term, impossibility of knowing that a partic course of action is indeed sustainable This owes to the **subjectivity and malleability** of this [concept], wherein there is no consensus as to what exactly should be sustained. Sug a continuum of criteria for sustainability from status qu enhancement of the local environment. |
| Donald, 2008 | Food systems | reducing a region s **ecological footprint**, addressing issues of **hunger**, and providing **more local jobs**; thus ultimately moving toward a more sustainable region in keeping with the **three classic pillars** of sustainabilit |
| Fitzsimons and Wescott, 2008 | Multi-tenure reserve networks | Noted primarily in terms of **natural resource use** and **ecological** sustainability |
| Kearney et al., 2008 | Participatory governance | Reference to the **three components**, but which cannot exist without **community wellbeing**; Emphasis should thus lie in maintaining or enhancing the **economic and sociocultural well-being, overall cohesiveness, and long-term health of the relevant human systems** |
| Wheeler, 2009 | Sustainability challenges posed by megaregions | **long-term** time horizon **holistic** approaches between goals (**environment, economy and equity**) the concept of **limits** the importance of local and r **sense** of place |

Table 1: Definitions of sustainability and sustainable development

In this work, we review the research on and application of sustainable regional development . Our research goal was triggered by a local non-governmental land-holding organization (NGO), whose staff desired to initiate a comprehensive regional sustainability initiative with local communities. The organization s interest was prompted by an ecological study of their conclusions that long-term survival of multiple species on the site could not be assured through management of the site alone. Rather, species survival was dependent on connectivity between the site and other habitats in the region and therefore, dependent on regional development. While the concept of biospheres has been adopted in Israel as one prominent model of regional sustainable development, the organization wanted to answer the following questions: 1) What models exist for regional sustainability initiatives? 2) What is the most suitable model for the NGO to adopt for the region, and 3) What would be the most productive role the NGO can play vis-à-vis setting the agenda and facilitating the process of a sustainability initiative? Our effort to answer these questions expanded into the current research, which consists of a comprehensive review, categorization and analysis of regional sustainable development initiatives.

## 2. Research Methods

The first stage of research relied on a literature and internet search for generalized concepts such as sustainable regional development and sustainable spatial planning. We reviewed the available literature (primary and grey) and analyzed the data in order to identify prominent themes that ran throughout the work. We then supplemented the initial with additional information on recurring themes from the literature, including terms such as ecotourism, sustainable agricultural landscapes, sustainable urbanism and landscape urbanism and others.

After reviewing the collected work, we developed a classification system based on four typologies of sustainability initiatives based on focal object of management, philosophical approach, disciplinary approach or other commonalities (Jabareen, 2006). Our typologies are 1) natural resource and ecology based initiatives, 2) urbanism initiatives, 3) issue-based initiatives, and 4) governance, participation and science-based approaches to sustainability. Particular models exemplify how the typologies are implemented on the ground. Models have specific managerial, planning or policy guidelines. For each typology and their associated models and case studies, we analyzed the following characteristics:

- Scope: At what spatial scale does the approach apply? National, regional and/or local? Who is involved?
- Fields of action and activities: Is the approach holistic or does it focus on a particular topic, resource or environmental characteristic? What specific actions characterize the approach?

- Successes and challenges: What has been the experience of implementation of the approach and what have been the challenges in meeting stated goals?

Finally, we present a set of thematic axes by which to understand each typology and associated models. We emphasize that no single sustainability initiative falls neatly into a single typology. To the contrary, we found common themes running through most of the reviewed papers. The typological classifications are meant to highlight themes and their relative dominance within particular initiatives. Along with the thematic axes, they are meant to assist the reader in defining the strengths and weaknesses of their own initiative and to tailor initiative in their own region.

## 3. Case studies of sustainability: Typologies and models

We identified four typologies for regional sustainability initiatives. We present each of the typologies with models that fall within each typology. For each model, we summarize salient details regarding scope, field(s) of action and activities, and successes and challenges.

***Typology one: Natural resource and ecology based initiatives***

The underlying primary foci of typology one initiatives are the natural resources and ecological integrity of a region and their core motivating goal is to protect biodiversity or prevent ecological degradation. Some are holistic on their approach, adopting region-wide sustainable land use planning that considers natural resources, biodiversity and ecosystem services (Fürst et al., 2013), and others focus on sustainable use of a focal resource. A prominent objective is landscape connectivity to assure viable habitats for a particular species or set of species (Fitzsimons and Wescott, 2008; Fitzsimons et al., 2013). Due to growing evidence that ecological conservation cannot succeed in the absence of human wellbeing (Dietz et al., 2003; Adams and Hutton, 2007), local community/stakeholder integration plays an increasingly prominent role in natural resource and ecology based initiatives. Nonetheless, sustainability is primarily indicated by ecological factors.

The typology is divided into two sub-categories, including multi-tenure reserve networks and community-based natural systems management. Multi-tenure reserve networks are areas of land owned and/or managed by diverse stakeholders that, for reasons of ecological integrity and desire to connect habitats, are integrated into a coordinated management regime (Fitzsimons and Wescott, 2008; Fitzsimons et al., 2013). A primary goal of multi-tenure reserve networks are protection of biodiversity. Models include biosphere reserves, biolink zones, wildlife corridors, conservation management networks, and ecoregions (Fitzsimons et al., 2013). Most of the models classified as multi-tenure reserve networks also have evolved to incorporate community-based management, as with biosphere reserves (Stoll-Kleemann and Welp, 2008).

Community-based management, a popular form of participatory governance for natural resource management (Kearney et al., 2007), is designed to address both ecological and socioeconomic goals by balancing exploitation of a natural resource with its long-term conservation. While it is generally focused on a particular natural resource, it internalizes the axiom that sustainable resource use should be determined by the communities that are dependent on the resources. The mechanism for initiating sustainability is through participatory governance. It addresses issues related to the access and control over commons resources by local and nonlocal actors based on the assumption that communities connected to natural resources are most likely to foster sustainable use. As such, it advocates devolution of decision-making power and authority to communities and community-

based organizations (Kellert et al., 2000; Wiber et al., 2004). Models for community-based management include social and community forestry, community wildlife management, buffer zone management and others (Kellert et al., 2000).

*Scope:* Multi-tenure reserve approaches are large scale, coinciding with habitats and their connectivity over the range of a species (Fitzsimons et al., 2013). Community-based management operates at scales according to the resource or biodiversity in question.

*Fields of action and activities:* Implementation of the approaches involves definition of the target species, resource or habitat, scientific research to define conservation needs, and then an identification of stakeholders. These can be forests, marine and wetland resources, grazing lands and fisheries, nature reserves and cultivated areas. Planning and management objectives include the devolution of authority, implementation of adaptive leadership, and encouragement of participatory governance. Initiatives encourage development of a scientific knowledge-base, strengthened communication and information dissemination, ecological/environmental monitoring, formation of learning communities, and clearly defining land rights. Partners include local communities, governmental agencies, non-governmental organizations, and experts in variety of disciplines.

*Successes and Challenges*: Success can be measured by the conservation status of the habitat, species or resource in question, or in terms of process (e.g. creation of multi-level community dialogues or engaged communities). Concrete objectives include revenues from resources, effective long term resource management and restoration of degraded ecosystems. Governance, leadership, and social and economic networks are all cited as elements of successful implementation.

Some challenges in implementing this approach are directly related to the size of the area and the wide variety of stakeholders within. This demands a high degree of coordination between stakeholders and governance structures (Fitzsimons et al., 2013), and initiators cite lack of trust between local communities, scientists and policy makers. Pre-existing conflicts between stakeholders that are left unresolved may demand attention and arbitration. Other challenges include failure to stimulate interest within local communities, failure to adopt truly participatory approach, lack of harmonization and coordination in actions of various partners and lack of enforcement of policies (Kellert et al., 2000; Stoll-Kleemann and O'Riordan, 2002). Lack of funding is also a common impediment to successful implementation and maintenance of the initiative (Kearney et al., 2007; Stoll-Kleemann and Welp, 2008; Fitzsimons et al., 2013). While the devolution of decision-making authority is encouraged, it also should be implemented with caution, as local communities may not have the social networks and governance structures needed to make, implement and enforce decisions (Wiber et al., 2004). This emphasizes the need and responsibility of government authorities to develop and foster the capacity of local communities to take an active role in decision making (Stoll-Kleemann and Welp, 2008).

***Typology two: Urbanism***

While urban areas are often touted as both inevitable and the prototype for settlement patterns in an increasingly populated world, they are also viewed as particularly challenging for sustainability (Wheeler, 2009). Many sustainability frameworks for urban regions have been developed to address environmental and socio-economic challenges (Jabareen, 2006). In contrast to the previous typology, urbanism typologies focus on the environmental and social aspects of urban development, with ecology taking a relatively minor role until recently.

The typology is divided into three sub-categories: new urbanism, landscape urbanism, and eco-urbanism. New Urbanists advocate design-based strategies based on traditional urban form goals of addressing suburban sprawl and inner-city decline (Bohl, 2000). Objectives, according to the Charter of the New Urbanism, include restoration of urban centers and town within coherent metropolitan regions, the reconfiguration of sprawling suburbs into communities of real neighborhoods and diverse districts, conservation of natural environments and the preservation of our built legacy (Congress for the New Urbanism, 2001). Within the New Urbanism sub-category there are several models that include neo-traditional town planning, the pedestrian pocket, transit-oriented development, Quartiers approach, and smart growth.

The second sub-category is Landscape Urbanism. Its main focus is organizing cities through the design of their landscape, rather than organizing them through their buildings. The concept offers a framework in which to consider complex urban conditions and the reciprocal implications of the city in the landscape (Mostafavi and Najle, 2003) and a sense that landscape can be used as a model and basis for urban initiatives, and a lens through which to examine cities (Grey, 2011). Models for landscape urbanism include the Machinic Landscape (Mostafavi and Najle, 2003), the field operations (Corner, 1999), infrastructural urbanism, Mat urbanism, and the Foreign Office Architect s phylogenesis.

The third subcategory is Ecological Urbanism, which is a successor and critique of landscape urbanism. It argues for a more holistic approach to design and management of cities, drawing lessons from ecology. Curiously, just as ecological typologies were becoming increasing human-centered, urbanism as witnessed by the development of ecological urbanism was becoming more ecologically centered. Ecological urbanism calls for city planning that is both multi-scalar and multi-disciplinary and proscribes that design exploit ecological knowledge to produce environmentally sustainable urbanism (Mostafavi and Doherty, 2010). Influenced by new ecological paradigms of dynamic and unpredictable nature and ecosystems theory (Pulliam and Johnson, 2002), Ecological Urbanists suggest that the modern challenge of landscape planning is leading the sciences, humanities, and design culture toward a more rigorous, robust and relevant engagement across the domains of ecology and design (Reed and Lister, 2014).

*Scope:* New urbanism is applied at various scales from the individual building to entire cities and regions. In the regional context, new urbanism considers a diversity of urban settings, from village, town, districts, and neighborhoods to cities and regions, and include their surrounding landscape (Bohl, 2000), which can range from local to regional scale. Since ecological urbanism aims to wed the theory and practice of city design and planning with the insights of ecology, it focuses on multiple scales from local to regional, often corresponding to ecological scales. The implementation of new urbanist, landscape urbanist and ecological urbanist initiatives depend on collaboration with and between government agencies at multiple levels, designers, urban planners, architects, private clients and local residents representatives. Ecological urbanism also incorporates the expertise ecologists and other natural scientists and land use managers.

*Fields of action and activities:* New urbanism acts mainly in the field of architecture and planning at multiple scales. Some of its activities include crafting flexible zoning standards, developing public parks and gathering spaces, promoting historic preservation, designing pedestrian and bicycle friendly neighborhoods, retrofitting of public housing projects, brownfield redevelopment and urban infill projects, transit-oriented development, and advocacy. Landscape urbanism incorporates expansive green space with urban areas, and designs spaces for infrastructure, water management, biodiversity, and human social and economic activities. Ecological urbanism acts in

the field of urban design and planning emphasizing reduction of urban footprints, design and planning for urban and local food production, developing productive urban environments and local energy sources, regulation of climate, disease, flood and drought and support for nutrient cycles and habitat for native plant and animal species.

*Successes and Challenges*: Advocates suggest success for these initiatives in influencing urban development. New urbanism-influenced initiatives have resulted in denser neighborhoods with improved internal connectivity and increased walkability. Landscape urbanism notes success due to its influence on raising environmental awareness and changing planning paradigms, with increased consideration of landscape integration. However, these approaches also face diverse challenges and criticism. New urbanism is often perceived as riskier than typical urban planning, due to its multiple-use goals and its strategies are sometimes viewed as exclusionary (e.g. a product of NIMBY). Both landscape and ecological urbanism raise issues regarding the question of the human presence in nature. In addition, urbanist initiatives are criticized as being based on loosely defined concepts and relying on ostentatious projects to promote the concept. Other critics challenge whether the typologies represent an honest integration of landscape architecture with principles of urban ecology.

***Typology three: Issue-based initiatives***

The general assumption of issue-based approaches is that by realizing sustainability in a given economic or social sphere, the impact will have impact on sustainability in all spheres. Donald (2008) emphasizes the potential, for example, of sustainability changes within food systems to have much wider ramifications of social, economic and ecological sustainability. Other initiatives focus on an economic or cultural mainstay of the region, for example salmon in the case of the Salmon River Watershed Roundtable in British Columbia (Day and Cantwell, 1998). The sub-categories of issue-based initiatives include ecotourism, eco-agriculture, and food-systems approach.

Agriculture and tourism are two prominent foci for issue-based sustainability initiatives at the regional scale. For many rural regions, agriculture and nature and landscape-based tourism are cornerstones of the local economy (Loibl and Walz, 2010). Both are considered to be ineluctably tied to environmental quality. Ecotourism is tourism that focuses on a component of nature and which should satisfy ecological, economic and socio-cultural sustainability (Wall, 1997; Weaver and Lawton, 2007) and encourage active learning provide transformative experiences (Weaver, 2005; Weaver and Lawton, 2007). Community empowerment has become a prominent feature in ecotourism initiatives (Weaver, 2005).

Donald (2008) advocates placing food systems at the center of regional sustainability issues: "Sustainable food production aims to involve nature's goods and services bet process, while at the same time minimizing the use of non-renewable inputs. In recent years, th focus has shifted from sustainable food production to a sustainable food syste beyond the farm to include the rest of the food chain, from organic fertilizers, fuel, food processors, food markets, eaters and waste management, as well as all the associated regulatory institutions and activities" (Donald, 2008, p.1253). He justifies the focus on food systems as a catalyst towards broader sustainability due to its impact and dependence on ecological, social and political systems.

*Scope:* As noted above, the scope of issue-based initiatives is consistent with the selected issue and can be local or regional depending on the issue and the goals of the initiator. For instance, an

agricultural initiative can occur at the site scale or can be part of a comprehensive regional (or national) policy. Salmon-based initiatives are by definition, conducted at the scale of the watershed.

*Fields of action and activities:* Fields of action are determined by the scope of the initiate and the particular issue in question.

*Successes and Challenges*: Donald (2008) suggests that success is measured by community collaboration. According to Weaver and Lawton (2007), ecotourism research suggests that it was unclear as to whether ecotourism in general was meeting ecological or economic goals. Wall (1997) is significantly more critical, drawing a sharp distinction between sustainable tourism (implying a holistic improvement in both human and environmental conditions) and ecotourism (an instigator of often unwanted change at the tourism destination). Rather, he prefers to consider tourism within the broader rubric of sustainable development.

***Typology four: Governance, participation and science-based approaches***

Agenda 21 states forthright that public participation in decision making is a prerequisite for realizing sustainable development (UNCD, 1992). The common feature of typology four is the underlying assumption that political and planning processes are the most crucial ingredient in the production of sustainable outcome. Various forms of community engagement have become cornerstones of sustainable planning and management in diverse fields of planning, landscape design, natural resource management, and environmental policy, and recent research suggests that new and innovative forms of community-based leadership are developing to meet sustainability challenges at the regional scale (Wiber et al., 2004; Horlings and Padt, 2013). Thus, much of the literature focuses either on systems of governance to maximize participation of relevant stakeholders or on the process of stakeholder integration into planning processes (Kearney et al., 2007; Loibl and Walz, 2010; Fitzsimons et al., 2013). This component of sustainability is considered so central that much of the literature treats participatory processes and governance as an indicator of sustainability in and of itself.

The literature on governance and participation in sustainability initiatives is diverse, but some examples can serve to illustrate the diversity. Loibl and Walz (2010) recount a science-informed stakeholder deliberation process in the Austrian Alps, where stakeholders were prompted to discussion with lectures about climate change and local socio-economic trends. Stakeholders provided their reactions, perceptions and knowledge of development dynamics in their region, and this information was used to generate scenarios and visual data to help the same stakeholders suggest sustainable development priorities and policies for the region s colleagues (2007) emphasize the need to build cross-scale horizontal and vertical interactions between various agencies and stakeholders to catalyze cooperation and avoid fragmentation of decision making. National parks in Switzerland combine bottom-up and top-down approaches to policy making, where local actors formulate policy that is then sent up the government hierarchy for approval. If approved, the federal government then supports the policy initiative financially and logistically (Hirschi, 2010).

Leadership is a recurring theme as an ingredient for success on initiatives. At the local level, leadership plays a central role in sustainability initiatives according to Horlings and Padt (2013). They explore regional development initiatives in rural Netherlands and conclude that leadership is crucial in the transition from the old economic path to more sustainable regio Others concur in noting that leadership is crucial for successful implementation and coordination of

multi-tenure reserves (Stoll-Kleemann and O'Riordan, 2002; Fitzsimons et al., 2013). Fitzsimons and colleagues (2013) warn that too much dependence on individuals is not sustainable over the long-term.

*Scope:* Diverse and a function of the target area and population. Primary emphasis is on including all of the relevant stakeholders.

*Fields of action and activities:* Diverse and a function of the selected target area and population.

*Successes and Challenges*: The case studies are generally portrayed by their authors as successful examples of governance and participation. But there are also examples of insufficient community participation (Kellert et al., 2000; Kearney et al., 2007). The primary challenge is to create a process that truly integrates community input, raising the community from an advisory capacity to one with a bona fide role in decision making (Kearney et al., 2007). Kearney and colleagues (2007) note three crucial shifts in thinking that must take place to create ideal community-based management, including 1) integrating the broad range of diverse stakeholders; 2) holding regulators and governments accountable and transparent to their public, and 3) allowing communities to take the lead in governance. Further, these empowering shifts must be officially recognized and codified (legally and politically). Kellert and colleagues (2000) report that according to their social and environmental indicators, community-based management in developing countries failed to result in equitable distribution of power and benefits, reduced conflict, or increased appreciation of local knowledge, biodiversity protection or sustainable resource use. The role of stakeholder engagement and participatory planning in regional sustainability is particularly challenging in megaregions, which are suggested to be inherently difficult to govern sustainably (Wheeler, 2009).

Also included in this typology is the science-based approach, which posits that research for sustainability must be local and, in part, stake-holder driven. An exemplary science-based sustainability initiative is the Long-term Socio-Ecological Research (LTSER) platform. LTSER platforms were conceived and implemented by the International Long-Term Ecological Research (ILTER) network over the past decade (Singh et al., 2013). The LTSER platform is a spatially-defined foundation for place-based, sustainability research, whose agenda is determined in collaboration between scientists and local stakeholders. The scope of LTSER is regional, although the size of LTSER platforms varies from several square kilometers to one-third of the area of Finland. Its focus is policy-relevant research, defining the scientific agenda in a way that suits the goals of regional sustainability. Collaborative meetings between policy makers, local residents and other stakeholders afford the opportunity to exchange scientific and local knowledge and to facilitate community-level planning. Partners include scientists, local/regional decision makers, land owners, local residents and other stakeholders. The LTSER network cites among their interim successes 1) a reorientation of scientific research agendas to be better aligned with regional socio-ecological challenges, 2) creation of collaboration between researchers, policy and management agencies and the general public, and 3) establishing an infrastructure for the collection of long-term socio-ecological data. Its challenges include lack of reliable funding mechanisms, a narrow scientific research agenda, and a socio-ecological focus that detracts from important pure-science research.

## 4. Thematic axes and discussion

This survey of spatial sustainability initiatives is a hopeful testament to the multiple ways which local communities, the scientific community, and policy makers are addressing contemporary

sustainability challenges. Sustainability the effort to secure socio-economic wellbeing while preserving ecological integrity, thereby assuring human wellbeing is a goal in regional management in thousands of projects across the globe. While this drive to address global development issues is encouraging, the efforts have often had limited success, measured at the regional scale (Wheeler, 2009) and at the aggregate global scale .

There is broad diversity in sustainability approaches, foci, management structures, implementation tools, and leadership. We derive from this analysis five axes with which to analyze both nascent initiatives and the overall conditions facing potential initiators of regional sustainability projects and to help clarify the potential strengths and weaknesses of an initiative based on sustainability planning theory and aggregate international experience. The axes are to be thought of as a continuum, and since initiatives are dynamic, their places on the axes are not static.

*Axis one: top-down versus bottom-up initiative* (Who initiated the effort, national government or international organizations or was the effort a local initiative by local residents?). Some initiatives are top-down, meaning that a specific tier within the governance structure, or other relatively influential groups (like academics, NGOs, or land owners), initiate, set goals and implement the project. While these initiatives may have well-defined and clear goals, they often neglect the aspect of community participation, even when explicitly part of the initiative. Biosphere reserves, when initiated by government agencies rather than by the communities themselves, can be hindered by neglect of community participation. But top-down initiatives benefit from institutional guidance and support. Bottom-up initiatives, catalyzed by community members themselves, can suffer from lack of focus, organization, and stability. They depend on the stamina, charisma and commitment of community members to implement projects. However, theoretical and practical data suggest that bottom-up initiatives are the most durable in terms of community support.

There are very clear roles for both governmental and community-based participation in sustainability projects. Without commitment of both participant groups, there is less potential for success. While stakeholder participation and empowerment should be self-evident, the role of government agencies, which includes financial support, capacity-building and facilitation, provision of information and expertise, guidance and connection to broader-scale (e.g. national and continental) policies should not be underestimated.

*Axis two: ecological versus socio-economic focus* (Did the effort focus on ecological priorities or did it begin with an emphasis on social or economic concerns?). While all sustainability definitions integrate and pre-suppose a balance between ecological and socio-economic considerations, in practice projects often reflect the priorities of their initiators. Biosphere reserves, for example, often reflect an inherent bias towards biodiversity conservation at the expense of socio-economic wellbeing. Stoll-Kleeman and O Riordan (2002) found that although they observed a paradigmatic change in the way biodiversity protection (e.g. in biosphere reserves) was discussed, towards an integrative socio-ecological approach with community participation, in practice the shift had yet to be actualized. Stoll-Kleeman and Welp (2008) suggest that, in order to fulfill biosphere goals, greater effort must be made to engage in interdisciplinary (rather than solely ecological) research as a path towards greater integration of communities and greater understanding of the socio-cultural and economic challenges. The evolution of the biosphere idea shows a growing attention to human well-being than early implementations of the model.

In contrast, while urban-based sustainability initiatives often place emphasis on open spaces, clean air and water, and clean transportation systems, they do not always reflect an understanding of

habitat conservation, ecological integrity and biodiversity. But overall, there seems to be a general convergence on full consideration of concerns on both ends of this spectrum.

*Axis three: subject-specific versus holistic systems approach* (Does the initiative focus on a single topic or target or does it take a holistic approach?). Both approaches on this axis have unique advantages for sustainability planning. The subject-specific approach (e.g. the Salmon River Watershed Roundtable) capitalizes on a culturally and/or economically meaningful component of the natural environment. Yet, even from the individual species or resource perspective, sustainable management will demand a more holistic approach to regional planning to assure long-term viability of the resource. Holistic approaches, such as multi-tenure connectivity initiatives, take the broad (ecological) view of a region and work to secure habitat protection for all biodiversity within.

The case studies show that both approaches can be effective, though they both face challenges. Some approaches may be too narrow to allow for a broader look at the ecological or societal impacts of a project (for instance, in ecotourism). On the other hand, holistic approaches, while inherently more appropriate for sustainability, can be too broad or vague to be effective. Further, holistic approaches are more revolutionary in their approach and may demand too much of various stakeholders, thus engendering opposition.

*Axis four: geographic scale of approach* (regional or local scale of resolution). Deciding on a spatial scale for the initiative is always a logical first step in a sustainability initiative. Scale will vary according to natural and political boundaries, social networks, specific sustainability approach (e.g. ecological or socio-economic; subject-specific or holistic), and administrative-political-economic considerations. The success of a project is contingent on proper definition of initiative boundaries (physical and social). The improper definition of boundaries will have an negative impact on a range of issues from ecological integrity to stakeholder engagement. All regions, regardless of size, are also subject to external factors beyond the boundaries of the initiative, and so exogenous change must also be considered within the sustainability initiative.

*Axis five: Urban or open space orientation*. This axis is closely tied to the ecological / socio-economic axis, as projects focusing on urban areas tend to also focus on human systems, while projects focusing on open space tend to more heavily emphasize ecological issues.

In conclusion, while specific characteristics of sustainability initiatives must be tailored for local conditions and priorities, we note a nearly universal convergence regarding key components of a successful sustainability initiative, including the importance of participatory governance and full collaboration and trust between agencies and stakeholders, a focus on local communities and their quality of life , and increasing linking of ecological and socio-economic wellbeing. Mechanisms and structures must be put in place to accommodate small-scale, community-oriented initiatives that receive crucial support from government agencies. Information systems must be reliable, timely and accessible. The target communities must be interested and willing to participate and initiative goals must be determined through a sensitive, though crucial, alignment of interests among stakeholders, who must formulate a common, dynamic vision for sustainable development (Kearney et al., 2007; Fitzsimons et al., 2013).

## Abstract

The development of the contemporary city produces deep changes in the organ
settlements and causes dramatic consequences on the natural environment. The re
the concept of Urban Metabolism as a model which considers cities as open syste
flows of material and energy as inputs and waste as outputs. A more efficient u
study with more effectiveness the relationship between urbanization phenomena
environmental contexts. The research approach is finalized to understand the c
European cities and extend the basic metabolism concept to specific mo
anthropological peculiarities of territories such as alteration of landscape, l
and their socio-economic behaviours, in a multi-layered framework, embracin
palimpsest and historical pre-existences. The research project focuses on per
Naples and Caserta in South Italy that was investigated through the lens of UM
in which flows go through this territory modifying its spatial configuration an
alteration of land use. The aim of this paper is to propose a multidisciplinary
the construction of an interpretative analysis of the local conditions, throu
design solutions that should support a more aware and appropriate urban plan
Mediterranean cities. This approach is based on the idea that metabolism is
transferable notion, rather it is an interpretation of specific relationshi
ecological context, which should be applied at a local scale.

## 1. The notion of Urban Metabolism

The development of the contemporary city produces deep changes in the organiz
settlements and causes dramatic consequences for the natural environment. The
adopts the concept of Urban Metabolism (UM) as a model which considers cities a
characterised by input flows of material and energy and waste outputs, and th
development of management systems that increase resource use efficiencies an
wastes. This allows to study with more effectiveness the relationship betw
phenomena and environmental contexts.
The paper is organized into two parts: the first one outlines a frame of
characteristics and potentialities, the second one analyses a case study, inte
the notion of UM.
Cities are characterized by huge flows of materials and energy in constant evol
constituted through dense networks of interwoven socio-ecological proces
simultaneously human, physical, discursive, cultural, material, and organic. Ci
water, foodstuffs, cars, fumes, money, labour, etc., move in and out of the cit
and produce the urban as a continuously changing socio-ecological landscape.
2006, pp. 20). These flows interact with one another producing spatial
transformations of morphological patterns at multiple scales. The UM proposes a
and characterize the quality and intensity of these flows starting from the an
processes of biological organisms. Indeed, the analogy assumes a powerful e
because both systems are organized on a livingnetwork.

The analysis of flows and the relationship between anthropogenic activity and urban areas aims to define the city s behaviour and its process of production flows. In particular, Kennedy and colleagues define UM as the sum total of socio-economic processes that occur in cities, resulting in growth, producti elimination of waste (Kennedy et al., 2007, pp.44).
This analogy has deep historical roots and emerged during the middle of the nir relation to the quantification of material exchanges between natural and human explicit application of the concept of UM to the city (Broto et al., 2011) was the engineer and geographer Abel Wolman wrote an innovative article "The Metabo in which he proposed for the first time the application of the concept of hypothetical U.S. city of one million people and calculated the inputs of mate waste using UM as a quantitative instrument to measure them. He defined the met as all materials and commodities needed to sustain the city s inhabitants at play . It is useful to underline that this consideration emerged in an era in problems were arising connected to the pressures of expanding urban populat natural environment and the question of the limit of resources essential for urb
Most recent reflections on the ecological aspect of UM suggest a more holi considers the analogy of the city as an ecosystem (Golubiewski, 2012; Pataki, by a sum of more metabolisms (not merely as an individual biological organism). emphasis on the exchange process and on the relationship among different parts better understanding of the complex and dynamic functioning of the city.
One of the criticisms to the basic original notion of UM is that the data snapshot of the resources and energy used by the city, that appears insuffic complexity of urban processes related to socio-economic activities, policie geographical data, historical palimpsest. The sustainable vision of the urba interdisciplinary and multi-level approach to understand the behaviour of a c urban metabolism method into a more comprehensive framework that both an biophysical material and energy parameters of cities as well as the human, economic, and related systems that both structure and govern specific urban m (Pinctel et al., 2012, pp. 200). For this reason, the biggest challenge to expe planning tool became the integration in this issue of a set of variables re considering together biophysical, energy, social and political parameters. colleagues described: The metabolism approach to cities is a purely biological much more than a mechanism for processing resources and producing wastes, th creating human opportunity (...) basic metabolism concept has been extended to in these settlements so that the economic and social aspects of sustainability environmental. (Newmann, 1999, pp. 222)

## 1.1 The UM: a sustainable approach to urban development processes

UM is a notion that inspires a new models to describe the city and that we urbanization process as a useful sustainable planning tool. Indeed, it is a tr involves very different disciplines (both environmental and sociological fie ecology, political ecology, industrial ecology, ecological economy) using it therefore noting the need of an interdisciplinary approach to understand the c phenomena. Each disciplinary approach adds and contributes to the understanding and interactions between social and natural processes in shaping urban phenom 2011). Nevertheless, different disciplines, spacing from social aspects to natu the concept in a different way, revealing the complexity and multiplicity of di urban system and underlining the need for interdisciplinary dialogue to devel practical approaches to urban metabolism with the aim of making progresses in u planning and research.
According to ecological economists and political ecologists, one of the contem that is useful to highlight here and that emerges from an enlargement of the socio-economic system, is that it can be considered as an useful tool for a

economic growth, urbanization and the environmental resources depletion. introduced here as an integrative concept for identifying areas of potenti decoupling at a city level, and the need for investment and capacity to reshape function (Hodson et al., 2012, pp. 796).
As a matter of fact, the study of stocks and flows entering the city, cross exchanged with the environment in which the city is embedded, is a necessary wa sustainable management and equitable distribution of resources without a growth consumption.
In an era of limited resources and of reduction due to the extractions, of lar production such as landfill, of climate change and uneven rapid urban growth, global impact and therefore they play a fundamental role in the challenge to growth. In this matter, the UM can be a useful tool to recognize the crisis p exchanges (transformation of resources and production of waste), to manag interrelations inside/outside of the borders and to understand how to interven promoting more effective urban planning policies. Beyond apocalyptic visions, i future will be played in urban areas, it means that the solutions lies in the c to assume an active role (Van Timmeren, Henriquez, Reynolds, 2015).
The review of the planning paradigms, no longer in terms of growth but of th monitoring of the resources use, and the redefinition of the interactions am and economic systems, means to intervene on the potentiality of existing resourc
In a sustainable approach, one of the recurring issues is to simulate the e behaviour of natural ecosystems to switch from the city s linear metabolism which wastes are recycled and return into the system as input (Girardet, 200 induce more efficient cities metabolic behaviours and to make cities less de resources and more self-sufficient.

## 2. Focusing on the local scale: land use as a metabolic indicator

This approach is based on the idea that metabolism is not a global and transfer is an interpretation of specific relationships between city and its ecological be applied at a local scale.
UM proposes a multiscale approach that puts in tension the global scale of me their pragmatic effects at the local scale, underlining the importance of the g in which these flows are embedded (Ibaæez, Katsikis 2014).
In this matter, the metabolism is a tool to understand the site s peculiaritie which are involved in a complex process of uneven growth that generate urban stimulate to study them with a new accurate methodology including all the contradictions of these settlements.
Emphasizing the importance, both theoretical and practical, of the geographic metabolism, the research aims to analyse the relationship between dynamic flow of geographical features at local scale in a relationship of mutual causality.

### 2.1 The periurban area of Casaluce

The research project focuses on periurban area of Casaluce[1], a town in the province of Caserta, with a population of 10,000 inhabitants. The municipal territory is mainly flat circa 9 square km. It is an area with homogeneous characteristics as part of between Naples and Caserta and it is composed of residual rural elements and m systems, often distinguished by low quality and a low level of infrastructures
The urban system of Casaluce is engraved by two important phenomena: on on abandonment and transformation of agricultural area and on the other the s

[1] The case study refers to the elaboration of preliminary studies for the new urban plan the Department of Architecture (DiArc) of University of Naples on behalf of the local ad

settlements and the depletion of the ancient urban centre, due to the underdev
areas.
The modern settlement has arisen in the last 40 years surrounding the historic
is possible to highlight three main morphological construction models based on
processes: a first growth led to a settlement of courtyard and multi-storey
related to the productive agricultural cycle. Isolated middle size buildings cl
phase of the urban growth. In the last 20 30 years, there was an urban sprawl t
building, especially houses, with low percentage of shops and offices, losing
with the ancient settlement related to the rural partition of the territory.
The complex structure of Casaluce was investigated through the lens of UM to un
in which flows going through territory, modified its spatial configuration pr
(Berger, 2006) and urban blight.
Periurban zones are fringe areas of consolidated settlements which includ
agricultural fields, trailer parks, landfills and few productive areas (some il

generate a dramatic scenario of natural elements and anthropic activities at
cycle.
The analysed territory exceeds administrative boundaries pursuing a broad stra
connection of historic polarities and ecosystem networks between them. The a
North-South road that links the Reggia di Carditello in the North side and t
Aversa in the South area. In the middle there is the compact settlement of
Norman Castle and the archaeological site of Castle of Popone located in the pe
historic and cultural emergencies combined with the Regi Lagni water system and
fields represent the land use layers of this Mediterranean area that have to re
stimulating a sustainable UM.
The historic palimpsest of the case study s area includes several significant
abandon. The Reggia di Carditello is a royal palace, built in the XVIII centu
big park that was the ancient hunting area but that is now a wild green land.
space, there is also the ruin of the Castle of Popone, an archaeological site
manor farm which is accessible by a neglected path through the country. Other
Norman Castle and the San Lorenzo burg are instead located in the historic cent
the border with Aversa) and represent the cultural points of an interrupted
contemporary settlements.
The water cycle is the Regi Lagni system: a network of water channels built in
the architect Domenico Fontana to reclaim marshes of Campania felix . The mai
North boundary of Casaluce and the water network serves the surrounding agricu
urbanization phenomena and the intensification of agricultural activities com
habitat because of the overbuilding of concrete riverbanks and the increasingly
water, due to the deterioration of groundwater.
The effect of the urban sprawl is land consumption and the fragmentation of r
process has modified the historic structure of the XVIII century system of co
outside the urban settlement. Nowadays the periurban area is a patchwork of ag
that are threaten by the urban and industrial activities, risen around them. T
decrease of agricultural economy due to the poor productivity of lands and the
of rurban landscape, not completely rural but not yet urban.
In this compromised landscape, productive and industrial areas emerge as spatia
relations with the context, but they rather damage the environmental ecosystem
the productive cycle era, lead to phenomena of partial disposal that generate di
that could be useful for the reuse.
The reading of the landscape through the land use geography tries to interla
metabolic process with the potentiality of the historic palimpsest of Casaluce
to highlight underdeveloped areas as a resource in reactivating processes of
whole town through a circular metabolic framework, according to the common wish
main elements which made this area a rich and attractive territory such as agr
infrastructures and historic and architectural heritage (Figure 2).

## 2.2 Applied UM to Urban Planning

The proposed multi-layered framework aims to link the notion of metabolis
morphological and anthropological peculiarities of territories.
The layers of historic pre-existences, water system and rural fields have bee
their condition concerning the time variable that is their state in the life cy
that their effects in the environment comes from socio-economic behaviours of
organizes the land use features as metabolic flow constantly evolving an
morphologies. In this matter the land use has to be considered as one of the me
anthropogenic activities on the ecosystem. Thereby the notion of UM is related t
uses the data flows to understand how they shape the territory and influence its
If the territory is conceived in terms of metabolic flows, it is possible to in
and the reactivation of declined, interrupted or ended land use cycles through
strategic renewal and regenerative chain mechanisms of specific actions.
It requires a systemic view and a new conception of the time variable. The time
for planning since it generates adaptive design scenarios and mechanisms of
which the outcome is not assumed in advance and appears flexibles to external
conditions. This point of view considers the project as a process that comes
influences among all the urban features in a dynamic way constituted by succ
phases.
Another concept related to the city as a product of metabolic processes, is th
physical and biological processes of resources conversion in goods and waste
time, the transformation of waste into useful products to be re-inserted into t
based on the laws of thermodynamics. It is similar to what happens in the human
process. These explain that the metabolic process requires energy for its
everything that comes out of the system depends on the amount of incoming m
physical and biological processes of converting resources into useful products
the human body's metabolic processes or that of an ecosystem. They are based
thermodynamics (...) (Newmann, 99, pp. 221).This means that it is necessary to
of resources putted into the system, by proposing a balance of input and output
it poses an important issue related to the power of the territory to activate m
in triggering changes: so the focus becomes the individuation of regenerative ac
to the reactivation of abandoned or declining life cycles (Formato, 2014).
Through this framework, the plan proposal is to intervene on the life cycle of
water, agriculture and historic-artistic heritage (Figure 3).

The restoration of water channels system s continuity needs a set of actio
riverbank vegetation and canals naturalization, the planning of wetlands
groundwater aquifer and to reduce contamination of water, the building
phytopurification. These interventions, based on the local impact of water chan
wide effect in the whole ecological network of Regi Lagni embracing the periur
Naples and Caserta. The water cycle is an adaptive system that changes due to ou
conditions so it is a potential device to produce new morphologies such as equi
to both agricultural and urban frameworks. Intervening on the process of ecolog
reduce the environmental contamination and catalyse public activities and tempor

The reactivation of the agricultural cycle results from a strategy based
developed from the system of denied areas which represent a wide strategic po
to reconnect different land s fragments. The proposal encourages the inte
activities promoting agricultural economy such as farms, farmhouses and other a
of agricultural production activities. The park aims to restore ecological cont
fragmented periurban areas and at the same time assumes a strong evocative powe
of this land. Denied areas follow the configuration of rural traces, creating
pedestrians and bicycles, emphasizing the use of typical natural essences
eucalyptus, vine, etc.). Therefore the network of denied areas constitutes a ke
high environmental value and increasing the liveability of places.

The historic emergencies life cycle induces to reuse spaces with new con activities. The cultural network links historic town centres and decentraliz periurban area generating a double cultural path: the archaeological path that architectural heritage as Reggia di Carditello , Castles and San Lorenzo burg mainly rural and generates a new relation among the manor farms of the ancient This planned approach enables to preserve historic buildings and to promote spaces, enhancing the establishment of new compatible functions.

## 3. Towards a Mediterranean metabolism

The research output is the application of a project device that use the UM as changing of the contemporary city and to understand which system layers are dir urban decay and represent the main elements for a future urban design project.
The applied methodology started to observe the territory in its material compon them in their dynamic organization gathering from the assumption that the UM r the city as a network of ecosystems.
The case study of Casaluce was analysed through site visits and public shared data were georeferenced using GIS technologies to elaborate thematic maps. Thi areas characterized by environmental decline, pollution, illegal buildings a settlements.
The purpose was to interpret places conditions and to construct planning s concept of metabolism as a key to identify the environmental decline and the co degradation and social marginalization, extending the notion of UM to urban and perspective, environmental remediation appears an important strategy to transfo and to encourage new actions for the economic and social development.
The emerging issues could represent an emblematic framework generally diffused areas of Mediterranean cities. Therefore, it is possible to propose a broade Mediterranean metabolism as a lens trough which studing periurban areas of M territories. The research approach, indeed, tried to apply the global notion dimension characterised by settlements morphologies, socio-economic beh emergencies and compromised ecosystems. The local scale induces to search a problems that could be solved by a strategic urban plan.
The preliminary plan proposal of Casaluce, which is the pragmatic output of thi result of a wider research aimed to perceive a different model of growth for different design solutions relating to rural-urban linkage with the usual featur The metaphor of UM is useful to increase the understanding of the cities wor find a balance between input and output. Rehabilitated environments, ecologi permeable lands for agriculture, are signs of a regeneration of commons, of coincides with the whole territory and its nature, promoting smart and ambitio city s spaces. The paper highlights that the aim of the urban planning is the t UM from a metaphoric means to a pragmatic vision of city s flows as sets of could generate new way to shape the city.

Paper presented at AESOP 2015 - Track 19: Smart approaches to responsible-minded planning practices

Keywords: urban planning, urban sprawl, periphery

## Abstract

Latin America s spatial policies have neither *regulated nor planned the urban growth. Not on growth can be desirable, it is also a recurrent situation. Therefore, it should be planned when it is necessary to avoid urban, environmental and social problems. These issues can be averted by distributing both the costs and the benefits of the urbanization process in a equalitarian way and preventing speculative processes that usually underlie rural-urban transformations. Urban growth* isn t always undesirable and also it s a recurrent situation that, when necessa *avoid urban-environmental and social problems, by fairly distributing urbanization costs and benefits and preventing speculative processes that are usual in rural-urban changes.*

*In Brazil, urban sprawl has been strategic for the* country s industrial *development and economic growth since 1930s. In the late 1960s, the federal government enacted regulations for land parcelling, however, as consequence, these rules left the control of urban expansion under municipal government, not requiring urban planning for doing so. At the same time, a huge program of housing financing transformed this expansion in an incomplete urbanization, known as periphery.*

*The democratization period in the late 1980s was accompanied by emerging new forms of urbanization gatted communities, theme parks etc. that can be explained by (i) little resistance to transformations from rural to urban uses, which were influenced by rural production and price variations; (ii) market-driven urban innovations, like new kinds of developments gatted communities, ranches etc.; and (iii) high investments in road systems and private transport. Nowadays, the federal Program My House, My Life (from 2009 and onwards) repeats history, reproducing the peripheral pattern on a large scale.*

*Will we ever admit urban growth is a recurrent process that requires planning? An analysis of land legislation from 100 municipalities points at two conditions: first, that these new types of urban development require more flexible urbanization permits in order to be implemented, and, second, that there is a need to plan the countryside as well.*

# SUBURBS AND BOUNDARIES: THE CONTINUED PUSH FOR PERIPHERAL EXPANSION IN THE LATIN AMERICAN CONTEXT

## 1. Introduction

The urban debate in Brazil has long faced the challenge of overcoming the paradigm that divides the space in either rural or urban areas (Graziano da Silva, 1997; Sposito et a etc.) and focuses on the potential of new territorial arrangements where urban-rural integration appears as a central element (Monte-Mór, 1994). This debate has also challenged the dual and homogenizing concept that divides cities in centre or periphery (Marques & Torres, 20 periphery by comprising its new dynamics (Costa, 2006). Additionally, it has sought to overcome the urban research historically focused on the metropolis and has sought to create another terminology for more diverse objects of investigation medium-size cities (Sposito et al., 2006; Andrade & Serra, 2001), non-metropolitan cities (Feldman, 2003), non-metropolitan agglomerations (IPEA / Unicamp-IE-Nesur / IBGE, 1999 apud Grostein, 2001), city region or polarized cities or commuting citties (Moura , 2005) and others.

In this sense, Brazilian urban research has devoted itself to new morphologies and typologies of urban sprawl (Reis, 2006; Abramo, 2009), a phenomenon that Monte-Mór (1994) calls extensive urbanization , focusing specially on gated communities (Freitas, 2008; sever 2006), a new typology that arrived in Brazil in the 1980s, later than in the US. These works have also dedicated themselves to urban-rural relations. However, these theoretical approaches have not investigated the relations between these forms of urban expansion and the norms that restrict or regulate the urban sprawl, which, in theory, would limit urban fragmentation and guarantee qualified urban growth.

Generally, most of the approaches on urban sprawl refer to two major forms of urbanization: (a) the "periphery", with dwellings occupied by poor families, with no infrastructure and precarious living conditions, possibly near industrial areas (also peripheral and dispersed) and important road transport; and (b) the "gated communities that offer housing for wealthier families, have distinction, exclusivity, near big urban facilities, such as shopping malls and theme parks, where the quality of road transport is a sine qua non condition for their implementation. The first form is a consequence of the industrial character of Brazil s urbanization and the second can be rela tertiary urban period.

These have been the basis of the occupation in areas of rural-urban transition. This paper seeks to demonstrate there are other urban typologies emerging, however the results reinforce unequal models and extensive and precarious new urban areas. How can one reverse this logic? This work began under the premise that ordering urban growth should be an important object for urban planning and city management. It seeks to overcome the idea that expanding the urban area is never desirable and to admit that this is a recurrent process, therefore, when necessary, it should be planned to avoid urban, environmental and social damages, distributing the benefits and costs of urbanization in a fair way and avoiding speculative processes, which often happen in rural-urban transformation processes.

Brazilian history shows that centralized governments were responsible for conceiving and approving the main laws that plan and control the urban sprawl, however, these rules have been traded and modified and their application has been accompanied by periods of amnesties and flexible policies that did not require any compliance with them, hindering their implementation. This negotiated city management, which considers growth and development synonyms, is structural in Brazilian history.

These periods of more centralized government are also marked by moments of urban sprawl, sometimes accompanied by population growth; such was the case of the São Paulo metropolis during the military government (1964-1986). This was also a feature during the Vargas era (1937-1945), the military dictatorship (1964-1986) and even nowadays with the economic policy being the driving force of urban expansion, based on its connection with urban and housing policies.

In order to understand the current period, this paper analyses 100 u municipal territory translated into master plans, zoning and land of Sªo Paulo to assess whether they have interfered in the urbanizat urban transition in order to regulate horizontal and urban growth, urban quality. Some hypothesis on this issue should be highlighted, regulations aiming to regulate and plan urban sprawl, however it happe policies for financing housing, urban infrastructure and facilities. urban sprawl regulation and planning , more broadly, concerning what look to urban space growth, specially stressing the need to investig be translated into territorial policies (Santoro, 2012).

## 2. Background: the origin of urban concentration in the Colonial Period

The origin of the Brazilian polarized and concentrated urbanization can be explained by the relationship between the colonial power and the colony in the international division of labour, where cities were the locus of movements of goods and where state institutions are settled. Therefore, only a few places concentrated the economic and institutional activities and functioned as ports for trading goods. In addition, the Brazilian monoculture agriculture aimed at exportation aborted an urbanization process that appeared in the surrounding of rural regions, which themselves produced primary goods essentially for exports, differently from what happened in Europe, where that process enabled the creation of more cities, smaller and less concentrated than the Brazilian ones (Oliveira, 1982).

## 3. The Vargas Era: economic policy as urban sprawl driving force

The strategy undertaken for metropolitan urban sprawl was relevant to the development when Brazil underwent the transition from an agricultural to an industrial economy. The housing policy was the great engine behind the urban expansion, and also worked as an structuring element for the economic development. In the context of restricted industrialization, between 1930 and 1955, the country experienced a strong land regulation, as well as labour and housing regulation, policy that resulted in a metropolitan urban sprawl. Territory regulation was the element behind the demands for industrial urban occupation, characterized by population growth, opening avenues and expanding the city to accommodate the first industries.

This expansion was done through peripheral areas, result of the context of crisis of the social rent housing model. The Tenancy Act (1942) froze rent prices, discouraging housing production for rent (especially in central areas where it was possible to rent for other uses), thus collaborating with the purchase of lots in the city s outlying areas. However, that required investment create accessible territories in peripheral areas. The response to this problem was opening avenues and roads and creating bus companies, while, simultaneously, peripheral subdivisions were being

deployed, mostly as illegal settlements (Bonduki, 2004). The creation of bus lines connecting periphery and downtowns allowed a rapid urban sprawl.

It was necessary to decrease housing costs, because it would be financed by the workers' salary in a process to guarantee to the reproduction of the labour power (Oliveira, 1982). In this sense, the suburbs contributed to lower housing prices in two ways: it offered cheap land and areas not completely urbanized, under almost rural conditions. The debates on the lack of urban infrastructure show that, to enable them as urban areas, only a few infrastructures were required, decreasing, then, the criteria of what is considered an urban area. For example, this process allowed parameters typical of rural areas like using water wells instead of piped water, cesspits instead of sewer pipes, lamplights and coal use instead of gas. Following this logic, if the laws requiring certain standards for urban expansion were translated into a complete urbanization, it would result in increasing land and housing prices, thus invalidating the project of home ownership and indirectly affecting the industrialization process. Since the industrialization was an ongoing process, these regulations could also increase the situation of irregularity, by making the infrastructure needs more flexible.

In 1937, Federal Decree n. 58/1937 was approved, the first addressing the land parcelling issue. However, its rules were idealized to guarantee the housing acquisition by stimulating homeowners to buy houses in instalments, in order to overcome the crisis of lack of buyers, therefore, it did not intend to neither regulate nor plan the urban sprawl.

On the federal level, the Vargas administration announced the first federal housing policy, under the premise that it would be provided by the State. However, the Federal Decree n. 58/37 transferred the mission to plan and regulate the urban growth to the municipalities and they were not sure about their own role in this process: Should they support the urban sprawl by providing infrastructure? Should they collaborate with landlors and charge for the valuation obtained in urbanization processes? Or should they let private developers do their job parcelling land and selling these parcels while the government would create and supervise the occupation based on regulations with good parameters on infrastructure, land occupation and land donations for public facilities?

In the 1930s and 1940s, municipalities begun to feel the need to regulate and plan the urban growth. But they tried to do so by recognizing opened roads through amnesty laws that, instead of preventing the expansion, ended up stimulating it. Another measure used by municipalities was creating some exceptions to the main urban rules, like smaller dimensions for working class houses, giving permits to land parcels with incomplete urban infrastructures, giving permission to build houses on unofficial streets, or not requiring construction permits for working class housing in rural developments. Clearly, these measures were not made for stopping the growth; these rules were established to support the occupation of slums and illegal settlements.

In addition, between the 1930s and 1950s, of the territory planning was conduced in another direction: zoning to set some lands apart and to maintain upper classes shareholders in the city s c (Rolnik, 1997), which also collaborated for urban expansion.

## 4. The military government: peripheral expansion to receive the population growth resulting from the heavy industrialization

Changes in the Brazilian agricultural production - crisis in rural productivity, in the Northeast region - and the agriculture expansion in the State of São Paulo, between 1945 and 1964, generated a process of conservative modernization (Graziano da Silva, 1982), which would result in a considerable rural-urban migration, that formed what is called the "reserve army" to serve

industrialization (1955-1970). In this period, urban expansion seemed a very appropriate response for the population growth experienced between 1940 and 1970, and it would be if it had been planned.

The ambiguous strategies focusing on the urban sprawl alternating between limiting and allowing the expansion appear to be a consented option to enable the city s physical growth. If and structured, it would not have been done so quickly. The metropolitan peri concept widely theorized by the Brazilian literature, which has mostly focused on the main metropolis, since non-metropolitan cities have not intensely lived this process until then.

Amid the attempts to formulate a national policy for urban development, this period of military government (1964-1985) was strongly marked by the development of laws that directly or indirectly address the urban sprawl issue, like the Federal Law on Urban Parcels (1979), the Law of Condominiums (1964) and the Forest Code (1965). Despite all these laws (most of them still exist today), the greatest impact of the military government in urban areas was a structured urban development policy, with the creation of the National Housing Bank - NHB, the Housing Finance System - HFS and the Federal Office of Housing and Urbanism - FOHU.

The planning followed the market-driven logic: investments were concentrated in (regional and urban) central areas, selected resources and social benefits, and the process of structuring the economic activity. In addition to this, the real estate activity was also structured, as part of a new phase of the industry, coupled with the policy of home ownership.

The NBH period was representative of a State intervention ensuring lines of credit for the housing demand (only for purchase, not for rent), expanding the real estate production by boosting the production through the market. This policy was translated as houses without a city , b consisted in a housing policy without the support of an urban land policy that should be done by the municipalities. That meant that the federal housing policy was, in fact, further limiting the access to the right to housing and the right to the city.

The type of financing policy and how it occurred explain the results:

a) the mismatch between housing interventions and urban interventions that should provide infrastructure, translated, for example, into houses built in places where there was no sewage or drainage systems;

b) local governments were often irregular in paying or had debts with its employees, among other local problems that make it more difficult to establish counterparts;

c) the behaviour of public and financial institutions was resistant to developing integrated policies through sectorial projects they focused on housing but not on making complete urban infrastructures , and, as a result, there were no commercial and service areas in housing projects;

d) the lack of funds for social facilities like sports equipments, for example, the fund was only available for amateur sports and prohibited covered gyms, swimming pools, among others;

e) the financial dependence of municipalities on the federal government and their consequent lack of autonomy to manage the urban space by themselves, using only their few resources;

f) the dependence on private initiatives, stimulating private developers who followed the logic of profit according to which public areas or facilities are seen as urbanization "costs", therefore are considered unattractive by the entrepreneurs;

g) the 'misplacement' of those who could not afford or obtain financing, relegating them to the spaces left on the sidelines for the private market, which immediately translated into slums, tenements and illegal subdivisions, under increasing urban precariousness.

Although this was the context during the NHB period, in its last years (extinguished in 1986) the Bank revised this programs in two important ways: firstly, a fund for urbanization credit lines was created in order to correct the course of housing interventions, trying infrastructure them a posteriori and facing the historical mismatch between housing and urban productions; secondly, there was an attempt to produce a land stock for social housing which could, in the long run, help regulate the market and land prices. This land stock initiative signalled an awareness that, concerning land, the policies collaborated with the speculation. However, the bad result of housing policies tripped the evaluation of the land stock results, which does not necessarily mean that the strategy was out.

On the municipal level, municipal plans were made but they were essentially developed by technicians with no participatory processes and while the actual interventions were under way. These, in turn, were very sectorial and unconnected: there was housing, yet the was not necessarily urban infrastructure.

Concerning the legislation, the laws created did not ensured the implementation of a complete urbanization as well. In a populist response, the military government (1964-1985) enacted the Federal Law on Urban Parcels (1979). With the end of the so-called economic miracle (1967-73) a fast-paced economic process of industrialization , Brazil faced a severe reduction of resources for the development of housing policies, consequently, there was a reduction in the urban production. Therefore, the new Federal Law changed the developer: although urbanization was a State mission, the law stimulated it to be implemented by private developers that should provide urban infrastructure and donate areas, as land reserve, for the government to complete their development with equipment and facilities. This equation was possible before the crisis, since the State no longer could finance the urban sprawl through the housing fund (NHB).

The Federal Law on Urban Parcels reserved public lands in each settlement, so that, later, when there were funds, the government would construct social equipments. It worked as to allow the urban sprawl happen in an accelerated speed, giving the time the public sphere needed to develop urban public spaces, in a slower process, recognizing the pace of the government performance. The rule based on reserving part of the land for public areas (between 30% and 35% of the settlement) seemed much easier to apply than if it were strict and careful regarding urban quality and complete urbanization. The government opted for simplicity so the rule could be followed, which does not always happen. The Federal Law was not critical towards the completeness of a "primary urbanization" (infrastructure) and it left the task to implement a "secondary urbanization" (equipment and services) to the municipalities, usually done in a very slow process, therefore, it ended up ensuring an "incomplete urbanization".

This law provided the language that threats the issue of land parcelling in Brazil. It left to the municipalities the task to regulate the urban expansion through limits and permits; for instance, whether the municipality requires urbanization contiguity or allows continuous flexible changes of urban areas over rural areas. This law did not provide the instruments to control the urban sprawl, not even required the municipalities to make a diagnosis quantifying the housing needs in order to justify the expansion desired.

There were two results not expected when this law was conceived. It served to determine minimum parameters for regularizing irregular urban occupation, at least regarding a minimum lot size. Although it has not achieved the percentages of reserves for public areas, and it did not guarantee success in the building of infrastructure by private developers. Among the causes for these incomplete infrastructures built by private developers, it is noteworthy the fact that the guarantees given by private developers to the government as a compromise to complete the infrastructure generally determined

by the amount of parcels reserved for the government to be donated if the developer does not complete the urbanization were not enough for the government to sell and finish the settlement infrastructures. Furthermore, the lack of penalty to developers that do not complete infrastructure, or that did irregular settlements, turned to stimulate irregularity, which does not require initial investments[1].

The strategy of transferring the infrastructure and parcels construction to private developers was not successful: it resulted in land valuation, usually appropriated by landowners in this process of rural-urban transformation, and in significant public costs in order to complete the infrastructure in unfinished plots, to provide equipment and services under a urban growth model based on physical extent, opposite to the idea of urban concentration and efficiency (Santoro & Bonduki, 2010).

Incomplete urbanization, perhaps not consciously at the beginning, was set as a strategy to progressively urbanize areas of urban expansion, maintaining urban needs that had to be gradually achieved through a relationship consisting of trading favours between groups of residents and the local government. The strategy to develop the infrastructure piece by piece, slowly and gradually, is interesting in terms of political gains and urban patronage maintenance. However, it still is possible to observe the important role held by technicians in this process, whose knowledge guided sectorial proposals, and, as Bichir & Marques (2001) affirm, it is possible to relativize the automatic association between support objecting votes on political elections (a term known as clientelism) and targeting infrastructure investments in the periphery.

Peter Hall (1996) argues that, in the 1970s, urban planning was falling into disbelief because, instead of controlling the urban sprawl, it encouraged it in every imaginative way possible.

## 5. The democratization period: municipalisation with no financial autonomy and the halt of the urban sprawl planning by the City Statute

Implementing democracy and municipalisation, two issues that emerge during the constituent process in the 1980s, did not promote deep changes in the urban expansion processes, since some elements were maintained, such as the incomplete urbanization logic, the dependence on federal resources and the lack of municipal autonomy, which were reinforced by frail local clientelist relations and the continuing land speculation processes.

Municipalities depended (and still do) on federal resources and, with both no funds and the crisis that culminated in the end of the military dictatorship, the government drastically reduced federal resources for urban development by the late 1980s and began dismantling the institutional structure built during the HNB period as well. The State of São Paulo, in a way, was an exception to this, because the resources obtained through the tax on the circulation of goods and services (ICMS) would keep the investments in social housing throughout the 1990s.

However, in the 1980s, the issue of regulating the urban expansion emerges in the bill that will create the City Statute. Carefully describing the features of the municipal Master Plan and providing an urban sprawl program, the initial proposal did not last long and was quickly substituted by another bill containing just the definition the minimal content that should be in the master plan, a definition in force in the City Statute, which does not address the sprawl issue.

[1] The crime of establishing irregular settlements begins when the developer sells the first parcel, but it is only discovered when it is open to public, or anyone starts to construct, many years later. So their sentence is often expired by lapse of time, enough to let them free from prison.

This initial proposal contains some elements that draw attention, like very detailed programs and their relation with the process of building information and decisions that allow assessing whether or not an urban expansion project is being proposed in accordance with the global planning of the municipality and whether or not it should be analysed ex-ante, that is, before the spontaneous process of expansion, so intensively lived in many metropolises during previous decades. These details were excluded in 1992, after an evaluation conducted by the Ministry of Social Affairs. According to Bassul (2005, p. 113), the technical sectors of the federal government criticized the exces mechanisms concerning the master plan that were not followed by explicitly instituting the ob content of the law. This critique, that Bassul (2005) calls an institutiona idea of a compulsory minimum content of the Master Plan that did not contemplate any of the proposals in the initial bill. At the same time, the obligation for plans to have rules for land parcelling and zoning was instituted, which would inevitably lead to the rhetoric-plans , since the r how (quantitatively and qualitatively) one can occupy a lot are what actually determines an urban project for the area.

Another significant loss was the exclusion of articles that sought to control real estate speculation, demanding that properties not inhabited by their owners (i.e., that essentially had exchange value) would be offered for renting, and that a single owner would have a maximum limit for landholding urban areas. These suggestions would not only collaborate with the urban sprawl would also have the opposite effect of the 1940s tenancy policy: by increasing the supply of properties for renting, they would probably discourage the purchase of houses.

Removing these clauses ended up making the master plan responsible for defining whether or not an estate is being underused, one of the few clauses that was kept in the law. An opportunity was lost: the State could introduce, in a democratic way, planning issues for areas under urban expansion, transforming these plans in instruments that would effectively fall upon the urban sprawl, not having the traditional rhetoric-plans .

## 6. The rules established by the City Statute

The City Statute (Federal Law 10.257/10) brought new expectations regarding the possibility that the new rules could help avoid the need to expand. However, the Statute has few instruments concerning the ex-ante and quality production of new urbanization processes. It does not require, for instance, establishing or revising the urban perimeter connected to the planning for the development of the municipality based on diagnosis and democratic decision-making processes; it does not connect the master plan s content and the rules for land parcelling, the municipality does it, in an arbitrary way; it does not contain instruments for regulating rural areas, showing even some ignorance over what can be planned for them (SANTORO; COBRA; BONDUKI, 2010). Since it is not compulsory it is very discretionary, municipalities can establish their own urban limits in laws other than the master plan, not connected to its planning. The main expectation concerned the democratic process of decision-making, which also proved to be mainly absent.

### 6.1. The experience of using the Onerous Concession for Changing Uses (OCCU)

Several instruments in the Statute can indirectly collaborate to avoid they were not conceived for exclusively doing so, like the ones that

demand for urbanized land in central areas, erasing urban vacuums an
for horizontal stretching, which increases with real estate speculation.

An instrument that the City Statute[2] brings and that can be used over areas of rural-urban transition is the Onerous Concession for Changing Uses (OCCU), aiming to recover land valuation in changing its use from rural to urban, by taxing the permit to urbanize or changing from a less rentable use to another (SANTORO, 2009). Santoro, Cobra and Bonduki (2010) provide an overview of this instrument in the State of São Paulo and show that it is not very applicable; few municipalities use it for sprawl areas, with goals that often differ from its planning, corresponding to an onerous form of land regularization[3]. Other municipalities that apply this instrument in discontiguous regions of the urban area, in order to either discourage the market to produce urbanization to stimulate the contiguous urbanization in the urban area (or would it be to benefit the owners of lands contiguous to the urban area?).

Despite being in an early stage, there already is a small dissemination of its possible use in master plans (SANTORO, 2012). São Carlos is one of the few municipalities that used this instrument in two experiences studied by Santoro (2010; 2012). The cases show that the urban project was not done, the amount collected had no connection to the valuation and very little was recovered; however, the value obtained was equivalent to the expenses of the undergoing city s urbanization pr

The challenge of implementing OCCU shows that legal interpretations are required to prevail over its oppositions: it is necessary to establish the basis or basic reference over which the Concession for Changing Use would be rated, analogous to the coefficient for minimal use Concession of the Right to Build (OCRB). Another requirement for delving the issue concerns establishing relations between the urbanization costs and benefits and to also address who is financing each cost, because the expenses with infrastructure, new facilities and services resulting from the urban sprawl demanded to the State are frequently not tallied in these costs. The stretching is interesting for the market-driven logic, that seeks smaller prices to diminish the costs; but the State has little interest in it, since the government needs to make considerable investments to build good connections between different regions of the city even though it may not account for these expenses, since they can be postponed to the next administration.

Regarding the definition of areas where the OCCU will be permitted (Federal Law 10.257/01, article 29), it is possible to observe that municipalities have delimited it in different ways: they delimited areas for taxing while leaving areas where land valuation can be incorporated by the owners outside this taxation. This is a threat for the equal taxation, pointed by Rabello (2006) as a guarantee of the equalitarian distribution of urbanization benefits.

### 6.2. Avoiding the occupation of areas of risk: the changes in the City Statute

In 2012, two articles were included in the City Statute: 42-A and 42-B (Federal Law 12.608/12), both aiming to address the landslide problems that happened in the Rio de Janeiro highland region, among other problems. The first article clearly aims to avoid disasters by including the requirement of planning areas that pose life risk, defined as susceptible to great-impact landslides, sudden floods and related geological or hydrological processes.

[2] Or instruments like the Consortium for Urban Operations that, theoretically, can work as an instrument for developing the urban expansion project, which would regulate the marked and recover the land valuation in the rural-urban transition.

[3] Among them: Araçatuba, Assis, Boituva, Botucatu, Marília, Mogi das Cruzes, Mogi Guaçu, Ourinhos, Poá, Porto Feliz, Santa Cruz do Rio Pardo, São Carlos and Tatuí.

The second article, 42-B, addresses the requirement of developing a specific project so the municipality can enlarge its urban perimeter, containing parameters for land parcelling, road system infrastructure, public facilities, as well as delimiting special zones of social interest or zones for the protection of historical, cultural and environmental heritage. This article embodies principles of ex-ante urban projects and should be established by a municipal law, therefore, it needs to go through democratic processes similar to the ones required for approving master plans or zoning legislation. Although its nature is revolutionary and positive, there still is no information on the effects of this legal alteration in the municipalities.

## 7. Urban sprawl norms in the municipalities of the State of São Paulo

Therefore, the lack of norms requiring the sprawl regulation or planning, during both the democratization period and the previous ones, coexists with the continuing urban expansion as a real estate strategy. Considering this has been maintained, the work sought to empirically assess how the urban sprawl planning happens in the municipalities of the State of São Paulo nowadays.

In the 1980s, the State of São Paulo underwent through processes of demographic transformations and reversion of big cities concentration associated with, on one hand, the deconcentration and changes in the industrial production process and, on the other, new condominial forms of urbanization. In the 1990s, some processes summarize the explanations for urban sprawl in these cities: (a) the fluctuation in rural land valuation which generated little opposition to the change from rural to urban use; (b) the dissemination of typologies, like the horizontal development of houses, ranches and small farms used for recreation purposes, among other diffuse forms of occupation; and (c) the investments in the road system and the stimulus to using private vehicles.

Little by little, the justification of the urban sprawl, by becoming more complex, has disengaged itself from the urban population growth or the peripheral growth pattern, which will culminate in a revision of the concept (SANTORO, 2012).

The analysis on the recent cycle of master plans, developed after the City Statute, offers examples from many cities in the State of São Paulo that are stimulating the urban sprawl, including some places where the population has decreased. For this analysis, it was created a tabulation with the quantitative and qualitative data collected in 100 municipalities in the State of São Paulo, whose master plans and complementary territorial laws were approved after the enactment of the City Statute (Federal Law 10.257/01), between 2003 and 2010. With no statistical intentions, this approach allows a more panoramic regard, pointing to recurring situations, some even surprising or that lack in this academic field. This analysis allowed making some considerations in two main senses, from the urban and the rural arenas.

From the urban sphere, the data shows that the real estate market employed a strategy aimed at the growth in physical extension, which gained new typologies and collaborated even more for a diffuse city structure, whose implementation seems to face no opposition from its planning, which keeps a high tolerance concerning urban sprawl, with perimeters rendered flexible on d logic of the real estate market.

Gated developments have appeared in this analysis as the main element of this new urban typology, especially in the State of São Paulo. However, even though the research has not properly identified it, this work raises a hypothesis (after a revision that should be made concerning the recent changes in the urban field) that creating new rules also modifies the parameters of land use, parcelling and occupation in force, in order to allow social housing production oriented by the federal housing finance program My House, My Life . Although it is not possible to frame these cases under a specific typolo

possible to observe changes in the parameters of housing quality, the quantity of implemented infrastructures and, in addition, the absence of land parcelling with donation of public areas, reinforcing condominial typologies inspired by gated developments. There are also cases where the parameters used for the occupations under urbanization and land regularization processes expand to other vacant areas where social housing will be implemented, commonly reproducing the peripheral growth pattern in new urbanization processes. That is the case, for instance, of identical parameters attributed to the Special Zones of Social Interest (SZSI) in occupied areas and in areas considered underused or vacant.

The analysis on the urban growth regulation in the macro-metropolitan paulista territory, where urban dispersion is easily perceived, points to the flexibilization of norms in two possible ways: to allow the expansion over rural areas, according to the market demand, by revising the perimeter and creating specific urbanization processes in these cases; and to regularize typologies like gated lots, at least in the municipal sphere.

The analysed norms are based on the urban and on the possibility to urbanize, with almost no constraints, except if there is any environmental restriction. Regarding the urban perimeter flexibilization on demand, it is known that:

- The laws that define the urban perimeter are changed on a case-by-case basis (either for building social housing or for other typologies), without requiring previous diagnosis that shows to where one wants to expand;
- In rare occasions, it is required a Study on Neighbourhood Impact, with a technical report from a Municipal Council or Office or with public hearings specifically held to permit the perimeter change;
- The urban borderline is generically defined through a width from the current perimeter, with no rigour or study, and there are even cases that demand growth by contiguity to the already urbanized area;
- There are norms created specifically to recognize the urbanization as soon as it happens. In these cases, it is sufficient to develop an infrastructure in the lot to be parcelled, that the change in the land classification happens automatically. This occurrence has been nicknamed if urbanized, it is urban ;
- Finally, in some municipalities, there is a rapid increase in zones with specific urbanization in the rural areas, in accordance with Federal Law 9.785/99, as a way to regularize urban parcels in rural areas, therefore introducing a process of regularizing urban dispers time that that it renders the urban expansion over rural areas flexible .

By observing these possibilities, one can conclude that, even if there is a defined urban perimeter, this does not mean that it is not possible to urbanize over the rural areas. These are the so-called hybrid norms, under which one cannot say there is no control over urban sprawl, since the limit is defined. However, the possibility of urbanizing is also rendered flexible, with norms that vary from too liberal to norms that establish changes by negotiations between the Executive and Legislative branches and the owners. This allows to argue that the analyses observing the effects of urbanization control policies in the land market in the State of São Paulo without qualifying them make a mistake, because the division is not based on whether they control or don t control the urbani and vary greatly over time.

The frequently identified flexibilizations and amnesties are examples of a behaviour that does not follow the restrictions, unless they are aligned with the stakeholders strat

growth and real estate development, in an alliance based on the idea that growth equals development (MOLOTCH; LOGAN, 1987).

In order to make some developments viable, it is required to annul the conflicts over urban legislation, usually resolved through an agreement between developers, public authorities and financing institutions, that alters the municipal laws. Royer (2002) and Silva et al. (2011) mention this kind of flexibilization in order to largely implement social housing through public funding, and the results from these researches will be corroborated by what is shown here. Nowadays, the federal program My House, My Life (from 2009 onwards) repeats history since it reproduces th on a large scale.

Concerning the rural sphere, the work points to the recent changes in the agricultural production that seem to be related with other current forms of urban expansion. For instance, essentially rural municipalities that lost their cultures go through diffuse processes of urban occupation, where the occupation by ranches, country houses and small farms is the keynote. The contrary can also be observed: when there is intensive agriculture, the urban occupation is refrained and more clearly delimited.

These disperse typologies, to be implemented, need to render flexible not only the urban norms but also the rural ones, drawing attention to the pressing need of planning what is wanted for the rural sphere, in terms of both zoning and structuring a policy for the rural area that involves funding other kinds of rural activities and controlling its occupation.

Although this historical recovery of the issue has met attempts to create laws requiring the expansion planning, like in the bill that created the City Statute, the Federal Law on Land Parcelling, from 1979, still is the norm that regulates urban expansion in Brazilian municipalities. This law holds the municipality responsible for controlling and planning where the city will grow to, while the municipal administration keeps meeting the market demands, in a reactive instead of proactive position, showing the role of the State concerning urbanization processes. The organized civil society sees the urban sprawl process as a strategy to maintain speculative processes and social segregation and it does not consider this planning necessary. Even though this issue is being constantly debated in the Brazilian urban field, it is rarely approached as a matter of social justice.

This scenario of municipal plans that render the urban sprawl flexible and that increase real estate activity, currently underway in paulista cities, will empower the dispute for land and land values, demanding a reaction from the State to orientate, control and plan the areas of urban expansion. The current federal norm that requires the development of urban expansion plans brings challenges in a range going from its construction to its implementation, proving the issue is relevant, present and deserves delving. Moreover, the alliance equating growth and development in non-metropolitan cities is a constant that faces little opposition.

Therefore, this work sought to demonstrate that, admitting the necessity and the recurrence of the urban sprawl process, it is necessary to plan it in order to avoid urban, environmental and social damages, fairly distributing both the burden and the benefits coming from the urbanization, avoiding speculative processes that are a common feature in the changes from rural to urban use and building *ex-ante* urban projects that are parts of a city, with a complete urbanization.

# HYDROLOGICAL CONNECTIVITY IN THE CITY-REGION LANDSCAPE: HAS PLANNING MISSED THE BOAT?

Silvia Serrao-Neumann[1], Paz Tayyebi[1], Gemma Schuch[1], Marguerite Renouf[2], Steven Kenway[2] and Darryl Low Choy[1]

[1]Urban Research Program, Griffith University, Australia, s.serrao-neumann@grif
[2]Advanced Water Management Centre, University of Queensland, Australia

Abstract: Urbanisation processes significantly impacted and continue to impac systems in the city-region scale. The current fabric of urban areas is largel land development and planning decisions in which there was relatively little impact upon hydrological systems within and outside urban areas. Typically, close relationship, urban and regional planning and water resources manageme carried out separately and guided by different institutional arrangements. impacts of urbanisation on hydrological systems extend beyond urban stream h include urban residents liveability. Further, climate change and ongoing po are set to add additional pressures on how both our cities are planned and are managed. Hence, there is increased need for better integration between th

Drawing on a conceptual framework based on urban metabolism, this paper whether an integrated greenspace framework could provide the missing link fo (re) thread hydrological connectivity in its decision-making process. The paper basis for this exploration the current state of greenspace planning in three city-regions: South East Queensland, Melbourne and Perth. The analysis foc documents, including plans, strategies and policies used to guide water reso planning and management in the three regions. Findings are discussed around themes related to hydrological and environmental connections, and whole c planning.

Keywords: water sensitive cities, urban metabolism, Australia

## 1. Introduction

Following a worldwide trend, since the late 1940 s, the Australian urbanisa favoured the use of engineering solutions to manage water flows in urbanised al., 2009). Accordingly, many urban streams were piped and located undergrou systems were channelized to enable urban expansion into floodplain areas. As continued to be buried, paved, and directed into culverts, pipes and concre greater became the habitat degradation, pollution and fragmentation of urban associated greenspaces such as riparian vegetation (Elmore and Kaushal, 200 Australian cities expanded to accommodate ongoing population growth, area greenspaces have become increasingly fragmented and replaced by impervious (Donofrio et al., 2009).

Additionally, at a catchment and regional scale, abovementioned urban water approaches have disrupted natural flooding processes by removing vegetation impervious paved surfaces, eliminating natural water storage capacity in th disrupting surface water flow paths (O Neill cited in Lennon et al., 2014). in severe weather events due climate change is likely to exacerbate water ma and thus compromise the liveability of urban areas (JimØnez Cisneros et al., urban areas are deeply connected to, and dependent on, the natural features they are located in and water comprises a critical linking element whose conn be better understood by and considered in decision-making processes concernin

## 2. Research Approach

Three case study areas have been selected as the subject for this paper: th
Melbourne Metropolitan Region and the Perth Metropolitan Region. Water mana
these regions is performed under distinct jurisdictional and institution
therefore providing scope for comparing water planning and governance ac
statutory and non-statutory planning systems.

Data was collected through a documentary search targeting online document
through state and local governments websites, including planning policie
strategies and secondary reports related to water resource management in the
in-depth content analysis was subsequently performed through a coding system
software. Coding reported by this paper refers to two themes: hydrological an
connections, and whole of landscape planning (see Table 1).

In total 106 documents were analysed, 37 for the SEQ region, 39 for the Mel
and 30 for the Perth region. However, it is important to highlight that thi
cover the review of all available plans and strategies but a selection of d
provide insights to water management at the city-region scale. Table 2 pro
analysed documents along with coding results across the three regions.

Table 1. Themes used to guide documentary content analysis

| Themes | Sub-themes |
|---|---|
| Hydrological and environmental connections | Ecosystem services |
| | Water quality |
| Planning | Whole of landscape planning |

## 3. Results

Themes discussed in this section are listed in Table 1. Results for each them
the following sequence: SEQ region, Melbourne Metropolitan region and Perth
region.

[1] The terms greenspace and open space are often used interchangeably by scholars, consultants and gove
around the world (Swanwick, C., Dunnett, N. & Woolley, H. 2003. Nature, role and value of green space in
overview. Built Environment, 29, 94-106). Generally speaking greenspace can be defined as areas within th
that may or may not be publically accessible. They may be part of a functional infrastructure or ame
churches, cemeteries, parks and gardens) or be a natural and semi-natural area (forests, wetland, etc.).

## 3.1 Hydrological and Environmental Connections

References to hydrological and environmental connections were registered in documents for the SEQ region. These include connections associated with wate well as large infrastructure projects. For example, the QLD Urban Drainage reference to the impact of land use types on hydrological regimes. Reference of ecosystem services were found in five of the documents. In particular, the outlines a clear framework to apply the concept of ecosystem services to na management in the region. The State Planning Policy recognises the need to co of ecosystem services in planning decisions.

Less than a third of the analysed documents for the Melbourne metropolitan references to hydrological and environmental connections. These referenc connections between stormwater and water quality, alteration of hydrological urban development, linking water quality of Port Phillip Bay with landuses a and traditional stormwater system designs focused on transporting water only.

References to hydrological and environmental connections were registered in l of the documents for the Perth Metropolitan region. Observed references ack relationship between landuses and hydrological balance; existence of groundwa systems; impact of hydrological changes on the region s wetlands; and role water management practices in reducing water balance problems by taking into the region s hydrological regimes, including groundwater and surface water Given the hydrogeological characteristics of the region, references to the ro systems in supporting the region s ecosystems and human population are frequ documents, particularly the Gnangara groundwater system. Specifically, th Regional Water Plan Discussion Paper outlines the need to protect this syste quality due to its high water supply value for the region:

> Drinking water source protection has had a dramatic impact on land-use the region. The urban corridor concept, in large part, reflects a desir high water-supply values of the Gnangara and Jandakot mounds from inco land uses. (p. 48)

Documents also make references to the need to improve stormwater management t impact on the water quality of the region s waterways and wetlands. Decline across the region has

been attributed to large modifications to surface water hydrology due to urban development as well as inadequate stormwater management practices t consider interactions between surface flows, groundwater hydrology and l characteristics of waterways. Only two documents make references to the ecosystem services. These include references to the ecosystem services pr region s wetlands, including flood control and improving water quality.

## 3.2 Whole of landscape planning

The analysis of 37 documents from SEQ reveals that only six of these docume consideration a whole-of-catchment approach to planning. These consideratio related to the water cycle and how management should take an integrated appr impacts on other parts of the regional landscape. For example, the Water by outlines that management practices need to consider the landscape scale:

## 4. Concluding Discussion

Under a more holistic approach, water resources management and planning need to
hydrological and environmental connections as there is a direct interdependent rel
resources supporting cities and their surrounding region. With the exception
hydrological and environmental connections were often identified amongst analysed
included connections involving both surface and groundwater (particularly in the

relationship between stormwater management practices and water quality objectives need for water planning to consider broader regional and landscape scales were rar all levels.

Greenspaces play a critical role in the water sensitive cities. Trees and other support a range of hydrological functions, including water purification and wa mitigation and erosion control (Millennium Ecosystem Assessment, 2005). Unfortu regional planning approaches in the three case study areas have not considered hy through greenspace planning in their main policy and decision-making processes. pressures from climate change and population growth demand a rethink in the way manage water resources in our urban areas to ensure they continue to be viable in t

Investing urban planning and management efforts towards establishing an integr greenspaces at the city-region scale could result in significant improvements to b streams. For example, Sander and Zhao (2015) list a range of benefits associated w spaces, including ecological, social and economic benefits. Additionally, they a contribute to the stability, adaptability and resilience of urban socio-ecologi Zhao, 2015, pp. 194). For Sch ffler and Swilling (2013), there is advantage in cor green infrastructure to enable them to be designed and planned to function a supporting the re-establishment of hydrological connectivity in the city-region sca re-establishing greenspace connectivity can support multiple functions, including t enhancement of natural heritage and cultural relics, providing opportunities for r 2003); as well as guidance for urban growth and preservation of access to the co 2006). Furthermore, greenspaces connectivity can also be complemented by urban s integrate ecosystem services in the built environment. In particular, urban desig structures, such as green roofs and rain gardens, contribute to ecosystem re strengthening ecosystem functions (Andersson et al., 2014, pp. 450).

Integrated greenspace networks require spatial planning to allocate areas for gre with the natural hydro-geographic features of a city-region before other landuses and Shamir, 2010). Further, such planning needs to occur at the regional or ca ecosystem services provided by a certain parcel of land or land management action existing landuses throughout the catchment (Guswa et al., 2014). Planning for gree scale also facilitates the incorporation of ecological and catchment corridors (G Shamir, 2010). Additionally, planning that is based on the recognition of hydrolog landscape would caution away from developing settlements in floodplains, instead d for recreation and/or agriculture, which can be temporarily suspended during acceptable losses (Carmon and Shamir, 2010, pp. 187). It would also involve pres vegetated surfaces and restricting infill development in lower density areas on s soils may assist efforts to adapt to increased flooding risks in some catchments (C

However, retrofitting existing built areas to establish greenspace networks may p challenges stem from complex urban and water resource planning systems, inclu administrative responsibilities and high implementation costs through to variabili (Nickel et al., 2014). Although there is no one-size-fits-all solution to overco greenspace planning and water management in metropolitan regions (Nickel et al.

greenspace networks may be enabled under the concept of multifunctionality (Selman, 2011), thereby contributing to support water-related ecosystem services and hydro the landscape.

Currently, different government agencies and water businesses manage different s cycle in Australia, including water supply, drainage, water pollution, groundwate conservation and land use planning. Hence, greater coordination is needed to ensur to water management taking into consideration an integrated water resource manage key endeavour of such improved integration between the urban planning and water m could be the restoration of hydrological connectivity across the city-region integrated greenspace framework (incorporating natural ecosystem and green infrastr

The literature provides many definitions and interpretations as to what constitut end, an integrated greenspace framework comprises natural and human-made ecosyste not limited to, riparian vegetation, wetlands, urban parks, national parks, commu water sensitive urban designs such as green roofs, bioswales, rain gardens and fl fundamental aim of integrated greenspace framework is the restoration and mainten connectivity at the city-region scale that has been altered by urbanisation process

An integrated greenspace framework can fulfil multiple objectives relating to bio water resources, land protection, recreation, cultural uses, development control, a mitigation and adaptation. In fact, many scholars have argued that interconnec planned and delivered greenspaces at the city-region scale can provide multipl populations whilst supporting ecological and social processes (Kenway et al., 20 2013; Demuzere et al., 2014; Low Choy, 2009; Benedict and McMahon, 2002; Bengsto Mounting pressures related to managing urban growth, climate change, water secu degradation in metropolitan regions provide an impelling case for a system of mul greenspaces that contributes to such objectives. Specifically, there is incre enhancing multifunctional greenspaces in metropolitan regions as a means to make sustainable, equitable and liveable (Pincetl and Gearin, 2005). However, urban unevenly distributed across urban areas and often rare in socially disadvantaged and Haase, 2014). Thus, the achievement of a connected multifunctional system o integrated greenspace framework, is reliant on the integration and mainstreaming hydrological, biogeochemical and ecological water-related ecosystem services of urban and regional planning processes, and needs to be supported by appropriate r (Ashley et al., 2011; Benedict and McMahon, 2002).

e-mail:ningjian71@126.com

**Abstract:**
*For the time being, China is at its primary stage of low-carbon city development and nearly all the work are done with the design of macroscopical framework while the low-carbon processes within urban expansion in the long run is ignored. Therefore, we should turn this pure low-carbon theory into specific practices and implement them to the urban spatial organization. Besides, it is more and more important to deal with the uncertainties and confusions in the decision-making process using tools of process management.*

*This study focuses on a totally new low-carbon city built from zero--Shanghai Lingang new town which has already become one of the best practice areas and demonstration areas in Shanghai for the discovery of effective ways to improve the planning management. Based on investigation analysis and case studies, we bring forward a new practical model about the process management of Lingang new town which is well organized in four phases, decision-making, planning, implementation, and maintenance. In this way, this new model correlates the urban development policy with the low-carbon practices and helps the seek of the* real management method of low-carbon growth .

*This paper includes:(1) make a plan of action by integrating low-carbon policy, future development features and implementation measures, and integrate the plan into the management framework; (2) adjust development measurements, divide the developing process into baby step (3)organize every* participant, make full use of up-bottom regulatory system and bottom-up *public get evaluation and feedback.*

**Key word:** low-carbon urban development, process management, Lingang New Town

## 1. Introduction

### 1.1 Research background

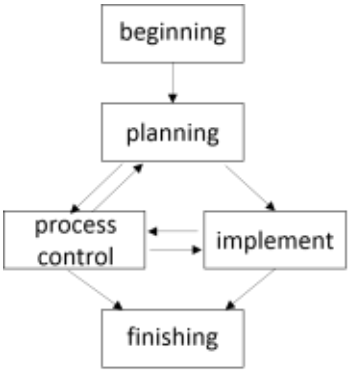
Low-carbon was a totally new concept born in the United Kingdom. Since the ye
government first proposed the idea of Low-carbon economy , the connotation of l

already extend from simply environmental research to a more comprehensive field including social, cultural, economic and environmental issues.

For the time being, China is at its primary stage of low-carbon city development and nearly all the work are done with the design of macroscopical framework while the low-carbon processes within urban expansion in the long run is ignored. There is a famous saying: three planning seven management. The implement of low-carbon strategies, complicated social conditions, multi-roles intervention, all of these growing issues imposed pressures on the process management of low-carbon urban development. Therefore, we should turn this pure low-carbon theory into specific practices and implement them to the urban spatial organization. Besides, it is more and more important to deal with the uncertainties and confusions in the decision-making process using tools of process management.

### 1.2 Definition of Research Object

Process Management first appeared in business administration, which is different from management, it emphasizes more on the sequence of time and how to put theory into practice step by step through overall supervision. The whole process consists five management phases,see in Firgure1-2, our research applied this concept to urban development and found out there existed one-to-one relationship, see in Figure1-2, and this bcomes our main research object.



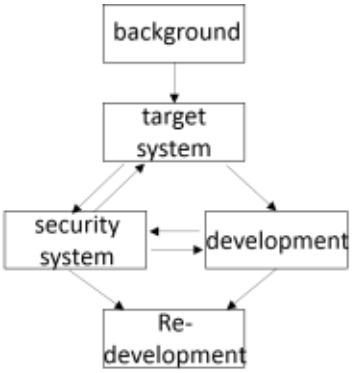


Figure1-1(left). Process management in business administration
Source: http://baike.so.com/doc/5381726.html
Figure1-2(right). Process management in urban planning
Source: drawn by author

### 1.3 Research structure

Firstly, we sorted out the related theories and latest trends by making a general literature review; Secondly, we did case studies to summarize different patterns of low-carbon development; In the third part, we studied every phases of Chinese low-carbon urban planning by using the idea of pr management ; In the fourth part, we focused on a specific case-Shanghai Lingang new combine theory with practices. Last but not the least, tried to summarize the features of process management during the whole phases and seek a real management method of low-carbon growth according to realities of our country.

## 2. Literature review

### 2.1 Connotation of Low-carbon city

Low-carbon city originates in the research and development of low-carbon economy and low-carbon society. As for its definition, different experts have different explanations. Low-carbon city can be defined as the city that is characterized by a low-carbon development pattern, citizens low carbon living and behaviors and urban management based on blueprint of low carbon society (Chinese Society for Urban Studies, 2009). Chinese scholar Xia Kunbao thinks that low-carbon city is to pursue the sustainable production mode and consumption mode (Xia, 2008). After summarizing different definitions Luo Qiaolin gives the connotation of low-carbon city from three aspects: low-carbon urban planning, low-carbon living style and low-carbon urban operation system (Luo, et al., 2011).

### 2.2 Related theories and research trend in Low-carbon urban planning

**(1) Low-carbon urban planning**

Low-carbon urban planning combines low-carbon idea and urban spatial planning, arranges time schedule to achieve the goal of sustainable development (Lei, et al., 2011). In 2007, ChinSiong H. and Wee Kean F. studied the relationship between energy consumption, carbon reduction and urban planning. They pointed out that urban carbon emission could be reduced in the next years by correct policy guidelines in the area of urban land use planning, transportation planning and architecture design (Ho & Fong, 2007). Glaeser E L and Kahn M found out that there was an obvious negative correlation between land development density and carbon emission, which proved the more restriction of land use conducted by urban planning the lower the carbon emission (Glaeser & Kahn, 2008).Professor Pan proposed planning strategies for low-carbon urban planning and distributed them into three levels of regional plan, master plan and regulatory plan (Pan, et al., 2008).

**(2) Low-carbon urban management**

Jenny Crawford and Will French thought the key to realizing low-carbon target is that planning system should be well prepared for new technology, then implement the advantages of nat management and regional power devolution, it was the urban managers and planners who could promote the development of low-carbon city. (Crawford & Will, 2008). Lu used the Delphi method and ISM to analyze the inherent links among 19 factors which affect the low-carbon development in China. The result showed there were 5 levels, government and low-carbon Index were in the highest level and they were the demands right from the area of management (Lu, et al., 2012).

### 2.3 The practices and development of Low-carbon cities in the world

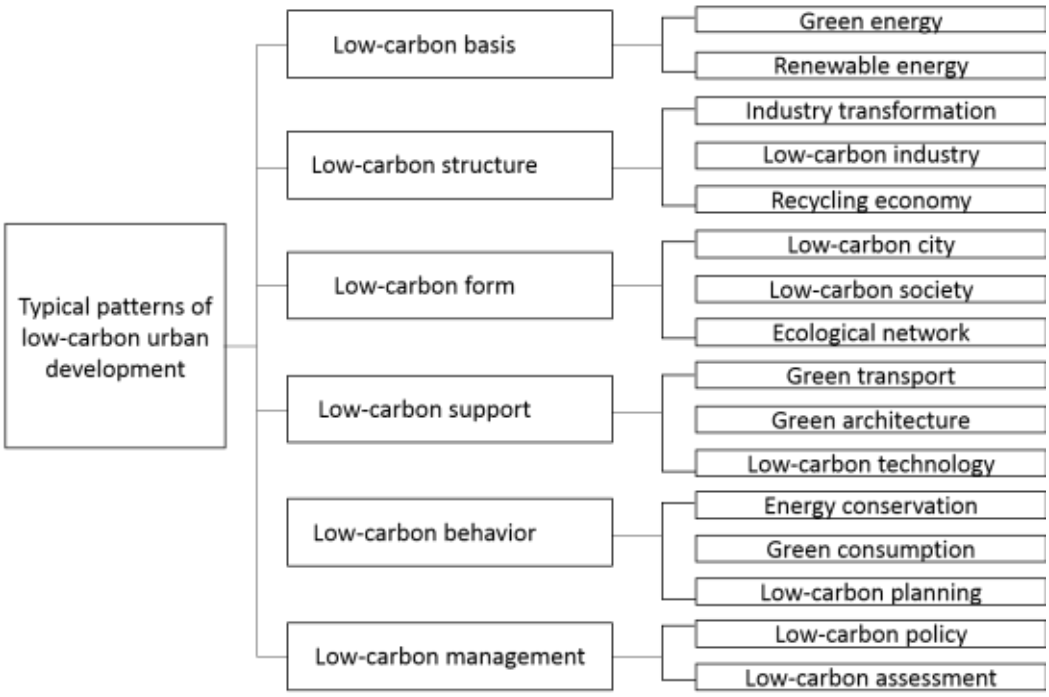
In recent years, more and more countries in the world have carried out practice activities for low-carbon

ISM, interpretative structural modeling

urban development. Some world cities have already made action plans successively, such as London s The Mayor s Climate Change Action Plan (Greater London Authority, 2007)and New Yor PlaNYC2030: A Greener, Greater New York (City of New York, 2007). At the same time, there emerged some international platforms which combined many cities on a global scale to explore the best way of developing low-carbon city, such as the famous C40[1], ICLEI[2], Covenant of mayors and so on.

In nowadays, the majority of successful cases are coming from C40 members, including London, New York, Copenhagen, Toronto, Chicago etc. most of them are in high level of economic development and have quantitative targets together with specific action plan (Large Cities Climate Leadership Group, 2005). Chinese scholar Lu studied all the members of C40 and then summarized five typical patterns of low-carbon development and we completed it to six patterns, see in Figure2-1.

Figure2-1 Pattern and structure of low-carbon city construction in C40



Source: Lu, C. J. et al., 2012. Analysis of Influencing Factors of Low- carbon City Development in China. *China Population, Resources and Environment*, Volume 22, pp. 58

### 2.4 Summary

After doing the literature review we found some common characteristics, first one is that all low-carbon cities share one development background which originated from climate changes; Secondly, low-carbon development should be supported by professional data processing technology; lastly, international

C40, Large Cities Climate Leadership Group
ICLEI, Local Governments for Sustainability

platforms played an important role in sharing experiences, technology and funds.

## 3. Case studies

In the 21st century, the notion of low-carbon development has been sinking deep into the hearts of people, some countries in and around the world develop practical constructions one after another. However, because of the different levels of urbanization and economic development, there would be diversity in choosing the constructive path and developing pattern. After doing the case studies of different patterns of Low-carbon urban development, we summarized three main patterns.

a) Comprehensive developing of low-carbon society . Representative city: London, Tokyo
This kind of pattern nearly concentrates on every part of urban development, range from energy supply to energy consuming, such as new energy development, green architecture, environmental transportation, and low-carbon consumption. These cities are usually in the late industrialization stage and have better foundation on transformation.

b) **Depend on low-carbon industry pulling power.** Representative city: Boston, Birmingham
Low-carbon industry is a new idea opposite to energy intensive industry, it can reach relatively high output by means of low emission of greenhouse gases. Such as Birmingham chose creative and cultural industry (knowledge-intensive) as its core strategy, Boston chose technology-intensive industry to promote low-carbon development.

c) **Build low-carbon community and demonstration area.** Representative city/country: Denmark, Masdar, most Chinese cities
This is a transitional pattern used at the beginning of low-carbon transformation, lots of cities firstly will build demonstration area or small-scale community to gain wider experience. Such as Freiburg in Germany developed two famous low-carbon communities in suburb areas and Masdar eco-city in United Arab Emirates tried to build a zero-emission park.

## 4. Analysis of process management of low-carbon urban development in China

In this section, we will analyze every phase of process management in detail, as the Figure 1-2 shows at the very beginning, which includes background, target system, domestic exploring of low-carbon cities and security system.

### 4.1 The background of Low-carbon urban development

The development of Chinese low-carbon city are influenced and promoted by international practices in the early time. In 2008, World Wide Fund for Nature (WWF) launched the low-carbon city development program in China (LCCI) with Baoding and Shanghai being the first pilot cities (Zhang, 2008), trying to explore new patterns of development for the other cities. Climat

low carbon leadership program in 2008, aimed at constructing city low-carbon leadership in China with the collaboration among relevant local governments, commercial enterprises, research institutions, news media and other shareholders. In 2009, many cities started to make low-carbon plan. It is estimated that there are at least 259 cities put forward slogans of low-carbon city in China by 2011 (Chinese S for Urban Studies, 2011), see in Figure 4-1, and this number is still growing. At the meantime, there has already been a specific framework of four large clusters among those low-carbon cities, they are Bohai costal region, Yangtze River Delta, Pearl River Delta and Southwest region (CCID Consulting, 2011) , among which all the cities shared advanced economic level and developed together as a whole unity.

Figure 4-1. Distribution map of Chinese cities with low-carbon targets
Source: CCID Consulting. (2011). *Strategic Study of Chinese Low-carbon Urban Development.* CCID Consulting.pp.2
Chinese Society for Urban Studies. (2011). *China's Low Carbon Eco-city Development Strategy.* Beijing: China Building Industry Press.

From this chronicle of events, we can see low-carbon pilot cities are the attempts of new urbanization in China. Because urbanization is always the most important driver about energy consumption and carbon emission and whether it can become greener and greener is still unsuspected and full of uncertainties.

## 4.2 The target system of low-carbon urban development

### (1) Low-carbon policies

CCID Consulting, China's largest research, consulting and IT outsourcing service company

In order to achieve the goal of energy-saving and environmental-friendly society and carry low-carbon planning smoothly, both Chinese central government and relevant departments have introduced a combination of policies, see in Table 4-. All these policies worked together to create a better condition for low-carbon development.

Table 4-1 China s main policy framework for low carbon city development

**(2) Low-carbon urban planning system**

After several years of low carbon practicing, some pilot cities summarized a 1+4+X plann based on the demand of central government and local characteristics (Qi, 2013), see in Figure4-2. Every pilot city should integrate low-carbon development into local economy and social development planning. At the meantime, provincial pilots made climate change project and Greenhouse ga every pilot city made low-carbon pilot implementation plan and low-carbon dev some of the local pilot cities had also made special planning projects according to their own features

and development conditions, such as energy saving, clean energy, circular economy, architecture, transport and so on. Those special planning projects played a vital role in supporting, completing and coordinating with low-carbon development

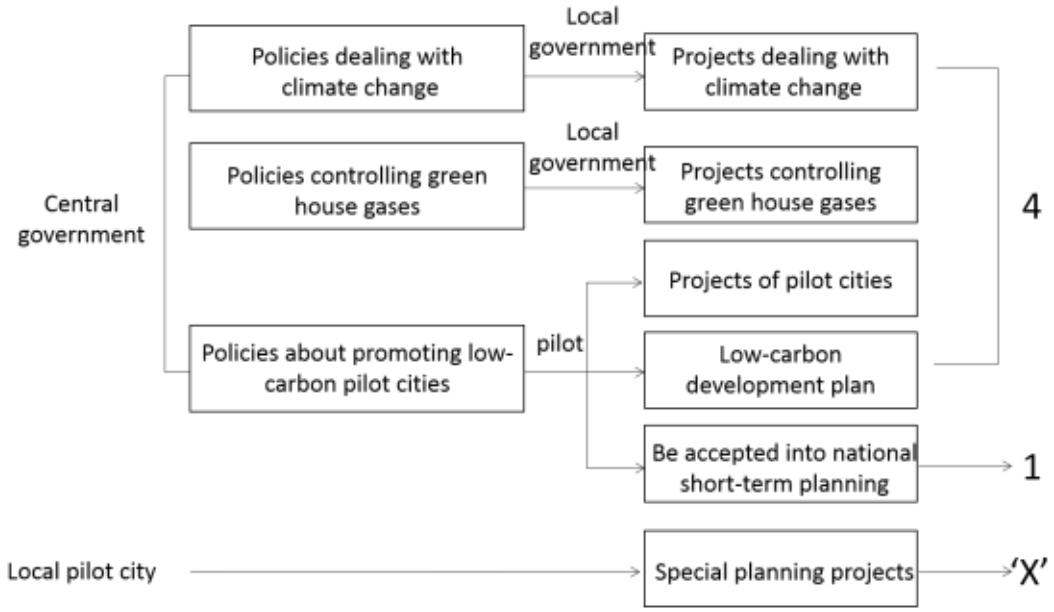

Figure4-2. Low-carbon urban planning system of pilot cities
Source: Qi, Y. (2013). *Annual Review of Low-carbon Development in China.* Beijing: Social Science Academic Press.pp.34

### 4.3 Domestic exploring of low-carbon urban development

Since China is a large country with complicated natural conditions and unbalanced regional economies, all these characteristics finally determine the diversity of low-carbon development. In order to achieve the goal of corresponding target system, different cities choose different constructive paths and time schedules, as Table4-2 shows.

Table 4-2. Low-carbon development patterns for different types of cities

| Classification criteria | Features of cities | Patterns of low-carbon development | Representative cities |
|---|---|---|---|
| Population scale | Small and medium-sized cities | Based on single industry or project | Kunshan, Yiwu, |
| | Large cities and metropolis | Comprehensive development of Mulita-industry or projects | Beijing, Guangzhou |
| Resource endowment | Abundant fossil energy | Combine urban development with industry transformation | Fushun, Daqing |
| | Renewable resources | Explore renewable resources | Baoding, Nanchang |
| Geographical | Coastal cities | Based on marine industry and marine | Tianjin, Qindao |

| | | | |
|---|---|---|---|
| location | | energy resources | |
| | Inland cities | Focus on structure adjustment | Wuhan, Chengdu |
| Industrialization stage | Industrial cities | Improve energy efficiency, change high-carbon industry into low-carbon | Zhengzhou, Taiyuan |
| | Post-industrial cities | Combine low-carbon energy system, industry system and technology system | Beijing, Shanghai |

Source: summarized and made by author

As we have already mentioned in literature review, there are six patterns of low-carbon urban development in the practices of C40 (Figure2-1.) However, most of the low-carbon cities in China are following the patterns of low-carbon basis and low-carbon structure , trying to explore new e and renewable resources, optimizing the industrial structure and striving to develop tertiary industry. By summarizing the majority of Chinese low-carbon practices, we find out two typical representative cities.

a) Baoding style. This type mainly depends on new energy as a breakthrough point, such as the construction of China Power Valley and Solar City in Baoding which contr development of low-carbon society.
b) Shanghai style. This type is mainly driven by some major projects or demonstration areas, such as Shanghai took the chance of World Expo to carry out low-carbon architecture and carbon-offset projects, promote green commuting and low-carbon living, chose Chongming Island and Lingang New Town as low-carbon best practices areas.

### 4.4 The security system of Low-carbon urban development

#### (1) Financial and technical supporting system

The financial supporting system for low carbon city construction mainly consists two parts: policy finance and commercial finance. Policy Finance is based on state credit and needs to get support from the government. And the commercial finance is the most important financial power for the construction of the low-carbon city (Ma, et al., 2012). In recent years, with the introduction of the concept low-carbon city, Chinese financial institutions gradually realized their role in promoting a sustainable society.

In addition to the financial support, there exist some scientific research institutions providing technical support for low-carbon development, such as CSUS and CRSUD , they are non-profit social organization including relevant departments, enterprises, communities, universities and volunteers. The scope of their work covers the research of carbon footprint, advanced developing patterns, low-carbon technology and products, they also hold academic exchanges activities regularly.

#### (2) Indexes system

As a complex giant system, urban construction involves many aspects of social and economic

CSUS, Chinese Society For Urban Studies
CRSUD, China Research Society of Urban Development

development, so we have to establish the macro-urban planning to make all low-carbon economic projects a system and build the evaluation indexes system to assess city development level.

In the view of different development phases of low-carbon cities, Chinese researchers built some corresponding evaluation indexes system from different directions. Such as CASC Index (The Chinese Academy of Social Science) which has 12 specific relative indicators and now widely used in China; Cao Feidian Eco-city Index (Katarina & Tan, 2009)and Tian Jin Zongxing Index (Singapore Government, n.d.)are designed especially for these two cities, which are quite suitable and convenient for local developments; Besides, there is a composite indexes method corresponds to the comprehensive evaluation index of low-carbon economy in urban areas, involving economy, technology, energy and pollution emission, society, environment.

**(3) Monitor and Assessment system**

The index system mainly works as a restriction at the early stage of low-carbon urban development, as to the whole process, there will be monitor and assessment system to guide and guarantee a successful procedure. For the part of monitor system, there are various management mechanism like land use plan, cap-and-trade system, urban scale control etc. For the part of assessment system, China has tried times recent years. In 2011, CSUS created Urban Ecological & Livable Development Index (UELDI) to assess the development situation. In 2013, Chinese Academy of Social Sciences together with Environmental Research Institute and Universities ranked 110 cities by using low-carbon development index, gave a general view of low-carbon cities in China and also provided a basic criteria for the other cities. Besides, Chinese government will publish research report every year to summarize the construction situation.

**(4) Public participation**

Low-carbon development is neither simple market behavior nor total government behavior, it is a process influenced by three main body, government-market-public . In China, ther of public participation in low-carbon development, like the widespread of low-carbon production in daily life, donation to low-carbon projects, and participation in environmental protection activities. Although the degree of participation and low-carbon sense had been improved, there still needs effective ways to guide people to take actions and combine up-bottom regulatory system and oversight system.

**4.5 Summary**

After doing the rounded analysis of the process management of low-carbon urban development in China, we improved the main structure into more detailed one. It turned out that every phase should be well connected, interact with each other and make full use of bottom-up public oversight system to get evaluation and feedback. In the following section, we will take a specific example to analysis the whole process in detail.

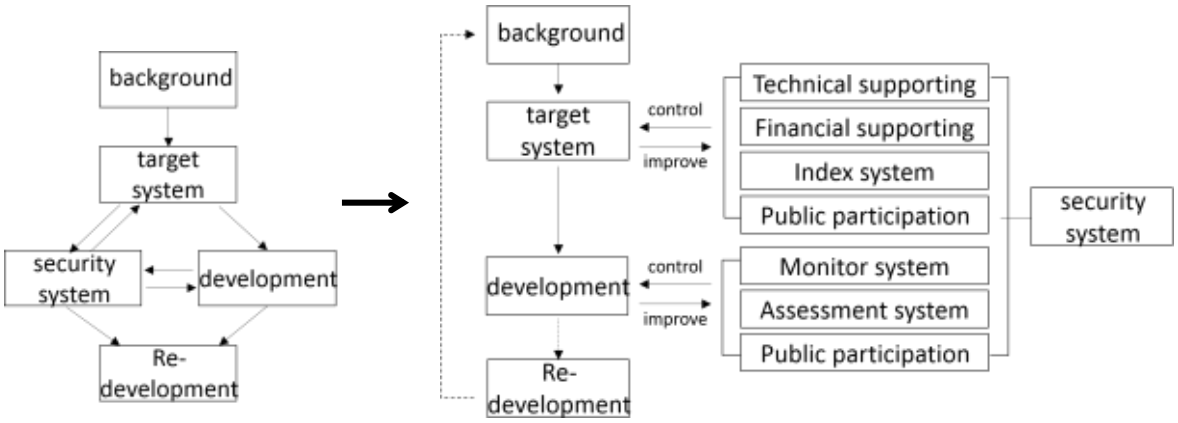

Figure4-3(right). Process management of low-carbon urban planning
Source: drawn by author

## 5. The case study of Shanghai Lingang New Town

### 5.1 Introduction

Lingang New Town is a totally new low-carbon city built from zero, and it has already become one of the best practice areas and demonstration areas in Shanghai for the discovery of effective ways to improve the planning management. Lingang New Town is located in southeast Shanghai, near the East China Sea, the central planning area is 70km$^2$, of which 4.5 km$^2$ is a big lake called Dishui Lake as Figure5-1 shows. The general layout is arranged radially, and it is estimated that all the construction will be finished in 2020. In the next research, we followed the pattern of process management in section 4.5, tried to analyze the low-carbon development of Lingang New Town and gave marks on each part.

Figure5-1. The master plan of Lingang New Town
Source: http://sh.house.163.com/14/0724/07/A1TEU2KK00074JAS_all.html

### 5.2 Background of low-carbon development of Lingang New Town

Lingang New Town was first called Haigang New Town in 2003, after Shanghai gove the research of its development scale, general layout, industry condition and municipal facilities, the name Lingang New Town was finally settled. Next year in 2004, the planning of was officially approved by Shanghai government. It was until 2008 that WWF chose Shanghai as one of the low-carbon pilot cities in China, Lingang New Town had become an important project to promote low-carbon development (Chinese Society for Urban Studies, 2009). In 2011, it was authorized as one of the eight practices area to build resource-efficient and environmentally-friendly society.

All in all, Lingang New Town has a potential to become a low-carbon city.

### 5.3 The building of Low-carbon target system

#### (1) Low-carbon urban planning system and strategies.

Depending on the national low-carbon urban planning system mentioned in the section 4.2(2), Lingang New Town gradually formed its specific one, which concludes four parts. Master planning, Special planning, Zoning and Regulatory plan (Figure 5-2). The establishment of Master Plan took two years, and emphasized more on top-bottom macro-allocation and general layout; Zoning bottom planning with bottom-up implementing needs, put Master plan into mor Special planning was mainly about the area of new industry; and Regulatory plan was the right linkage between theory and reality.

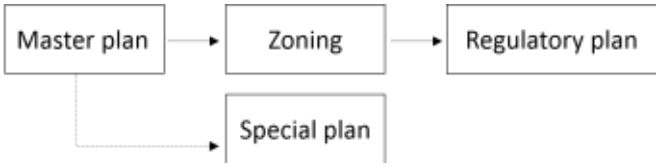

Figure 5-2 low-carbon urban planning system of Lingang New Town
Source: drawn by author

By collection information in all kinds of medium, we have summarized d low-carbon targets and strategies in corresponding planning phases, see in Table 5-1.

Table 5-1. Low-carbon target system of Lingang New Town

| Planning phase | Low-carbon target | Low-carbon strategy |
|---|---|---|
| Master planning, , | Theory of Garden City | Ring and radiate layout of space |
| | Intensive land-use | TOD mode |
| | Green transport | Green corridor |
| Zoning | Efficient urban spaces | Refine Master Plan |
| | | Reasonable urban block scale |

TOD, Transit Oriented Development

### (2) Security system and management

a) Technology support
Along with the huge amount of constructive programs, there are abundant researches as well, such as, questionnaires, marine industry investigation, technical standards of industrial parks and landscape research. Besides, the cooperation with foreign design companies also brought lots of new ideas.

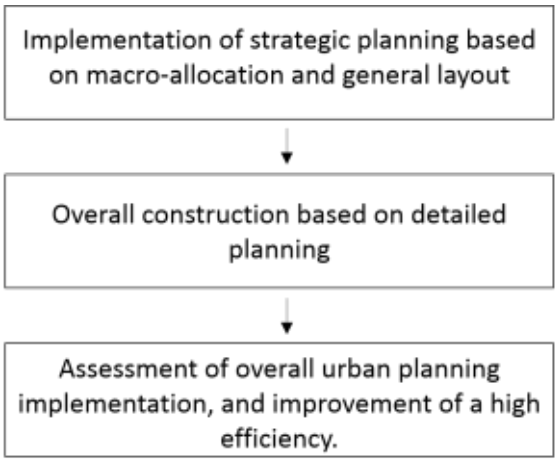
b) Multi-phase organization
The whole planning system is divided into three main phases and each phase is divided again to a smaller step. This kind of system meets the basic requirement of process management and lower the risks in each phase.

c) Trans-department cooperation
Different departments and organizations will take part in every different phase. Such as, before making urban planning, environmental department gives advices on sites selection; in the designing part, municipal department, transport department and other related departments will work together to reach an agreement, this will help to make special planning in turn.

## 5.3 low-carbon urban development and management

### (1) The process of development

Since the Master Plan of Lingang New Town was officially approved, the construction activities showed three phases clearly (Luo, 2009, p. 57), see in Firgure5-3.



Firgure5-3. Three phases of the process of development
Source: Luo, Q. L., Hu, Y. D. & Qiu, Y. D., 2011. The Theory, Practice and Prospect of the Low Carbon City Planning. *Planners*, Volume 5(27), pp. 57

a) First Phase: from 2004 to 2005
2004, 2005 are the first two years to start the overall construction of Lingang New Town, everything needed to build from zero, so the implementation of strategic planning became a main feature.

b) Second Phase : from 2006 to 2007
The revise of urban planning provided a great challenge for overall construction. At the same time, More detailed community planning has been finished and put into actions.

c) Third Phase : from 2008 to now
In 2008, the publication of new Urban and Rural Planning Law pointed out that assessment of urban planning implementation was compulsory in the process of development. And this just fitted in the time schedule of Lingang New Town. We picked out the major outcomes from the detail assessment materials (Sun, 2011) and put them into the table we made before to see the differences between targets and realities (Table 5-2).

Table 5-2. The assessment of low-carbon implement of Lingang New Town

| Planning phase | Low-carbon target | Assessment |
|---|---|---|
| Master planning, , | Theory of Garden City<br>Intensive land-use<br>Green transport | Land function is relatively the same, simplex and isolated.<br>Over-reliance on cars |
| Zoning | Efficient urban spaces | Large scale of green space caused extensive land use |
| Regulatory plan | Mixed land development | Living area is too big to form sense of community<br>Lack of entertainments and service industry |
| Special planning | Job-housing balance | Excessive municipal facilities<br>The development speed of industry areas is faster than residential areas |

## (2) Security system and management

a) The assessment of low-carbon implement

Lingang New Town is the first area to carry out the assessment of low-carbon implement in Shanghai. It has ten aspects: land use, industry development, index system, job opportunities, public facilities, comprehensive transport, road system, municipal system, planning management and technical standard, almost covered the major contents of five different departments and formed a relatively complete system at last. The assessment is not confined to the planning itself, but also includes the general situation of the whole society.

b) Public participation

The development of Lingang New Town was originally driven by government, and followed path of upscale strategy, which means the participation part mainly consist relative departments, design organizations and green groups, so it has a higher standard to choose its residents and developers. This kind of development pattern made it difficult to include ordinary citizens and also had negative influence on the implementation of plans.

### 5.4 Evaluation and Solution

Taking Case studies (section3.) as a reference, the development pattern of Lingang New Town is more like the first one, nearly concentrates on every part of urban development, range from general layout to energy consuming, however the result seemed to be unsatisfactory (Table 5-2). The reason lies in two aspects: firstly, the target is too ambitious and abstract to put into practice without a specific index system and flexible spaces, thus making all the perfect ideas just blueprints; secondly, there lacks enough public participation during the phases of building low-carbon target system and low-carbon urban development.

As a result, Lingang New Town should try to divide all the work into baby steps, make sure every part is done and then move forward, in addition to this, the feedback and interaction of each part are also of great importance. Another solution is to build a cooperation model of governmen role of government is guiding other participants to engage into the process of low-carbon development. For those reasons and solutions we improved the process management of low-carbon urban development for Lingang New Town and make full use of up-bottom regulatory system and b oversight system to get evaluation and feedback, see in Figure 5-4. We hope this new model will correlate the urban development policy with the low-carbon practices and help the seek of the real management method of low-carbon growth .

### 6. Research conclusion and outlook

Chinese low-carbon development started relatively compared to other western countries. The original

motivation concentrated more on economic growth, and the major content of low-carbon urban planning is huge and complex. As to the implement phase, western planning usually take use of the market power, however, Chinese planning depends on the guidance of government in most cases. Since more and more cities are in a common background of climate changes, high-risk natural disasters, excessive high-carbon emission and serious urban pollution, changing our traditional way of planning into a more resilient system becomes an urgent issue nowadays.

The planning of Lingang New Town provided us an international view and a new platform to improve our planning theories and technical levels, we still have a lot to learn about low-carbon urban development.

# AN OPEN GAME FOR DISSENT: TOWARDS CRITICAL TOOLS FOR COLLABORATIVE PROCESSES OF PRODUCTION OF SPACE

Ana Paula Silva de Assis

Instituto Mineiro de Educa ªo e Cultura (UNI-BH) and
Escola de Arquitetura da Universidade Federal de Minas Gerais (UFMG)

ap.assis@gmail.com

Keywords: Social participation, dissent, open game

Abstract:

This paper presents the conception and application of a game designed for and p
teenagers living in a slum area in Brazil that is currently under structural inte
large spatial transformation project. The conception of this game is based on th
segregation of the city. Players have been invited to deconstruct such a propo
encouraged to imagine other forms of occupation and enjoyment of their environme

Ranci Łre's account of dissent will be discussed as a counterpoint to the cons
current participatory policies in an attempt to reveal their limitations rega
potential. Flusser s concept of open game will also be discussed as an alternati
of critical tools for collaborative processes of production of space. The outco
presented in order to discuss the capacity of games to overcome social obstacle

beyond the current models used to analyse and produce the city. It concludes games as a conceptual framework towards an emancipatory participation.

## 1. Introduction

The Game of Dissent was an experiment held in May 2013 with a group of teenager situation in the Aglomerado[1] Santa Lœcia. This favela[2] is currently under a spatial restruc process promoted by the city of Belo Horizonte with funds from the federal g process, the implementation of interventions as well as the definition of th participatory process is delegated to outsourced companies contracted by the mun

In the current context of decentralization of State s responsibility for the pro we propose thinking of fuzzy responsibilities beyond public–private partnershi model undermines state s strategic responsibility for the balance between marke Architecture, when subordinated to the logic of business, becomes a commodity. space as a mere opportunity to produce surplus value excludes the possibility o from its process and the formation of autonomous citizens able to appropriate th This model tends to homogenize the sensitivities, under consensual arrangemen production, the use and the appropriation of space.

Using as reference the process of the Aglomerado Santa Lœcia s restructuring pro approach the responsibility sharing in the context of production of space thro This process will be taken as the basis for a critical review that will be deve evaluating the results presented by the Game of Dissent. Then the elements and will be presented. Before proceeding with the evaluation of results from the en application of the game, the current institutional framework of social pa problematized in face of both the meaning of dissent by RanciŁre (1996a; 1996b) open game according to Flusser (n.d.). The game results will be presented as a questioning of the process for spatial restructuring of Aglomerado Santa Lucia. The overcome social obstacles will be presented as a possibility for an agonistic between stakeholders. Creative spatial imagination, shown throughout the game by dwellers, will enable to question the participation model used in the spatial re Aglomerado, since the current model does not allow openings to include the verna the dwellers. The virtual nature of the game will be accessed as a possibility o of the participatory process, suggesting an open source participation. As a concept of meta-game is presented, by which we intend to emphasize the ability expand the current thinking towards an emancipatory practice of architecture and

## 2. The Game of Dissent

The game was designed in the beginning of the formulations that motivated the re study is part. It was applied as part of the activities of a university exte elaborated in response to an invitation from one of the educators of the ProJove Reference Center for Social Assistance (CRAS), held by the city government. The the proposal was to introduce the debate about the city among the teenagers of t

[1] Aglomerado is the term used to refer to the set of slums in the Santa Lucia area. In translate the term, considering it the name of the place.

[2] The term favela will also not be translated, since we understand that the favelas in image brought by the terms ’slum’ or ’shantytown’. A better distinction between the Baltazar & Kapp (2007).

of Dissent was designed to be played by the ProJovem teenagers and by a grou students attending to the extension project.

## 2.1 The context: Aglomerado Santa Lucia and the Vila Viva program

The Aglomerado Santa Lucia[3] is an area consisting of four favelas, located in the South of the city of Belo Horizonte[4]. The area is currently going through the urbanization proce of the Vila Viva program, held by the city government. The program includes era geological risk, sanitation, restructuring of the most important streets, ho implementation of parks and green areas. An intervention on this scale inevitab bonds established between the community and its everyday space. Despite the imp conditions provided by the program, it is known that the impact of such interver the removals and the resettlements required for implementation these improvement

The game application did not intend to solve any direct conflict, since the tar teenagers, did not participate in the assemblies and negotiations between the and the community. However, they did experience, along with their families a violence of the removals and the resulting laceration of the social-spatial re the imposition of a new spatial order.

One of the interventions with the highest impact in the program is the enlarg Main Street and the creation of a new street, called Bicªo, which will connec avenues. The main purpose behind the creation of this street, although not annou to relieve the already overloaded vehicle traffic of the upper and middle class around the Aglomerado. This reformulation of the main street in order to adapt standards of the formal city disregards the aggregating role played by the fav alleys in favelas are usually the place where people meet and exchange experien a wide range of events and represent the plurality of spatial means of appropr favelas.

Many families of the Aglomerado have already been removed from their homes to construction site of the Vila Viva. Others still live in the area with the immin uncertainties about their very near future. Some teenagers of the group reporte been "sealed" (the technical term used to indicate the houses that are to be construction work) and that a number of friends and neighbors had been removed a different destinations. Some families were relocated to housing units built by t the site. These units, which are built by a consortium of private companies, fo of minimal cost and therefore of minimal area. In addition to that, as part of deadlines for their design and implementation tend to be reduced in order to suit goal set by the companies.

## 2.2 Elements of the game

The game has in its essence the Le Corbusier (1993) propositions published in Charter, which separates the city functions in residential, leisure, work and c all the criticism made over the century that followed its publication, this mo practical repertoire of technicians and city planners. Therefore, the argument o

[3] The Aglomerado Santa Lucia is the group formed by the villages Estrela Santa Rita, Sª Santa Lucia. It currently has about 20,000 residents and 3,848 household. Its hashas a
[4] Belo Horizonte is the capital of Minas Gerais State. The metropolitan region of Belo largest in Brazil with nearly 5.7 million inhabitants.

players were not familiar with this theoretical background, was the deconstru
separation of functions, blurring the boundaries between them and freely prop
spaces.

Each of the functions (housing, circulating, working and leisure) was associa
represented by a team of players. Before the game begins, each team has to dra
spaces and infrastructure that usually correspond to the functions assigned t
circulation team indicated streets, bus stops, stations and bike lanes. The
houses and apartment buildings. The working team indicated factories, supermarke
schools, hospitals and offices, and the leisure team indicated parks, courts, mo
as well as bars and restaurants.

For each color/function a group of cards was prepared associating everyday situa
the four functions. For instance, the set of green cards from the circulating g
modalities such as bicycle, car, bus, roller skates, etc. The set of orange card
group suggested actions that take place inside a home, like resting, eating,
working, etc. The set of purple cards suggested actions related to work, like s
surveilling, manufacturing, building, managing etc. Finally, the pink card set
as playing soccer, flying a kite, going to the movies, walking, dating etc. For
there were also other cards that had question mark, indicating that if the play
freely propose any action related to the corresponding function of the card colo

## 2.3 Game Dynamics

The game was developed over a large white cardboard, the game board. On it,
supposed to represent, through drawings, solutions for the combination between
randomly selected from the cards and one of the spaces previously listed by the
only used to set the order of the groups in each round. The group that won in th
by choosing an action card in a different color from that of their own group. Th
action picked in the cards, which by the very structure of the game was never
usually correspond to the prescribed use of the place.

Thus some possible combinations were a space to play ball in a circulating st
where you can play football or a basketball hoop at a bus stop); a place for c

one of the housing structures (such as houses with bars and shops at the fr
manicure/pedicure signs); a place to study in a park; a space to rest in the sup

As the game progressed a city was designed over the white cardboard. Cha
combinations of cards, the players imagined other possible spatial assemblage
solutions were a clear reference to the everyday spaces of the favela, others we
the formal city repertoire, presented in creative combinations. Along the two ho
was played, the white cardboard was filled by the spatial imagination of the pla
city which they called Bem Vinda (Welcome).

## 3. Participation, dissent and the open game

In an attempt to relate games to the production of city space, a look back to th
enables us to observe the effects of the consolidation of the process of pro
spaces. The regulation of free time, understood as a condition for the reproduct
its spatial equivalent in the production of specific spaces for recreational
consequence, there is the abandonment of the street as a territory of play, of e
The counterculture and the contestatory movements of the second half of the twe
the political importance of games as a means of resistance. The Situationist Int
city a territory open to playful imagination, an expanded playground that calls
of the streets, a strategy for what Arendt (2005) calls the resumption of the pu

The very argument of the resumption of the public sphere is one of many that s
discourse and public policies that attempt to promote social engagement. From an
view, participation is called upon to balance social inequalities, as it presup
of decision-making power. However, the institutionalisation of participatory pr
the responsibility for social mobilization. Therefore, tends to eliminate the a
and civil society, creating an illusion of consensus that instrumentalizes the p
legitimizing decisions that have actually already been made.

Participatory policies follow bureaucratic models that tend to undermine its e
The fragmentary questions posed when society is called to make decisions elimina
a broader critical debate. On the other hand, the model of deliberative democ
guides politics, bases its central idea on the assumption that, in a full demo
should be reached through a process of deliberation among free and equal cit
strongly influenced by Habermas  idea of communicative rationality, presuppose
symmetrical conditions for argumentation and knowledge. However, such symmetry
and this fact is neglected in the structure of participation.

RanciŁre's account on dissent (1996a; 1996b) points to the structural incompatib
communicative rationality and democracy. Accepting the dissensual nature of de
implies reinventing forms of communication between State and civil society. If
presented as the main communication channel between these two instances, it is
to rethink the parameters for an effective communication, beyond institutional b

In Brazil, although popular participation is recognized as a key component in
processes that present themselves as policies for social transformation, one mi
balance between the available legislation and the actual production of space. F
of the City, the Federal Law that regulates urban policy in Brazil, has in its
citizen participation and democratization of urban management. These instruments
participation in various stages of the urban planning process, such as urban
consultations and public hearings, plebiscite, neighborhood impact studies
budgeting. Although the City Statute has meant a great legal democratic achieve

number of instruments to enable social participation and a more democratic use
comes to its impact on the city s space, the emancipatory promise that dominated
it is clearly lost. Looking at participatory policies, it is possible to point o
have contributed to this failure.

The first concerns the institutional context. Because they relegate the pedag
critical debate, participatory processes become fragile and are easily capture
power. They become mere instruments to legitimize decisions made by technicians
State, reproducing the same top down model they are trying to fight off. The s
the informal production of space. Although they represent a significant portion
cities it is estimated that an average of 25% of the population of large Br
informal settlements the illegal condition excludes them from institutional poli
in both private and public space.

After this first analysis we propose to take on dissent as a counterpoint to
orientation of participatory policies. The game is brought to the debate on par
ability to transcend the communicative rationality and because of its openness t
The communicative properties of games are closer to learning through experie
through speech. Thus we will take the concept of open game proposed by Flusser (
for thinking about participatory processes that are capable of accepting the dis

Flusser considers an open game the one in which the repertoire of the thought
whose structure can be modified. In the open game the totality of possible con
structure of the game can never be used up. The game can always expand its repe
enable increase or decrease of repertoire, and structural change [...] reper
processing noise into game elements" (Flusser, n.d, p.3). This research argue
participatory processes in order to recover the emancipatory aspects of social
context, games may represent a key in shifiting the enphasis from learning by
experience. Open games could help stakeholders interfere in the structure of pa
thinking social participation through the lens of games may represent a st
emancipatory role of participatory processes, towards overcoming the mere repr
models for the production of space.

## 4. Results, observations and considerations

The main occurrences perceived during the application of the Game of Dissent wi
support for a broader discussion that goes beyond the game itself. We will take
a reference for a critical review of the spatial restructuring process in the
This review is directed to the instances of social participation and to the lack of tho

### 4.1 Overcoming social obstacles

Among the many features common to games, we emphasize their ability to overcom
foster antagonisms and strengthen social structures. In the application of the G
see how the game facilitates the relationship between the ProJovem group and t
The application of the game happened at the second meeting between the two
meeting had happened two weeks before, during the course of a workshop held at
In this first approach, the group of college students had been received wit
suspicion by the ProJovem teenagers, which made it very difficult to hold the w
hand, at the second meeting, as soon as it was announced that the activity of th
no more sign of resistance was seen. The teams were quickly formed with parti

groups, and within minutes they were calling themselves by their names and supp
the game preparation task.

The Game of Dissent features some of the elements described by Caillois (1990)
games[5]. The Mimicri and Ag n elements are the ones of relevance to this argument
game (Mimicri), the Game of Dissent differs from traditional role-playing ga
context of Serious Games, the RPG s basic structure usually puts players in the
is quite different from their reality. When one analyses other role-playing ga
these characters are usually stereotypes, which tend to become caricatural
simulation chances in the structure of each game. In the Game of Dissent the sir
if the player is not supposed to be anyone but himself. However, in the game, h
freethinker of the urban issues. This role that has been denied to him by th
program of the Aglomerado is thus restored by the game.

## 4.2 Transforming antagonism into agonism

Considering the Ag n element, that represents competition, it is verified that
this element plays a merely symbolic role. In close observation we realize tha
competition in the dynamic of the game, and its structure doesn t include any
measurement, such as accumulation of points, or any breakthrough system that wou
achieve a certain goal, which could mean a victory over the other teams. The gr
against the board or against their own luck either, which would characteriz
described by Caillois. It is precisely the lack of such structures, however, tha
dimension to the analysis of the game. How can one explain the competitive a
during the game, if the competition was not even one of the game s premise
interpretation is that, in the game, the players competed with themselves, as t
overcome their own imagination. Another answer would refer to the symbolic ro
dynamics and the playful elements of the game. Dice, game board, cards and tear
references to competitive games.

In attempt to introduce the game into a political debate, we propose to establ
the principles of Ag n, formulated by Caillois (1990) and the agonistic model of
by Chantal Mouffe (2000). For this author, the political[6] is the dimension of the antagonism
inherent to human relations, which can be expressed in many ways. She crit
deliberative model, as it seeks to eliminate the antagonism through the const
consensus. Mouffe alerts us to the hegemonic nature of every form of consensus.
a given moment considered as the natural order – jointly with the comm
accompanies it – is the result of sedimented hegemonic practices (Mouffe, 2007, p
understanding that power is not an external relation of two already constitu
constitutive part of them, the consensual orientation of the current politics
depoliticisation of society. Mouffe therefore proposes to transform the antagoni
relations into agonism. That means not facing a contrary position as an enemy
Recognizing the opponent and knowing their point of view enables a space for neg
establishment of mutual commitments, even if the potential conflict has not ceas

[5] Roger Caillois identifies four elements in games, due to their essential nature. The
game at least one of the four elements can be found: Ag n (competition games), Alea
Mimicry (simulation games) and Ilinx (vertigo games)

[6] Mouffe distinguishes between "politics" and "political". The first concerns the set o
institutions that seek to organize human coexistence in scenarios often conflicting. "Po
of the antagonism inherent in human relationships, which eventually is expressed violent

In the Game of Dissent the agonistic model of negotiation can be translated into about identifying the antagonism between the players involved in the symbolic co the game. The actual agonism behind the Game of Dissent involves, on one hand spatial model based on rational consensus about the means of production and use other hand, the statement of other possibilities of production, appropriation an

### 4.3. Revealing the epistemicides of pseudo-participation

In his reasoning in defense of an epistemological diversity of the world, Santo concept of epistemicide, referring to the death of popular knowledge on behalf statements.

The spatial arrangements formulated as answers to the challenges of the Game of imaginative richness of space repertoire shown by the young people from the Lucia. The solutions are mostly very close to the creative diversity characte favelas. Some answers provided by the players were houses that are also workpla and streets thought of as a space of permanent negotiation between cars, playi meetings. In the same way, the self-produced space made by favela s dwellers t representation of their daily needs. It is a dynamic space in a state of per reflecting a continuous creative negotiation between individual needs and collec

When discussing the intervention models that are usually adopted in the favelas (government, academia and NGOs), Baltazar and Kapp (2007) point out that these by architects and urban planners, frequently ignore the dynamics and the auto favela s spaces. The opposite of autonomous logic developed by Cornelius Castori Souza (2013) as heteronomy.

> "The opposite of autonomy is heteronomy: here the laws [...] that go community are imposed to some [...] by a minority, on the marks of a asymmetry, i.e. from an institutionalized separation between rulers and ru 2013, p.174)

The heteronomous mode of intervention is unable to include the vernacular production, which in the context of the favela, are much more reasonable when everyday dynamics that represent that way of life. According to Baltazar and Kap

> These initiatives completely ignore the dynamic of the spaces of f self-production processes. They are indiscriminately done from top-d the same corporate logic of the legal city. If this is a problem in takes another dimension in favelas as besides leading to alienat spaces designed (and built) are minimum in cost and consequently in s flexibility at all. This leads to a recurrent process since, by beco lose any chance of political articulation and then they receive interventions with no criticism. (Baltazar & Kapp, 2007, p.3)

This alienation identified by the authors is in general terms the condition performed by the Vila Viva program. A critique of this operative mode should not exaltation of poverty or with the denial of the many possibilities of improv intervention, with the aid of the state s funding, could bring to this community to highlight the inefficiency of participatory processes that should enable technical planning and popular knowledge in the spatial restructuring of favelas

### 4.4 Towards an open source participation

Popular participation happens in a preliminary stage of the process proposed by
corresponds to the elaboration of the PGE (specific global plan). Kapp and Balta
another paper, a fairly detailed discussion of all stages of the PGE, where deci
scale and the guidelines for interventions are set out. In the structure of Vila
only stage open to community involvement. They are represented in participato
reference group that includes, among others, representative members from the dw
the Aglomerado. Community assembly should approve the guidelines set out
accompanied by the budget, in order to obtain the necessary resources for int
stage, all interventions become responsibility of private construction compani
municipal government. Therefore, both the hiring of executive projects and t
become responsibility of these companies. The municipal government only monitor
companies on site, to ensure the implementation of the guidelines that have beer
in community assembly. In the stages following the approval of PGE there is no
openness for community involvement. We present below (Figure 2) an interpretatic
diagram of the main stages, their competences and degree of participatory ope
spatial restructuring process of Vila Viva.

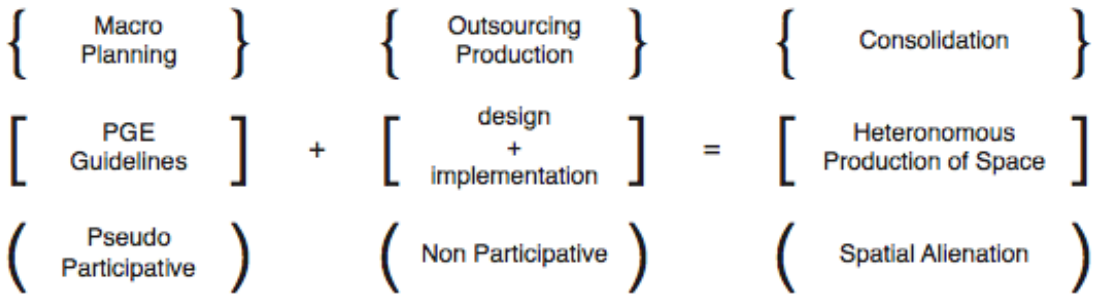

Figure 2. Interpretative summary diagram of urban restructuring stages of

This participatory process tends to instrumentalize the participation due to a
in its structure. First one must consider that a discussion placed in very gen
happens in PGE, inevitably escapes the possibilities of a balanced debate betwee
community. Unable to understand the real dimension of the issues placed at that
is led to agree with decisions that are often presented as the only possibilitie
for spatial inventiveness, with which they could contribute. Second, the PGE
dialogue only when it is related to what must be done , and not to how it sho
ignores what would be the greatest contributing potential of the community in
process. Discussing the processes of production, or the how to do , would
participatory process to the real scale of understanding of the community, whic
the production of everyday space, the scale of the neighborhood relations.

Furthermore, the model of communicative/collaborative participation by which the PGE
is not the most appropriate when taking into account the level of social inequa
initial reasoning of this paper, we argue regarding the incompatibility between
models based on communication. In Brazilian favelas, the balance of the condi
Habermas for a decision-making based on communicative reason does not exist. So
about the risks of a communicative/collaborative planning, when under condit
inequality, becoming weak in the face of conservative forces of instrumentalizat

> "However, the very existence of deep inequalities make the

> the achievement of more autonomy, but at the same time, a certai
> individual and collective autonomy is a prerequisite for the commun
> (Souza, 2013, p.150).

We propose to think of games as one of the possible tools to produce this minimu
by Souza. We understand that some critical repertoire would be crucial to the
between the technicians of the Vila Viva program and the community representa
assemblies. As a pedagogical tool designed for this first instance of spatial
facilitate learning by means of experience, in contrast to other processes based
They could therefore make it easier for the community to approach and understan
that will be placed under discussion, besides encouraging community engagement.

In the Dissent Game match, we witness the players in a process of taking into
qualities of their immediate space. During the session, the teenagers compared
with similar examples known by them. Comments like: "My uncle's house is like t
same as in my street" were often heard. At the same time, less common solut
something new to the repertoire known by them were mentioned with exclamation,
such a street!", or even questioned, as in "is there a square like that?"

In addition to the previously mentioned PGE problems, Kapp and Baltazar (20
discussion by proposing a reflection on how participatory process tends to contr

> Autonomy is the ability of individuals and, foremost, collectivities
> own means of action and interaction, as long as they do not restra
> autonomous means being ruled by self-defined norms. In contrast,
> participation indicates that people are allowed to take part in decis
> being able to change its norms. (Kapp & Baltazar, 2012, p.1)

This reflection confronts us with the challenge of thinking about the game not
tool for civic-spatial learning. The greatest leap forward into an indeed ema
should be thought of in relation to the open game logic. An open participatory p
community to participate in the decision-making process with enough autonomy to
interfere with the structure of the process. To turn noise into game elements
longer a metaphor from a philosophical abstraction, but a real possibility of o
listening channels to the contributions of popular spatial knowledge, in orde
adequate space to the lives of their real users.

### 4.5 The virtual as a possibility for dialogue and cooperation

The Game of Dissent was proposed as an alternative activity that would allow in
reflection among young people from the Aglomerado, moving it from the personal angu
immediate. A shift from the real problems into a virtual plataform. For Huizin
features of the games in general is that they are not everyday life or real li
escape from real life to a temporary sphere of activity with its own orientat
p.11).

Considering the virtual nature of the games, we associate the "escape from rea
Huizinga with the virtualization scheme proposed by LØvy (1996). In it, the disp
(real) to the virtual consists of an "inventive return" of a given solution
Therefore, virtualizing the territory through the game is an attempt to shift
platform where the problematization would become possible. On the virtual plan
an oriented dialogue to critical reflection about the changes in everyday spa
easier way.

Also according to LØvy (1996), the opposite movement, the return from virtual t
allows "other operations to emerge, unleashes conflicts, unlocks situations, int
of collaboration "(Levy, 1996, p.6). In this regard it is interesting to thi
between the Game of Dissent and reality. The game board consisted of a white
spatial representation formulated during the game came from an abstract support
players, oriented by the dynamics of the cards, contributed with spatial soluti
As this process occurred, we realized the effects of collaboration between the
favela and the architecture students. The space represented on the board reveale
everyday space of the favelas, and it also absorbed the contributions of studer
some degree, to the codes of architecture and urbanism.

The virtualization of the process of spatial design via the game turned out
disruption in a consolidated cycle of architectural production process, which

dissensual actualization of space, that is, an indeed collective production of s

## 5. Conclusion or the meta-game

To conclude this paper, we would like to return to the initial proposal, that
sharing of responsibility for the production of space through the lens of games.
will use Flusser s proposition of relating every game to a meta-game. Flusser
occur in games (Flusser, n.d., p.2) and therefore, that every game opens a co

game (Flusser, n.d., p.3). Through these statements, we will conclude with two in different directions.

The first one refers to the emancipatory role that we claim for social particip be understood as more than decision-making process. Participating also repres autonomy, empowerment and the increase of imaginative repertoire. In the open ga emancipated player is the one who is able to propose changes on the game stru stating that "games occur in games," Flusser (n.d.) invites us to think ab emancipation in a dialectic way. To play (to participate) would be a means to em same time, emancipation would be a way to propose other games.

The second consideration arises from the statement that every game opens a comp game. The experience of the Game of Dissent, described in this paper, enabled u competences that allowed us to establish a critique of the urban restructu Aglomerado Santa Lucia and also to reflect on the structure of the current part consensual orientation. However, another competence was outlined in the last se the case of developing it in depth in this paper, we would suggest it to be reflections. An open source participation, as in the open games, emerges a emancipation also for the fields of architecture and urban planning. When it co of space, replacing the centralizing role of the architect/planner by the collab to break up the architectural mode of production driven by real estate market, conception of production of space, currently thought of as the production of sense, this would represent the opening of the architectural field to reinventi limits and possibilities.

tools proved to be unsuccessful in addressing multi-dimensional problems conn
communities.
A pilot project on the basis of partnership between local authorities, communit
Shack to 3E house', was established in 2012, aiming to improve quality of
neighbourhoods, using tools typical for developing countries, such as micro-mortgages schemes, slum-
upgrading and self-help housing provision. In 2014 also started implementation of
project ideas into the national strategies.
Proposed paper looks at a process of transfer of knowledge, planning pra
implementation from developing countries into a 'developed country'. Paper also
of Third Sector in testing experience gained through the project, elaborated pr
governmental sector into the large-scale institutional solution.

## 1. Introduction

After 1989, transition of economic and politic system in Slovakia has brought
planning practices and instruments. As before the planners served merely as
supranational ideologies and economic decisions into the physical fabric of pa
and Stanilov, 2009), today they have to face various environmental, economic and
requiring comprehensive solutions. Also, as the 'public involvement' in pla
processes was during the former regimes only formal (if any), thus new plannin
embrace also new approaches and instruments, allowing for people to participate
their environment. Similar to other transitory countries, for planning systems
challenges, the transfer of ideas and planning practices from abroad is an i
Budi , 2001). At the same time, the system change has also brought new fra
stratification into the society, widening the social and economic gaps between
top and many others on the bottom. Of the most challenging and requiring u

solutions is the situation of Roma[1], living in marginalised, segregated settle
easter part of the country. In these settlements, the poverty combined with long
and attempts of assimilation, resulted in social exclusion of many of these comm
al., 2003), while number of people living in these area has been increasing (UND

However, the government attempts to address the needs of the communities have
failed, resulting in deepening the Roma dependency on the paternalistic st
stereotyping of Roma community as 'undeserved' (Mu inka, 2012a). Even though
governmental shift in rhetoric aiming to eventually promote 'empowerment' appr
bring an positive shift into the mainstream policy making, however, it without
strategy. Thus, the NGO local municipality of Rankovce in partnership with ET
local-based civic association 'Pre Lep ivot' decided to test the possible pr
services to people who needed them most. Based on the tools often used in devel
micro-financing schemes and incremental housing strategy - drafted a project o
through which individual families are provided houses according their needs, w
informal education and vocational trainings, as a first steps of the traps
marginalised settlements.

In the first part, paper outlines the current context of situation of Roma
approximately 200,000 Roma live in, - using Yiftachel's (2009) concept - 'gray
landscapes, in spatially segregated and separated areas, urban and rural ghetto
article briefly introduces the planning and state framework that governs addr
Roma communities, with a particular attention to the housing, as this is the
study. In the third part is introduced the project 'From shack to 3E house'
community associations provides alternative housing delivery method, based on m
incremental housing, developing a missing instruments in state systems. However
in the following part, there are deep differences between government approach
Roma communities. In this contexts, the role of community-based civic associatio
only in developing alternative ways of service delivery and planning instrum
translating the values of the community and positive role-modelling in current
solidarity and empathy among Slovak society is decreasing (Radi ovÆ, 2001). In
proposes the question for further research and challenges that needs to be addr
more harms and negative consequences of new policies.

This article is based on the study of written sources, enrolment in various Thi
and policy making processes, especially of being a housing programme coordinato
organisation ETP Slovakia, and interviews with experts and Slovak policy-maker
observations and experiences made during number of research and work stays in
settlements in Slovakia.

## 2. Segregated Roma communities in Slovakia

### 2.1 Current situation

The most recent territorial mapping of Roma residential patterns published i
communities (UNDP, 2014) show that 60% of Roma live integrated among the majo
society. The rest, almost 220,000 people, live in 800 segregated or separated R
in urban concentrations (ghettos) or spatially separated and segregated concent

[1] following methods used by national monitoring of Roma communities, see UNDP 2014.
komun t 2013 [Atlas of Roma communities], Bratislava., by Roma are meant peopl
themselves Roma and are considered Roma by their surroundings, as well as those wh
themselves to be Roma.

located predominantly in rural areas, commonly called 'Roma settlements' or 'm
communities' (as adopted by national strategy 'Long-term Housing Conception' (SR

The living conditions in these areas, especially on the countryside, display
deprivation and social exclusion: poverty, level of unemployment reaching up
education level, socio-pathological phenomena (crime, alcohol abuses), and deper
help (FiladelfiovÆ et al., 2014). The physical structure of the fabric in thes
with very low technical status of building stock, reflected also in poor sani
Another problem is also the informality of the dwellings and whole areas, an
access to basic infrastructure and services. Facilities and amenities are usuall
parts of the urban structures (UNDP, 2014). Also, most of these areas are l
marginalised and less-thriving regions of easter Slovakia. Thus, the segreg
supported by marginalisation of the whole region. Radi ovÆ (2001) calls this
marginalisation' and warns that this situation often results into definitive so
community from overall economic and social life of major population.

Table 1. Example of municipality NÆlepkovo. In the municipality there are locat
forms of Roma concentrations (1) separated on the margins of the village, (2) s
(2), and segregated in distance 2 km (3,4), in which the segregation was supp
development of new housing, in socialist period (3), in late 1990s (4), rece
disaster planning (1).

Even though there are difference among the settlements, in general, as several
(Va e ka et al., 2003, Mu inka and eds., 2012), the residents of these areas
generational circles of poverty - neighbourhood effect in these areas is so
mobility towards up is in many cases almost impossible.

To put it shortly, Hurrle (2006) depicts the overall environment in the settl
World in the First World'. Also a shift in government rhetorics, replacing 'R
'socially disadvantaged', ebesta (in Scheffel et al., 2004) recognises as an
make Roma 'invisible'. Thus, Yiftachel's concept of 'gray spaces' (Yiftachel,
more than appropriate when thinking of the situation of Roma communities, as f
centuries have Roma population in Slovakia been under constant threat of evict
the marginal, impoverished, environmentally degraded outskirts of Slovak towns
spatially segregated location, where there 'otherness' cannot be seen (JurovÆ, 2

## 2.2 Government actions

As in many post-socialist countries, planning practice in Slovakia have in rec
deep shifts and transitions. During the communism, the planning system was al
centralised. National identity and economic planning was executed on the highes
role of the local planners was to 'act as a technical translators' of the sup
physical layout of the individual cities' (Hirt and Stanilov, 2009,p.22). The
planning was thus not really meaningfully integrated into the physical. System
any spaces for citizen participation. Thus, in practice the most of the plannir
passive, distributing the values of communism theories of united citizenry and s

After 1989, transition of political and economic system brought not only new so
environmental challenges, but also requirements for instruments and methods
integration of all these dimensions and market-based ideology. Thus, pre-occupi
new system, it was not until 2000s, when Slovak Republic also started to deal w
of Roma communities. This was in particular since becoming an EU member state
started the preparation for Roma Inclusion Decade 2005-2015, the situation of
became also on EU priority list (Mu inka, 2012a) and thus under the pressure
institution, several national strategies have been adopted (Hurrle, 2006).

At the same time, increasing body of researches providing insights into proce
discrimination and poverty of Roma on both, micro- and macro-level (see for in
2001, Zoon, 2001, Va e ka et al., 2003)), emerged. Particularly considerable pi
the gaps of state disinterest was promoted by the local civic association. A re
Union and the Open Society Foundation identified over 900 projects in yea
implemented by NGOs, which had been targeted to Roma (www.osf.sk).

Stemming on both of these streams of academic and practical information, th
strategies occurred. As noted by several studies (Hurrle, 2006), one of the m
'Comprehensive Development Programme of Roma settlements' (SR, 2002). Document
multiple issues underlying Roma poverty and thus aimed at providing strategie
'slum-upgradings', particularly of underdeveloped and spatially segregate
Programmed argued for integrated interventions that were supposed to empower and
households, calling for involvement also a non-Roma parts in order to ensure pr
development strategies.

However, in reality, due to lack of financing (depended on external fundings a
weak political will, unclear departmental responsibilities, and lack of concre
the programme did not succeed. What have been left are fragmented pieces of pr
work, employment and housing provision, which are under responsibilities of var
and did not provide any systematic set of instruments. Since that, government h
new conceptions and strategies, re-formulating approach towards interventions fo
again, these national documents have been hardly binding and have not prov
instrument and integrated tools for addressing the complex innovative tools.
addressing problems of marginalised Roma communities have ended up in the resp
dependent on good will and proactive approach, of Local Authorities with onl
available (Mu inka, 2012b, SmatanovÆ, 2014).

## 3.1 Housing delivery innovation

State-supported housing delivery is one of the few tools that are available
NGOs to address the bad living conditions of segregated Roma communities. Natio
housing has been since 1998 covered by "Programme of housing development". With

of this program, Ministry of Transport, Construction and Regional Developme provides subsidies for local municipalities for the acquisition of municipal Programme is fore mostly aimed to fill in the deficit in public sector socia restitution processes after 1989, only small percentage of housing stock re administration. 'Long-term housing conception of marginalised society groups' obliged the housing programme to provide also solution for addressing bad hous Roma settlements.

The programme is now governed by Law no. 443/2010 (SR, 2010) on subsidies f development and social housing. The Law adjusts subsiding of construction of apartments, available to local authorities and selected non-governmental organi of apartments are delivered – of normal standard ($m^2$) and of lower standard (max flat area up to 60 $m^2$). Demto the higher construction state financial subsidies (8 targets Roma communities. However, this type is not only lower in floor area, mainly simple, unfurnished flats, in the row/apartment houses with a shared s support participation processes, the rest 20% of the construction costs are in off by the future Roma tenants of these apartments.

Being undoubtedly appropriate solution for some cases, in relation to segrega Roma communities the programme have number of critics. Firstly and most importan reinforces the Roma dependency trap and promotes again, paternalistic and cont as this tool is available only to LA and limited NGOs. The individual resident accessible tool through which they could improve their situation on their own. the construction does not in fact promotes 'empowerment', as it is not comple assistance (SmatanovÆ, 2014). Also in reality, due to lacking skills, this work by professional construction company (SmatanovÆ, 2010). Also quantitative rese low effectiveness of such a model. Regarding the scope of a deprived are programme seems to be costly and not very time-efficient (MTCRD, 2014). F quantitative evaluation prepared by Milan ime ka Foundation (Hojs k, 2008) almost 92% of new rental housing 'conserved' or deepened spatial segregation. spatial segregation is closely linked to deepening poverty and overall soc exclusion, the question of the purpose of such construction arises. Renting financial burden for tenants (Ma ÆkovÆ et al., 2014).

Important to note is also wider societal implications of the program. Direct di contributes to worsening of the general society mood. By majority is this pra favouritism 'because Roma again receive new free apartments', which may have term consequences than just short-term improvement of living conditions 'fort (see for instance (Mu inka et al., 2012)).

## 3.2 Project 'From Shack to 3E House'

Since the deficiencies in state housing model have become more apparent, the involved in delivering alternative services and dealing with disadvantage gro with number of initiatives. One of the most successful in providing social innov on transfer of knowledge has been a non-profit civic association ETP Slovakia.

ETP Slovakia was established as a direct continuer of Environmental Training Pr and Eastern Europe. This was initiated in 1992 by U.S. Agency for International was implemented until 1998 in six countries of Central and Eastern Europe. ETP S an independent entity since 1995. Since its establishment, ETP Slovakia has co local government and businesses as well as with NGOs in programs that increase of local development and improve the environment as well as provide assistance

individuals and families. Currently ETP has its traditional donor organisa
activities, e.g., on international level (Open Society Foundation, Habitat for
Financial Mechanism) as well as local profit-based companies. The background
funding in particular allows to promote the projects that have some idea-backgr
of the world, especially in developing countries. The international funding gi
also an accountability, what attracts Slovak professional who were educated in
to provide their voluntary consultancy and knowledge in the activities put for
was also the case of the author of this article, who was educated in univ
implemented this knowledge as a housing programme coordinator in the analysed
Shack to 3E House'.

The first projects focused on improving living condition of Roma from segrega
promoted ETP with an assistance of international donors in 2000s through m
programmes. One of the most successful proved to be financial tools allowing i
to 'help themselves' through small micro-mortgages and savings schemes (Bœtor
Mu inka, 2012b). Since 2004, organisation has provided more than 600 micro-mortg
amounts of up 1000 euros for housing improvements, or building basic sanitation
aimed at disadvantaged households who were not eligible for commercial and
mortgages. An essential part of this financial assistance was also partici
education programmes, delivered also by the same organisation.

In 2011 was ETP Slovakia asked by LA in Rankovce, a municipality in the easter
with 300 non-Roma and 700 Roma residents living on the municipality's fringe
provide an assistance with addressing housing shortage and bad living conditio
community on a larger scale. Due to the commitment and strong sense of care, I
for more holistic approach in addressing needs of local Roma community. With a
of UNDP and partnership with local-based civic association 'Pre Lep ivot',
providing community and social work in the community, project 'From Sha
House' (Ecologically and Economically Efficient) was elaborated.

In the first year of the project, number of meetings with all the stakeholders
understand the real requirements of the future clients, attitudes of all actors
informal education was provided. The meetings with the clients revealed that the
housing is an individual family house standing on its own plot of land (Ma Æ
This finding was in contrast to the state-distributed form of row/apartment ho
spaces. However, since the standard of individual family house requires more f
model of the 'incremental housing' was adopted. Based on the principle of three-
as a 'core' is delivered a house of 75 m² which can be later on by the residents easily extend
100, or 150 m² (see Table 2 for further details).

Project does not only envisage empowerment of clients by upgrading them fro
standers to active participants in their home construction, but also by helpi
skills and supporting their sense of responsibility. Essential part of the pr
beginning been the involvement in activation programmes. Initiative families h
the process of housing provision delivered also informal education, vocatio

### 3.3 Results of 'empowerment approach'

The pilot project involved first 6 houses that were build in 2013. The succe
escalated a snow-ball effect among the rest of Roma families across the region
the financial limitation of the micro-financing revolving fund, the project
another 12 families in building their houses (for details see Table 3).

As the project has been still evolving, it is difficult to make final evalu
September 2014 was executed preliminary monitoring, involving series of s
interviews with several members of the municipality, from both communities. The
depict the changes that have taken place in their life since the project sta
subjectively evaluate the project success. All of the respondents agreed th
significantly improved the life for the whole community in the positive way (
Also, the women from families involved in the project became more active, and w
local based community association 'Pre Lep ivot' that is run by non-Roma, wh
social work in the community, established a micro-business with second-hand cl
man have focused on production and sell of 'eco-bricets' (www.ozplz.sk). Also,
became a members of the civic association 'Pre Lep ivot' are apart from m
being active in addressing the cleanliness and safety in the municipality.

## 4. Transferability hurdles – attempts of institutionalisation

In a way, it can be summarised, the project 'From Shack to 3E House' follows al
in 'Comprehensive Development Programme of Roma settlements' (SR, 2002) and thu
the ideas set up in national strategies are feasible, effective and successful
set up the missing instruments that the state strategies lacked – incremental ho
argues Ferguson and Smets (2010), institutional housing finance is in crisi
countries, and particular schemes of incremental housing and micro-finance s
addressing needs of low/moderate-income families.

Thus, the final aim of the civic associations involved has been to introduce
Slovak legislation (national action plans and official strategies) as comp
solutions. Governments representatives from all fields and key bodies (Ministr
Ministry of Finance, Ministry of Inner Affairs, Ministry of Family and Labour)
regular site visits and participated in all the 'checkpoints' of the project ev
reports during 2012-2014, including the presentation of the project in House of
2013 (Ma ÆkovÆ et al., 2014).

However, until now, the central government in spite of having recognised benef
was not committed to officially acknowledge the likewise alternative solution
financial administrative support, even though the 2011 Proposal of Pilot Appro
Housing Infrastructure from Structural Funds of the European Union , which als
projects of building rental apartments for marginalised groups for EUR 18.529
Structural Funds between 2013 and 2015, or a National Housing Strategy 2015-2
2014), provided good chances for that.

The common problem of implementation of grassroots projects, and thus the 'acco
NGO (Kilby, 2006) is in this case not an issue – number of social innovation pr
ETP Slovakia have by legal institution already been implemented (Bœtora et al.
illustrate this situation, it is useful to adopt the idea of 'conflicting rat

illustrating how deep are the differences between institutional approach in un
'correct way of housing' and the real needs of poor Roma, translated into the
programme by civic association.

What is mentioned by the relevant government representatives is that such sol
integrated, multi-departmental approach, what is difficult to accomplish. It is
the consensus of all the state departments is almost impossible, as each depar
priorities and approaches in addressing Roma problems. Also, there are several
of the project that government representatives consider as not very appropriate.

The different rationalities causes by step-by-step construction and ownership n
strategy. What for Roma families symbolises their ability to stand up on theii
institution has not been recognised. Government programme delivers rental apa
idea of 'enabling vertical mobility' (MTCRD, 2014), however in reality, to esca
requires also accumulation of financial sources. As described already as vario
actually the homeownership that performs a critical economic, as well as
Homeownership is of key importance in building households wealth and way out o
low-income to middle-class (Ferguson and Navarrete, 2003).

Another 'clashing rationality' lies behind the incremental approach of the hous
the process of obtaining housing, including self-help constructions, which is g
as a 'correct method of housing'. Even though this methods have been already by
as rational, innovative and creative (Turner and Fichter, 1972, Smets, 2006
elaborated within valid EU building standards and requirements, from the instit
can perceived a mistrust in 'Roma being able to build the house themselves' and
the long consolidation time. As note Ferugson and Navarrete (2003), such an ap
the institutional bodies, in many countries all over the world governments and
the 'paradigm of housing as a product' and spread this model at any costs. A
'mistrust' can be observed in institutional bodies' seeing a 'risk' in provid
allowing Roma, who are mostly unemployed and depend on welfare benefits, as due
shortage of many the repayment is constantly under threat. Saving encourages the
of their money aside and demonstrates their ability and willingness to make regu
also proves the 95% repayment rate of micro-financing provided by ETP Slovakia

Last but not least is the non-respecting of Roma specificities, which is anchor
housing model, providing uniting solutions for everyone. However, this featur
programmes seems to occur often, as also LiØgeois (1994,p.95) argues that 'so
house the Roma at any price in the conditions that we regard as appropriate to
stem on the fundamental perception of 'what is right' and 'for whom'.

## 5. What made the project successful? Role of NGO

The role of community associations in the planning is not new, however, there ca
renewed interest on international level (Choudry, 2013, Banks et al., 2015), as
parts of Europe (Healey, 2015). In the transitional countries is the role of c
even more relevant, not only in promoting democracy (Choudry, 2013), but also a
basis and values different to these of state and thus being more effective and s

Since the fall of communism regime, Slovakia has experienced the explosion of ci
number of Third sector organisations has been continuously growing. According t
data, the number of registered civic associations exceeds 40,000 (Ministry of I
of persisting weak institutional environment, there is a growing number of new
involving not only 'laic activist', but also many professionals in the field wh

feel strong commitment and responsibility to the local issues and want to parti
the country's future (Bœtora et al., 2012).

These associations in Slovakia, as in many other countries, provide basic fur
representation of the voices of the certain societal groups, as an (1) experime
control of power – watchdogging, (3) alternative service delivery provision, an
source of alternative approaches to public policy. So far, the NGOs were the
promoting the ideas of 'empowerment' into the real life. These include most
through providing social services, such as social field workers, Roma adviso
assistance, and health assistance for Roma communities (see also (JarÆbik, 2003)

In fact, in real every-day activities of Slovak civic association cover all the
discussed case study. Project 'From shack to 3E house' is based on a gap in ins
in state housing delivery. Since government instruments are available only to L
comes with a provision of instrument available to individual families and thus a
decide about their future. These ideas and practices are based on a general shi
approach' towards the 'empowering approach', using specific tools of micro-m
schemes, and incremental housing. However, these tools have also their critique
developing countries. Many of them where in this case however transformed into a
help, often being criticised for depletion of sources for the poor, is in thi
Roma families their first work, thus it provides also the training for the
opportunities. Important is also to stress that this programme does not aim to
only option, on the contrary, project aims to be recognised as a complementary
state housing strategies.

Being of special importance in case of addressing ethical issues, such as of R
and successfulness of civic associations to (5) promote equity and different mo
transition from a social structure based on forced equity a developed profit-dr
influenced general societal moral settings and preferences. As notes also Radi
an overall trend of decreasing of social solidarity among Slovak society.
The situation is even sharper when Roma are concerned, as any institutional hel
by majority perceived as unacceptable, unfair and thus left merely on the basis
charity (Hojs k, 2010) of the voluntary-based civic associations. As Friedmann
non-governmental organisations/third sector/civil society show hope that an a
might be possible through the voluntary actions of civil society

Therefore, the role of civic associations, as a value-driven bodies, is in th
essentials. The value-basis drives civic associations to pursue public benefit
profits or social/political benefits. Kilby (2006,p.953) sees the values of NG
Weltanschauung, a world view, from which derives their motivation to serve for
relation to the case study, it is thus important to look at the underlying r
problems connected to Roma communities. On the level of national-state rhetori
identified two basic principles that underlie these actions. First is the
discriminatory measures – to level the inequality in chances caused by histor
which has resulted in current state of exclusion and marginalisation (see for in
This approach is complemented by the knowledge that without an external help,
Roma there is no-way-out to get from the poverty traps and state dependen
segregated Roma settlements (Radi ovÆ, 2001, JarÆbik, 2003, Marcin in and Mar
However, the approach of civic association was based on different basis, s
development, protect the environment and assist in the development of the s
educational and cultural potential of people, organisations and communities wit
problem solving within disadvantaged regions, socially disadvantaged group

minorities' (Ma ÆkovÆ et al., 2014). This approach is not based on promoting e
the pubic-led are, but also, promoting development, empowerment and care.

The crucial part of the civic associations activities is then their step-by-ste
the standard practice and formal procedures. As also Murphy (2014,p.146) argue
are community-based planning founded on a new ethic and morality: 'A new worl
imagined as divorced from charity and based on care. Within this framework, int
a gift but the expected response from community members who support one ano
conclusions and vision for future provides also Friedmann (2011), aruging also
step incremental approach in planning practice, no-longer based on ideologies
transformative momentum of a more responsible and public-good based societies.

## 6 Further research

This article aimed to open up a discussion that have receive so far only marg
each of the issues presented requires further, deeper elaboration. Firstly, ta
associations in finding innovative solutions for empowerment of given Roma c
model for planning practice in Slovakia on the local level; there is still an
state planners on regional and national level to address the marginalisation o
provide a solutions on these scale. If not, any long-term future solutions for
non-Roma will not be efficient.

Secondly, the overarching challenge is that of values and attitudes of the soci
both ready, able and willing to address the issues of Roma marginality? A
stereotyping among non-Roma in the courtly persist, shall there be taken any in
order to change the attitudes and values of a majority society?

## 6. Conclusions

To sum up, paper looked at the situation of Roma communities living in segregat
settlements in Slovakia. For a decades have Roma minority in Slovakia expe
deliberate attempts of assimilation, creating a 'gray spaces' in Slovak la
illustrated on the case of housing, since the fall of communism regime, the go
instruments have been also failing in addressing needs of these communities. On
'From Shack to 3E House' and its unsuccessful attempts of institutionalisation
between government approach and perception of Roma needs and the reality. As
especially in the case of addressing needs of marginalised Roma is the invo
associations vital due to the lack of solidarity and networks within these co
study also illustrated the role of civic association in filling the niches
services in alternative ways and developing innovative approaches, with an a
formal, institutionalised planning practice. However, as these issue in Slovak
been articulated, further researchers are needed and the values and underlying
assistance for Roma in need must be re-thought.

# How to establish a disaster-resilient ageing community based on local eld Institutions in Taiwan?

Ya-Ting Wang[1], Tzu-Yuan Chao[2]

[1]Department of Urban Planning, National Cheng Kung University, e-mail: bonniewang1010@icloud.com
[2]Department of Urban Planning, National Cheng Kung University, e-mail: tychao@mai

Keywords: resilience, disaster resistant community, elderly welfare institution.

## Abstract

While ageing population in Taiwan surged to 11.5% in 2014, ageing in place emerging concept in public health policy, which proposes a community-based ca increasing ageing population. Among all the issues regarding population ageing, from natural disasters would be the most challenging. Meanwhile, local elderly w with relatively sufficient storage, professional nursing/medical care services be able to sustain better self-support status during and after disaster. Ac experience in Taiwan, rescue force usually could not reach most rural area very occurring due to the disconnected communication and destructed routes. Local el could act as shelters for community residents. In recent years, there have been given to capability of disaster resilience for elderly welfare institutions disaster management. Discussion regarding how institution resilient capacity co in the community is still lacking.

The aim of this paper is to explore how well communities could respond to disas integrating the existing elderly welfare institutions. This paper would divide first part is the analysis of the spatial distribution of elderly welfare in disaster potential area in Taiwan. And the second part will define the role of about institution for community, and identify the disaster-resistant level for di institutions. Finally, it would feedback to overall institutions in community f policy at local level. The framework is expected to propose a community-level and enhance disaster carrying capacity.

## 1.! Introduction

### 1.1.! Research background

#### 1.1.1.! Long-term care challenges for the ageing in Taiwan

In Taiwan, the population above 65 years of age reached the standard of an ageir and the proportion was over 11.5% in 2014, which surpassed the benchmark of an which is 7%. It is estimated that the proportion will go up to 14% in 2017 an society. After one-decade, Taiwan will become a super-aged society. Meanwhile make younger population decrease and dependency ratio surge. The demographic ch not only in the age structure but also in the size of households. Only half of long-term care live with their children, yet the size of households continues to shrir elderly by families has declined due to the lack of caregivers among family mer care, however, is not affordable for most families. ("White paper of population

Compared to the complete network available for evacuation and disaster reductio people in rural areas face more threats and difficulties regarding the disaster process. Since young people leave their hometowns, this also increases both t

!

elderly living alone and their vulnerability to a disaster. So, the establishme
is necessary at the local level.

### 1.1.2. Ageing in place

A common issue of ageing is the lack of adequate and affordable health care in t
people live, as they are no longer able to live in their own homes. World Healt
guide for global age-friendly cities, based on the concept of active ageing. I
friendly city should adjust the structure of urban spaces to make services
environment more available for the elderly to meet their needs.

One of the principles of an age-friendly city is to offer community-based su
services, which are important for maintaining the health and independence of old pe
community. On the other hand, the community should be responsible for emerger
including older people s needs and capacities in preparing for and responding to

Shih (1999) proposed that long-term care should transform from care in the com
by the community , and finally to care with the community. Wu and Chuang
mentioned that the goal for a long-term care policy in 21st Century Taiwan shou
local services that connect resources in the community to establish a long-term
on the community. This kind of long-term care follows the ageing in place
enhances the cost-effectiveness of the service. At the same time, the key role
gradually transfers from the home to the community.

### 1.1.3.! Long-term care model in Taiwan

The long-term care model in Taiwan can be divided into three parts, and each
provide different kinds of services to meet the needs of the elderly. It shoul
based services, community-based services, and home-based services. Home-based
incompetent elders get continuing care, and caregivers will provide services at
Community-based services are aimed at enhancing the willingness of family car
advance the independence of the elders in the community, which provides services
the elderly. These kinds of services help the elderly to stay in their familia
accept different professional services at the same time. Finally, institution-
care for the elderly in daily life and with whole-day medical assistance.

In recent years, the local government tried to promote community care services.
term Governance, from 2013 to 2016, there were subsidies for nutritious catering
services, and various other welfare activities for the elderly.

In the Senior Citizens Welfare Act, Article 19 clearly states that institution-
integrate with family-based and community-based services, and give support to i
community-based services. It shows that long-term care in Taiwan has been dev
community-based care to fulfill the spirits of aging in place, so elderly wel
addition to the original work of these institutions, should take up the crucial
for the elders of a community.

### 1.1.4.! The need for community-oriented long term care facilities

The focus of long-term care for elderly people has gradually shifted from instit
communities, and the institutions have become part of the professional caregive
based services. At the same time, institutions can make use of resources in
provide informal assistance to residents inside institutions, so community-bas
people is regarded as a concept of self and mutual assistance (Chen, 2009). Lai
an institution as more than just a place separated from the outside with a hi
should integrate with the community actively and remain in a good relationship
of the community. On the other hand, community-based care is a welfare provic
from nation to community, so he defined the community-based cares of an i
localization, decentralization, and service based.

Localization is to provide long-term care, varied according to local characteris
that long-term care is not a fixed and inflexible mechanism to apply everywher
long-term care providers shifting from central government to local governmer
decentralization. Deinstitutionalization aims to support elderly people receivi
the community where they live, so all the cares correspond to a miniaturizati
community.

While institution-based services tend to integrate with community-base care, the
welfare institutions has been given more attention. Chuang (2008) mentioned tha
offer a variety of community-based care, such as home-based care and day care; c
residents in a community take advantage of the facilities in institutions to ac
functions. Furthermore, institutions could act as emergency shelters because
living facilities. For instance, there is safety management in kitchens and bat
medical care providers. In addition to providing care to the elderly, elderly
have become shelters for the elderly and residents in the community when d
Institutions can supply their storage of food and water, and they are a compa
sleep (Dosa et al., 2008). Disaster mitigation gradually is incorporated into o
community-based services that elderly welfare institutions offer. Laditka et al.
preparedness of elderly welfare institutions after the Katrina Hurricane, and i
plans for disaster prevention and protection at the community level excluded
Likewise, institutions were not aware of existing health care resources, so vul
the face of a disaster.

!

Above all, the role of elderly welfare institutions, which provide services onl
institutions, transformed into an important core of the community elderly care
outreaching professional medical and multiple care such as emergency care and disaster
prevention services to community, the network of long-term care becomes more access
available to the elderly.

### 1.1.5.! Ageing society & disaster vulnerability

With the ageing population quickly growing, there is more attention given to t
people belonging to a high vulnerability group (Cohen & Ahearn, 1980; Tierney &
Fernandez et al. (2002) stated that the vulnerability of the elderly includes
mobility of the elderly decreases due to the degeneration of physical function o
of health. Compared to healthy people, the speed of the elderly to respond to
slower. Another aspect focused on the alertness of the elderly to escape a di
sensory functions of the elderly decline, they are not able to respond to disast
elderly people the loss of social capital, social networks, and socio-economic s
capability to recover.

FEMA (2012) pointed out the evacuation capability of elderly people is much low
population, and mental traumas make them take longer time to recovery when di
Therefore, the elderly suffer higher vulnerabilities from different physical
conditions. In the case of an increased proportion of elderly in a populatio
resilience to disasters and reducing their losses from a disaster have become
Corresponding to the specific needs of disaster response, The Disaster Preventio
Plan (2013) regards the elderly as a disadvantaged group, so they are a prio
assistance after a disaster. The Ministry of Interior, the Ministry of Health a
governments should promote preparedness for disadvantaged groups, offering hos
social welfare institutions, and other places to shelter the elderly.

Taking into consideration the different health conditions of elderly people, the st
change according to differing levels of vulnerability. The National Disaster Pre
Center (NCDR) (2008) categorized the elderly into four groups according to di
conditions.

(1) The elderly rely on institution-based care:
Because people in this group live in elderly welfare institutions, the preparedn
disaster focuses on the safety of the physical environment of an institution, th
protection and prevention, plans for disaster management, the delivery of ev
support among regional institutions, and disaster insurance.

(2) Incompetent elderly receiving community-based care:
People in this group need assistance regardless of mitigation, preparedness, and
disaster. Consequently, it is necessary to plan shelters with professional car
aids, and to provide relative medical facilities for the elderly of specific dem

(3) The elderly capable of looking after themselves receiving community-based ca
The strategy focuses on education about disasters, so people in this group
knowledge of self-protection in the face of a disaster, and strengthen their ab
who live alone or are incapable of movement by themselves in a disaster.

(4) Others:
Offer recovery planning about economics and housing reconstruction assistance to

!

### 1.2.! Research Objectives

The vulnerability of elderly people in the face of a disaster differs accordin
and need for caregivers, and the differences are worthy of more discussion, specific
enhancement of resiliency to a disaster.

Hence, our research scope covers the review of different types of elderly welf
the situation that extends from the services of elderly welfare institutions to
identifying the role of existing elderly welfare institutions in response to d
provide some suggestions to the entire institution-based service system.

Objective 1: Enhancement of the function of elderly welfare institutions: Disaster response
! Objective 2: Identification of elderly welfare institutions in disaster pron
! Objective 3:Suggestions about disaster management to various kinds of elderl institutions

## 2.! Conceptual framework

### 2.1.! The role of elderly welfare institutions based on ageing in place

According to the population projection of WHO World Health Organization , th
incompetent elders will grow four times from 2000 by 2050. And The average
elderly people in Taiwan will become 30% then. There will be plenty of demand
care, including home-based care, community-based care, and medical institution
"Global Age-friendly Cities: A Guide", it was mentioned that health and suppor
community are a very important part of maintaining active ageing. Through sup
available and multiple services, a long-term care network based on community can

AARP (American Association of Retired Persons) echoed the concept of ageing in
and they advocated for the establishment of a liveable community. The community
the spirit of active ageing. The principles of a liveable community includ
connectivity between community and health facilities, supporting home-based or c
related services, and relative health-based resources to improve the health of
community.

Ageing is a continuous process, and the concept of active ageing can only slow
ageing. When ageing reaches a certain level, elderly people still have to rely
services, which can provide 24-hour medical care and professional nursing. In
Welfare Act Article 19 mentions The institution-base service shall be formed as a combin
home-based and community-based services, and shall support home-based or comm
service, which expect elderly welfare institutions can be the main providers o
and home-based services and contribute to elderly people s active ageing in th
from this act amended from 2014 to now, elderly welfare institutions are not af
the community-based care (Shih, 2013) and there is still a long way to develop
from elderly welfare institutions in the network of long-term care in Taiwan.

### 2.2.! Strengthening the relief role of elderly welfare institution by red of at-risk communities

According to Establishment Standards of Senior Citizens Welfare Institutions,
service can be divided into domiciliary care institutions and long-term care ins
Domiciliary care institutions provide seniors who can take care of themselves fo
life but without any relative with legal support obligation living. The average

!

residents in domiciliary care institutions are better than those in other types medical device is relatively simple. On the other hand, long-term care instit characteristics of residents and can be classified into three categories:

! Nursing: services for incompetent elderly people who are unable to take care elderly people in need of nursing services such as a nasogastric tube or cathe

! Long-term care: services to elderly people with long-term chronic diseases w nursing services 24 hours a day.

! Caring for senior citizens with dementia: services to senior citizens who ar middle degree dementia, are capable of moving by themselves, but are in need services.

Long-term care institutions and nursing institutions should possess the foll support 24 hour care: dormitories, bathing and hygiene facilities, and kitch heating, storing and freezing. In comparison to domiciliary care institutions, l care institutions lack capabilities and the average health condition is worse. nursing records, pharmaceuticals, storage of medical equipment, and adequate emergency rescue, long-term care institutions possess nursing stations equipped room, service stand, and treatment trolley. These medical facilities meet each demands. In the face of disaster, long-term care facilities have more complete consequently, this type of institution-based service has the potential to provid the elderly in a community.

Similarly, the arrangement of caregiver corresponds to different types of instit below presents the comparison. Due to better health, the elderly in domicilia need fewer caregivers than the elderly in long-term care institutions. The dens of personnel between the three categories of long-term care institutions from respectively, from caring for dementia senior citizens with dementia, long-term nursing. In other words, the order of dependency on care giving is that caring with dementia is the highest one, and long-term care is higher than nursing. Th based services in Taiwan will be sorted by the arrangement of personnel and med this paper: institutions for senior citizens with dementia are on the highest l followed by long-term care institutions, nursing institutions, and finally institutions.

Table 2. Comparison of caregiver ratio (caregiver to residents) and medical

| | | Domiciliary care institutions | Long-term care institutions | | |

## 2.3.! The role of disaster prevention according to the type of the instit

According to the abilities of taking care of oneself in daily life and the strength institutions provide, the capabilities of disaster protection for institution- divided into 4 levels. From high to low, the level of disaster protection is citizens with dementia, long-term care, nursing care, and domiciliary care. When institution are more incompetent, the institution should possess more medica example, regarding self-relief, long-term care institutions that provide care t dementia are much more vulnerable in the face of disaster due to the health elderly people in the institution. When disaster strikes, elderly people in th cannot rely on their own strength to escape, so the density of caregivers shoul limits for selection of the location of the institution should be stricter. On the othe care institutions providing care to senior citizens with dementia should be at disaster protection due to high resiliency and coexistence with disaster.

Table 3. The analysis of disaster protection in types of institutions

| | Domiciliary institutions | Long-term care institutions | | |
|---|---|---|---|---|
| | | Nursir | Long-term c | Caring dementia senior citizens |
| Medica Resources | Lowes | Lowe | Highe | Highes |
| Caregivers | Lowes | Lowe | Higher | Highest |
| Level of dir protection | Lowes | Lowe | Higher | Highest |

## 2.4.! Challenges elderly welfare institution faced when provide relief se disaster prevention

The relevant norms about the establishment of elderly welfare institutions foc conditions of the building, including the differences among the health conditio the arrangement of caregivers and medical facility. However, these norms stil regarding the influence of disaster prevention. In addition, the Establishment Citizens Welfare Institutions only refers to the requirements of facilities re residents inside the institution, but not to regulations corresponding to disast

Regarding local disaster prevention, the Disaster Prevention and Protection A Regional Plan of Disaster Prevention and Protection should be conducted by the c and township (town, city) level. Furthermore, township authority is responsib community disaster prevention and protection affairs. In addition, for disadvantaged government should provide the necessary assistance at the stage of prevention, protection at the stage of response.

Although the elderly are regarded centrally in the Disaster Prevention and Prot still a lack of further discussion about the elderly with different needs in dis

!

Regarding the lack of regulations about the location of an institution, ins
anywhere in a community. As such, there are increasing challenges in response t
institution. Lee (2013) discussed the problems institutions meet in the proces
event-oriented method. Many institutions located in rural areas with properties
lack medical resources because cost is the first consideration. Although rural
the formal relief network is incomplete in response to a disaster. In additio
evacuation and the facilities for disaster protection should be taken into t
disaster management of institutions. Benson (2002) generalized the factors of e
CDC s records. The factors included how long institutions spend on evacuati
institutions prepare for disaster mitigation, whether the arrangement of manp
whether the storage of water and food is enough, the complex demands for medicin
plenty of difficulties institutions will meet in the process of long-distance
prevention of disaster tends to seek for a local shelter. In this paper, the
elderly welfare institutions will develop on the basis of self-rescue, and then
assistance of residents in communities.

## 3.! Methodology

### 3.1. Scope of the study

!

In order to identify the role institutions should play in disaster prevention a
this paper uses the village as a spatial unit of analysis, which corresponds to

### 3.2.! Secondary database collection

Because the spatial units in this paper are village administrative units, the
digital maps will be based on villages. The main sources for data are from t
information" of the Ministry of the Interior Department, in 2013, and digital m
Ministry of Transportation and Communications. These contain "Taiwan county
administrative boundaries" and "Taiwan village boundaries." "The position of slo
from 2008 to 2013 ", "inundation potential map of rainfall up to 600mm in one
"distribution of fault map" are from National Disaster Prevention and Rescue Cen

### 3.3.! Overlay analysis of Geographic Information System (GIS)

Through the overlay analysis of potential disaster areas and the distribution
institutions, the institutions in high-risk communities can be pointed out. Aft
roles of these institutions face in a disaster according to the type of service
can be used as basic data for the establishment of the community disaster prevention
future.

## 4.! Issue discussion and preliminary GIS analysis results

### 4.1.! Preliminary issue of identification and analysis

#### 4.1.1.! Issues I: The distribution of medical care resources in Taiwan do
demand of the elderly population in the face of a disaster. When dis
elderly in hazard-prone communities are highly vulnerable, and they
immediate services of medical resources.

! Analysis:
The distribution of large medical institutions corresponding to the villages
that major medical resources are located unevenly and cannot assist every village.
hand, comparing the distribution of large medical institutions with are out o

!

of large medical institutions. As a result, medical resources cannot handle
ageing trend, and the communities elderly people live in are unable to provi
continuous medical services. The elders are incapable of receiving med
immediately, so several problems for ageing in place emerge. In addition, whe
a hazard, those villages cannot get timely medical care.

A community with a high proportion of elderly people contains not only high v
also low accessibility to medical resources. Under this uneven distribut
institutions, communities should seek other local resources with medical and

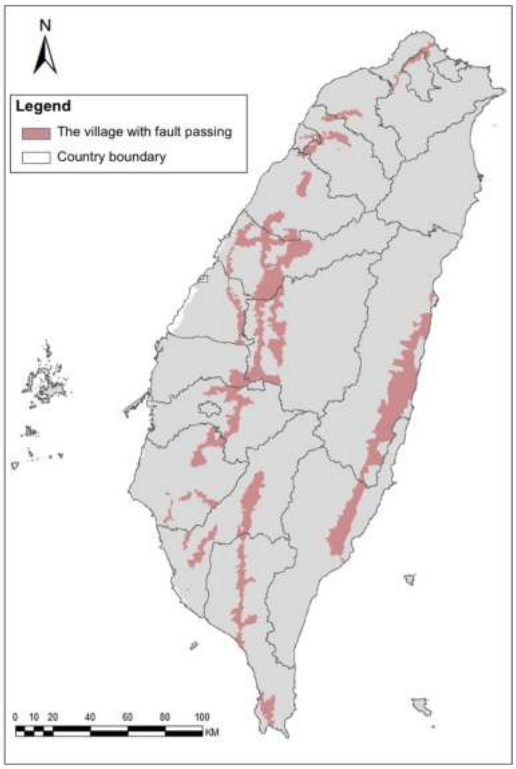

Figure 4. Earthquake disaster

!

Figure 5. Inundation potential map of rainfall up to 600mm in one day

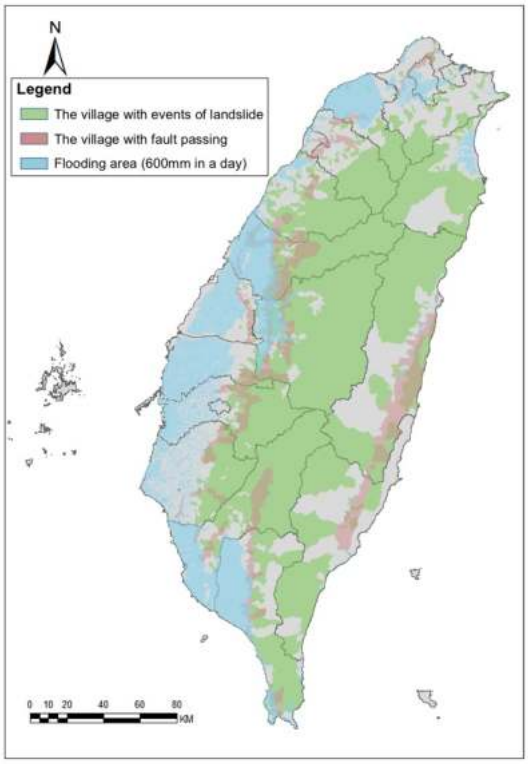

Figure 6. Multiple disaster risk map

4.1.3. Issue III: Review of elderly welfare institutions: elderly welfare institutions should avoid selecting a potential disaster area as a location.

- Analysis:

In order to implement the spirit of the land of ageing, the role of elderly welfare institutions in the community contains community-based care services and medical services. Therefore, they are in an important position to provide services to the elderly, and they should strengthen their response to disasters and enhance resiliency.

Besides the interior facilities discussed earlier, the location of elderly welfare institutions is also the risks in disasters. Therefore, the following analysis will focus on the distribution of facilities prone to slope disasters, earthquakes disasters, and flood disasters to understand the higher level of vulnerability of these elderly welfare institutions.

Table 4. The analysis of disaster distribution in types of institutions

| | | Disaster type | | | |
|---|---|---|---|---|---|
| | | Fault distribution | Slope disasters | Flood disaster | Multiple disaster |
| Domiciliary care institution | | 1 | | 2 | 0 |
| Long-term care institutions | Nursing | 48 | 38 | 185 | 6 |
| | Long-term care | 13 | 5 | 41 | 0 |
| | Care for dementia senior citizens | 0 | 0 | 2 | 0 |

-

| | | | | |
|---|---|---|---|---|
| Tota | 62 | 45 | 230 | 6 |

Finally, after a comprehensive analysis of the three disasters corresponding
community, it turns out that there are 304 institutions located in potential di
accounting for 29.50 % of the total number of elderly welfare institutions
nearly 30 % of elderly welfare institutions suffer from damage in the face of
the residents in the institutions belong to disadvantaged groups, so the vuln
gets higher. Thus, elderly welfare institutions should have more stringent s
the selection of a location.

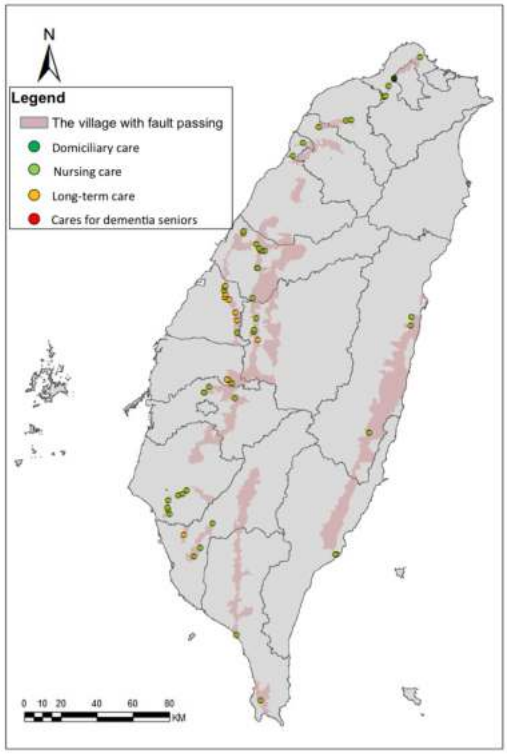

Figure 8. The distribution of institution earthquake disaster risk m

!

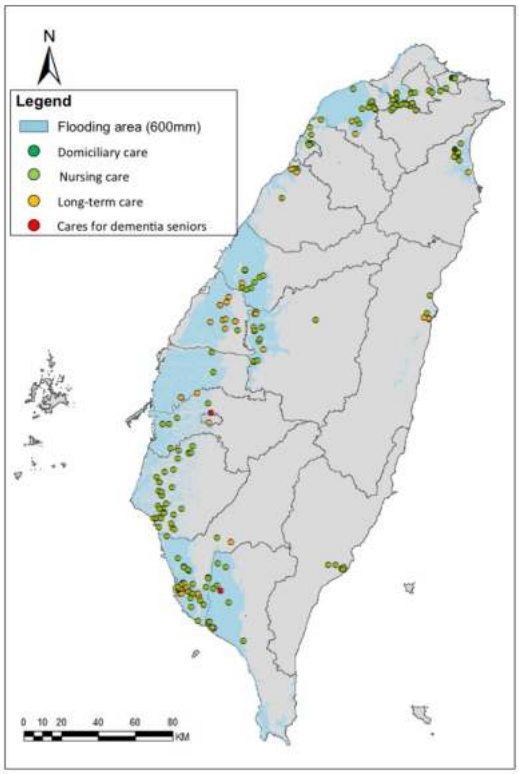

Figure 9. The distribution of institution and inundation potential map of rainfall up to 600mm in one day

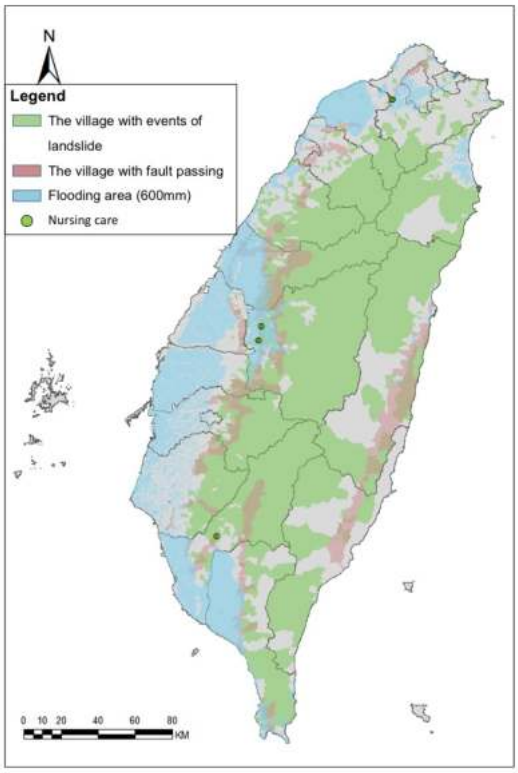

Figure 10. The distribution of institution and multiple disaster risk map

### 4.2.! Discussions

Overall, the enhancement of the function of elderly welfare institutions can su
medical resources. In addition, to strengthen the function of disaster preventi
about the selection for a location is as follows:

#### 4.2.1.! Location Guidance of elderly welfare institution

First of all, the location being selected should not be in a potential disaste
into consideration its feasibility as a shelter for the community. The authorit
should propose limitations and regulations for location selection in order to r
vulnerability of an institution.

#### 4.2.2.! The equipment for the mitigation of disaster in existing elderly

Regarding the distribution of existing elderly welfare institutions,
institutions are not in disaster potential areas. In other words, nea
institutions might suffer damage in the event of a disaster. While the ex
the institutions cannot prevent a hazard from striking, the institutions
structure of building and obtain equipment for the mitigation of disast
gates and ramps to improve disaster response.

!

### 4.2.3.! Special designs of elderly welfare institutions in a disaster pot

Since community-oriented elderly welfare institutions will be set up in disaste
the future, those institutions should enhance the function of disaster mitigation
Urban Planning Law and Building Code and Regulations. The special designs inclu
relatively low damage prone area as the location, setting water gates, and the
above two floors, which allows residents in the institutions to evacuate to the

### 4.2.4.! Multi-services of elderly welfare institutions

While the role of disaster response varies in different types of institutions, t
type institutions could increase the resiliency of the institution itself. For
institutions can adopt some elderly people able to take care of themselves,
education and relative training in response to disaster. When disaster strikes,
of the institution can help evacuate incompetent elderly people. Thus, the
institution does not completely rely on the staff, thereby increasing the ef
response.

## 5.! Conclusions

In this paper, the community-based services of elderly welfare institutions
regarding disaster mitigation in the aim of carrying out the spirit of ageing in
the facilities and caregiver allocations among the different categories of in
institution-based services can offer 24-hour care and medical assistance.
institutions in a community as the disaster mitigation core could provide outrea
pharmaceutical services and living facilities. This would reduce the vulnerabili
in the community. A neighbourhood elderly disaster shelter is particularly si
communities disconnected with outside. Community-based care can reduce the harm
environment in the face of disaster, instead of waiting for external rescue. On
community-based care network is built, it enhances the awareness of the residen
in coping with disaster while increasing the resilience of community. The resil
coexist with the disaster (Beatley, 1998) and implement the concept of resili
future, there will be a more in-depth discussion the cognitive role plays when f
a community within different kinds of institutions.

When responding to a disaster, institutions should be more open to the residents
and should strengthen the role of resistance to a disaster between institutions
resiliency of a community considers not only the old and spaces but also th
between individuals, institutions and community. In consequence, this paper ide
role institutions play in the face of disaster and proposed some suggestion
institutions use when policy making. On the whole, communities and institution
an intimate network of disaster response and mitigation under long-term car
enhances both of the resiliency of community and institutions at local level.

Keywords: Bottom-Up Regeneration, Planning, Mechanism, Local Actors, Songzhuang Art Village

## Abstract

This research discusses about the bottom-up regeneration process of Songzhuang Art Village in Beijing, China. As a typical but unusual development process in urban regeneration, Songzhu case shows the vitality of the local actors. The research includes three major issues. First is the study of the regeneration process of Songzhuang, in which the government-led top-down planning process and the local bottom-up development process are both discusses and compared. The second issue discuss is about the mechanism of such process. The last issue to discuss is the role of planning in the bottom-up regeneration process.

According to the research, Songzhuang s success relies on bottom-up regeneration rather than the top-down process. It is been discusses that such spontaneous growth path could have more actors involved, with dynamic local economy and opportunities for spatial restructuring.

Most importantly, the mechanism of Songzhuang s bottom-up regeneration process is composed by four key items: core actors (artists, villagers, and village government), extended actors (investment groups, marketing groups, and public services groups, etc.), conditions and catalysts (flow of people, capital, spaces, information, and policies), and reactions. All of these items contribute to the growth and prosperity of the art industry.

Finally, we look into the role of planning, in order to find out better approaches for planners when dealing with the cases like Songzhuang. To rethink planning strategies. To be aware of the emerging new economy, and to cooperate with local self-management principles.

This research could be helpful for gaining deeper understanding of Songzhuang Art Village, but also understand the general mechanism of similar cases. In a context of the rapid growing creative economy around the globe, such research seems crucial and necessary.

## 1 Introduction

### *1.1 Songzhuang Art Village and Art Villages in China*

Songzhuang Village locates in Tongzhou District, the east periphery area of Beijing. The distance between Songzhuang and east 5th ring road is 10 km of the city, with 26.4 km to the east 2nd ring road. Figure 1. Songzhuang Art Village. (a), Location of Songzhuang Village in Beijing shows the connection between Songzhuang Village and downtown Beijing.

Songzhuang Village covers a total area of 116 km$^2$, with 24.86 km$^2$ area been constructed, and more than 3.37 km$^2$ area, 13.6% in proportion, is considered to be the core zone of art village. Figure 1. Songzhuang Art Village. (b), Circumference of Songzhuang and Songzhuang Art Village shows the Area of Songzhuang Village, with the dark black parts representing the constructed area and the red part representing the Songzhuang Art Village.

The circumference of Songzhuang Art Village is blur. Though Songzhuang Village has much longer history, the art industry composes almost the whole part of Songzhuang s daily people usually use both Songzhuang and Songzhuang Art Village to represent suc specialized area by art industry, so it is with the following context.

Since the year 2005, Songzhuang became more popular in China for its artists community and art industry. Over 7,500 artists working in Songzhuang (Songzhuang Cultural and Creative Industry Cluster Management Committee, 2013), with the annual 3.10 billion dollars of contribution in GDP (FAN Lingzi, 2008). As the largest original art community in Asia, Songzhuang created a miracle not only for the prosperous art industry, but also for the bottom-up regeneration process in perspective of urban planning.

Many studies divide the development process of Songzhuang into three part, the agricultural development phase, the industrialization phase and the creative economy phase (JIANG Yifan, 2007). In our research, we studies such dual-approach, the top-down and bottom-up processes that assigned or applied in Songzhuang.

In recent years, art villages are commonly seen in several metropolitan cities in China. The common characteristics they share are the periphery location, the agglomeration of artists and the related art industries they bred. In 2009, Oriental Painters Village in Shanghai became the famous and larges painters community in Yangtze Delta Region (QIN Yuanyuan, 2011). Another famous one, is the Da Fen Village, known as the oil painting village in Shenzhen (ZHANG Kun, 2014). Besides Songzhuang, 798 is another crucial place for art industry in Beijing, many years ago (FAN Linzi, 2008). Considering the rise of the creative industry in China, places like Songzhuang are getting more popular (Michael Keane, 2006).

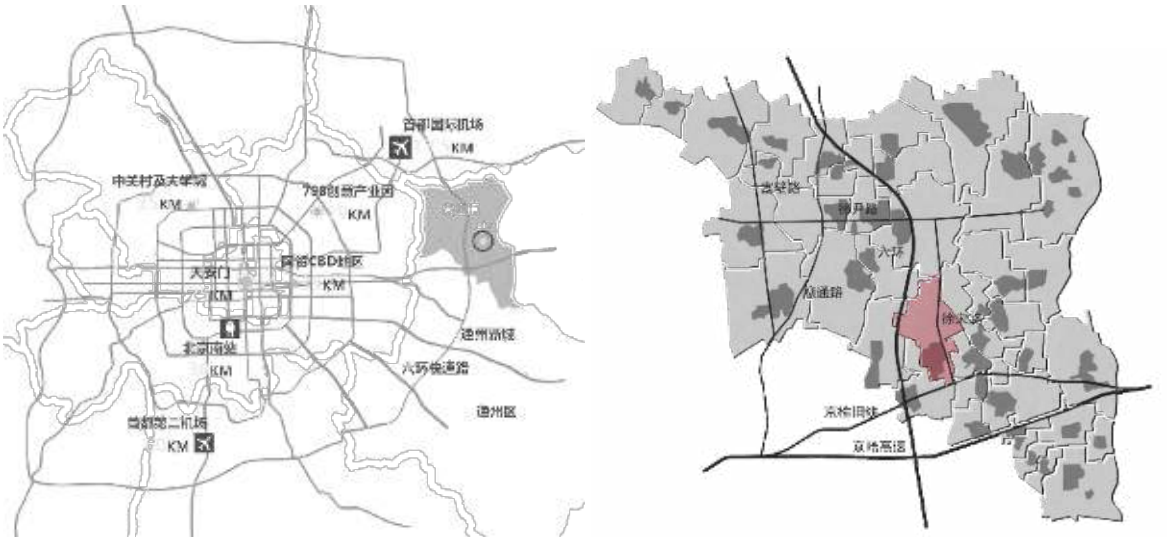

Figure 1. Songzhuang Art Village. (a), Location of Songzhuang Village in Beijing. (b), Circumference of Songzhuang and Songzhuang Art Village

### *1.2 Literature Review: Creative Class and Informal Urban Regeneration*

The term of creative class was studies due to the trigger transformation is caused by a group of artist, typical in creative class. Though some scholars call them new-industrial class (Michael Indergaard, 2009), the term of creative class is widely accepted. Richard Florida shall be men in this field, for his research on creative class around 2002. In his research, besides the normal groups of workers, creative class is a group of bring economic growth to countries that can attract its members (Richard Florida, 2002). This could well describe the process of artists group that gathered

and settled down in Songzhuang. However, the artists group in Songzhuang shows some extra characteristics, not only the specialized technics they have (Richard Florida, 2002).

We also concern about the process of places chosen. The special attractions that drive the creative class to agglomerate. Most of the scholars think such factors include the tolerant local policies and culture that allow the creative activities and economy to grow (KONG Jianhua, 2008). Florida raised the theory of 3T , Technology, Talents, Tolerance, and this Tolerance shows th that required. Moreover, some scholars believes the process of agglomeration is due to other characteristics, such as the native environment, and the stable rent value are the main factors (KONG Jianhua, 2007). Policies are playing a relatively important role in the whole process. Place-making strategies are very crucial (John Paul Catungal, etc., 2009). Florida pointed out that the competiveness of a country relies on the ability of motivate, attract and keep the creative class (Richard Florida, 2002), in other words, the public policies towards creative class will decide the fate of the country.

On the other hand, as the main focus of this research is on the process of bottom-up regeneration. How is the mechanism for such process? Songzhuang s bottom-up regeneration process could be described as a kind of informal development by local actors, since the actors are not the conventional ones from the top institute that we ve commonly seen in many urban development ca

Fran Tonkiss studied the informality in her book about the connection between the physical space and the unphysical society. She describes the informal development around the globe due to many reasons, though some of them are described as slums or jerry-built. However, there is still some good sides of informality (Fran Tonkiss, 2013). One of the positive side that been mentioned is a more effective way of dealing with the fragmentation of the land in periphery areas (ZHU Jieming, 2008). Moreover, the informal development usually implies such kind of social relationship that each members would receive the self-help from the community (Fran Tonkiss, 2013). Especially, she pointed out that the informal development in creative class shall be regarde informality (Fran Tonkiss, 2013). And such kind of informal space they created could even emerge new economy, as the term of system of production is used to describe such phenomen Scott, 2006).

In a word, combining with the literatures we had reviewed, not limited in the materials we listed above, and knowing the differences between creative communities, we think Songzh should be studied carefully and systematically. Therefore, we designed a structure for the research.

### *1.3 Research Structure*

The research studies both the development process of Songzhuang and then the mechanism of the process. In total, five major parts are related.

In the first part, the research discusses the failure of the government-led planning on Songzhuang, in which different roles were assigned, but never been realized or adopted by Songzhuang.

The second part discusses Songzhang in reality: with the bottom-up regeneration process that make Songzhuang a special art village.

Thirdly, we compare such assigned Top-down approach and the spontaneous bottom-up process from the perspective of social transform, economic transform and special transform.

In the fourth part, we discusses the mechanism of bottom-up regeneration, considering the case of Songzhuang. A structure consists of core actors, extended actors, conditions and catalysts, and the reactions is raised. And such abstract model for bottom-up regeneration process could be seen as the mechanism model for similar cases.

Finally, we pay attention to the role of planning in such process. The research discusses several principles that could make planning more effective in dealing with cases like Songzhuang.

## 2 Government-led Planning: Assigned Roles through Top-down Planning Process

### *2.1 Assigned Roles by Municipal Government*

Beijing is the capital city and the second largest city of China, acting as the political and cultural center through ages. Along with several eastern coastal cities like Shanghai, Guangzhou and Shenzhen, Beijing has long been the pioneer city benefiting the rapid urbanization process in last 37 years. However, the municipal government had made nearly mandatory decisions of previous planning programs and policies towards Songzhuang s role.

Our study reviews the planning programs and policies that interfered Songzhuang since 1957, summarizing their differences in the assigned role, authorized level, attitude to art village, etc. Tracing the planned development orientation for Songzhuang, the dominant idea is always the centre periphery principle. Table 1. The Assigned Role of Songzhuang from Official Planning and Policies Files displays such three kinds of functions assigned for Songzhuang during the years: manufactory zone, eco-protection zone or residential zone.

Table 1. The Assigned Role of Songzhuang from Official Planning and Policies Files

| *Original Art Industry Cluster* | Concept Plan for Songzhuang Creative Industrial Park | - | Town | *Art Industry* |

(Source: Urban planning files and Policies of Beijing (1991-2013))

### *2.2 Periphery Eco-Protection Zone: Restriction in Urban Development*

In 1957 edition of master plan of Beijing, the downtown city was the only part that been urbanized, while Datong County (Tongzhou District) was assigned as the assistant city (ZHAO Yanjing, 2004). Together, they formed a structure of the mother-satellite cities (Beijing City Construction Master Plan Proposal, 1957). In 1982, the number of satellite cities increased to 4. Those cities functioned as residential zones, including Tongzhou (Beijing City Construction Master Plan Drafts, 1982).

In 1993, in order to avoid such single-centred structure, the focus of urban development shifted to suburbs. 14 satellite cities were planned in the urban periphery. Till now, 11 out of the 14 satellite cities had developed into more integrated new towns, forming a belt around Beijing (ZHAO Yanjing, 2004). In the previous master plans, Songzhuang haven't been absorbed into the urbanizing area, therefore, it was assigned as a space for primitive agriculture region or eco-protection zone.

However, as the national political centre, downtown Beijing has always maintained a strong attraction (ZHAO Yanjing, 2004). Such strong central structure integrate with a top-down

development tradition, Beijing s structure is similar to the prototype of the land-valu Alonso s theory. In other words, places like Songzhuang had no resource or opportunity for development before 1998.

### *2.3 Manufactory Dream: Attempts for Industrialization*

During 1998 to 2004, the de-industrialization policy of downtown Beijing advocated manufactory enterprises displace outward. Villages in periphery started to foster their own "industrial compound", not an exception for Songzhuang. In the next seven years, 122 industrial enterprises occupying 120 hectares of land which attracted migrant labors of more than 4,700 people (JIN Shiming, 2008).

However, in 2004, the restructuring of Beijing s industries required the periphery areas to adopt the de-industrialization policy either, for the excessive productivity would been expelled outside of Beijing, with low efficiency enterprises to close down. Soon as such proposal became a compulsory movement, "Industrial Compound Clean-up Movement", which put an end to Songzhuang s industrializing process.

However, by 2004, there were 173.33 hectares of industrial land in Songzhuang. Such abandoned industrial land became one of the priory problems confronting Songzhuang, as many villagers transformed their own homesteads into family workshops. During the industrial period, the untreated pollutants made rivers seriously polluted, while families turned farmlands into small production sites, which is now abandoned. As ecological spatial coverage gradually declined, large numbers of farmland been eroded.

However, the primitive accumulation providing premise for development in Songzhuang is also due to this period, though the environment was damaged.

### *2.4 Residential Zone: Affiliated Area of Tongzhou New City*

In 2004, according to the Beijing City Master Plan (2004-2020) , the city structure shifted to two axis- two belts- multi centres . Songzhuang was involved in one of the hot spot in development, the Tongzhou New City. Enacted in the same year, "Tongzhou New City Plan (2005-2020)" determined its comprehensive concern on service functions as well as cultural industry base, However, according to the plan, Songzhuang was assigned to be the residential area, with the main body of the villages were cleared up for the new city.

### *2.5 Start to Realize the Fact: Take Art Community into Account*

In 2005, Tongzhou New City regulatory detailed planning (district level) clarifies the development density and spatial of Tongzhou. Though it had taken Songzhuang Art Village into consideration, the land use function for Songzhuang still remained as eco-protection zone and residential area.

It is from the year of 2005, that the municipal government started to realize the existing and potential of Songzhuang Art Village. Beijing confirmed the creative and cultural industries as its pillar industries, batching the creative industrial park (Desmond Hui, 2006). In 2006, Songzhuang was confirmed as the first batch of 10 cultural and creative industry communities.

## 3 Songzhuang in Reality: The Process of Bottom-Up Regeneration

The urban regeneration of Songzhuang is a typical process of bottom-up regeneration by social, economic and spatial transformation. This process was triggered by the artists groups. Comparing to the process of top-down planning, the bottom-up approaches are coincidental, flexible but practical.

### *3.1 Beginning: Emergence of Artists Community*

In the year of 1993, the first artist from the downtown settled down in Songzhuang. In the following 2 years, a total number of more than 400 artists quickly gathered and started their careers.

In 1995, Yuanmingyuan Painters Village had been banned in the name of remaining the social order , most of 1114 freelance and artists of Yuanmingyuan Painters fled to Songzhuang. Among them were famous artist like FANG Lijun, YUE Minjun, Xianting, HUANG Yongyu. Prestigious figures attracted more artists to agglomerate in this village. In 1997, artists accomondationed in every natural village in this region.

### *3.2 Blooming: Rapid Development of Art Industry*

Due to the fact that the art industry in Songzhuang not only benefits the villagers and artists, but also enlighten other villages in Beijing to find proper ways for development. For this, Songzhuang was awarded one of the first pilot villages of Beijing new countryside planning in 2005 (Jin Shiming etc., 2008). Art industry gradually drew the official attention and turned into one of the leading development industries of Tongzhou.

The spontaneous growth of the artists community promoted the process of social, economic and spatial transformation. Art industrial park, art institutions grew rapidly. Only from 2005 to 2010, in Songzhuang, art galleries increased from 1 to 113, while art museum grew from 0 to 14. The total art production grew from 3,000 to 100,000 with the artist's studio increased from 300 to 4,500(Songzhuang Cultural and Creative Industry Cluster Management Committee, 2013).

## 4 Transformation: Spontaneous Bottom-Up Process VS. Assigned Top-Down Approach

As been put forehead, the regeneration of Songzhuang took place due to the spontaneous process that attracted actors and resources to gather, instead of the assigned Top-down approach. We started to compare the different process, in order to gain better understanding of how the local actors achieved the bottom-up regeneration in Songzhuang.

We compared such approaches, the top-down one and the bottom-up one from three aspects: social, economic and spatial transform.

### *4.1 Social Transform: Involving More Actors*

#### *4.1.1 The Increase of Actors in Urban Regeneration Process*

To distinguish from the actors like municipal government of Beijing or the district government of Tongzhou District. This research uses the term local actors to refer those actors who are as the vital entities of the bottom-up process of urban regeneration. For instance, artists, villagers, village government, organizations, investment groups, etc. In the mechanism part, we would define the characteristics and resources of the actors.

In the top-down process, the development remained stuck and homogeneity, manifesting the lack of basic public services, no lift in inhabitants living conditions and less social or cultural activities. This could be ascribed to the less actors involvement in the local agenda of development. As the city center occupied all the development resources, it seems difficult for Songzhuang to adopt a normal way to get resources from a top-down process.

However, from the bottom-up point of view, the art industry involved actors like the village government, villagers, etc., which also attracted actors like groups from the third sector, the investment companies, and other art related actors to join the process of regeneration in Songzhuang. In a word, it is the increasing in number and density of local actors, as well as the activities that resulted in the transform of economy and space consequently.

#### *4.1.2 Organization as an Actor to Support the Art Society*

In 2005, Songzhuang Art Promotion Association (SAPA) was founded. As the first NGO in Songzhuang servicing local artists and art institutions, SAPA set up the network for local artists, gaining the knowledge of the art community in general, as well as making plans for aiding artists in needs. Along with other associations, organizations and different level of government, SAPA have played a crucial role in art information sharing and cultural promotion.

Songzhuang Youth Entrepreneurship and Employment Service Centre (SYEESC) and Songzhuang Agglomeration Public Service Platform were established in 2010, with a clear goal of promoting employment locally and providing temporary housing, funds, supports and services. The target groups include not only the artiest, but also local villagers.

#### *4.1.3* Actors Influence on the Process

Local actors in Songzhuang showed a great influence on the process of regeneration. Figure 2. The Events Classified by Actors, 1992-2014 shows a significant attitude change of municipal government and town government, for the decisions are made more adopted for art industry development later on. However, the activities led by local actors became more impressive, as more local development affairs are managed by local actors. This figure also implies how the influence transfer from actors from the top to local actors, and how such cooperation emerged since 2005.

Another way to prove the increase of the local actors influence, is by looking into the social and cultural activities happing in Songzhuang. The creative events had led to consumptions and tourism. The nationwide largest and most influential art festival, Songzhuang Art Festival, generated. Such kind of art convention increased from 50 sessions in 2005 to 3,500 sessions in 2010, including 1,000 sessions of local exhibition, 2,000 of domestic ones, and 500 of international ones. The number of visitors also increased from 30,000 to 500,000 in 5 years as showed in Table 2. The Comparison of Art Convention between the Year 2005 and 2010.

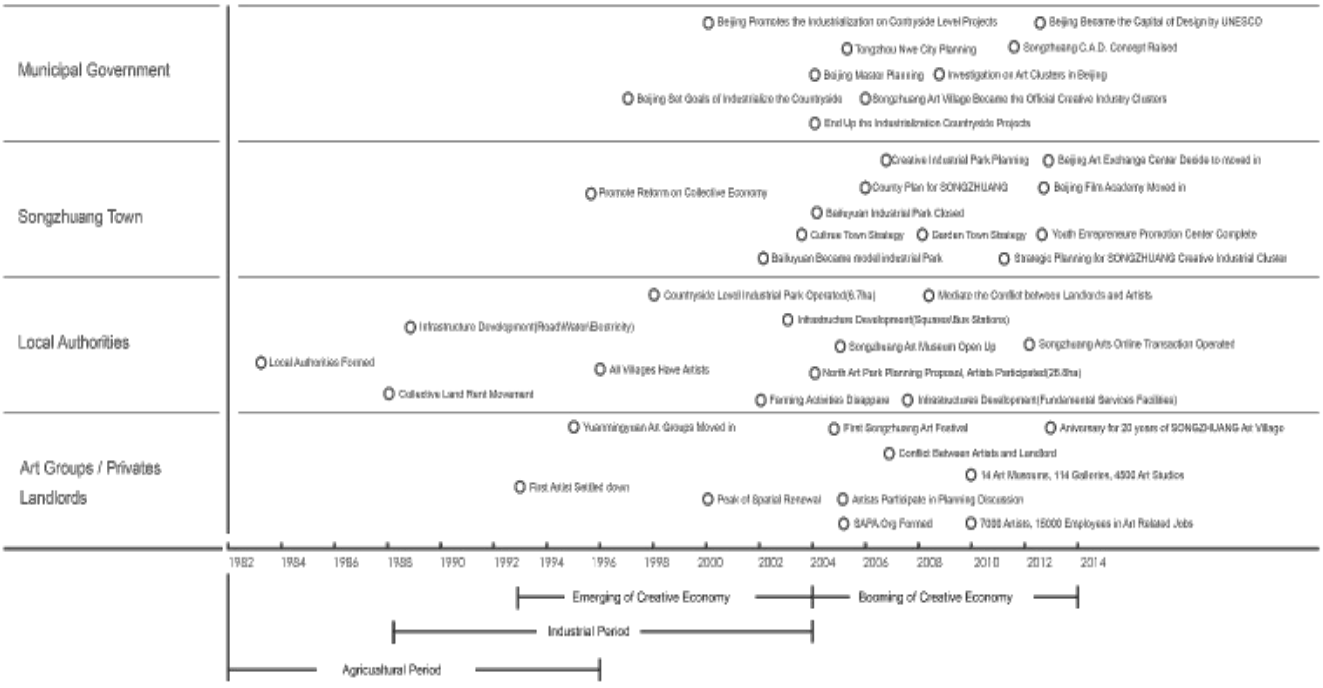

Figure 2. The Events Classified by Actors, 1992-2014

## *4.2 Economic Transform: From Periphery Manufactory to Art Industry Headquarter*

### *4.2.1 Manufactory as Failed Attempts but Primitive Accumulation*

Though the manufactory existed for a long period of time in Songzhuang, but in small scale and economic insignificant. Technically, the restriction of development in periphery areas had not changed until 1998. In 1998, the policy of promoting the industrial compound in periphery ar like Songzhuang was published. During that time, industrialization is regarded as a radical development. As respond to industrial compound , the top-down policy, the number of manufactor enterprises in Songzhuang grew to 122 in 2004, Songzhuang's main income were from those enterprises during that time.

Due to the low efficiency, low productivity, high cost of environment, serious industrial homogenization, intense competition, inconspicuous jobs increase and the policy changing from the top-down, Songzhuang s industrialization put to an end. This left polluted rivers and poisoned lan with only 70% (YANG Jiaqi, 2008) of land been eroded by construction activities (including the existing farm houses).

However, Songzhuang village government got the primitive accumulation for development. The capital form those manufactory enterprises provides premise for the attract art activities. It is also in this period of time, the infrastructures of the village had been improved a lot, both of the accessibility and individual mobility improved at the same time. Moreover, the connection between Songzhuang and downtown Beijing had been enhanced.

### *4.2.2 Art Industry from Spontaneous to Municipal Strategy*

It witnessed a rapid development of Songzhuang Art industry since the year 2005, not only attracting artists to settled down, but also created more than 1.5 million art related job opportunities. Artists' need for residence, creation, social interaction and marketing had been realized in those deserted sites or villagers houses. The industry compounds were turned into art workshops or small bars. Related investment summed up to 3.23 million dollars from local villagers and private investment groups (Songzhuang Cultural and Creative Industry Cluster Management Committee, 2013).

From a small artist agglomeration to a large art community, more art industry projects located in Songzhuang. Such market driven investment proved that the bottom-up regeneration process helped Songzhuang to earn more resources from outside, rather than from the municipality. The municipal government started to adjust its policies. In 2005, Tongzhou District set developing goal of Central Art District" for Songzhuang for the first time (Tongzhou New City Master Plan, 2006-2020).

By defining the community a success, the municipal government decided to remain the 55.7 hectares original art creation zone, with three state-invested projects for art exchange, convention and exhibition. The National Art Trade and Exhibition Complex, 29 hectare of construction area, 0.8

billion dollars of investment, the National Fashion and Creation Centre, 60.9 hectares, 4.85 billion dollars, and Beijing World Trade Art Centre, 23.8 hectares, 0.29 billion dollars (Songzhuang Cultural and Creative Industry Cluster Management Committee, 2013).

Although it is still under debating the impact of giant development on the protected original art creating zone, such attitude change from the municipal government and district government implied the potential of Songzhuang s art industry.

#### *4.2.3 Spill-over Effect of Art Industry*

The spill-over effect on increasing local villagers income is another benefits brought by the art industry. It was possible for both local villagers and immigrant workers to open up their business in Songzhuang. Villagers established galleries, restaurants and cafes, providing public services, and even running art schools. In that way, villagers are involved in this art industry.

In 2013, the average income of villagers in Songzhuang had rised to 6,462 dollars per year (Yang LIU, 2013), which matched the overall Beijing urban annual per capital income. Comparing to other periphery areas, of which people could only earn 2,908 dollars per year (Beijing StasticalYear Book, 2014), Songzhuang s bottom-up regeneration is quite a success from the point view of economy.

### *4.3 Spatial Transform: From Function Implant to Restructuring*

Before the year of 1998, to develop the rural land to other uses is restricted. The land use function for Songzhuang was implanted with either eco-protection zone, agriculture, industrial compound, or residential area. Eco-protection zone and agriculture zones belong to non-constructive land, which suppressed the possibility of economic activities in Songzhuang (Urban Land Use Classification and Standard of Planning and Construction GB50137-2011).

However, through the process of bottom-up transformation, artists could find and make use of a proper space. By trading with villagers privately, they could gain rights to use the land or houses for a relatively long time. This could be seen as the catalysts and premise for further spontaneous gathering of art related actors.

Meanwhile, it is the artists and art related actors, who brought about new functions and meanings at the beginning, along with the resources that could reform the space. The restructuring process of the land reactivated the power of spaces. New types of function, like the creation spaces, marketing spaces, exhibition spaces, art investment spaces, etc., are emerging in a short time.

Not only the type of functions that increased, but also the shared actors and their lease relations. In total, the type of spatial transformation could be concluded into five categories, according to the records of the survey in Songzhuang (Songzhuang Cultural and Creative Industry Cluster Management Committee, 2013). As Figure 3. Five Types of Land Transfer in Songzhuang shows such five types of land that been transferred into art industry use. The solid arrows imply the direction of rent activities, while the hollow arrow describes the reclamation of land. The term of Art related actors is used to describe actors like artists, art investment groups, etc. relationship with the industry.

Type 1, the land is owned by different villagers, which could be rent entirely or partially by art related actors. Type 2, the land is owned by villagers collectively but abandoned, which authorized the village government to handle daily affairs, could be rent directly or be built into art district and then rent to art related actors. Type 3, the land is owned by villagers collectively for industrial use, which is out of use now, could be rent by art related actors. Type 4, the land is owned by villagers collectively but already rent to manufactory enterprises. In the case of the manufactory enterprises would like to keep the land, they could rent the land to the art related actors in second hand. Type 5, the land is owned by villagers collectively. Given the fact that the current right of use belongs to the manufactory enterprises, in the case of the contracts between the villagers collective and enterprises are over, the land would be reclaimed and rent to the art related actors.

## 5 Mechanism of Bottom-up Urban Regeneration

### *5.1 Overall Structure*

Songzhuang Art Village is formed based on the resources exchange between villagers and artists. For the artists, through the exchange, they could get the space for art creation. For villagers, they could gain rents from the artists. Later on, as the village government joined the arena, they began to support more artists to settle down in Songzhuang. And they take the responsibility for mediation between villagers and artists. They regenerated the infrastructure for artists. Such three actors forms the basic relationship in the structure.

As the art industry grew bigger and more complex, diverted actors joined the arena. The art related actors in second phase and supporting actors in the third phase together complement the groups of actors in Songzhuang.

Besides the actors, the conditions and catalysts for the regeneration process is also crucial, along with the regulations derived from the self-managed local wisdom. Figure 4. Structure of Bottom-up Urban Regeneration Mechanism shows the whole structure of the mechanism.

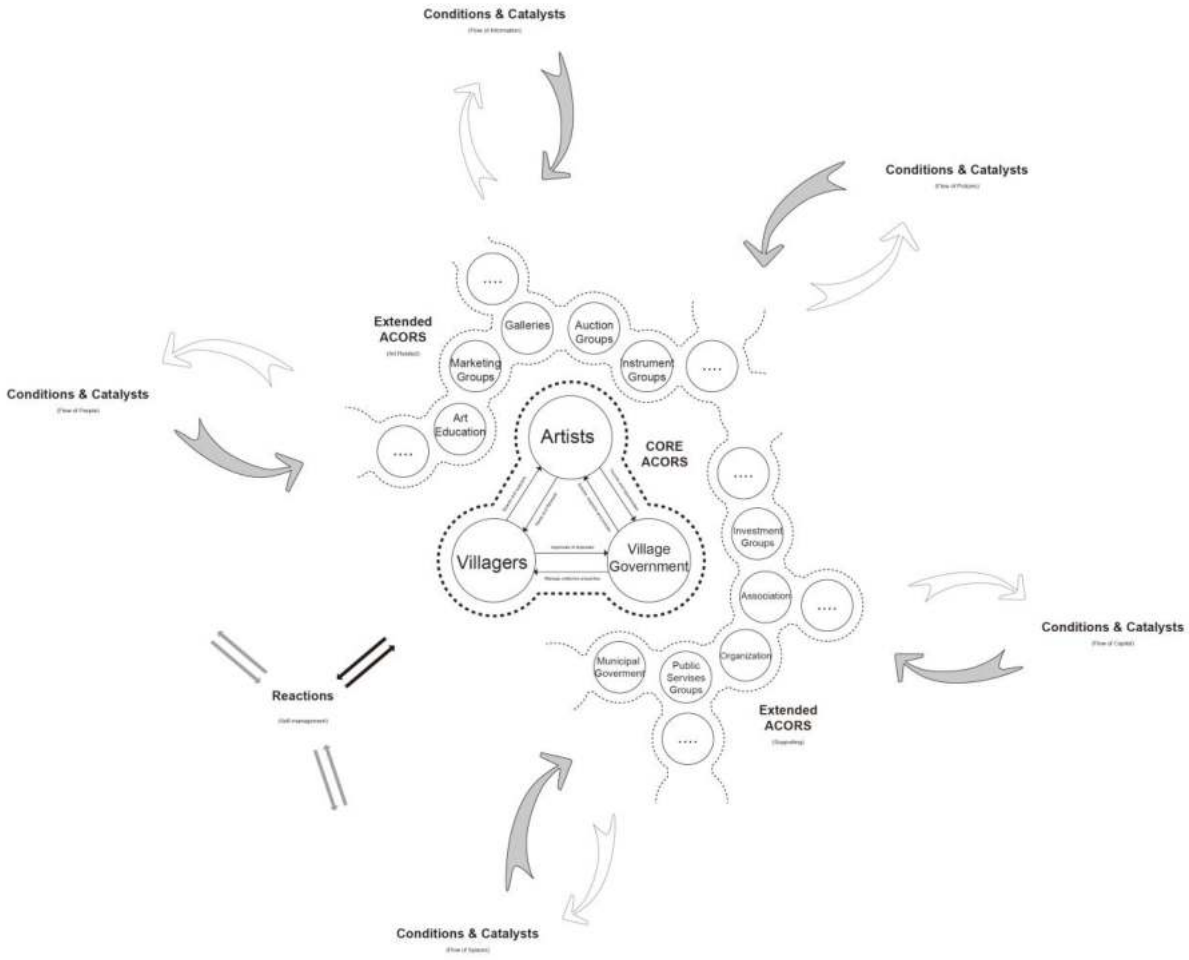

Figure 4. Structure of Bottom-up Urban Regeneration Mechanism

(Source: Information Based on Field Survey, Organized by YE Qiming, 2015)

## *5.2 Core Actors*

Three main actors from the bottom sector compose the core of such regeneration structure: artists, villagers and village government. They exchange the resources of what they have, for the goal of better art industry and better livelihood.

### *5.2.1 Artists*

For artists, they played the role of art creators, who attracted other art related actors to come. In that way, the prosperous art industry help the village government to gain more resources for lifting the living conditions for local groups. On the other hand, the artists will directly contribute to the rise in income of local villagers, by renting the land or houses. Artists also benefit to their own groups by establishing a professional network (J.ScottA.J., 2006), providing social networks for individual artist in or out of Songzhuang.

### *5.2.2 Villagers*

For villagers, who have the resources of individual land and also could collectively influence the results of dealing with collective land, play the role of supporting artists and the art industry. Villagers offer spaces, life necessities, opening up restaurants and bars, delivering materials for art creation. Later on, most of the functions are replaced by professional services groups. Anyhow, the spaces that provided by villagers are crucial.

#### *5.2.3 Village Government*

For village government, the most local level authority who keeps the resources of the collective land and primitive accumulations from the manufactory era. In Songzhuang s case, it i village government plays an active role in providing fundamental services, collective spaces and supporting policies for artists. On the other hand, village government done well in managing the land and sharing the profits to villagers, which earns the approval of further actions.

#### *5.2.4 Summary of Core Actors*

Over all, artists, villagers and village government in Songzhuang established a very efficient resource exchange rules and negotiating network form the very beginning of the transforming process. Such close interests links went tighter since the industry rapidly grew since 2005. Hence, the extended actors would invited into this system to seek opportunities in Songzhuang art industry.

### *5.3 Extended Actors*

In many studies, Songzhuang s developing process had been divided into sections according to the contribution of each economic sectors. However, from the point view of the mechanism, it is important to rethink the division according to the development path of art industry. In this research, we would like to regard this process as the growth of an organic entity, which consist of three major parts: the core actors primitive phase, the extension of art industry phase, and the supporting services phase. Thereore, besides the core actors, such art related actors and supporting actors are crucial in promoting the art industry to more comprehensive level.

#### *5.3.1 Art Related Actors*

Art related actors include marketing groups, galleries, auction groups, art education groups and art instrument manufactory enterprises, etc. Art related actors find their market, in Songzhuang, by the meantime contribute to the growth of art industry here.

Galleries groups are the first groups that followed by education and instrument manufactory. It is natural to know that since the industry chain extending, art industry is never only about art creation, but marketing, education and also the material supporting system for art creation.

#### *5.3.2 Supporting Actors*

If the roles of art related actors are crucial, then the roles that supporting actors play are necessary for art industry to survive. This large group with the aim of supporting the life system in Songzhuang includes the investment groups, organizations, associations, public services sectors, etc., as well as the municipal government later on. They provide capital, social help, food, leisure of life, exterior policy, etc.

Songzhuang s experience shows the hardware of the supporting system always come road, the public spaces, the internet, etc. Then, the software for supporting system, the supporting actors, would emerge naturally, as the art industry grows.

#### *5.3.3 Summary of Extended Actors*

Moreover, the art related actors and supporting actors work together to promote the industry more comprehensive and influenced. On the other hand, they helped reshape the core actors, as they could interfere the market and livelihood of Songzhuang. In that way, the core actors and the extended actors are interactive somehow.

### *5.4 Conditions and Catalysts: Five Mutative Flows*

As the trigger action of the process, it is easy to think that what kind of condition or what is the special characteristics that Songzhuang had to have attracted the artists while breeding the art industry. As Richard Florida stated, the most important factors that influence the creative class is Technology, Talent and Tolerance, which is widely known as 3T theory. He stresse elements are crucial to the creative class in the perspective of environment, mechanism and policies

(Richard Florida, 2002). Other scholars think that the knowledge, economy and spaces are highly relevant when referring to creative industry (Graeme Evans, 2009).

However, Based on the very fact that Songzhuang locates in the periphery area of Beijing, and the art industry is still growing. Unike those creative places that are gentrified, Songzhuang even complicated. Given the fact of that, it is necessary to think completely the factors, not only constrained in the dimensions of 3T .

This conclusion is made also by comparing Songzhuang Art Village with SOHO Creative Cluster, New York, and 798 Art Districts, Beijing. As shows in Table 3. Comparison between Creative Communities: SOHO, 798, and Songzhuang, Songzhuang manifests more primitive characteristics with the still growing number of art related population, and the less relatively expensive rent cost, etc. Most importantly, Songzhuang remains the large ratio of art creation group. While in the other two cases, the major function of the space is marketing or exhibition in both of their last period of time. In other words, Songzhuang still keeps the primitive motivation.

In general, we think there are five flows that could influence the actors as well as the process of urban regeneration. Such five flows include: people, spaces, capital, information and policies. All the five flows formed not only the conditions that could explain the reason of attraction, but also in the state of mutative. Hence, each flow could be sensitive to another and comprehensively acting on the art industry and the process.

#### *5.4.1 Flow of People*

People is always the main factor in any regeneration process. And Beijing as the capital city of China, has many art schools and companies, with a long tradition of cultural and creative industry development in China. Young artists are attracted by such a network (J.ScottA.J., 2006) to come to the city to find a fortune. This provides premise for the gathering of artists in Songzhuang. On the other hand, it is the Artists nature to cluster and escape from the main stream that contribut formation of Songzhuang Art Village. In the point view of people as flow, Songzhuang s prosperous could largely credited to the constantly input of artists and the art related population.

Nevertheless, it is not the talents, as Florida put, that only matters, but the overall group with both good and bad ones. As Songzhuang s artists formed a structure of pyramid. The more you reached the top of art, the little number of masters there are. While, the bottom artists group is in a state of flux. Though cruel, such flux is essential to keep the artists group in good quality and fresh.

#### *5.4.2 Flow of Spaces*

Rent cost is the first characteristics of space. As the rent rose in centre Beijing 19 times in 1994 to 2012, while Songzhuang s rent just rose 6 times. Such rent is acceptable to most forms a positive conditions for artists and art related actors to agglomerate.

Convenience of transport comes secondly. Songzhuang is not far from the downtown Beijing, but not inside of the downtown city, not quite as usual as many other creative clusters around the globe (Thomas A Hutton, 2009). However, it is quite convenient to reach through public transportation and it is important to keep such convenience for both artists and people who would know about Songzhuang.

Native environment is the third characteristics of spaces. It is important for artists to be satisfied with such kind of situations (Trevor Barnes, 2009). Unlike urban environment, Songzhuang serves as a sanctuary, or paradise for artists. The rural life style inspire them to create more freely (KONG Jianhua, 2007). Once such condition gone, the attraction for artists would fade away.

However, as the spaces could be changed from time to time, artists and art related actors would react to such changes. And this always depends on how much degree it changes and how does that feel individually. It is some cases in Songzhuang that due to some contract conflict between villagers and artists (YANG Liu, 2009), some had chosen to leave. Also, this could happen when the environment turned more commercial, as showed in Table 3, the SOHO and 798 s case.

In a word, the flow of spaces describes a mutative Garden City for artists. St on the distances between reality and their dreams.

Table 3. Comparison between Creative Communities: SOHO, 798, and Songzhuang

| ***Factors*** | ***Parameters*** | ***SOHO*** | ***798*** | ***Songzhuang Art Village*** |
|---|---|---|---|---|
| | Located City | New York | Beijing | Beijing |
| ***Spatial Information*** | Area(ha) | 44 | 40 | 130 |
| | Distance to Downtown (km) | - | 6.7 | 10 |
| | Agglomerate Time | 1950 | 2001 | 1994 |
| ***Development Period*** | Boom Time | 1960 | 2005 | 2006 |
| | Decline Time | 2000 | 2010 | - |
| | Local Residents | 6,541 | 0 | 1,500 |
| | Artists Number (Peak) | 5,000 | 2,000 | 7,000 |
| ***Demographic Information*** | Population Number (Peak) | 8,000 | 100 | 8,500 |
| | Employees Number (Peak) | 14,000 | 230 | 15,000 |
| | Artists Ratio of City (Peak) | 30% | 0.20% | 5% |
| | Galleries Number (Original) | 0 | 0 | 0 |
| ***Gallery Information*** | Galleries Number (Peak) | 300 | 207 | 113 |

| ***Rent Values*** | Current Rent (Dollars/$m^2$/a) | 55.8 | 5.8 | 0.9 |
| | Growth Multiples | 71.5 | 9.7 | 4.5 |

(Source: Multiple Source form Internet, Organized by YE Qiming, 2014)

#### *5.4.3 Flow of Capital*

In the process of urban regeneration of Songzhuang, one of the most important factor that drives the transformation is the capital flow. In the very beginning, Songzhuang got the first real capital flow through the manufactory period. This primitive accumulation was crucial for village government to upgrade the infrastructures. For that reason, the accessibility, mobility and the living conditions could reached the criteria of the first arriving artist group.

The second capital flow is the money artists brought to Songzhuang for space regeneration. They rent the land or houses for a relatively long time, and renewal the space according to the agreement with the villagers or manufactory enterprises. Some of them even build their own houses with yards. Capitals make all the renewals possible, as Andy put: from art to culture economy (Andy C Pratt, 2009). And this also give opportunities for new business to start and new talents been found.

Thirdly, the capital flow was attracted by the value of art productions, as many investment enterprises and projects emerged in Songzhuang, the capital largely reshaped the structure of Songzhuang and also helped to form the market rule of art industry. Nevertheless, including the artists, the whole art industry never create capital flows, they manipulate the flow through the value of art productions and the rule of market. As Florida puts, the base for creative class is economy, as the creative class could transfer this into capital value (Richard Florida, 2002). Once the value faded, the flow would respond quickly.

#### *5.4.4 Flow of Information*

Florida believes that through the events planning and marketing, the information flow could broadcast the creativity through the network (Richard Florida, 2002). The power of information at the first stage spread from artist to artist, which delivered the message of Songzhuang would become a new paradise for art creation, a symbol and cultural highland (HU Xiaowu, 2012).

Therefore, the function of information is quite important. Not only as an information receiver, but also the generator, through the massive festivals, exhibitions and exchange activities, Songzhuang generated more information than the era of manufactory or agriculture, and soon became headquarter of art. And the products of art also communicate with the world by sharing the spirits and value of Songzhuang.

From the point view of the market, the information exchange could largely help the market find the right artists to support. For artists, it is easy to have more tunnels and choices to make themselves been found. Moreover, not only the actors would be influenced by that, but also other flows.

#### *5.4.5 Flow of Policies*

For the flow of policies, two dimensions should be mentioned, the first is the supervision and constrains from the government, and the second is the support policies from the government.

Comparing to the events that happens in downtown city in 2005, which the artists had to flee from Yuanmingyuan Painters Village, the governance environment is quite loose in Songzhuang. This is crucial, for the nature of artists is chasing freedom (YAN Changyuan, 2005), that they could express their disagreement even in some sensitive matters. Besides that, though the trading and rebuilding the rural land or houses is forbidden according to the law, somehow, as not the only case in Songzhuang, people could complete such exchange privately. As a blind region in supervision, the regeneration in Songzhuang could be that prosperous.

Secondly, as the top-down plans fail, the village government plays a very important role. It should be stressed that the `village government s` attitude towards the artists decided the emerging of the new economy. If the attitude were negative, the art industry would never appear. By supporting the art industry, village government are active in attracting investment in civic projects, negotiating among stakeholders, and appealing for privileges from top actors. The way they dealt with such affairs were quite smart, that most of the stakeholders were involved in the process rather than standing outside.

As many key urban policy actors continue to focus on developing strategic programmes and policies to boost creativity and economic growth (Rowland Atkinson, etc., 2009), it is important to know the influence of polices that could have on the art industry. Hence, if the policies were to change, the art industry would suffer. Till now, no signs show the change in policies. But some policies that would accelerate the commercialization of Songzhuang to a gentrified art marketing place like 798 and SOHO, dramatically changing the characteristics of the spaces flow for art creation, would certainly strike the industry.

### *5.5 Reactions: Principles of Self-management*

As the outcome of the reaction, the self-management are generated spontaneously. Confronting the crisis of the rising population in Songzhuang and the limited spatial, natural resources, along with the occasional conflicts for rents, several prestigious artists and the village government formed a group in charging of setting principles for Songzhuang, along with artists and villagers.

Such principles mainly constrains the construction activities that could do harm to the public spaces and environment of Songzhuang, on the other hand, it sets the limit for rent, in order to prevent the land owners driving up the rents. Other regulations like the projects with public concern should have a public hearing. Such kind of democratic action is the addition to democratic village collective institute combining with the art groups inside. In a word, the main idea of the principles is to involve more actors to get benefits from the industry. Such reaction is spontaneously generated from the bottom, which functions well so far.

By self-management, in 2005, Songzhuang Art Museum became the first projects that involves the local actors of Songzhuang, with the designers, the sponsors, art groups and village government mostly come from the local community. It is believed that Songzhuang Art Museum is not only the real start of the art industry, but also a symbol of successful self-management.

## 6 The Role of Planning

Considering the bottom-up regeneration, Songzhuang s case shows how the actors excha resources, establishing the industry step by step, and managing themselves in a smart way. On the other hand, the failure of the hypothesis from the top-down process proves that the any strategies ignore the local initiative would lose effectiveness. Hence, the question is for cases like Songzhuang, how planning could respond?

Though the top-down process fails in Songzhuang, however, in our point of view, the role of planning is still needed and even crucial in the future. The only matter is how we revise the attitude and be more inclusive in interfering the process in cases like that. It is important to switch the traditional planning models to the one that are more insightful, practical and flexible.

### *6.1 Rethink Planning Strategies*

First of all, to rethink planning strategies. Songzhuang s case witness how suc the municipal point of view lost effect on the local level especially in such periphery area. The reason of this is the ideology that planners usually adopted: centric-periphery structure, of which, it is usually natural to regard the downtown city as the most important part that takes the leading role in every aspect. It is not wrong, however, it would be easy for us to ignore the possibilities for development in areas like Songzhuang.

To rethink the strategies, it does not mean that the previous thoughts would be totally turned over. However, a more flexible strategies are needed in those less important areas . It is not for the sake of the development in those individual regions, but also to seek economic development opportunities for the entire city. The more flexible and diverted functions a city adopted, the more sustainable it would be (Jane Jacobs, 1970). Such adjustment in strategies could be quite crucial but also tough in technical, for the balance between constrain and flexibility.

### *6.2 Understand Better of Local Actors and Resources*

In the process of bottom-up regeneration of Songzhuang, the initiatives are created by local actors. The artists, villagers, and the village government act as the primitive core actors, which attracted more extended actors to agglomerate in Songzhuang. Such actors could been gathered and such process been managed only through the market-driven way, rather than the process from top-down.

On the other hand, the resources such as the flow of capital from the investment groups, the land resources of the individual or enterprises, the flexible and supporting policies from the village government, and the network of local community are something hard to define and been taken advantage of without a better understanding of the local situation. All of these resources are brought by local actors promoting the transform in a spontaneous way according to the mechanism we analysed before.

Hence, it is crucial for planners to define these local actors, including the core actors and the potential extended actors. Through the process of understanding the resources, planners could pay more attention to how to conduct those resources and integrate them in the process of planning. The cooperative way to take advantage of those resources could contribute to a better integration of planning and the local participation. On one hand, this could amend the strategies and orientations from the top, on the other hand, to have common goals with the local actors, gaining better the trust and cooperation.

### *6.3 Cooperate with Local Self-management Regulations*

To make planning more effective and practical in local context, it is better to understand the local regulations, for the local policies are the important knowledge to get (Lachlan Barber, 2014). First, in those areas with the bottom-up regeneration, the self-management should be learnt. Secondly, find the common interests shared by both self-management and the planning process to seek cooperation. For example, in Songzhuang s case, the self-management regulated the jerry-built (Fran Tonkiss 2013), which is also banned in the point view of planning institute. Then the cooperation could be bridged between local actors and planners. Besides that, planners could provide more effective solution to these matters.

Sometimes, it is needed to conduct in a cooperative way with the local actors. In case of there is some occasion that could not been dealt with through a self-management way, or there is some exterior projects needed to be implanted, then, the participatory process with local actors is necessary. Try to conduct and intervene the process by put the planners themselves as the stakeholders in the management process.

### *6.4 Summary: Smart Planning in Local Context*

In a word, it is required to have a better senses and insights for real local place, as well as for local development. Make flexible strategies to allow new economy and lifestyle to emerge, know better of the local actors, take better advantage of the resources, cooperate with local wisdoms, and participate in the process of self-management. Only in that way, planning could be accepted and practical in local context.

These should be regarded as the quality and responsibility for planners, in order to avoid ineffective top-down process, and to confront a more mutative planning environment.

## 7 Conclusion

As a typical example of bottom-up regeneration, Songzhuang s development implies the ineffective conventional top-down approach of planning, and also shows the energy of the bottom-up process by local actors.

The research studies both processes individually, and make a comparison eventually. By comparing of the assigned role of Songzhuang, the research discovers that through the spontaneous growth path,

more actors are involved, more powerful the local economy could be, and more chances to get restructured, from social, economic and spatial perspectives.

Most importantly, the research discovers the mechanism of bottom-up regeneration, considering Songzhuang as the case. The crucial part of the mechanism is the core actors, which consist of artists, villagers and village government. It is believed through the resources exchange among core actors that attracted more extended actors, such as investment groups, marketing groups, public services groups, organizations and associations, etc., to join the community. Besides the core actors and extended actors, five flows as the conditions and catalysts are important in the mechanism. The flows of people, spaces, capital, policies, and information are quite mutative, and influential in the process of regeneration. And it is such five flows that contribute to the growth of the art industry. Moreover, during the process of regeneration, local actors have developed a self-management principles, that promote the art industry and local community to develop sustainably.

Finally, we look into the role of planning, to find out better approaches for planners when dealing with the cases like Songzhuang. To rethink planning strategies and be aware of the emerging new economy in those areas, flexibility are called. To understand better of local actors and resources, in order to make plan more practical. To cooperate with local self-management principles that made by local actors, participating in the process and combing the planning wills with the appeals from local actors, could make the plan more acceptable.

## Acknowledgement

The research on Songzhuang Art Village started in 2013, in Beijing. Such topic had been deepened in different dimensions. Several groups are involved in this research. The special thanks shall give to professor TONG Ming, Professor WU Zhiqiang, Prof. BAO Xiaofeng. Meanwhile, we are also thankful for the cooperation among group members, Mr. ZHANG Ze, Miss. GUO Yuchen, Miss. LIU Yuan, Miss. ZHOU Mimi, and Miss. LI Xiang, etc.

## Territorial Cohesion in the Multi-Actor Arena

# Territorial Cohesion Planning Based on Multiple-Stakeholder Demand: A Case study of KDW Region in China

Kai Yao[1]

[1]A1 Studio 3, Shanghai Tongji Urban Planning & Design Institute，China, sehrfan@sina.com

## 1. Introduction

Since reform and opening, with the rapid progress of urbanization, Chinese cities gradually stepped into territorial cohesion stage. Under the pressure of decentralization and free market economic policies, the stakeholders of regional spatial is becoming diversification. The territorial cohesion has been into a multi-actor arena involving government, market and social individuals.

The paper studies a case-- Kuitun-Dushanzi-Wusu Territorial Cohesion Planning . KDW distr locates at Xinjiang Autonomous region in China. It is an important national petrochemical base. Due to historical reasons, the administrative division is complex there, involving several governments, central and local enterprises and many other stakeholders. Recent years, although the rapid development of the petrochemical industry, it brings up the extensive growth, homogeneous competition, local barriers and etc. It exerts serious threaten to the environment of the overall region as well.

Firstly, this paper analyzes the development demands from multi-interest stakeholders in KDW district. The Matrix was built to describe the different stakeholders demand regional spatial, industry and resource environment. Secondly, this paper analyzes the complex interest relationship exerted from multi-interest demanding and the external driving force exerted from territorial cohesion development. Finally, under the premise of guaranteeing the environment quality, the paper uses scenario planning and set three kinds of scenario: transforming petrochemical industry, reducing the production of petrochemical industry and continuing petrochemical industry. What s more, it simulates three scenarios, based on go implementation orientation, and explores the plan of regional integration.

## 1. Background of regional integration development in China

After reform and opening-up, with the rapid progress of urbanization, the traditional urban development mode within administrative territory cannot catch up with the pace of rapid-changingsituation any more. More and more Chinese cities have initiated the new development mode of regional integration. When the region enters the stage of integrativedevelopment, frequent, close and diversified interaction will be generated among different cities (Friedman 1966). Under the promotion of political decentralization and economic marketization, the stakeholders of regional space

are becoming diversified. Regional integration has developed into a gameof multi-Stakeholder, involving government, market and various social entities.

*1.1Decentralization promotes competition and cooperation among local governments*

The essence of China s economic reform is to promote economic development through opening and administrative decentralization. (QIAN Yingyi and Weingast, 1996) By sta system of tax distribution in 1994, decentralization has effectively stimulated the development enthusiasm of local governments. It makes local governments pay more attention to the growth of urban economy. Meanwhile, the corporatization characteristic of local governments becomes increasingly obvious.

In the decentralization system, under the drive of land-for-budget fiscal strategy, China s urban space expands rapidly. As a result, the distance among cities is reduced day by day, the externality of spatial economy becomes increasingly prominent, and competition among local governments is hastened. On the other hand, resources of different level oflocal governments are limited, and administrative territory cannot be adjusted in a short term. Therefore, regional cooperation is required among the local governments.

*1.2 Marketization drives integrative development of multiple parties*

With the transformation from planned economy to market economy in China, free site selection of enterprises becomes possible. With the reform of household registration system, cross-regional population migration has already become a normal state. The increase of population mobility means the possibility of selecting residence and working place according to the market price mechanism. Under the stimulation of regional traffic improvement, inter-district development of regional integration is promoted through the market-oriented action of voting with feet .

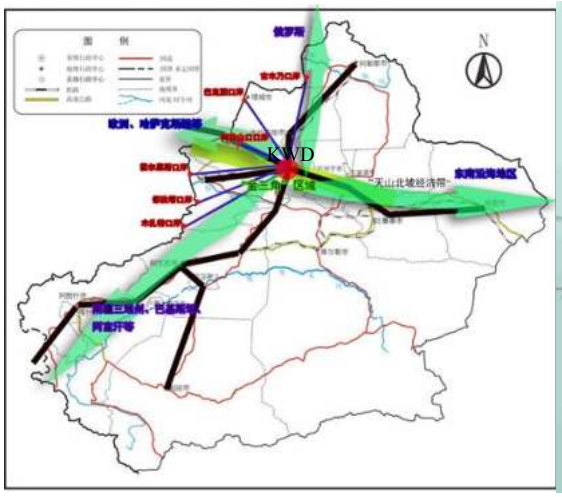
**2. Foundation for competition among multiple stakeholders**

In this paper, the research on regional integration is conducted by a case study of KDW region. This region is an important petrochemical industry base in China, and its economy grows rapidly in recent years. However, local barriers, extensive growth, and homogeneous competition are formed gradually in the development process. As a result, the environment of the overall region is severely threatened. Therefore, regional integration planning is urgently required to standardize development of local governments and promote positive, orderly and sustainable urbanization.

*2.1 Location and historical development*

Including three adjacent cities of Kuitun, Dushanzi and Wusu, KDW region is located in the middle of Xinjiang Uygur Autonomous Region of China. It is an important node on Silk Road

Economic Belt and international energy channel. This region was the nomadic place of Mongolia Oyiradtribe at ancient times. Qing Government established Wusu county system here in 1761 and garrisoned this place. In 1897, petroleum was found in Dushanzi in the southeast of this region, and mine area was formed later. After liberation, the 7th Division Headquarter of Xinjiang Production and Construction Corps (XPCC) migrated to Kuitun in the northeast of this region in 1957. At that time, urban construction was started. In 1958, Dushanzi Mine Area was separated from Wusu County and managed by the newly founded petrochemical industry city, Karamay City. In 1975, Kuitun was separated from Wusu County and Kuitun City was established. In 1996, Wusu County was changed into Wusu City.



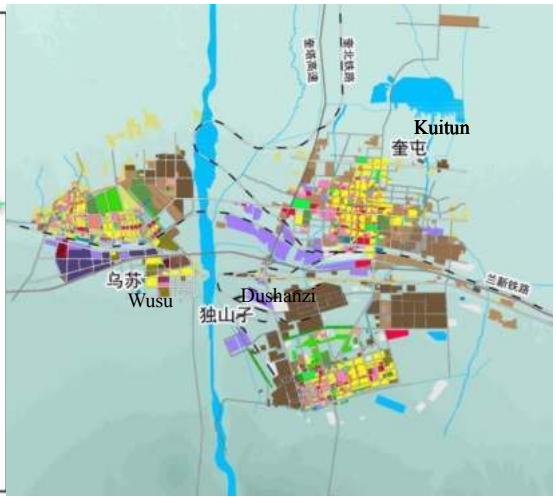


Fig. 1 Location of KDWFig. 2 Current situation about regional space of KDW

*2.2 Complicated administrative and governance system*

Due to historical reasons, the administrative system of KDW is quite complicated. Besides the three cities, it also covers multiple stakeholders such as the large-scale national enterprise Dushanzi Petrochemical Corporation of PetroChina Company Limited, XPCC and Tia District . Among them, Kuitun is the city of XPCC. Joint development will be conducted between it and XPCC for a long time and it represents the development demand and interest of XPCC to some extent. Dushanzi continues the management mode of unifying government and enterprises in planned economy period and represents the development demand and interest of central enterprises to some extent. In the population of Wusu, ethnic minorities occupy a high proportion (36.7% in 2013), and it represents the development demand and interest of minority autonomous regions to some extent.

**3. Challenges faced by competition among multiple stakeholders**

*3.1 Industrial isomorphism and repeated construction*

Processingpetroleum resources has created alike industrial structuresin this region. In 2013, the location quotient of petroleum processing industry in KDW region reached 3.52 in Sinkiang, while the location quotient of other industries was below 0.6,which reveals the fact of petroleum-processingis itspillar industry. In the past, Kuitun and Wusu had advantages in cotton spinning and featuredagricultural processing industries respectively, but these two regions begin to invest in petroleum refining industry construction by imitating Dushanzi in recent years. The phenomenon of industrial isomorphism and repeated construction is increasingly intensified. Almost all 6 industrial parks in KDW region treat petroleum refining as the leading industry. On the one hand, this is driven by the handsome profit of petroleum refining. On the other hand, the monopoly of Sino-Petro for petrochemical materials has controlled its pricing mechanism. As a result, Kuitun and Wusu were forced to make a fresh start and build their own industry systems. It is hard to form coordinatedupstream and downstream value-chain mechanism of petrochemical industry with differentiation in this region.

*3.2Extensive growth of urban land*

From 2006 to 2014, urban construction land of 93.4 square kilometers was newly increased in KDW region with rapid land expansion. On the contrast offast land expansion, the population growth is slow. From 2006 to 2014, the population was increased by only 217 thousand. Therefore, intensiveness of land utilization declines continuously. In this region (except Wusu), reserved land resources are severely insufficient. At present, relatively extensive urbanization is not sustainable.

*3.3Increase of ecological environment pressure*

Under the influence of wide inversion belt and high still wind frequency, diffusion conditions of atmospheric pollutants are poor in KDW region. Owing to the rapid expansion of upstreampetrochemical industries, the ambient air quality in this region declines year by year. From 2009 to 2013, the days of good atmospheric environment decreased by 12%, especially in Kuitun which is located in the downwind direction. The amount of coal quantity in winter will rise in this region, so the major atmospheric pollutants have exceeded corresponding national standards.

## 4. Analysis on multiple demands of various stakeholders

One Belt And One Road Strategy proposes that the unique regional advantages of Sinkiang should be expressed and Silk Road Economic Belt must be promoted. As a result, KDW region has developed into a hot spot of national and Sinkiang development in a short time. Resource conditions of the three cities are different. Kuitun has population and service advantages, but it is located in the downwind direction. Dushanzi possesses advantages of petrochemical industry base,

but its service support is insufficient and the space is limited. Wusu is equipped with advantages of space resources, but its industry development lags behind and the population congregationis insufficient. Faced with the same development opportunity, the three places have demands of both competition and cooperation.

### **4.1** *Industrialdemands*

Dushanzi is the site where large-scale national petrochemical enterprises are located, so its major development demand is to consolidate and expand petroleum refining capacity. With talent and service advantages, major development demand of Kuitun is to developemerging industries like downstream petrochemical industry and equipment manufacturing industry. At the same time, Kuitun possesses advantages in service industry like trade and logistics. Industry development lags behind in Wusu, but its space is huge. Therefore, development of petrochemical industry with high profit is naturally set as the major development demand. Besides, its late-mover advantage in service industry is also obvious.

### *4.2Spatialdemand*

Limited space in Dushanzi has severely restricted the expansion of petrochemical production capacity. Therefore, it hopes to develop Kui-dong (east of Kuitun) region under the cooperation with Kuitun and expand its development space. Kuitun needs to keep a distance fromDushanzi in space, so as to prevent petrochemical pollution. Meanwhile, it plans to exploitKui-bei (north of Kuitun) and Kui-dong (east of Kuitun) regions which are far away from the downtown, so as to develop emerging industries. With a huge space in the south and north, Wusu hopes to develop the north region and promote petrochemical industry as well as to develop the south region and turn it into the new carrier of regional service agglomeration.

### *4.3 Environmental demand*

Kuitun is in aunfavorable downwind and downstream geographic position, and its requirement for environment is quite urgent. It requires both Dushanzi and Wusu to reduce pollution of atmospheric environment and water environment. Dushanzi and Wusu require each other to reduce pollution for them.

Table 1 Demand matrix ofregional integration development in Kuitun, Dushanzi and Wusu

| | Kuitun | Dushanzi | Wusu |
|---|---|---|---|
| Strength | High population; concentrated service | Upwind direction; good industrial base | Upstream of water source; huge space |

| | | | |
|---|---|---|---|
| | facilities | | |
| Weakness | Downwind direction; downstream; under great influence of pollution | Limited space | Low population; low economic level |
| Industry demand | To develop emerging industries and service industry; to develop downstream chemical industry under the support of petrochemical industry in Dushanzi | To expand petroleum refining capacity | To develop multiple industry system dominated by petrochemical industry and to perfect service industry |
| Space demand | To develop Kuibei and Kuidong regions and promote emerging industries | Hope to develop Kuidong region together with Kuitun and expand the development space | To develop the north region and promote petrochemical industry; to develop the south region and turn it into the new carrier of regional service agglomeration |
| Environment demand | Require Dushanzi in the upwind direction to reduce atmospheric pollution and Wusu in the upstream to reduce water pollution | Require Wusu in the upstream to reduce water pollution | Require Dushanzi to reduce atmospheric pollution |

## 5. Scenario analysis on regional integration under multiple demands of various stakeholders

Regional integration development involves multiple stakeholders and the external environment has great uncertainty. Therefore, it is necessary to introduce scenario planning into regional integration in KDW. Different from the traditional one-way and rigid planning thought, scenario planning puts forward multiple scenariosthrough setting scenario elements and premises. It tries to simulate multiple scenarios, carry out evaluation, and provide intellectual support for development decision-making.

### *5.1Scenario elements and scenario premises*

The core issue of KDW region is the relation among industry development, space and environment. Therefore, major scenario elements cover industry, space and environment.

KDW region is still at the stage of resource driving development, and positive externality of economy is formed due to the rich petroleum resources and large-scale petrochemical enterprises in Dushanzi. Meanwhile, there is a lack of necessary supervision means and transaction rules. Moreover, excess emission of pollutants is the concentrated reflection of negative economic externality. Therefore, scenario premise of regional integration development in KDW is to adopt the same technical measures of energy-saving and emission reduction for pollutant enterprises on the basis of a uniform development bottom line (bottom line of atmospheric pollutantemission). At the same time, different scenarios must be established on the system of combining the government with the market. Either simple government intervention or laissez-faire market is undesirable.

*5.2 Scenario scheme*

5.2.1 Scenario 1: Transformation and comprehensive elimination of pollution

The current situation where upstream petrochemical industries take up a dominant position should be comprehensively changed by grasping the opportunity of national economic transition and relying on the construction of Silk Road Economic Belt. Petroleum refining projects under planning should be stopped immediately and existprojects must be relocatedto external regions gradually. Replacement with equipment manufacturing and modern service industry should be reachedstep by step. The upstream petrochemical production capacity must decrease by 50% till 2030. In this way, substantial elimination of pollution sources will be realized.

5.2.2 Scenario 2: Optimization and moderate elimination of pollution

The development foundation of the existing petrochemical industry should be consolidated, and petroleum refining industry must be positively guided to develop toward the direction of downstream fine chemical engineering. Thethreshold of industry project development can be set up, and petroleum refining projects with a total investment amount of less than RMB 500 million Yuan should be relocatedto outside regions gradually.Upstream petrochemical production capacity must decrease by 20% till 2030. In this way, elimination of some pollution sources will be realized.

5.2.3 Scenario 3: Continuity and control for newly increased pollution

The existing development trend of petrochemical industry should be continued. Production capacity of large-scale petrochemical projects must be expanded and small-scale petroleum refining projects should be controlled. The newly increased pollution sources must be controlled effectively in the aspect of environmental protection.

*5.3 Scenario simulation*

5.3.1 Simulation of scenario 1

Economic industry: Due to the large range of industrial adjustment and transition, economic growth in recent period will slow down. However, after 2020, a new round of rapid growth will be realized. The economic aggregate in 2030 will be 4.2 times more than that during the current period, and proportion of the tertiary industry will increase from 23% to 42%.

Population and land use: Development of modern service industry and new-pattern industries will boost employment, vigorateurbanization of local regions and attractlabor force outside the region. By estimating the employment posts based on the industry scenario, urban population in 2030 will double the current situation. With adjustment for industrial structure and decrease of land occupation demand, growth of land use will slow down and construction land index percapita will be reduced substantially when compared with the current situation. Thus intensiveness and consolidation of landcan be realized.

Pollutant emission: Pollutant emission model is established according to industry development and capacity in various regions. As per the calculation results, the emission load of SO2, NOX, PM10 and VOCs in 2030 will decrease by 51.48%, 64.14%, 43.20%, and 57.80%.

5.3.2 Simulation of scenario 2

Economic industry: Due to moderate transition of industries, economic growth in the region is relatively gentle. The economic aggregate in 2030 will be 3.1 times more than that during the current period, and proportion of the tertiary industry will increase from 23% to 36%.

Population and land use: The employment posts will rise. The population urbanization demand of the region can be met and a few labor forces outside the region will be absorbed. By estimating the employment posts based on the industry scenario, urban population in 2030 will increase by 40% when compared with the current situation. Construction land index percapita will be reduced to some extent.

Pollutant emission: The emission load of SO2, NOX, PM10 and VOCs in 2030 will decrease by 33.89%, 48.15%, 19.84%, and 13.90%.

5.3.3 Simulation of scenario 3

Economic industry: It is still dominated by traditional competitive industries. In recent period, the economy will grow rapidly and the growth will slow down during a long term. The economic aggregate in 2030 will be 3.0 times more than that during the current period, and proportion of the tertiary industry will increase from 23% to 30%.

Population and land use: The employment posts provided by the industry system dominated by upstream petrochemical industry are limited. By estimating the employment posts based on the

industry scenario, urban population in 2030 will increase by 10% when compared with the current situation. Construction land index percapita will rise substantially.

Pollutant emission: The emission load of SO2, NOX, PM10 and VOCs in 2030 will rise by 14.57%, 4.29%, 35.14%, and 22.30%.

*5.4Scenario assessment*

Scenario assessment is conducted from two aspects: (1) to evaluate whether different schemes can promote economic development & prosperity, intensiveness and high efficiency of landland usage, and improvement of environmental quality by directing at the development objectives; (2) to evaluate from the aspects of implementation cost and transaction cost by directing at planning implementation. Meanwhile, due to the existence of multiple stakeholders, operation of any scenario will affect various stakeholders. From the angle of welfare economics, KDW region has already broken the critical point of Pareto Optimality and Karldor-Hicks efficiency is more acceptable. If a reform is enough to make the beneficiary s income compensat party s loss, such reform is called Karldor-Hicks efficiency. According to the standards of Pareto Optimality, in multiple subjects, the reform cannot be continued once one subject is damaged. However, according to Karldor-Hicks efficiency, the reform can be continued as long as the compensation transfer can increase income of the overall region. Therefore, Karldor-Hicks efficiency is an important standard of evaluating the possibility of scenario implementation.

Scenario 1: Ideal scheme; low implementation feasibility

Through comprehensive industrial transformation and elimination of pollution, economic development & prosperity, intensiveness and high efficiency of land and improvement of environmental quality can be promoted. Therefore, it is an ideal scheme under goal orientation. However, its implementation cost is high. Meanwhile, powerful administrative means of the government is required to advance relocation and adjustment of petrochemical production capacity. There is a lack of market cultivation, which goes against reduction of transaction cost.

Scenario 2: A feasible and implementable scheme suitable

Through moderate industrial transformation and effective control for pollution sources, it plays a positive role in economic development, spatial intensification and improvement of environmental quality. Meanwhile, the implementation cost is moderate. By giving consideration to the demands of three parties, it meets Karldor-Hicks efficiency.

Scenario 3: Breaking the bottom line; not recommended

Implementation cost of this scenario is low, but the environmental quality has broken the bottom line of ecology according to the simulation. Therefore, it is not recommended.

Table 2: A list for simulation of three scenarios

| | Goal orientation | | | Implementation orientation | | |
|---|---|---|---|---|---|---|
| Evaluation factor | Environmental dimension | Economic dimension | Spatial dimension | Economic cost | Transaction cost | Karldor-Hicks efficiency |
| | Emission load of SO2, NOX, PM10 and VOCs | Economic aggregate and growth rate | Changes of population and land density | Enterprise Relocation cost andopportunity cost of reducing capacity | Administrative intervention and marketization degree | Whether Karldor-Hicks efficiency is reached |
| Scenario 1 | Decrease by 51.48%, 64.14%, 43.20% and 57.80% | The economic aggregate is high; growth at the earlier stage is slow; growth during the later period is fast | Population rises rapidly, the density increases substantially, and the space is intensive | High | Strong administrative intervention is required, and the marketization degree is low | Yes |
| Scenario 2 | Decrease by 33.89%, 48.15%, 19.84% and 13.90% | The economic aggregate is high; growth is steady | Population rises moderately, the density increases, and the space is relatively intensive | Moderate | Administrative intervention of a certain degree is required, and the marketization degree is moderate | Yes |
| Scenario 3 | Rise by 14.57%, 4.29%, 35.14% and 22.30% | The economic aggregate is high; growth at the earlier stage is fast; growth during the later period tends to be gentle | Population rises slowly, the density decreases, and the space isextensive | Low | There is a lack of administrative intervention and market failure exists | No |

## 6. Conclusion

The case of KDW region represents the typical phenomenon of regional development when administrative intervention reduces and the imperfectmarket rule exists in the process of transformation from planned economy to market economy in China. In regional integration of multiple participants, scenario planning will provide effective schemes for decision-making under complicated and uncertain environment. According to the regional integration planning in KDW, key points of realizing multi-party regional integration are summarized. Firstly, based on uniform cognition about the bottom line of regional development, the game rule is formed and external effect is internalized. Secondly, effective compensation mechanism should be established by facing multiple stakeholders, Karldor-Hicks efficiency must be realized, and increase of overall benefit in the region should be promoted.

Keywords: fuzzy governance, revitalization policy, industrial land regeneration

## 1. INTRODUCTION

The package of measures to facilitate redevelopment and wholesale conversion of buildings (the revitalization policy ) came into operation in HK on 1 April 20 owners to apply for waivers at a nil fee for change of use of the existing buildings. Reg bottom-up revitalization enthusiasm, hard negotiation for all the owners of t building to agree the conversion, 26% of the applications withdrawn by applicants slow conversion process made the HK government worried.

The objective of this research is to explore fuzzy governance methods and opti revitalization policy at the operational level. Kwun Tong is chose as the typ research mainly consists of two parts. (i) Find problems: because of the scatte hard negotiations between owners restrict the wholesale conversion applicatio conversion procedures have strict structure restriction and make interior space modern needs. The regional supporting system is lack, such as parking and pedest Kwun Tong is supposed to be changed from an industrial district to a commercial d fuzzy governance methods: a) Three-layered fuzzy negotiation and after-compensat b) Individual floor conversion (such as ground floor); c) Flexible building c process for better spatial uses in the future; d) Regional planning guidance to benefit-oriented conversion in order to gain a double-track balance.

## 2. GENERAL REVITALIZATION POLICY AND IMPLEMENT RESULT

### 2.1policy of redevelopment and wholesale conversion

Measures To Encourage Redevelopment In Non-Industrial Zones: Allow lease modifi exchange for redevelopment at "pay for what you build" premium (i.e. based on th proposed development intensity) for redevelopment of industrial buildings situat zones.

Measures To Encourage Wholesale Conversion In "Industrial", "Other Specified Us And "Commercial" Zones: Owners may apply at a nil waiver fee for change in use existing industrial buildings during the lifetime of the building or until expi whichever is earlier.

### 2.2implement result

The package of measures to facilitate redevelopment and wholesale conversion of buildings (the revitalisation measures ) came into operation on 1 April 2010. shows the latest position with regard to the applications under the revitalisati

Table 1. Applications under the Revitalisation Measures (Position as at the en
Source: HK Development Bureau

| | Wholesale Conversion | Redevelopment | Total |
|---|---|---|---|
| Applications received | 133 | 21 | 154 |
| Approved | 91 | 17 | 108 |
| executed | 64 | 7 | 71 |
| pending execution | 6 | 4 | 10 |

| Under processing | 19 | 4 | 23 |
| Withdrawn by applicants during processing | 18 | 0 | 18 |
| Rejected due to not meeting the eligibility criteria | 5 | 0 | 5 |

For the applications for wholesale conversion approved by the Lands Department, located in Kwun Tong and Kwai Chung, and the major proposed new uses for the conve include office, eating place, shop and services, and hotel. For the approve redevelopment, they are situated mainly in Kwun Tong, Yau Tong, Cheung Sha Wan, and Wong Chuk Hang, and the proposed new uses after redevelopment include commercial and hotel.

Generally speaking, whether the wholesale conversion or the redevelopment is acc

## 3. FUZZY GOVERNANCE APPROACH TO WHOLESALE CONVERSION

### 3.1 case selection: Kwun Tong, Hong Kong

Site of the study involves 81 hectares of all kind of land. Among them, there a industrial land and 256 industrial buildings, 37 cases wholesale conversion applicat industrial buildings, including four multiple applications) and one case applications.

Figure 1. Site: Kwun Tong industrial area

From the view of land uses in 2010, 62.1% of industrial land, totalling 50.4 hec institutions, communities land follows, totalling 17.5 hectares, 21.6% ; relativel commercial land , accounting for 7.5 and 4.5 hectares respectively , accounting the remaining land for the road.

Figure 2. Land uses layout (M:industrial/ C:commercial/ G/IC:government/ C

3.2problems during wholesale conversion of industrial buildings

Firstly, according to statistics, within the scope of the study a total of 84 si buildings. Layered unit including 70 industrial buildings, 9 industrial / office warehouse and four vacant premises; and work with a number of owners of a total including 165 tiered units of industrial buildings, 6 Block industrial / office mix. Because of the scattered property rights, hard negotiations between owners conversion application

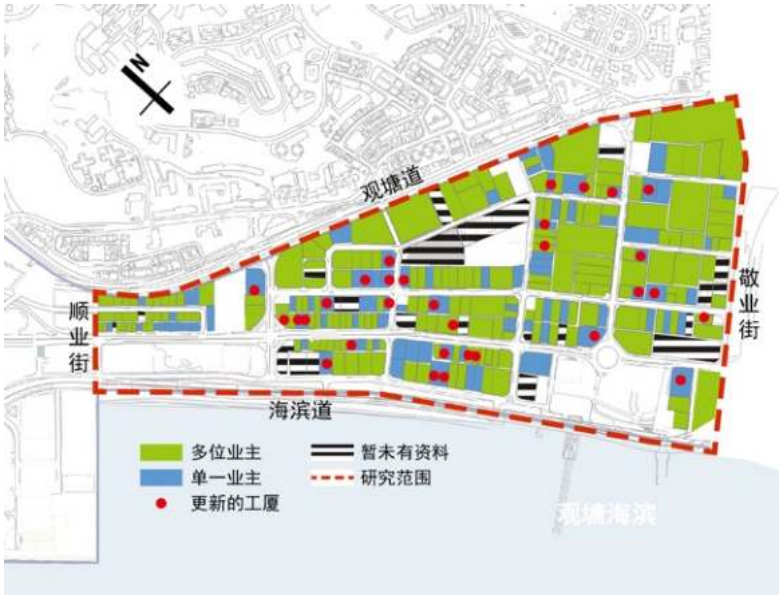

Figure 3. The relation between property rights (green: scattered right, blu right) and conversion implement (red dot)

Secondly, as we know, the height of the level during the industrial era is much h distribution is not flexible. During the research, a lot of the property right o

conversion procedures have strict structure restriction and make interior space modern needs.

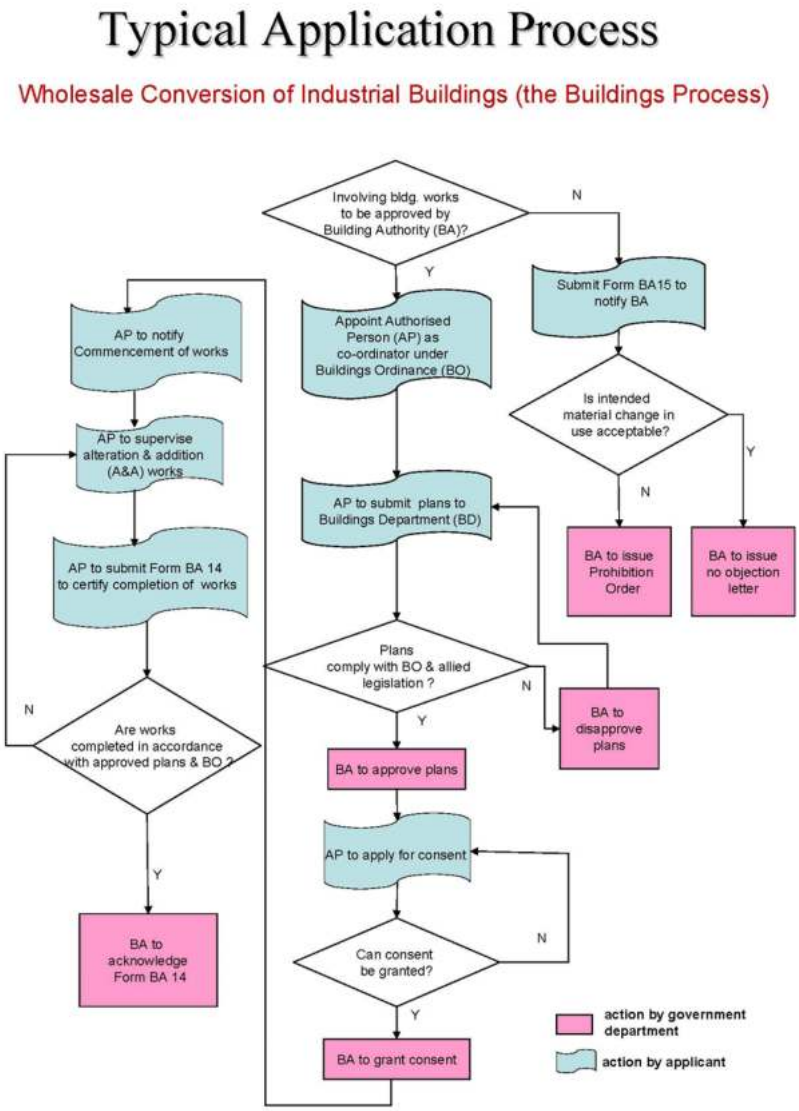

Figure 3. building application process in HK

Thirdly, HK Government did not make excessive interference in the planning, no s adjustment of land, simply set for industrial use to commercial alternative. The industrial building is independent and lack of co-ordination. So regional suppor such as parking and pedestrian bridge, when Kwun Tong is supposed to be changed district to a commercial district

3.3fuzzy governance methods

a) fuzzy negotiation and after-compensation mechanism

Firstly, it is after-compensation mechanism (for planned land property of the profit
the land compensation in accordance with the standard, the District Government
appropriate proportion from land-transferring fees and return it to the original
establish a special fund to encourage reinvestment in Kwon Tong.

Secondly, it is transfer payments (for planned land property of the non-profitable
detailed plan, a lot of land for public service facilities, green spaces and munici
these industrial land blocks, resulting in great economic pressure on the implement
encouraged to have transfer payments or package sell with planned land of the profit
level.

b) Individual floor conversion (such as ground floor)
A lot of conflicts occur because the owner of ground floor property want to have
the upper level right owners have lower interests. As a result, the conversion
according to the existing policy (100% supporting rate of the conversion). So,
individual floor conversion is suggested to solve this problem. However the co
tested by the Experimental permit is welcomed.

c) Flexible building conversion approval process for better spatial uses in the
Due to the flexible space distribution need of the modern company, if the polic
building conversion in the perspective of the structure, the outcome and fit to
satisfied. So such kind of restriction should be removed gradually.

d) Regional planning guidance to optimize bottom-up benefit-oriented conversion in
double-track balance.
Regional planning guidance is needed, such as parking and pedestrian bridge, whe
supposed to be changed from an industrial district to a commercial district.
oriented conversion can only accelerate the process of the renewal but lack of t
Up-bottom planning control is advised during the whole industrial land regenerati
track balance can be achieved.

## 4. Conclusions

As to the problems which HK government is facing and the difficulties during the
conversion of the industrial buildings, the following fuzzy governance methods a
fuzzy negotiation and after-compensation mechanism; b) Individual floor conversi
floor); c) Flexible building conversion approval process for better spatial uses

# The urban and environmental analysis of The Mokotowski Ventilation Corridor

Anna Malgorzata Jachimowicz, Warsaw University of Technology, Faculty of Geodesy and Cartography, Warsaw, Poland, a.m.jachimowicz@gmail.com

Martyna Wlodarczyk, Warsaw University of Technology, Faculty of Geodesy and Cartography, Warsaw, Poland, martyna.wlod@gmail.com

Keywords: Sustainability, Ventilation corridor,

## Abstract

*The Scientific Project made by the Student Scientific Association of Spatial Planning placed on Faculty of Geodesy and Cartography Warsaw University of Technology titled*: The urban an environmental analysis of The Mokotowski Ventilation Corridor . *The project focused on c many sided researchs and analysis indispensable to assess the actual impact of buildings in the corridor on air exchange system in its proximity.*

*Undertaken actions indicated the complexity of a problem with location buildings in open urban areas, which are at the same time significant elements of the ventilation system of Warsaw. All implemented analysis led to conclusion, that the buildings recently introduced into aforementioned ventilation corridor affect adversely air exchange, not only on the premises, but also in the areas adjacent. Students performed air flow simulations and shading analysis of the corridor region. Additionally, they conducted researchs to urban barriers. Moreover, students took into consederation Polish law regulations concerning buildings these sites impact of local statutory plans, zoning, buildings permits, agreement with developers for suitable improvements of analyzed area.*

*The final work is the concept of area development plan sitated in a fragment of the corridor. Plan is a proposition of proper land development, which does not interfere with the ventilation system and includes needs of local population.*

## The impact of variuos types of land use on city ventilation process, based on example of Mokotowski ventilation corridor

### 1. The reasons of current condition

Ventilation corridors are important elements of urban greenery system. They deliver clear air from suburbs to centre. Similar function is provided by wide streets and open airport areas, due to their lack of urban development. Ventilation corridors are characterized by fast and undisturbed airflow during windy weather.

In the last twenty years, which were the period of Polish political transformation, urban landscape has changed significantly. Process of transformation is thus far unaccomplished and it still provokes plenty of modifications. It is not only related to the urban planning. The concept of transformation

contains multiplicity of changes that took place in Poland since introduction a new, democratic political system in1989. These changes refer to economy, industry, society, democracy, and many other related domains. Urbanization is also included.

Urbanization is interpreted as a process of population concentration in certain points of geographical space, mostly in the cities. Along with liberalization of market, economy and industry from central planning, it became finally possible to start a private businesses and investments. As a result process of urbanization accelerated and changed its nature ultimately free from central planning. Open market attracted many developers who wanted to build new facilities, like multi-family houses, office buildings and shopping centres.

Lack of supervision over the use of land for construction purposes, caused by confusion in state and local government legislation, has led to chaotic and mostly thoughtless development of open areas in cities and in suburbs. Constant changes in legislation of construction, urban planning and environment impeded a proper supervision. It prevented uniform spatial planning, which is the responsibility of local government units. All mentioned factors led to urban disorder in Warsaw and reduction of green areas, whih ceased to be protected due to constant amendments and revisions of law.

## 2. The influence of green areas for city climate

The green areas in Warsaw are arranged in irregular system, which is characteristic of the remains of former palace garden units, protected areas or large forests. It is impossible to determined compact green areas system in spatial structure of the city. It is random and gradually decreases.

The Mokotowski ventilation corridor, which is the important part of Warsaw green areas system, has been protected for many years by the planning documents reffering to whole city area. This documents prevented the creation of new buildings on ventilation corridor area. In this way, city government tried to keep the free corridor to air exchange in the city. The main assemtion defined these places as areas of low buildings, green areas and sport areas. The main assumption was sustenance monocentral linear layout development.

In 1916 Prof. To wi ski prepared The sketch of the Regulatory Plan of Plan was placed the first conception about compact green area system. The main ventilation corridor supposed to be the Vistula River. Additional parts of this system are formed from green areas corridors or unbuilt areas e.g. railway areas. This planned green system survived communism period of time. In the 1995 year passed The Act on Protection of Agricultural and forest land. This kind of land use stopped be protected in this Act.

Figure 1: Extent of Mokotowski Ventilation Corridor.

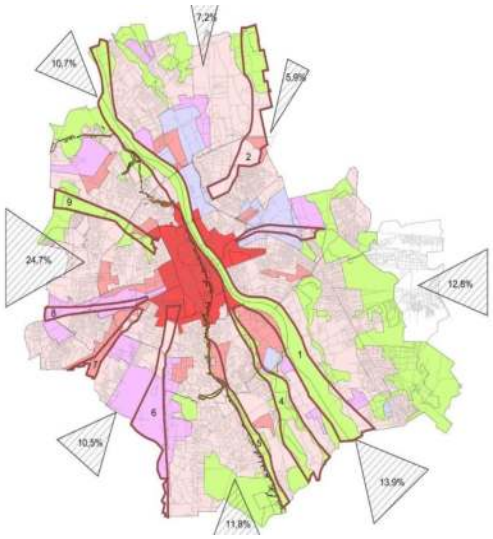

Figure 2: Urban ventilation corridor system in Warsaw

The attractiveness of undevelopment land become more important than city ventilation system in the period of capitalism. That procedure result of systematic reduction of ventilation corridors areas, which had an impact on the deteroration of health air condition. In Mokotowski ventilation corridor, on the biggest green areas was created new housing estates Marina Mokot w, Eko Park and Wi niowy Business Park.

The existance of green areas in the city is very important for air condition and local climate in the city. Green areas in the city are the areas, which are defined as air refinery . Clima the result of natural and anthropogenic factors. The second kind of factors can degrade climate. There are: the size of development area, the structure and building density, type of industry and pollution and the degree of interference in the environment. It is impossible to avoid these factors, because they are inextricably linked with the city. They are also cause the exsistence of phenomena as heat island. It occurs in places where the atmosphere gets a large amount of heat from energy and technological processes and the substrate absorbs the rediation of the sun. However, it should limit the impact of these factors to climate of the city. It can be done by designed of adjacent thermal surfaces and nonthermal green areas. The green areas should have linear shape and be in accordance with the prevailing wind directions, and layout development should include the topography and local angional air circulation.

The green purifies the air in the proces of photosynthesis and reduce the temperature and humidity of air. Planning the location of green areas in the whole city should be taken into account the characteristis of the wind: speed, direction and return. The green areas and development may be the barier for wind, which can loose its speed immediately on it. In that situation can be formed the phenomenon called nozzle and aerodynamic shadow. The aerodynamic shadow is that place, where the wind speed is very low. While in the aerodynamic nozzle, the wind speed increases rapidly. When the air mass enters the tunel, it begins to move with the direction of the tunel. Remember these specific behawior of wind it can be influenced on ventilation of the city and local climate.

## 3. Built impact on the climate of the city and wind flow

Wind fields modification on city area is determined by air pressure difference between city area and suburban area. The amended thermal conditions inside the city are generated local air circulation e.g. breeze. Higher temperature in city area creates local circulation with winds blowing to inside the city. The main factor causing this type of circulation, is change in the air temperature field inside and over the city.

The wind directions in the city are also generated by street layout. When the air circulation is powerless, which mostly happened in the evenings, the main streets allow air penetration from the outskirtes to city center.

The air flow in urban area depends on surface roughness. This index is calculated as item area projected on a plane to total area, multiplied by the average height of element. The city surface roughness increases thermal and mechanical turbulence, especially in the nights. The city surface reduces the local wind flow, when the winds speeds are high and strengthens the air flow during periods of weak regioanl winds.

Varied heights and building orientation cause certain effects in air flows. The air flow around and between buildings was recognized in researches in aerodynamic tunels.

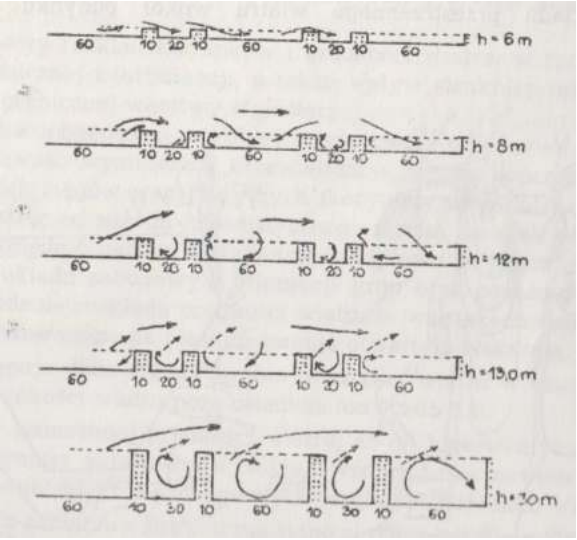

Figure 3: The air flow in urban area

Groups of the high building cause an increase in wind speed on the courtyards and wind flow over the buildings to next street canyon. Smaller courtyards cause wind deceleration on them, while massive blocks cause wind deceleration in adjacent streets. In wide streets canyons, the wind direction is parallel to street axis.

## 4. Land use structure of Mokotowski Urban Ventilation Corridor -the types and characteristics of individual areas

Mokotowski Urban Ventilation Corridor is located in four districts of Warsaw: Mokot w, Ursyn w, Italy, Ochota. Each of these districts has a different structure and form of land use. There are public facilities, numerous green spaces, allotments and all types of buildings: residential, office and brownfields. What is more, we are able to distinguish the production and service areas (5,3%) the areas with predominantly single-family housing (20.3 %), the areas with predominantly multi-family residential buildings (13.9 %), the areas of health services, science and administration (9.6 %), the areas of sport and recreation services (11.4% ) and the areas of services ( 39.5 %).

Therefore, it is hard to define the name of building system for the entire area of the urban ventilation corridor. There are built-up areas with modern office buildings, luxury apartments and little aesthetic industrial buildings or neglected multi-family residential buildings. Residential buildings are inscribed in a rectangular street layout. On this area dominated development of low buildings - 3-4 floors. There are also the 7- and 8 - storey blocks where at the lowest levels established services. A large group of buildings are a modern apartment and office buildings belonging to the settlements Marina Mokot w and Eco- Park. The area of Mokotowski ventilation corridor have got very well developed public transport network and the satisfactory condition of the roads and pavements. These housing estates are characterized by a clear urban layout.

The first settlement - Marina Mokot w is located entirely inside the air corridor. In the southern and central part of the settlement are located the highest 8- storey buildings. In the eastern part of the settlement the buildings are lower 2-3 storey. The average number of floors is 4.26 , and the rate of development intensity is 1.31. These parameters are accepted in local zoning plans.

The second of settlement EkoPark is characterized by higher rates than residential Marina Mokot w. The average number of storeys is 5.87 and the whole area of the project took the 18000 sqm. The rate of development intensity is 1.46. The whole project represents 10 residential quarters. The quarters are rectangular and adjacent to each other by longer sides . The quarters making the significant barrier aerodynamic, because they are a long string of buildings.

Green areas can be divided into: appointed green areas (27 % of all green areas) , greenery under a system of fortification nineteenth - century fortress Warsaw ( 2%), green forest ( 6%) and allotments (65 %). Among the appointed green areas we can distinguish The Pole Mokotowskie Park. This place is frequented by residents of Warsaw. It is a place of rest , relaxation, sport.

## 5. Frontal area index the method to show the buildings impact for the ventilation city system

The frontal area index is a method that is used to designate architectural barriers blocking the flow of air and determine the most probably ventilation paths between buildings. There are many opportunities to use this method in spatial planing, especially in urban areas. This method was used for the first time at the Technical Unversity in Hong Kong. The frontal index is calculated as the total area of building facets projected to plane normal facing the particular wind direction, diveded by the plane area. This relationship is shown in the following equation and figure:

$$f = Afacets/Aplane$$

gdzie:
f the frontal area index,
Afacets - the total area of building facets facing the wind direction,
Adzia ki the plane area.

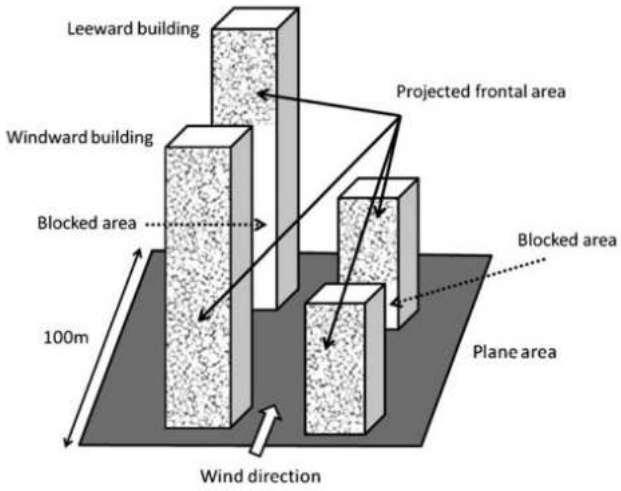

Figure 4: Graphical idea of frontal area index ratio

This method shows the influence of different landuse on city ventilation system. Analyzing the Mokotowski Ventilation Corridor, the frontal area index shows that development effects on the air flow through the Corridor area. Additionally, it was possible to visualize the air circulation through the Corridor before implementation of housing estates.

To show the differences in local air circulation, they were made two analyzes. The end result of this analysis was raster with grid cell of 100 m 100 m. Each pixel con index s value on this sguare plane.

The first analysis was based on Corridor s land use in 2002 year. At that time, th the airport (in the south) and service buildings (in the north of corridor) were the only clusters of the buildings in that area. It can be noticed that the frontal area index for the significant part of the study area was in the 0 0,017 interval, which is the low value. In this areas are also green areas e.g. parks, squares, cemetery.

The second analysis was made for data from the 2012 year. For ten years, investors have built housing development in the corridor area. The new development is low ( to 12 m) and medium high (12 25 m). The frontal area index has changed significantly for this areas. The new housing estates have built in the central part of ventilation corridor, which is also the narrowest part. Most of new buildings have got 12-25 metres high, so they are valid architectral barier, which locks air flow through the Corridor.

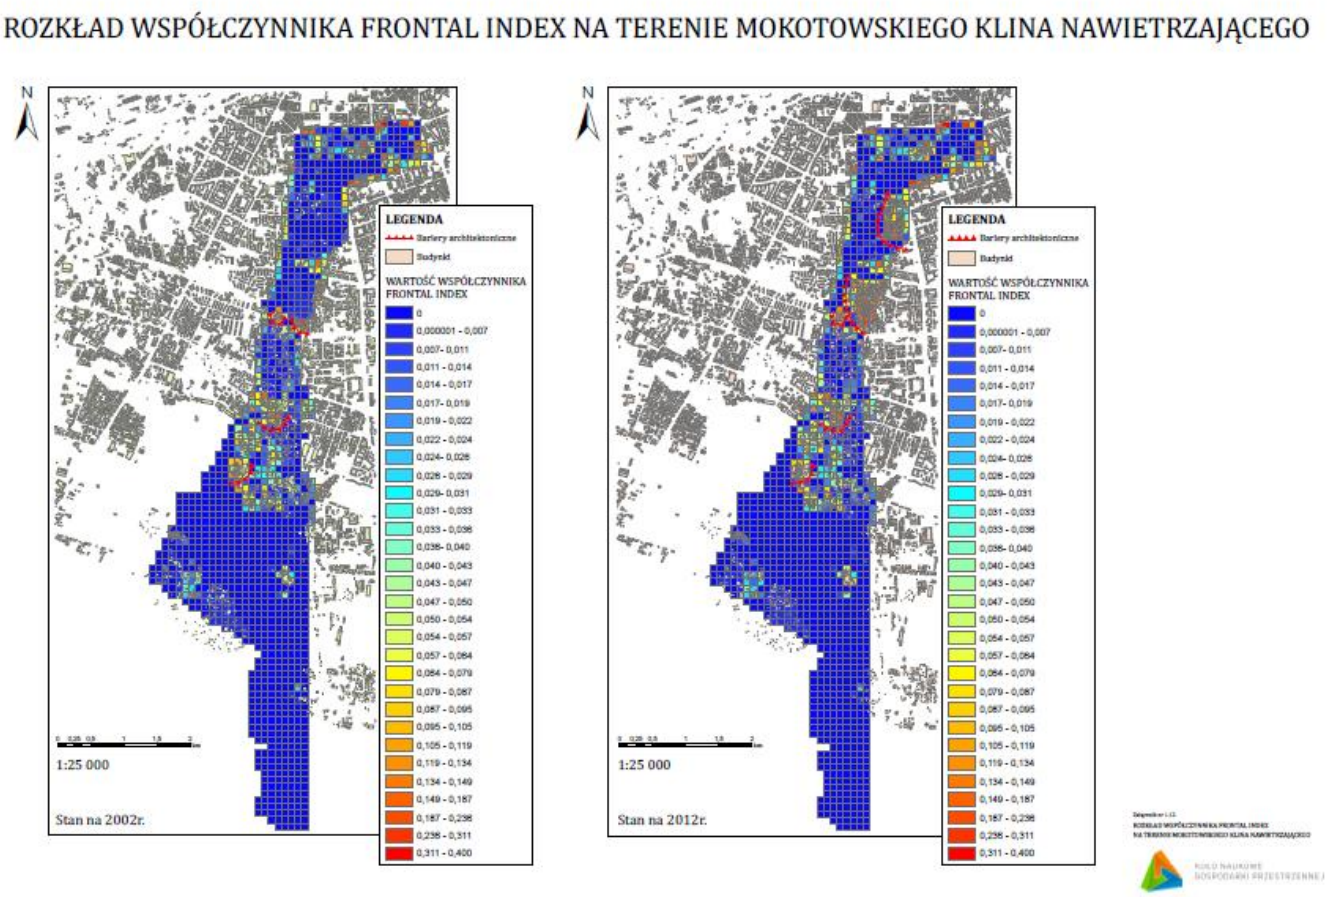

Figure 5 Distribution of frontal area index in Mokotowski Ventilation Corridor

## 6. The wind flow models for housing estates Marina Mokot w and Eko Park

The frontal index analysis confirmed the hypothesis that new housing estates are significant architectural barrier for air flow. The next analysis was made in the Autodesk In this application were made the wind flow models through the development areas. Using Vasari Application it was possible to mark aerodynamic shadows and nozzle in this areas, because in this programme it is necessary to input typical wind direction and wind speed.

The first model was made for Marina Mokot w estate. It can be noticed that south-western wind has got the same speed before the housing development. When the air flow hits on narrow spaces between buildings, the wind speed increases and formed an effect called aerody is not the predominant trend in this case. The housing estate constitutes the barier for wind flow, which is more observable. Group of buildings locks air flow and formed aerodyna north part of Marina Estate (navy blue in the figure). As a result of the estate construction is reduction in functionality of Mokotowski ventilation corridor.

The second analysis focused on Eko Park Estate model. As in the previous case the urban grid formed some places, in which we can observed aerodynamic nozzles and aerodynamic shadows. The second form is dominant trend, because the longer facades of buildings in this estate areperpendicualr to prevailing winds.

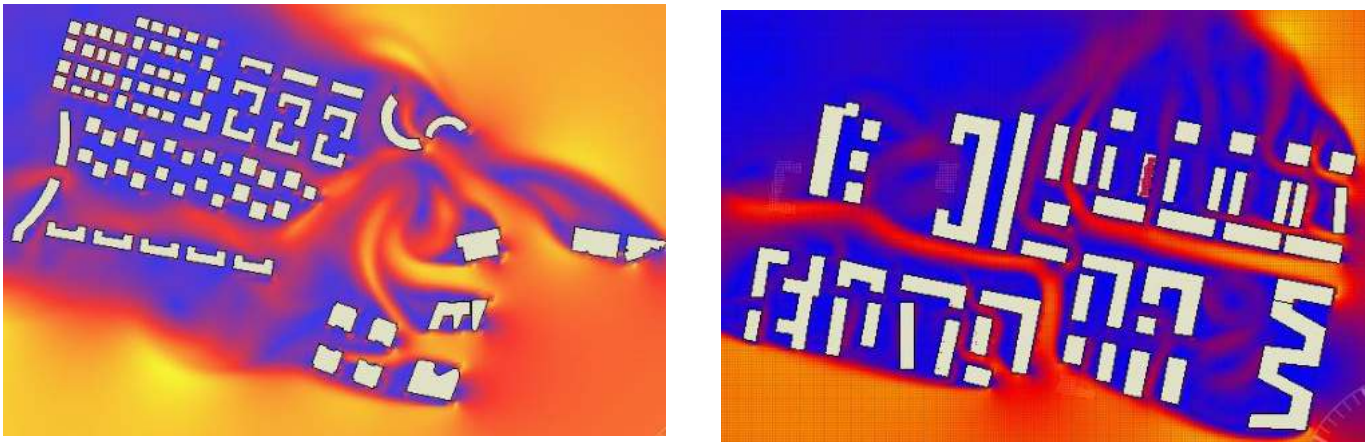

Figure 6: Visualisation of projected frontal area

In both cases, the residential geometrical structure stops vertical air flow, which means that efficiency of Mokotowski ventilation corridor is significantly reduced. But it does not mean that both of this built-up areas completely blocks air flow. In places, where wind has got the lowest speed formed the low-pressure zones. When the wind bypasses the urban areas, it is sucked to windless zones, where the air pressure is very low. Thereby follows air flow through the next part of ventilation corridor, but the wind speed is lower. This situation occurs when the wind do not hit on the next barrier immediately.

**Conclusions**

Urban areas are addicted to air flow and air pollution. Large complexes of green areas in the city can improve residents health conditions. This areas affect on local climat: wind speed and direction, temperature and air humidity, sunlight. Compact green system provides natural permanence and stimulates local air exchange. The ventilation corridors are important part of cities ventilation system. They are created mostly to the city center and running along prevailing wind.

For recent years, the total green area in cities have decreased. A large part of this areas, which have attractive location are planned for new urban areas. Situations like these, provokes discussions about leave the green areas in central parts of cities.

The analysis, which were made, allowed to extract the conclusions about the relationship between development and air flow through the Mokotowski ventilation corridor.

Analysis of air flow through the urban area shows that high buildings create architectural barier, which changes winds directions and reduce the wind speed on the leeward of buildings. This situation has an impact on air health conditions in built-up areas in city, especially in the lowest level of atmosphere the level, in which live residents.

The green areas next to built-up areas is positive phenomenon, because green areas reduce the heat island areas and cause intensive, local air mass flow. This flow formed when extremely hot urban areas adjacent to the much colder green areas. This atmospheric phenomenon influences to atmosphere regeneration and it is very important in summer time, when occur the atmospheric silence.

To maintain health and normal Warsaw ventilation system it is necessary to protect unbuilt parts of ventilation corridors and restrain city government from allow this areas for new housing estates, services or offices. This is important, because high development is the barier for clean air mass. Ventilation corridors should be continuous, green strips which connected city green areas with green areas abroad the city. Thanks to described land use planning, the supply of clean air to the dense city centre is possible.

The undeveloped part of Mokotowski ventilation corridor forms the air exchange proces in housing estates on its territory, in the neighborhood and in the central part of the city. This proces is very important for inhabitants because it guarantees adequate air quality. Therefore, it is imperative to prohibit construction new development on the discussed area. Local Spatial Management Plan and Study of the Conditions and Directions of the Spatial Management should protect the Mokotowski Ventilation Corridor and promote a larger share of biologically active area. Spatial planners mission is creating urban spaces with respect for the environment.

## 1. As an Introduction

> *Man make their own history, but they do not make it as they please; they do not make it under self-selected circumstances, but under circumstances existing already, given and transmitted from the past.* (Marx, 1852)

People, the subordinated, citizens of somewhere have been under an illusion of imitated democracy interjections, which just whispers justice, freedom and equality while shouts submission, obey, hegemony and authority as an indirect voice of the power. Such illusion is inserted in our very daily life; in schools, in workplaces, in street, in park, in museum, in justice hall, or merely in our homes. We are, subliminally, exposed to certain rules and obligations through which we are conditioned to do or not to do. Such illusion, therefore, would be maintained as we, people, accumulate impositions and oppressions while they accumulate surplus and capital. Such illusion prevent us to see the reality, or we just wait for a milestone that would trigger u from the given, break our everyday routines and go beyond shackles that we were urged to be submitted. We inherently respond this trigger as seeking for a ground to manifest ourselves, both individually and collectively, and form a collective resistance to overwhelm invasion of public realm by the government. We, therefore, create a room to breathe again where we lose fear and live dream;

taste the freedom. This ground, which is encouraged through a social movement or makes us real we ; such we does not belong to any typical group or i homogeneity. Rather, in a social movement, as it s a collective action, we contains m men, children, elder, disabled, LGBTI, conservative, nonbeliever,marginal, political and even, apolitical. This collectiveness prompts people to pull away their labels and act as a whole in this heterogeneity. The ground this collective action initiates becomes a very unique place for those who labelled as marginal from subculture , since they, as others , find a gro actively and freely. This ground, physically and mentally, would be turned into a space where they contaminate their marginality. This marginality comes from their unusual way of dressing and hair style, unconventional behaviours unlike majority and different everyday routines. This marginality comes due to their different sense in politics, sociality, music, arts, and fashion, which make them stand as an opponent of mainstream: Mainstream media, mainstream styles, popular music, dominant political ideology, accepted social gender, and so on. Maintaining, therefore, an opponent standing in urban life, they take antagonist position against the homogeneous, the ordered, which makes them to be treated as transgressive . The spaces they produce tend to be regarded as spaces for crime or illega operations. On the other hand, the spaces they produce are those where they inherently express themselves as an active participant of urban life. Those spaces are the spaces of other who are too different to be anywhere else. (Zurkin, 2008, pp. 724-728) Reminding us Foucauldian concept of heterotopia , such spaces of other do exist in terms of intersections, juxtapositions and superimpositions of differences and interactions within urban life, by its actors. For that matter, heterotopias are the spaces that cannot be utilized through conventional type of property regulations; again they cannot be limited within borders of physical plans and; therefore, cannot be reduced into a physical space. Rather, those spaces can be what Lefebvre called as lived spaces social interactions and daily experiences with urban space. Within these framew and lived space , it should be pointed here that how social movements trigger and encourage, especially marginals, to produce their other space via emerging collective action in such would be discussed throughout this paper. Among those productions, which require use and appropriation of space, squatting is one of them based on the concept of occupying an abando uninhabited space to form a communal habitat for uncovering public use. Regarding such concept, this paper aims to seek how Don Quixote House, Turkey s first squat emerged after park forums organized as an extension of Gezi Uprising, was prompted by inhabitants as an other space whereby triggers of Gezi and its inherent call for collective action.

## 2. Introductory on Social Movements

> Social movement is a system of practices resulting from the articulation of a conjuncture of the system of urban agents with other social practices, such that its development tends objectively towards the structural transformation of the urban system, or towards a substantial change in the balance of power in the class struggle, that is to say, in the power of the State. (Pickvance,1975, pp. 29-49)

Social movements, with various initiator causes, recall public action and collective decision-making processes in a way to obtain a social change regarding civil rights, environmental problems, rights of homosexuals and trans, labour, anti-globalization,anti-capitalism, feminist action, women rights, workers rights, student rights and so on. Whether they eventuate wit systems or not, they tend to uncover potentials of societies emerged through collective action. It cannot be ignored that revolutions may be occurred via ineradicable changes in systems, as Luther King stated: A social movement that only moves people, is merely a revolt. A movement that changes both people and institutions is a revolution. (King, 2000) However, it is also in regard social movements with their revealed potential and encouragement to make people change their

daily routines to change whatever they would be able to. Even could not reach concrete results for some cases, social movements tend to uncover various interactions in society with its actors. Whether emerged as an organization or a spontaneous occurrence, social movements often exhibited a capacity to contain transcending social borders through cross-class mobilization (Prujit, 2007, p.516), which leads to horizontal cooperation rather than the vertical one with hierarchical requirements. This non-hierarchical cooperation consists of participants of different class backgrounds such as urban poor, middle-class activists (like students), workers, academicians or public employees. This variety is obtained since such movements are prompted via public action, not with top impulse or authority order. People from different backgrounds, with different reasons behind them, participate in such actions.

Regarding their organizational patterns, social movements may differ as bottom-up or top-down. Bottom-up mobilizations are more likely to what we discussed as horizontal cooperation, as it involves networks of activists and occasional participants, creation of committees, newsletters and neighbourhood centers. On the other hand, top-down mobilization occurs via political parties to build local organizations when they aim to dominate or exploit a movement started by bottom-up. (Prujit, 2007, p.516)At that point, any top-down intervention by political groups or parties often considered as detrimental since it may turn into a state-oriented bureaucracy, which clashes ideal of self-management. (Prujit, 2007, p.516) Such state-like interventions cause contradictions among inner formation of social movements. Souza also pointed that out:

> It goes without saying that social movements are not free of contradictions; they operate inside heteronomous societies, that is, in the middle of a more or less hostile environment, and in terms of political culture and political practices one can find quite often problems such as imitation of statecraft and state-like structures at the microlevel (or to remember Foucault [1984], at the level of the microphysics of power ) on the par authoritarian leaders, ambiguities, and so on. However, civil society and even the poor are not only or entirely powerless people who need to be empowered ; em course mean revolutionary changes sometimes, but it is also a *process*. A process of conquering *autonomy* and overcoming *heteronomy*. (De Souza, 2006, p.329)

Being discussed by philosophers since the 18th century, the concept of autonomy and heteronomy are also valid for today s discussions where former means living a laws and later means an external law or a law imposed from outside or above.(De Souza, 2006, p.329) Here, our previously mentioned bottom-up mobilizations fit well to conce it consists direct action of oppressed groups who are the subordinated. Unlike top-down mobilizations, that of subordinated deals with production of a local power that resists through inner potentials of daily life in a spontaneous and temporal action sublimed from commanders and imperial orders. (qtd. in Sarg n, 1997, p.29) What Foucault also contributed to relation between bottom-up mobilizations and social movements is that he emphasized the power of knowledge, particularly which refers to knowledge of the space, of people s needs and language and important for oppressed groups to exert some kind of power. For him, that bottom-up power is based on people s knowledge, the local one, and for social movements; the more they use their knowledge, the more strategic they can think and act. (De Souza, 2006, p.330) By this local knowledge , which should not be underestimated, local tools and ways of operations can be produced against state apparatuses. Such local knowledge, which makes way to a local resistance , can be able to unpredictable, unplanned, indeterminate, but new, domestic and perspicacious actions, tools, methods and ways to define its respective sphere of resistance and ground for counter-hegemony.Providing its impressive reflections by means of public participation and their bottom-up power, such social movements gain relatively great success even if they do not result with what is understood as

conventional type of revolution. Their success is in what they revive and whom they awake, that is to say, it inspires a revival and an awakening, at least.

## 3. What Gezi Revives, Whom It Awakes

> In Gezi, you first met with yourself. There was a specific moment when you came face to face with who you are and what you fear. Then, you also had to take a look at what you believe in; how you relate to your body, to authority, to justice, to knowledge; and ultimately, of course, to freedom. After this first check-up came the sensations. Feeling Gezi came before thinking it. Sensations ran along the soft core, because it is through bodies - rushing up hills, hidden in staircases and in each breath- that desires stretched into force. Gezi started with a joyful display of real anger against the assemblages of capitalism, urban pillage, environmental destruction, conservative morals, body policing, selective justice, and whirling injustices. Gezi was just the beginning -the struggle continues. Freedom has a price and a hope its joys.
>
> Love was hypnotic in Gezi. It brushed away the rational. It left you naked, vulnerable, and happy. It breathed air into passion-torn little hearts. It had a transformative effect, like some psychedelic trip that queers you up some more. Love was surprising, again and again. Death was there too. One, two, three, four dead in the street, shot in the h One does not get used to death. Smiling sweet people have been dying in this country before, during, and after Gezi.
>
> Killed by some sort of love; dead at work; found dead in the street; crushed in factories; strangled by family, hanged, starved to death; lynched in the neighborhood; burned alive with fire or acid; just missing. Some of the dead become heroes while others become martyrs. Death has a texture in this country, just like love. More softl selves collectively died in Gezi, each in their own way. Smooth quiet deaths of the ego faced the monstrosity of unaccounted crimes. With its dosage of love and death, Gezi was poetic. (Ayka , 2014)

In our previous discussions on social movements and the bottom-up power as the most effective initiator of such movements, Gezi Uprising should be placed as one of the bottom-up mobilization which breaks out with a spontaneous manner of people. Being leader-free, party-free and free from any kind of political groups,Gezi (I d prefer to use Gezi , instead of Gezi Uprising) social movement for those people who had never participated in any political actions, any rebellions, any manifestations or meetings, even who had never, merely, think of what is going in world, in country or just in street.For those, and others of course, Gezi is an awakening which opens a path to think, question, challenge and act. Looking back to beginning of the protests, one can surely say that it was, at first, a call for environmental, also urban, action which exhibited an antagonist standing against transformation of a public park into a shopping mall with a replica architecture body of Ottoman style. This detrimental, discretionary (on Sultan s desire) and hege urban public space not only damages publicity, but also the life there; the trees, the homeless, the lovers, the children, the elder, the graffiti-maker, the street artist, the street hawker, the friends who just drink beer after work or the lonely who just passing through. This intervention of state underits brutalism is for submitting its power, baring its teeth, and showing how its authority can control everything, even private lives as well as public one.

Here, a Lefebvrian classification of levels; global (state), mediatory (mixed) and private (habiting) fits well to our discussion regarding Gezi. For Lefebvre, in global level, we simply see the representation of power of state both mentally and physically; like the hegemonic pressure of politicians over public or their political strategies. For that matter, the built and unbuilt domain like schools, churches, monuments, towns, roads, highways, and urban fabric could be considered as physical representation of power. (Lefebvre, 2003, p.79) All of them remind the desire of state to control people by means of creating a centrality which eases the dominate everything. Those built and unbuilt domain also shows the capacity of state to collect capitalist commodities. The mediatory level; the mixed one, is like a link between global and private levels. As Lefebvre indicated, it s the level of city :

> ...Yet this level is nothing but an intermediary (mixed) between society, the state, global power and knowledge, institutions and ideologies on the one hand and habiting on the other. Wherever the global attempts to govern local, whenever generality attempts to absorb particularities, the middle level (mixed, M) comes into play: it is a terrain suitable for defence or attack, for struggle.(Lefebvre, 2003, p.80)

The misperceived, but relatively the most significant level is the private one, which is the level of habiting . However, it is somehow misconcepted with term habitat which merel typologies; like apartments, private houses, squatters and campgrounds. Different form habiting, habitatis a basic formal frame that reduces human being into simple life acts and reproducing. However, on the other hand, habiting , which private level substantiall of, is more than a physical boundary or a collection of simple habits. Habiting includes all lived experiences of a human being, her/his being and her/his acts on public sphere, her/his resistances, and her/his reactions to pressure. Habiting covers the revolutionary potential. (Lefebvre, 2003, p.82) It implies that revolution will be on street; so it encourages acting on street. Therefore, appropriation of public space will emerge right after that, and a space which initially belongs to mediatory level will transform into something else, like in Gezi, where a public park turned into a communal living space after such protests against state.

Regarding Lefebvre s levels, in the case of Gezi, it s so clear that th Gezi Park is simply the direct interference of global level to mediatory one and later on, the private level of habiting.Although the protests started up with environmentally conscious concerns, together with continuing brutal interventions of state and its police force and accumulated oppressions and prohibitions of state, the protests turned to be something else: It s the transition of a to social movement which instigated masses of people. With this transition, Gezi should be attributed to be achieved a success to reach masses of people without containing them under single monotype shelter. Therefore, Gezi achieves a certain potential for social change, which Castells put forward three goals to get it: First one is to realize collective consumption demands which promotes city as a use value against commodification. Second is to establish and strength an autonomous cultural identity and promote communication instead of programmed one-way information flows. Third is to provi territorially based self-management. (Castells qtd. in Prujit, 2007, p.516)

## **4.** Something of Personal Gezi Experiences

No matter which satisfying concrete results Gezi does reach, what it revived has, still, been affecting socio-political conjuncture of Turkey. Feeling Gezi, in person, makes me to see, hear, and observe this revival; in streets, squares, parks, and even wherever one could keep her/himself hiding

from police. Hazim Nazim Hikmet called you to be as unique and free as a tree while being as friendly as a forest. Marx reminded you that the shadows of trees were not for sale. On the walls, you could read that the revolution would not be televised- that was the point at which penguins met Guy Debord DenizGezmi and his friends called out for a long life to the brotherhood of Kurds and Turks. Emma Goldman invited us to dance through the revolution. (Ayka , 2014) I great challenge for those who dreams revolution from his couch reading a book on it, writing an article on it, thinking on it or just growing an endless desire to get it. It was also an experience of challenge for those who had never think of a revolution, who even know nothing on revolution, or who had never questioned the life we forced to live and just kept livinglike however it goes.

Gezi called something new which we had never met or faced before: It s to act tog together I don t mean reduced/restricted togetherness of people from same political ideology, same ethnicity, same religion,same team supporters or any other same purpose. By acting together, here, I mean real all, except lovers of Erdo an. Had I not experienced it myself, I would hardly believe tha those people have never leaugued together, come and move as a whole. I would hardly believe those people can barely sleep at night because of thinking other people, even they don t know who they are,who still continue protesting on streets. I would hardly believe people, even me myself, trust a stranger from resistance and stay at her/his home to protect from police and gas. I would hardly believe people, me myself too, forget all their fears on gas, pressurized wate Akrep , police or even, custody. In this sense, Gezi is the groundbreaking; it provided a ground to surpass all conventional discourses, prejudices, charges and old methods. We just woke one morning and saw brutal treatment of police to protestors on 28th of May, and after we found ourselves in streets as if we have always been there. Had I not saw it myself, I would hardly believe such thousands immediately and spontaneously come together after organizing on social media. I would hardly believe such thousands, after being exposed to gas for several times, still keep waiting for some other time to be exposed by gas again. I would hardly believe,every morning I wake up by hoping- surely know that the rest also wake up with that hope- resisters who injured previous night can also wake up too. I would hardly believe I have difficulty in controlling my anger and nerve when I saw lawyers were beaten or when I saw, on 15th of June, that Gezi blockaded and resisters sheltered Divan. Gezi, therefore, is where we left our fears behind, where we started to learn thinking from different perspectives, where we tried to think of others. It is where we saw potentials of collective reaction and where we regret traditional resistance templates. By means of it, we constructed Gezi Spirit, which maintains itself not only in street mobilizations but also in park forums and other post activities emerged as an extension of Gezi Uprising.

## 5.Gezi Spirit: From Streets to Park Forums and *Post-Gezi*

Gezi Spirit which recalls our humane sides does not limit itself with street mobilizations and active resistance; rather it continues in passive field and begins as Post-Gezi eventsone of which is park forums emerged after violent evacuation of Gezi on 15th of June. These forums are what Gezi gave birth to our urban lives like other concepts it did so: passive resistance, horizontal organization and civil disobedience. Before Gezi, we used parks and other urban public spaces as if they are merely urban blanks . Parks, therefore, are spaces where state attributed a functi where we subliminally force to recreate our bodies there by sitting on proper and definite arrangements and maintaining certain activities that state lets us to do. Theoretically, such parks are the unique spaces of cities where people can touch and feel green; however, in to step on grass. That is, even in a space to recreate , people are strictly restrai saying them what and where to do.Despite their innocent appearance of serving a space citizens; what is in real is that parks as recreational spaces obscure a hidden message which provides a

social control over people by state. (Batuman&Ak , 2000, p.23)This reduction of green into an imitated nature functions as a control mechanism of state causes certain misconceptions towards parks as a combination of green and urban public space. Park forums, as a Post-Gezi activism, straighten this misconception by reclaiming parks as an urban public space and revealing its essence; publicity. As a society, we had not been familiar to such alternative uses of parks in a way that we desire to use it. Organizing forums there? Before Gezi, it was almost impossible to organize a forum in parks and gather people there to make them mention their problems, solutions, and proposals on agenda and also listen others whether they agree with them or not. However, with revival and awakening by Gezi, we start to question every operations and interventions of state and other power blocks, as well as concepts like democracy, equality and freedom. Here, one of the essential impulses to arrange such forums is privation of democracy. Horkheimeralso explains privation of rational basis of democracy and its relation with power-holders:

> Deprived of its rational foundation, the democratic principle becomes exclusively dependent upon the so-called interests of the people, and these are functions of blind or all too conscious economic forces. They do not offer any guarantee against tyranny. In the period of the free marketsystem, for instance, institutions based on the idea of human rights were accepted by many people as a good instrument for controlling the government and maintaining peace. But if the situation changes, if powerful economic groups find it useful to set up a dictatorship and abolish majority rule, no objection founded on reason can be opposed to their action. If they have a real chance of success, they would simply be foolish not to take it. The only consideration that could prevent them from doing so would be the possibility that their own interests would be endangered and not concern over violation of a truth, of reason. Once the philosophical foundation of democracy has collapsed, the statement that dictatorship is bad is rationally valid only for those who are not its beneficiaries, and there is no theoretical obstacle to the transformation of this statement into its opposite. (Horkheimer, 2004, pp. 19-20)

Seeking democracy s rational foundation, park forums are pertinent and hopeful to maintain Gezi Spirit by addressing to all. The horizontalcooperation they have, also gives opportunity to make all people, especially marginals/others those who were exposed to certain prejudices, participate in and give voice. Providing a platform for freedom of speech, park forums have a single rule which is to be respectful to others and listen to them. Therefore, a remarkable awareness is raised up which provides working in solidarity and collective production of ideas, solutions and actions. Even in the most crowded forum, every participant could directly express themselves. People discussed political issues, organized meetings and reported forum sessions in the media to inform the public and create a web of solidarity. Since some forums harboured a great number of individuals from various ideological backgrounds, there was great effort to continue the emphatic dialogue that was discovered at Gezi, mostly successful.Workshops were continued in public spaces. Someforums emphasized a communication strategy with local residents who did not necessarily support Gezi. (Ahkat, 2014) With such inclusive approach, park forums reach different voices and alternative decisions would be taken whereby free expression. Here, urban public spaces are attained more importance since people realize what those spaces really submit if they occupy it, use it and appropriate it.

Yelde irmeni Forum, one of park forums in Kad k y, was initiated as a st car park in their neighbourhood into a green area. Like other forums flourished different regions of country, Yelde irmeni Forum tends to raise a public awareness to protect unity of their neighbourhoo and the heterogeneity their neighbourhood brings. They try to uncover forgotten relationships and

practices through expressing and discussing their ideas freely in forums. As one of the concrete results of such discussions, they planted car park in their neighbourhood which is a concrete urbanization/overbuilding in Istanbul. They, therefore, provide a room for breath within this overbuilt environment. Apart from discussing territorial issues, their very domestic demands for their neighbourhood includes more green, safe places for kids to play, convenient restoration of historical buildings, and arrangement in bus lines. (Y ld ral, 2014) Later on several discussions and meetings in neighbourhood, sometime, Don Quixote occupied Yelde irmeni.

## 6. In the Way of Gezi: Don Quixote Occupied the Neighbourhood!

> Gezi Park continues blowing its spirit! 'Chapullers' have interiorised freedom, solidarity and communication of the Gezi period and now they transform the inspiration they got from Gezi into new forms. Yelde irmeni Solidarity, one of the forums which neighbourhoods after Gezi invaded a desolate building which has been functioning as garbage for 20 years and now is trying to turn it into a public space. This organisation with no hierarchy wants to create here a 'miniature' Gezi, put it into service of the inhabitants and in this way show that another world is possible. (P nar, 2013)

Watching Fatih Pinar s, an activist participated both Gezi protests and Post-G mobilizations, documentary on Don Quixote House and how it was constructed with solidarity and voluntary consciousness, it can conveniently be said that *Another world is possible* . Even saying that motto shows how Gezi change minds, how it encourages and triggers all, especially others/marginals to express themselves. These precious attempts of organizing forums, squatting, solidarity events, barter and second hand bazaars, workshops, direct actions and the rest, at least, make us satisfy ourselves that those hearts of Mehmet, Ethem, Abdocan, Ali smail, andHasanF ratcan feel free in peace that their loss is not needless.

In documentary, one of the activistssaid Under the domination of money and unearned income, all the commonly used places are being taken away. Whilst they are invading our lives, we need new public spaces to make possible again our sense of community , and one another adds What we are after is, in fact, to create again the public spaces that have been taken from us. (P r Their attempt is for reclaiming the space by occupying it, redefining and reproducing with a necessary appropriation. Those people in Yelde irmeni, by taking all the responsibilit organized a community by themselves rather than to wait local politics to do so. (P nar, 2013) Why they did occupy this abandoned building is so clear, as one of a marginal activist explained in such documentary: Because they have not left us any space in city, because there are no more places w we can breathe, because there are no areas where we can express ourselves, or because we cannot find the real tranquillity and from now on we take the initiative. (P nar, 2013) D miniature Gezi, is a cultural, political and economic encounter-intervention that re space not on behalf of any particular group, but for the ancient and progressive notion of a popular commons . (P nar, 2013)

Being a production of a collective initiative, Don Quixote House is Turkey s first formed via courage of Gezi. It is the first for Turkey, but squatting is r world. It has been done in New York City, indeed, in this very neighbourhood, for more than 130 years -that is, ever since the 1860s, when urban development became an observable, cyclical process (of construction, inhabitation and use, abandonment, dereliction and destruction) that repeated itself every 30 years or so. Squatting, as either an individual act or as a movement of some kind, c

little, if any, attention in the world of surveillance. (P nar, 2013) Later on firs New York, it had flourished along different parts of world where people suffer from capitalism, property rights, human rights, lack of social space or any other state oppression. Activists, punks, hippies, street kids and other homeless individuals took over and reclaimed derelict buildings and squatting would continue whenever housing crisis emerge, or whenever some others are alienated from society and have no place to breathe, to act, simply, to live. As Mayer further explains:

> As with squatters of social centers or large buildings, the occupied squares represent(ed) not only a collective form of residence on the basis of shared resources, but also a political action: in this case laying siege to centers of financial and political power. Importantly, they have also served to explore direct-democratic decision-making, to prefigure post-capitalist ways of life, and to devise innovative forms of political action. As with squatting, the practice of occupying has enacted a democratic (re)appropriation of public squares epitomized by their inhabitation. As with squatting, the power of bodies that continue to be present that don t go home at the end of the demonstration and that speal rather than being represented by others exerts a forceful message as it gives *ongoing presence* to political protest. In today s situation of the worldwide spreac of the Occupy movement, it is helpful to take some lessons from squatte they have influenced the trajectory of many contemporary movements and struggles. Squatting is a unique form of protest activity that holds a potential of unfurling energies; it focuses action in a way that is prefigurative of another mode of organizing society and challenging a paramount institution of capitalist society: private property. (Mayer, 2013, pp. 1-2)

For that matter, squatting recalls Lefebvre s right to the city together with his lived space and habiting . For our case of squatting, these concepts intertwined that one requi another to be realized. The emergent need for a communal gathering space for inhabitants of Yelde irmeni generated Don Quixote Housing as a lived experience of coll domestic memory. As for Lefebvre s question of Who has the right to the city terms of the problematic of possession regarding struggle between private and communal use of public space. For case of squatting, the appropriation of space to establish the notion of dispossession through a communal production and sharing of space turns individual interest into a communal one, which eliminates conventional forms of possession. By this way, the squat becomes a place of resistance not only for providing a social and cultural action, but also towards emerging gentrification which is the privatization of public domain. The new definition that squats submitted for public space recalls what Lefebvre suggested as lived space . (Lefebvre, 1991, p.33) Approaching space as a social producti lived (social) space is where inhabitants, as real actors of urban life, generate either individual or collective actions to provoke new formations both spatially and socially. Therefore, lived space is the immeasurable one; a space that directly interacted with limitless borders of imagination, experience, personal and collective memory, and individual expression, where expression deserves quite importance among others; since, expression requires an act, a stand, and a real use. By this expression, inhabitants would play key role in organizing urban life where s/he resists, decides, uses, initiates, changes, appropriates, and gets. Interrelated deeply with lived space, Lefebvre s ha itself from formal guidelines of *habitat* and reaches an alternative meaning of comprehension of existence, series of experiences and a collective place of change and revival. Habiting can simply and essentially considered like being , as he pointed out in *The Urban Revolution*:

> Although we cannot arbitrarily assimilate habiting to unconscious of psychology and psychoanalysis, there is a definite analogy to the extent that our failure to recognize habiting can serve as an illustration of the theory of the unconsciousness. In order to rediscover the word and its meaning, in order even to utter them, we need to make use of concepts and categories that fall within the scope of the inhabitant s proximity to the unknown and the misunderstood in the everyday, and go beyond, to general theory, to philosophy and metaphilosophy...the relation of the human be its own nature, to being and its own being, is situated in habiting there.(Lefebvre, 1991, pp.81-82)

Don Quixote House, regarding those theoretical conceptualizations, is a new means of habiting and lived space which constructed in the hands of activists and inhabi The occupation story of that building abandoned for fifteen years is best summarized with Selin Top s words who is a participant of the occupy : We came and opened the door. So then we said: N is ours, this is everybody s . (Zucker, 2014) Her words do not only describe the squatting process but summarize their mission as well: it was never the squatte the house, like in most other European squats. Rather, it was about giving the Gezi experience a home; finding a place for the newly reclaimed sphere of interaction, political activism and non-hierarchical deliberation to put down roots. To create a free space, outside of the reach o transformation in the interest of capital- open to everyone. (Zucker, 2014) Unlike other examples of squats in world, Don Quixote House is not for permanent living; indeed, it serves as a social center where everyone can come and join the meetings, workshops, and other activities of art or just drink a tea and have a chat with others. With its temporal usage, it desires to appeal to everyone, not only inhabitants of Yelde irmeni. At that point, TalatDo ano lu s, who played a and reproduction of squat, words are remarkable to catch an attention towards dynamic structure of Don Quixote House: Here, every change is welcomed. For instance, the name o change next month as HacivatKarag z. Or if somebody come and suggest placing instead of windows, new stuff would be placed there. Here, a dynamic structure would exist. 2014) For that matter, Don Quixote House serves an autonomous ground where anyone can do/organize whatever s/he wants providing writing down the program table.

Here, the context of Yelde irmeni neighbourhood should be emphasized that the supports have remarkable contributions in development of solidarity for constructing Don Quixote. For Kadik y, the district that Yelde irmeni neighbourhood is part of, this is a vital issue. Mo another urban renewal project is threatening to raise the rents in the area even more: the train station Haydarpa a, a huge historical building at the water front right next to Kadik an iconic site in Istanbul for over a 100 years. In 2010, a fire of still undefined origin destroyed part of its roof. Having lost its function to other means of transportation like the recently inaugurated intercontinental underground railway Marmaray, Haydarpa a is having closed. (Zucker, 2014) Having such critical position regarding rent ownership and land value, inhabitants of Kad k y, has maintained a kind of reactive and conscious attitude towards bruta Being close to leftist ideologies, Kad k y is a home to what society called as margina artists, intellectuals, punks, hippies, rappers as well as neo-nationalist aunts . This heterogene therefore, provides an inclusive atmosphere towards differences, changes and novelties, one which is initiative of Don Quixote House.Selin G. from squat also pointed inhabitants respectable during construction process of house: While we were working in house, neighbourhood brought tea; another cooked some food and gave us. Except from our solidarity, inhabitants of neighbourhood also supported us so much. (Kural, 2014) Selin Top also recognizes the need to do something for them, to catch their attention and make them feel is everyone s. For her, this task is essential to the squat s mission of

center and free space for the neighbourhood. (Zucker, 2014) Therefore, all necessities of house are tried to be provided via this solidarity between activists and domestic inhabitants.

One last, but quite important, point for Don Quixote House is that it reclaims publicity by means of an unconventional way of redefinition/reproduction of space. Its nonapparent motto of turning street into a space/moving space to street is just a result of seeking the other space and reclaiming that other . Therefore, activists of Don Quixote started such reclaiming by putting exteric walls away which sets a barricade-like separator between house and street. They placed transparent glass walls instead of previous masses, which was the first attempt to gain *publicity* back. The others followed that initial attempt: open up space to sky, transforming space into a street and spatialize the street. Don Quixote, therefore, become a communal house that serves as a st winter and summer. (Balpetek, 2014)

## 7. Conclusion

Don Quixote House in Yelde irmeni, has its very inspiration from Gezi and wh as Gezi Spirit, have put important contributions to our public lives by attributing new meanings to it; collective production, communal life, solidarity and space for others, of those also recalled during and after Gezi. Being as a concrete reflection of Gezi, Don Quixote does not merely construct a new physical space for communal sharing; however, it also presents a social space that make us dreaming of again: another world is possible. Yes, another world is possible where money is not the ba necessity, where individual awareness turns into a collective one, where personal interest becomes an interest for all and where all people kindly welcomed without questioning who they are. It might appear as a romantic dream, but it is what Don Quixote and other squats cou Let me say again: *another world is possible.* which lives on public space, which is not televised, which is not on books, may be which is not written; but which is on streets.

***Title:*** *Assessment of public participation process by using urban coding methodology in urban design: case study Bostanci urban block*

***Author****: Merve Basak*

*Middle East Technical University, merve.basak@metu.edu.tr*

***Keywords:*** *Participatory Urban Design, Urban Coding, Parametric Urban Design*

***Abstract:***

*One of the most important pillars of social dimension in urban design,* ***participation****, basically means the integration of users into the urban design processes. Participatory design processes seek a balance among variable thoughts that belong to users. Participation requires flexibility in the production of urban spaces since it theoretically needs to bring different thoughts together and let them change in the context of design goals.*

***Urban coding****, as defined by Marshall (2011: 6),* is the application of any kind of code used in t context. Urban codes include form*-based codes, building codes, layout codes, zoning codes, and generative codes. Not to be confused with design guidelines or general statements of policy, urban codes are regulatory, not advisory (Talen, 2009). For the creation of healthy and sustainable communities, urban codes should create the flexibility that participatory design demands. This requires a bottom-up* approach like generative coding, which rejects predetermined forms and patterns in *stepwise process by which a form might emerge from the evolutionary actions of a group of* collaborators (Mehaffy, 2008*: 57). In this context urban coding and participatory design approach have a significant relationship and impact on making a decision.*

*The aim of the presentation is to demonstrate the social dimension of urban design by using quantitative methods and to show how urban spaces alter by using participatory methods and how this change can show itself in the context of urban coding by giving an example from Bostanci neighborhood in Istanbul.*

## *1. Introduction*

Participation basically is identified as the involvement of group of people to the design process. One of the most important pillars of social dimension in urban design, **participation**, the integration of users into the urban design processes seek a balance among variable thoughts that belong to users.

According to Sherry Arnstein, participation is a categorical term for citizen power which means the redistribution of power that enables the have-not citizens, presently excluded from the political and economic processes, to be deliberately included in the future. Arnstein defines eight levels of citizen participation starts from non-participative levels to citizen control on which have-not citizens obtain the majority of decision making seats, or full managerial power (Arnstein, 1969). Participation levels on urban design scale has been directly or indirectly related to political and democratic ideologies which contributes to participation process on urban planning scale. Arnstein s ladder of citizen participatio contributes to the analysis of the level of democratic situation and making an inference about decision making process on urban design scale as well.

Actors and stakeholders and most importantly user of the specific area contributes to design process by having an interaction with institutions and with each other as well, is replacing the simplistic debate on urban participation which asks whether cities should be organized bottom-up or top-down (Tan, 2014).

Participation requires flexibility in the production of urban spaces since it theoretically needs to bring different thoughts together and let them change in the context of design goals.

Urban coding, as defined by Marshall (2011: 6), is the application of any kind of code u context . Urban codes include form-based codes, building codes, layout codes, zoning codes and generative codes. Not to be confused with design guidelines or general statements of policy, urban codes are regulatory, not advisory (Talen, 2009). For the creation of healthy and sustainable communities, urban codes should create the flexibility that participatory design demands. This requires a bottom-up approach like generative coding, which rejects predetermined forms and pattern in favor the stepwise process by which a form might emerge from the evolutionary actions of a group of collaborator 57). In this context urban coding and participatory design approach have a significant relationship and impact on making a decision.

Bostanci neighborhood in Istanbul is defined as a hypothetical research area of urban design studio in Middle East Technical University in Turkey. Rapid urban transformation and ignorance of actors/stakeholders causes different kind of problematic situations. This research has been based on parcel by parcel urban coding methodology as a controlling mechanism and gives an opportunity for creating a flexible design process. Bostanci neighborhood has been selected as a representative of any urban transformation area in Turkey.

## *2. Design framework*

Bostanci is located on the Anatolian side of Istanbul, neighborhood of Kadiköy. Area fronts the Sea of Marmara. Research area is determined as one specific urban block in Bostanci which is approximately sixteen thousand square meters with eight parcel and eleven building (Table 1)

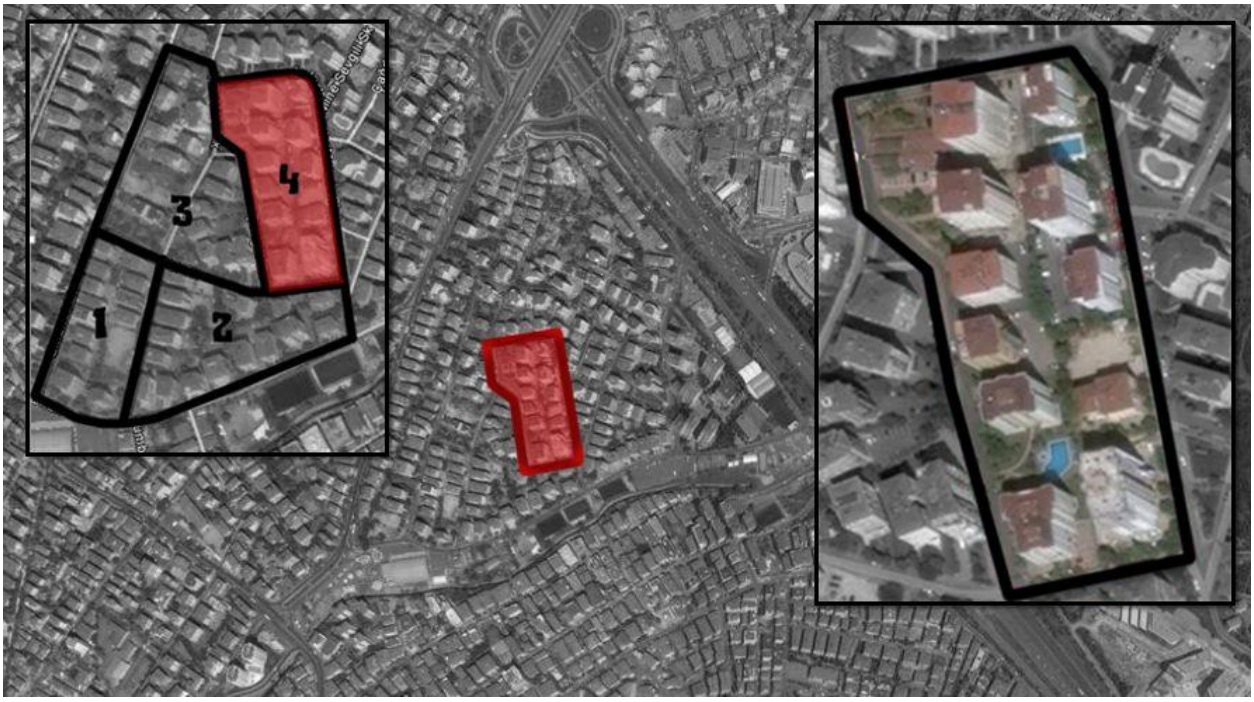

Figure 1. Location of the block in Bostanci Neighborhood

Existing building layout changes from two to five hundred square meters. Building coverage ratio is between 0.18 and 0.46 and floor area ratio starts from two to eight point eighty four (Table 2). Block has parcel size, plot depth and rugosity variation and good sun exposure and wind permeability. It creates an opportunity for privacy because of its impermeable structure which does not let access to urban block except the apartment residents. On the other hand this impermeable structure is considered as a weakness of the block according to plan decisions. Typical architecture, disconnection within buildings, having no common and semi/public spaces in urban block and morphological variation due to lack of functional usage are another weaknesses which do not let flexible growth of the block.

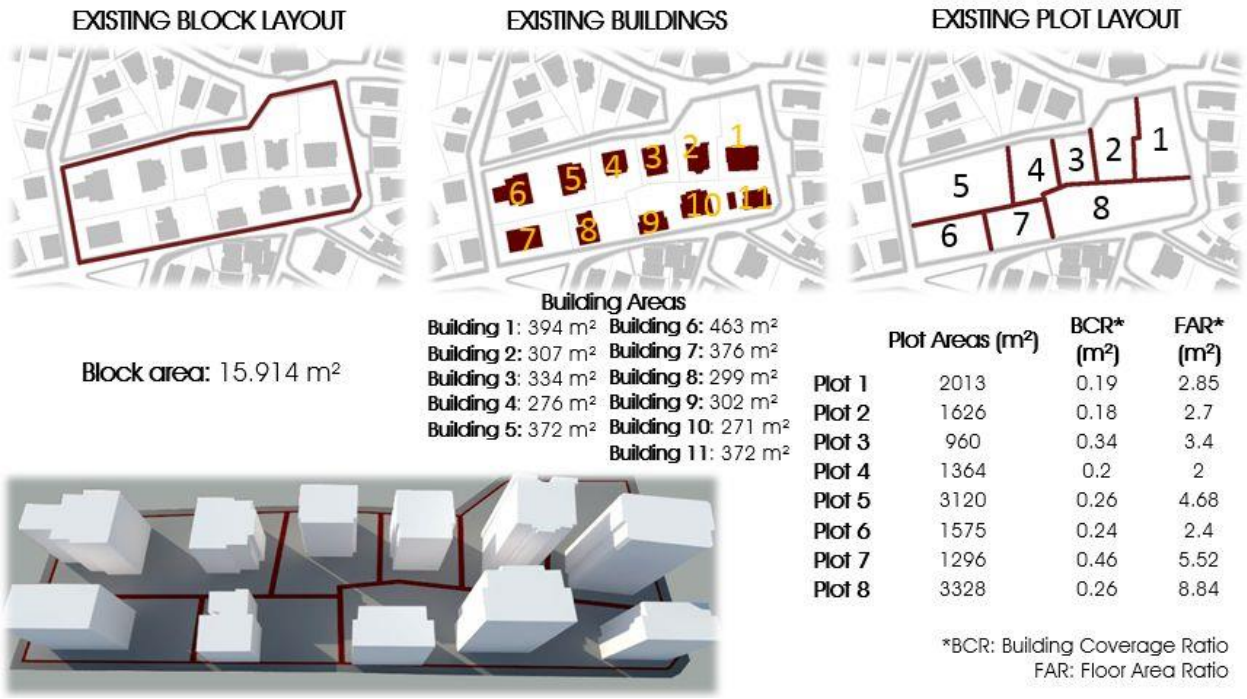

Figure 2. Existing Physical Structure of the Urban Block

Firstly plan decisions have been determined as a challenge of this hypothetic research project. In order to keep the building development right the same, plot layout will be remain the same. The ground level of the buildings will be commercial area and residential units have been planned on t levels. Floor area ratio will be three in the block which distributed equally unlike existing buildings which changes from two to eight because of several high rise buildings in the block. Last plan decision is composing an attached building housing.

Fine grain urban composition as a design concept will widen the spectrum of architectural types which can intervene monotonous architecture of the block. In addition to the design concept there is two different design principles; creating an inner space within the block and active street frontage for commercial area on ground level.

### *3. Design codes*

The aim of the research is demonstrate the social dimension of urban design by using quantitative methods and show how urban spaces alter by using participatory methods and how this change can show itself in the context of urban coding. Urban coding system has been separated into four morphological elements; street, block, plot, building. Street is a public thoroughfare in a built environment. A block is defined as the smallest unit of development which give access to its plots by street/s. A plot is identified as a piece of land which represents the smallest expression of undivided ownership. Buildings is any relatively permanent enclosed structure on a plot of land, usually having a vertical surfaces, covering

surfaces and openings. The main elements of urban morphology and their relationship in different combination created the code matrix. For example one of the results of block and plot relationship is continuity which is the internal circulation within a block. The total number of segments on a route gives the value of continuity of the route. Continuity factor is basically expressed as the amount of segments on the routes and the total amount of the routes in the network. Expected performance of the continuity is efficient use of internal space in block in terms of the provision of parking space, fire safety and supporting the possibility of the emergence of retail. Building and building relationship can cause the emergence of the code of compactness. Compactness is the ratio between the total external wall areas of the building envelopes to their total volume. Compactness factor is calculated as the external surface of the building envelope and volume of the enclosed space of the building. Expected performance of this code is passive heating of the close-connected units problematic conditions for the efficiency of solar access.

In the urban block of Bostanci, firstly active street frontage has been coded in accordance with the plan decisions and design principles. Active street frontage is the building facades of the block facing with the public space. Different kind of commercial usage, diversity of local facilities and characterization of urban block provides an opportunity for an active frontage. Thus granularity, strip width and façade openings have been coded.

Granularity of an urban for can be revealed in terms of plot layout. In comparison of the two different patterns having the same size of surfaces, which are subdivided into the different amount of plots, the one involving more amount of plots can be regarded as multi-particulated in grain with the more relative granularity factor value.

Granularity is formulated by using plot surfaces and external setbacks. In this case since our plot layout will remain the same and does not let fine grain urban form, plots are divided into a number of strips. So the granularity is going to be increased in the block provides an opportunity for diversity in plot composition different building types which means variety in commercial usage, efficient use of the leftover spaces.

Second code for active street frontage is creating a variety in strip width. In order to create more variety in street segment plot should be fragmented into defined range of strip widths. According to the code minimum division of strip width should be minimum twelve meters in this context. In order to create a rhythm on the strip widths, each plot should have at least one twelve-meter strip. After dividing twelve-meter strip for each plot, remaining parts should be maximum number of strip width which is twenty three in this context. The reason for this number is, when strip width reaches to twenty four, it can be divided into two according to the situation which is unwanted in this case.

Repetition of façade openings is another code for rhythm which is defined by total façade opening areas on surface of buildings fronting the street, is a tool to create a rhythmic visual order. In accordance with the parcel by parcel development, rhythm on façade opening code is defined by initiator. When the first developer has designed its own façade openings, other building that has the same range of strip width with the first initiator, should have the same façade openings. For example if fourteen meter strip has a thirty percentage of façade openings the other strip widths between from twelve to fourteen should be thirty percentage of façade openings.

Second design principle is creating an internal common space which consists of three different variety in depth, permeability and counter positioning. The variations in the length of side edges of plot change the depth of plot which constitute the block median. According to sense of enclosure theory optimum height to width ratio should be decided according to the block width. Thus ratio is considered as part of the code formulation while creating usable common spaces.

One of the plot strips within plot can reach to block median in order to create variable (open/close/semi close) common spaces within block. In this case back facade of the building will be blind facade and confronted strip should reach to the block median and should have the same strip size.

Permeability code explains that one of the plot strips within plot can reach to block median in order to create variable (open/close/semi close) common spaces within block. In this case back facade of the building will be blind facade and confronted strip should reach to the block median and should have the same strip size. If openings are going to be given from edge of plot; whole front surface of the building should be regressed at least 4m. If opening are going to given from inside strip plots; at least 4m opening in first floor should be given.

Third code is counter-positioning is measured by calculating the ratio between the numbers of building entrances visible from any other building entrance located opposing sides of block median and the total number of buildings on the street.

### *4. (Trans)Formation of the block*

Urban design codes is used for plot-by-plot urban transformation process for Bostanci urban block. Transformation of the block has been appeared from first building to eighth building in accordance with the design codes which is explained previously. All these codes has been implemented (SIRASIYLA). In this scenario three different actors contributed to the process.

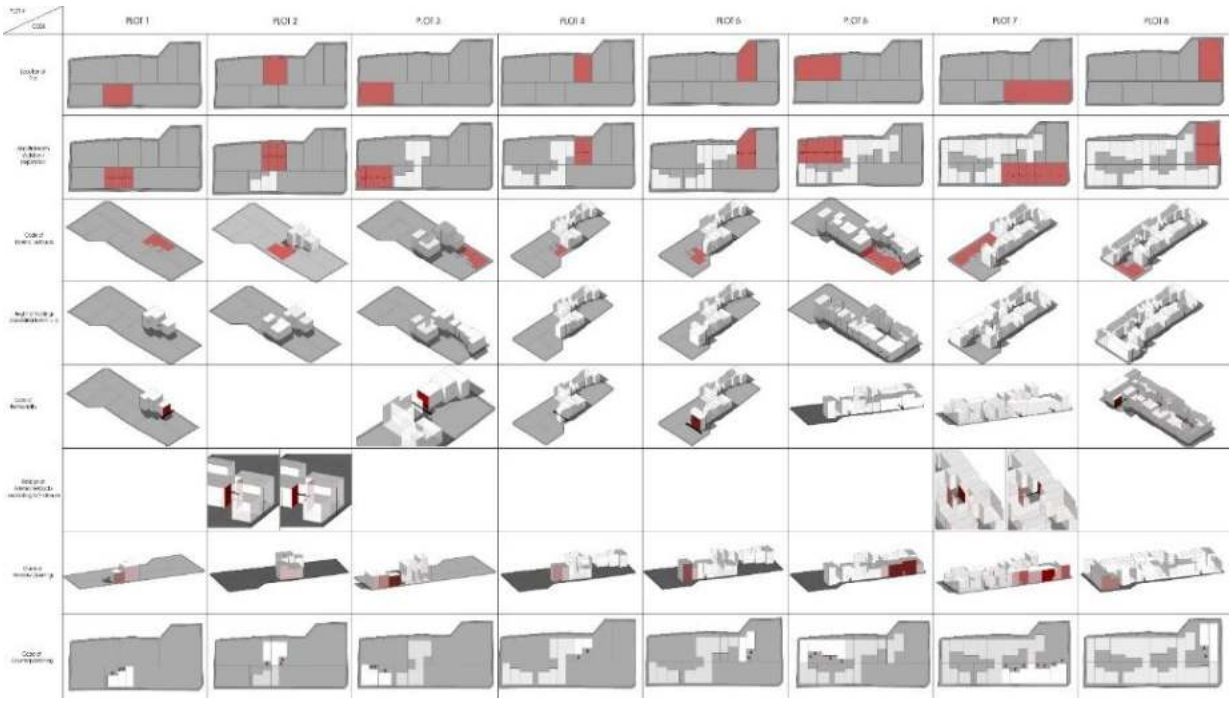

Figure 3. Formation of the Urban Block

When the first plot has decided to build his own house, owner or developer of the plot determines firstly its plot strip width in order to contribute its active street frontage principles in accordance with the codes given by urban designer. Developer can determine its strip width in the range of designer s codes. For example first plot has divided its own plot into three different strips. According to the repetition code, developer should define at least one twelve meter plot strip in its own plot. Other strips should reach maximum strip widths for creating variety in commercial area.

After defining strip width of the plot building mass is defined, building mass is distributed into three strips according to the developer s and architect s decision. In order to create a plot, building mass should give a setback from block median in accordance with the code of variety in depth. Access and service into the courtyards is provided by permeability code and since the access is given from the edge of plot, whole front surface of the building is regressed four meter. Finally entrance of the strips has been located inside of the block according to the counter positioning code. Façade openings have been defined as thirty percentage transparency.

Second plot is facing first developed plot, so firstly developer decides a random ground area of massing according to given codes. Setbacks of the buildings from block median should be formed according the height of counter positioning buildings for creating meaningful spaces in between them. According to the decided Floor Area Ratio, considering height of these buildings, setbacks should be rearranged in order to provide needed distance between them. In this case one of the strip plots should increase its setback, in

the last version of its buildings ground area, its height is increased. Access is given agai of the plot and façade opening is defined as forty percentage of the total building façade.

Remained six plots have been transformed in the same process and final version of transformation of the block is identified according to the owner/developer of the each block within the design principles.

## *5. Conclusion*

Urban morphology and urban coding gives an opportunity for the decision making process for all the actors/stakeholders. After defining basic plan decisions, design concept and design principles with all stakeholders, urban block can transform itself by using urban coding system of the urban designer who leaves the main decisions to the user or the owner of the plot on architectural basis. This method is based on plot by ploy development which refers to phase by phase development in practical life and takes fourth dimension into account.

Finally general aim of the poster presentation is to demonstrate the social dimension of urban design by using quantitative methods and to show how urban spaces alter by using participatory methods and how this change can demonstrate itself in the context of urban coding by giving an example from Bostanci urban block in Istanbul.

# Study on the Adaptive Utilization of Urban and Architectural Heritages under Urban Renewal from a Human-oriented Point of View

## -- Taking York and Pingyao as Examples

**Fei Duan Tongji University molymo@263.net**

**Wenjing Mo Tongji University molymo@263.net**

**Abstract:** How to protect the urban and architectural heritages from being damaged and how to utilize and develop these heritages to satisfy the demand of people against the background of rapid economic and social development are two significant subjects in urgent need of solution. Taking Pingyao and York as examples, this paper studies the utilization of urban and architectural heritages under urban renewal from a human-oriented point of view.

First of all, on the basis of the humanistic theory, urban renewal theory, urban and architectural heritage protection theory, this paper adopts the method of document research and theory deduction, to provide solutions for the protection of urban and architectural heritages under city renewal from the perspective of cognition.

Secondly, by applying the comparative study and empirical study to compare and study the protection and utilization of urban and architectural heritages on national level, urban level (Pingyao and York), and on specific instances (the South Avenue of Pingyao and the Shambles of York) of Britain and China, this paper analyses and concludes different architectural utilization methods under different environments that are applicable to the development demand of human, so as to provide instruction and guidance for the protection and utilization of urban and architectural heritages.

## 1. Background

With the rapid growth of our economy and the vigorous promotion of urbanization process, the ecological environment of architectural and urban heritages have been subjected to severe threats, especially in the process of urban renewal. Under the banner of "Transformation of the Old City" and for the purpose of maximizing economic returns, some cities have invented the "crew-cut" demolition strategy to blindly build new high-rise buildings in the old city, as a result of which both cultural heritages and historic environments have been severely damaged. 1 In face of these circumstances, what we can do, besides feeling the unavoidable pains, is to reflect in depth on the roots of these problems. To fundamentally address these problems, the first step is to employ the dialectical thought to clarify the important role of the protection and succession of architectural and urban heritages in promoting urban, social and economic development (why protecting architectural and urban heritages?). RUAN Yisan et al. (2003) hold that "The historic heritages of a city constitute its precious wealth and strategic resources, and a rational and effective use of these historic heritages on a long-term basis is of significant importance for achieving the sustainable development of the city." ZHANG Song (2005) believes that "Protecting historic environments does not mean that we freeze historic buildings and protect them like museums; instead, such protection should constitute an important strategic part of urban development. Besides protecting cultural relics and historic sites as well as historic streets, it is also supposed to integrate the positive factors of urban economy and social culture to become a deep control force of social development."2 CAO Changzhi (2012) claims that, "The basic attributes of historic and cities include not only the authenticity of historic heritages, but also the succession of historic contexts and the dynamics of conservation patterns. Each historic

city itself is a social space and a dynamic survival environment, and must be developed under protection and protected through development."[3] The second step to be taken is to properly deal with the relations between protecting and using architectural and urban heritages (how to protect architectural and urban heritages?). Some scholars propose that "Adaptive reuse provides the best protection of existing buildings (HE Jing, 2004)[4]; Professor CAO Changzhi, based on his theoretical study of the intrinsic attributes and characteristics of historic cities and the laws of their protection and development, believes that the critical conjunction point of the success of the renewal of historic cities lies in rationally using architectural and urban heritages, and he has preliminarily generalized and abstracted several patterns of protecting and using architectural and urban heritages. Each of these patterns emphasizes different aspects in terms of protection objects and protection methods, and their applicability and theoretical basis still need to be discussed in depth. Then, have they embodied the inherent laws of urban development? Do they have any universal relevance in urban renewal? How should we select a proper pattern of rationally using architectural and urban heritages? Questions like these will become the points of penetration for further studying how to achieve a harmonious win-win situation between the protection of architectural and urban heritages and the development of cities and societies at large.

## 2 Theoretical basis

### 2.1 Ideological basis of people orientation

According to great American philosopher Frome, "The so-called humanism means that each person embodies all the humanities, thus each person has all that the mankind has."[5] Fundamentally speaking, "Humanism means that human is the measure of all things, and that the comprehensive development of the mankind is the goal and criterion of all social efforts."[6] For Marx and Engels, the history of social development is the history of the purposeful activities of the mankind. They think that the objective regularity of the development of human society can not be separated from the analysis of the purposiveness of the mankind. On that account, the present paper attempts to explore the purposes of both the renewal of cities and the protection of architectural and urban heritages from the perspective of "human development".

### 2.2 Maslow's Hierarchy of Needs

Maslow holds that the inner strength of individual growth and development is the motivation constituted by various needs of different natures, that these needs follow a an order of priority and a hierarchy, and that the needs at various layers and their satisfaction will determine the realm or degree of individual personality development. In *Maslow's Hierarchy of Needs*, he divides human needs into five layers according to their order of priority from low to high: (1) physiological need, (2) security need, (3) social need, (4)need of self-esteem, and (5) need of self-actualization, among which the former three are needs of lower layers and the latter two are needs of higher layers.

### 2.3 Practical patterns of rationally using cultural heritages

When exploring the patterns of rationally using cultural heritages, Professor CAO Changzhi mainly summarizes five major patterns: viewing pattern, practical pattern,

experiential pattern, memorial pattern and composite pattern.[7] To be specific, the viewing pattern refers to those cultural heritages which have distinct characteristics, rich connotations and precious values but have lost the space available for use by the modern society, can only be used as historical memories and physical evidence and must be repaired and stored completely according to their original form. The practical pattern refers to those historic buildings and structures which have direct use values and whose appearance, internal facilities and so forth can be partially and properly changed to satisfy the needs of contemporary life on the basis of protecting and keep authentic historical information, styles and characteristics.[8] The experiential pattern mainly refers to those cultural relics and historic buildings which have special functions and cultural significance. The memorial pattern mainly refers to those buildings and structures which imply important historic, revolutionary or memorial significance. The composite pattern refers to those which require at least two patterns of protection. Among these five patterns, the practical pattern, as the basic pattern of rationally using cultural heritages, is mostly widely applied to the practical cases of the protection and use of architectural and urban heritages in urban renewal. Thus, the further theoretical study conducted in the present paper mainly concentrates on "the practical pattern".

### 2.4 Life cycle of buildings

The length of the life cycle of buildings is determined by two factors: its material life and functional life. The material life of buildings points to the life that can be normally sustained by their structures, maintenance systems, equipment and so forth under the conditions of adequate maintenance, repair and transformation, and it constitutes the premise and basis of the sustaining and development their life. The functional life of buildings refers to their use functions endowed by the society when they adapt to its needs. The adaptive reuse of buildings directs attention to the adjustment of the gap between their material life and functional life in their full life cycle. When the material life of a building still remains but its functional life has gone, it's necessary to inject new functions into the building to extend its functional life; conversely, when the functional life of a building still remains but its material life can no longer adapt to the needs of development, the building must be transformed, repaired or otherwise treated to extend its material life. In the full life cycle of buildings, these two circumstances are mutually dependent and take turns to dominate until the full life cycle is over.[9] From the perspective of humanistic thought, attention is paid to the material life of buildings for the purpose of satisfying people's physiological and security needs, and to the functional life of buildings for the purposes of satisfying people's social need and need of self-esteem and further providing a guarantee for satisfying their need of self-actualization. The innovative point of the present paper lies exactly in selecting the pattern of using architectural and urban heritages based on human needs.

## 3. Conceptual Framework

### 3.1 Relations between protecting and developing architectural and urban heritages

As proposed by the *Venice Charter* in 1964, "The goal of protection is not only to protect

a specific historic site to satisfy people's remembrance of history and culture, but also to continue our culture or even our life itself at the material level. Using historic sites for the goal of social sharing is always favorable for the protection of historic sites, and this constitutes the tenet of such protection." The *Charter of Machu Picchu* further fully elaborated the above viewpoint in 1977. As explicitly proposed by the Charter, "The protection, restoration and reuse of existing historic sites and historic buildings must be combined with urban construction, thus to ensure that these cultural relics continue to have their economic significance and vital force." In other words, to better bring into play the role of architectural and urban heritages in contemporary social life, it is logical that they must be rationally and effectively put into use.

There is a dialectical relation between protection and development, that is, while protection is a relatively static concept and points to the preservation and succession of the essence of history, development adapts to the needs of historical development and innovatively uses and continues architectural and urban heritages. After being influenced, renewed and used by social development, architectural and urban heritages tend to have richer contents and more use values, so adapting to the needs of social development constitutes the path of sustainable protection and development. Thus, in correctly dealing with the relations between protection and development, the key lies in identifying the integration point between "protection" and "development" and finding an effective approach of inseparably interconnecting them to achieve a harmonious and win-win situation.

### 3.2 Goal of protecting and developing architectural and urban heritages -- Promoting social and human development

The protection of historic and cultural heritages is a relative protection concept, and its significance lies in summing up the course of development of human civilization and getting people to understand the developing venation of human culture. Generally speaking, the goal of protecting architectural and urban heritages can be interpreted from the following aspects: First, to improve people's life quality. Architectural and urban heritages are embodiments of people's traditional lifestyles and living environments, and protecting them helps to alleviate the destruction of people's life quality by the abruptly-changing urban environment. Second, to reflect urban diversity. Due to the increasingly intensified trend of homogenization in building techniques and architectural styles, the architectural environments created all over the world tend to follow the same pattern. In the face of such danger, the protection of historic regions can not only greatly contribute to the preservation and development of each country's culture and social values, but also enhance the richness and diversity of the world's cultural heritages and historic buildings. Third, to promote sustainable social development. Just as pointed out by the *Venice Charter*, it's our responsibility to pass on the heritages we have inherited from our ancestors to our children "in such a way as to embody their authenticity". Fourth, to improve the competitiveness of cities and drive urban revitalization. In short, the goal of protecting architectural and urban heritages is to employ the special values possessed by these architectural and urban heritages for the purpose of promoting urban development in various aspects, or, to say it in another way, the development of the mankind and society at large.

### 3.3 Study on the adaptive use patterns of urban and architectural heritages in the renewal of historic cities from a humanistic perspective

Starting with the above researches, the present paper has taken the perspective of human development to analyze the common value orientation between urban renewal and protection of architectural and urban heritages, and cited two typical historic cities (Pingyao Ancient City, China and York Ancient City, UK) as cases to conduct a horizontal (among several patterns)/vertical (between China and UK) comparative study with regard to the patterns of using architectural and urban heritages they have adopted in their urban renewal. It also attempts to further construct a theoretical model of the adaptive use pattern of architectural and urban heritages in urban renewal and answer the question of how to architectural and urban heritages, with the expectation of providing a scientific basis for selecting a proper pattern of rationally using architectural and urban heritages in urban renewal in the future.

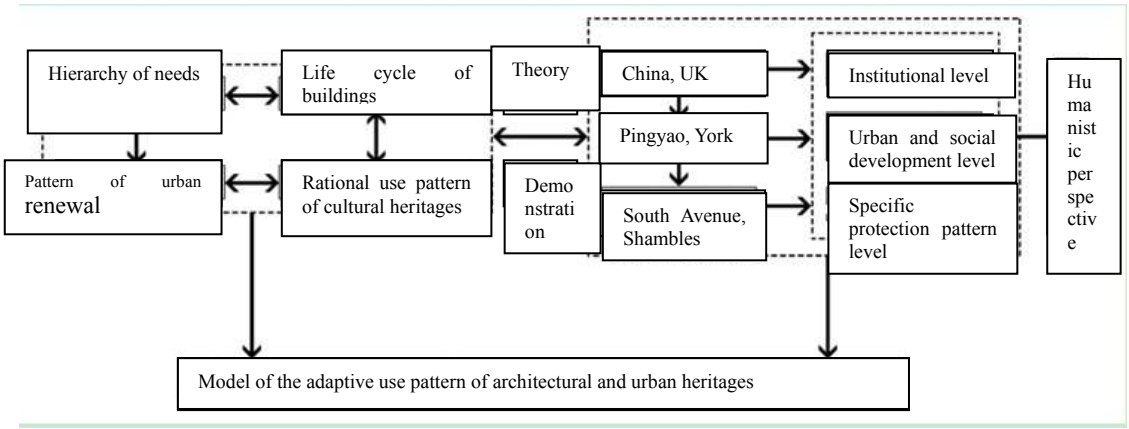

Figure 1. The study Framework

## 4. Case Study

### 4.1 A case study of Pingyao and York in terms of urban heritage protection

#### 4.1.1 Protection of urban heritages in Pingyao

Pingyao Ancient City is located in central Shanxi Province, on the south edge of Jinzhong Basin. Since the Tang Dynasty, it has gone through the rises and declines of the Five Dynasties as well as the Song, Liao, Jin, Yuan, Ming and Qing Dynasties. In the era of exchange shops in the late Qing Dynasty, driven by the prosperity of commercial economy, the building of the ancient city saw a golden time, and, with the gradual increase of luxurious mansions, the architectural style of the ancient city basically took shape then.

(1) Style and features of the ancient city

Pingyao Ancient City was built in strict accordance with the codes of etiquette in a square layout, basically facing the south in direction; taking into consideration local terrain and sunshine conditions, it was slightly shifted eastward by 15 degrees. As a county jurisdiction, Pingyao followed the codes of etiquette to set the size of its city wall and moat (1.5km in side length), and was built with six city gates (i.e., one south gate, one north gate, two east gates and two west gates). Taking the south as the superior direction, there were

upper east gate, lower east gate, upper west gate and lower west gate, respectively named as Taihe, Qinhan, Yongding and Fengyi. It can be said that Pingyao Ancient City has provided a living example of the form system of city wall and moat at county level in the ancient China. The overall spatial layout of Pingyao Ancient City fully reflects the historic and cultural features of the Chinese Han nationality: Adopting the South Avenue as the central axis of the city, and laying out various buildings facing the south; following the traditional codes of etiquette regarding "left as superior and right as inferior" and "left honoring civil and right honoring martial" and adopting a balanced and symmetric layout to deploy Confucian temple, academy of classical learning, Wenchang pavilion, Kuixing tower and other buildings with civil connotations on the east (left) side of the central axis and to deploy the temple enshrining and worshipping Guan Yu, military drill field and other buildings with martial connotations on the west (right) side; properly laying out the city god's temple and county government office also according to the codes of etiquette, etc. As for the street layout, there is a grid road system constituted by four avenues, eight streets and 72 narrow alleys, so there are arterial roads, sub-arterial roads, streets and alleys arranged and interconnected distinctively and in strict sequence, retaining the neighborhood system prevailing in the Ming and Qing Dynasties.

(2) Protection strategies

Methods of protecting the ancient city: The ownerships of all the cultural relics protection units within the ancient city belong to the government, and they are put under the centralized management of the protection and management committee of the ancient city; the ownerships and power of operation of other buildings basically belong to individuals and enterprises, however, in the case of any individual or enterprise wanting to transform their buildings or change their use functions, the approval of the protection and management committee of the ancient city must be obtained. The ancient city is divided into protection zones of three levels, for which different protection strategies are employed.

When renovating traditional dwelling houses, it is required that the original external appearances of these architectures (architectural complexes) be maintained, and that their original structural forms, configuration modes and decorations be retained; that the buildings, structures and appurtenances of the original architectures with historic and artistic values be repaired and reinforced with original materials and by original processes in situ; that original doors and windows be repaired or replaced with traditional wooden doors and windows; and that the painting of wooden structures after repairing these traditional dwelling houses be conducted in strict accordance with the traditional practice. Buildings built in violation of relevant laws and regulations or out of tune with the style and features of the ancient city should be dismantled; the ancient Confucian temple, city god's temple, Qingxu Temple, Rishengchang Exchange Shop and a series of other architectures and dwelling houses from the Ming and Qing Dynasties and with the value of cultural relics have been successively put under protection, and reinstated to the largest extent. The damaged city wall, city gate towers, barbican entrances and other facilities have also been reinstated to exhibit the integrity of the form system of the ancient city; the county government office, city god's temple, Confucian temple and so forth have also been renovated to embody the features of the codes of etiquette implied by the layout of the ancient city.

### 4.1.2 Protection of urban heritages in York

York is one of the four key protected historic cities in the UK (and is about to be applied for the list of world heritage), and, having been well preserved, it mainly concentrates on the development of the tourist industry and is similar to the Pingyao Ancient City of China in many aspects. York is famous for its history, which is also preserved in its architectures. Each year tens of thousands of tourists pour into York to visit the survived Middle Ages architectures and the relics of the Romans and the Vikings interspersed among these architectures.

(1) Style and features of the ancient city

The distribution of the 35 protection zones in York roughly surrounds the core protection zone to form a large area, and the rest protection zones are dispersed in radial pattern on the seven main passages extending outward, which is consistent with the outward extension of the ancient city itself and has well reflected the traditional pattern of the ancient city.

The core protection zone of the ancient city has inherited the spatial characteristics of cities since the eras of the ancient Rome, Anglo and Middle Ages. At those times the lanes, alleys, public spaces and internal architectural spaces were very narrow and compact in cities, showing apparent traces of planning, and York is very much similar to many frontier cities in China, in that they all developed due to the needs of wars. The core protection zone of the ancient city includes the entire ancient city and the traditional blocks on its northwest side. On its east, south and north sides it is demarcated by the circular road outside the city wall, and on its northwest side it includes the entrance areas of two main entry passages outside the city. Within the scope of the core protection zone of the ancient city, both historic architectures and environments have been well preserved, like the relics and residual city defense system of the ancient Rome, the ancient city wall and city gates, etc., and even a segment of dilapidated wall is protected by a grass lawn. To protect historic environments, besides building circular roads outside the city along the city wall, pedestrian streets, half-pedestrian streets, one-way traffic lines and so forth have also been planned, supplemented by the green spaces both inside and outside the city wall to combine heritage protection and park construction. In addition, many historic parks and gardens have also been designated here.

(2) Protection strategies

Having gone through a series of urban transformation, York Ancient City has saw some changes in its urban pattern, however, the transformation of York is based on urban protection. The historic blocks of York have distinct local characteristics, and the traditional shops beside the streets are not only the favorite of tourists but also provide the daily necessities of residents. Thus, to maintain the vitality of historic architectures, the functions of some historic architectures may be correspondingly changed according to market needs. For example, the lower layers of historic dwelling houses beside some historic blocks may be transformed into commercial facilities, but the upper layers can still be reserved for use as residential facilities or office space. A rich variety of mixed use is insisted and encouraged to achieve the building of a sustainable residential quarter. To balance the traffic needs of the city, a pedestrian system is also planned in the urban center.

## 4.2 A case study of South Avenue and Shambles

### 4.2.1 Study on the use pattern of architectural and urban heritages on the South Avenue

The South Avenue is the central axis of the symmetric layout of Pingyao Ancient City, and is a south-north avenue facing the south gate (Yingxun Gate), serving as the backbone of the city. Starting from the gate of Xingguo Temple in the south and ended at the junction of the East Avenue and West Avenue in the north, it runs through the city, and is 690m in length (738m calculated from the south city wall).

(1) An operation type-based analysis on the adaptive use of shops on the South Avenue

Among 22 shops which have adopted the use pattern of continuing the original functions, 21 (95.5%) are dwelling houses and one is a shop. It can thus be seen that the continuity of residential function is stronger than that of other operation types. Among 48 shops which have adopted the use pattern of leaning close to the original functions, 42 are shops (87.5%) and six (12.5%) are cultural facilities (like museum, etc.). It can thus be seen that people have sometimes chosen to transform historic architectures into commercial and cultural facilities to memorize their original states. Among 51 shops which have adopted the use pattern of renewing the original functions, 30 (58.82%) are shops, 18 (25.30%) are hotels and restaurants and the other three are respectively residential, cultural and financial facilities. It can thus be seen that people mainly transform historic architectures into service facilities for the purpose of adapting them to the needs of modern society.

(2) An architectural life cycle-based analysis on the adaptive use of shops on the South Avenue

Among 22 shops which have adopted the use pattern of continuing the original functions, all of them have a weak material life and a normal functional life. This suggests that, as far as the historic architectures adopting the use pattern of continuing the original functions are concerned, a higher demand is imposed on the adaptability of their functional life in comparison to their material life. Among 48 shops which have adopted the use pattern of leaning close to the original functions, 41 (85.4%) have a normal material life, six (12.5%) have no material life and one (2.1%) has a weak material life; none of them has a functional life. This suggests that, as far as the historic architectures adopting the use pattern of leaning close on the original functions are concerned, a higher demand is imposed on the adaptability of their material life in comparison to their functional life. However, given that people usually have relatively strong emotional appeals with regard to the historic architectures for which the use pattern of leaning close on the original functions is adopted, further demonstration is always required before decision making. Among 51 shops which have adopted the use pattern of renewing the original functions, 49 (96.1%) have a normal material life, and two (3.9%) have a weak material life; none of them has a functional life. This suggests that, as far as the historic architectures adopting the use pattern of renewing the original functions are concerned, a higher demand is imposed on the adaptability of their material life in comparison to their functional life.

### 4.2.2 Study on the use pattern of architectural and urban heritages on the

**Shambles**

Starting from the Newgate Street in the north and ended on the Belfrey Street, the Shambles is 103m in total length, and is not only the most ancient street in York but also one of the most well-preserved streets from the Middle Ages in Europe. Many houses on the street were first built in the 15th century, and protruding arcades were designed on the second and third floors of these houses in a ladder pattern.

(1) An operation type-based analysis on the adaptive use of shops on the Shambles

Among 38 shops which have adopted the use pattern of continuing the original functions, all of them are dwelling houses. It can thus be seen that the continuity of residential function is stronger than that of other operation types. Among five shops which have adopted the use pattern of leaning close to the original functions, three are shops (60%) and two (40%) are restaurants. It can thus been seen that the use pattern of leaning close to the original functions is adopted in York in only a few cases; they have chosen to adopt the use pattern of continuing the original functions for most architectures which can still basically adapt to the needs of modern society, and, for those which can not adapt to such needs, they have adopted the relatively thorough the use pattern of renewing the original functions. To put it simply, there are not so many cases in which the eclectic use pattern of leaning close to the original functions is adopted, which reflects the characteristics of British culture which are different from the Confucian mean characteristics of Chinese culture. Among 51 shops which have adopted the use pattern of renewing the original functions, 35 (68%) are shops, seven (14%) are office spaces, six (12%) are restaurants and the other three (6%) are cultural facilities. It can thus be seen that people mainly transform historic architectures into service facilities for the purpose of adapting them to the needs of modern society.

(2) An architectural life cycle-based analysis on the adaptive use of shops on the Shambles

Among 38 shops which have adopted the use pattern of continuing the original functions, all of them have a weak material life and a normal functional life. This suggests that, as far as the historic architectures adopting the use pattern of continuing the original functions are concerned, a higher demand is imposed on the adaptability of their functional life in comparison to their material life. Among five shops which have adopted the use pattern of leaning close to the original functions, four have a normal or weak material life, and all of them have a normal functional life. This suggests that, as far as the historic architectures adopting the use pattern of leaning close on the original functions are concerned, a higher demand is imposed on the adaptability of both material life and functional life, because, when Shambles adopts the use pattern of leaning close on the original functions, they have introduced some new functions which can better adapt to the needs of modern society than original functions. To put it simply, although the original functions can adapt to the needs of modern society as well, they can not adapt as well as these new functions. Such a practice is different from that employed by Pingyao which adopts the use pattern of leaning close on the original functions in cases where the original functions can no longer adapt to the needs of modern society but people still have relatively strong emotional appeals for these original functions. Among 51 shops which have adopted the use pattern of renewing the original

functions, 49 (96.1%) have a normal material life, and two (3.9%) have a weak material life; 47 (92%) have a normal functional life, and the other four have no functional life. This suggests that, as far as the historic architectures adopting the use pattern of renewing the original functions are concerned, a higher demand is imposed on the adaptability of both material life and functional life.

## 5 Conclusion

Based on a field survey of the above cases and related analysis, it can be seen that, no matter it's in the rapidly-developing China or relatively stable UK, the goal of urban renewal, i.e., the adaptive transformation of cities and architectures, is always to adapt to the needs of modern society. The adaptive applications of these protection patterns have shown certain laws, as described below.

(1) To continue original functions

When an architectural or urban heritage has both its material life and its functional life, it means that it can not only satisfy people's basic needs (physiological and security needs) but also meet their higher needs (social need, need of self-esteem and need of self-actualization). In this case, the use pattern of continuing the original functions should be adopted to well preserve their original style, features and use functions. Correspondingly, urban renewal should employ the mode of comprehensive improvement, mainly covering fire protection facilities, infrastructure, public service facilities, street fronts, environments, energy conservation transformation of buildings, etc., but should not change their main structure or use functions.

When the material life of an architectural or urban heritage has gone (or is already very weak) but its functional life still remains, it means that it can no longer satisfy people's basic needs but can still meet their higher needs. In this case, the use pattern of continuing the original functions should be adopted to cautiously restore (or repair or transform) its material remains, so that it can satisfy people's basic needs. Correspondingly, urban renewal should employ the mode of comprehensive improvement.

(2) To lean close on original functions

When the material life of an architectural or urban heritage still remains but its functional life has gone (that is, its original use functions can no longer adapt to the needs of modern society) and people still have relatively strong emotional appeals for its original functions, it means that it can satisfy people's basic needs but can not fully meet their higher needs. In this case, the use pattern of leaning close on the original functions should be adopted to retain the characteristics of its original use functions in a special way, so that it meet people's higher needs. Correspondingly, urban renewal should employ the mode of comprehensive improvement to partially or wholly change the use functions of the architecture without changing the subject of right or the term of the land use right. The original main structure of the architecture should be retained, so that, on the one hand, its overall style and features can be continued, and, on the other hand, its internal functions can still meet the needs of modern society.

When the material life of an architectural or urban heritage has gone (or is already very weak) and its functional life no long exists (that is, its original use functions can no longer adapt to the needs of modern society) but people still have relatively strong emotional appeals for its original functions, it means that it neither satisfy people's basic needs nor fully meet their higher needs. In this case, the use pattern of leaning close on the original functions should be adopted to cautiously restore (or repair or transform) its material remains, so that it can satisfy people's basic needs; meanwhile, a special way should be employed to retain the characteristics of its original use functions, so that it meet people's higher needs. Correspondingly, urban renewal should employ the mode of comprehensive improvement.

(3) To renew original functions

When the material life of an architectural or urban heritage still remains but its functional life no long exists, it means that it can satisfy people's basic needs but can not meet their higher needs. In this case, the use pattern of renewing the original functions should be adopted to replace the original functions with new functions which can adapt to the needs of modern society, so that it can satisfy people's higher needs. Correspondingly, urban renewal should employ the mode of functional renewal to partially or wholly change the use functions of the architecture without changing the original main structure of the architecture, so that, on the one hand, its overall style and features can be continued, and, on the other hand, its internal functions can still meet the needs of modern society.

When the material life and functional life of an architectural or urban heritage have both gone, it means that it can neither satisfy people's basic needs nor meet their higher needs. In this case, it should be allowed to disappear without making any efforts to restore it. Correspondingly, urban renewal should employ the mode of rational transformation to orderly transform the architectures in the city, and to rationally use the land in the city in a way that adapts to the development of the city.

**Table I Model of the adaptive use pattern of architectural and urban heritages from a humanistic perspective**

| | | | Architectural life cycle | | | |
|---|---|---|---|---|---|---|
| | | | Material life | Functional life | | |
| Pattern of rationally using cultural heritages | To continue original functions | Cautious restoration, repair or transformation | No or weak | Yes | Comprehensive improvement | Mode of urban renewal |
| | | Daily maintenance | Yes | Yes | | |
| | To lean close on original functions (retain the characteristics of its original use functions in a special way) | Cautious restoration, repair or transformation | No or weak | No, people still have relatively strong emotional appeals for its original functions | Comprehensive improvement | |
| | | Maintenance of appearance, and internal transformation | Yes | No, people still have relatively strong emotional appeals for its original functions | | |
| | To renew original functions (replace the original functions with new functions which can adapt to the needs of modern society) | Maintenance of appearance, and internal transformation | Yes | No | Functional renewal | |

| | | | | | | |
|---|---|---|---|---|---|---|
| | Others | Allowed to disappear | No | No | Rational transformation | |

| | |
|---|---|
| Basic needs (physiological and security needs) | Higher needs (social need, need of self-esteem and need of self-actualization) |
| Maslow's Hierarchy of Needs | |

Note:

Material life: No: The heritage no longer exists;

Weak: The heritage is incomplete, and only has a few remains that can not be put into normal use;

Yes: The heritage can still be normally used.

Functional life:

No: The original use functions of the heritage can no longer adapt to the needs of modern society;

Yes: The original use functions of the heritage can still adapt to the needs of modern society.

# SCENE OF PUBLIC SPACE

Veronika Kastlova
CTU in Prague, Faculty of Architecture, Department of Interior and Exhibition Design
kastlver@fa.cvut.cz

## PhD Thesis Theme

Scene of Public Space.
Developing Trends of Social Rituals.

## Veronika Kastlova (1985)

Completed studies of Theatre Direction at the Faculty of Theatre of the University of Janacek in Brno and also at the Faculty of Architecture of the Czech Technical University in Prague where is, at present, specializing on the Scenography in public space theme, within the framework of her PhD studies, and under supervision of Arch. Vladimir Soukenka, Associated Professor. Produced several short documentaries dealing with topics closely connected with architecture and urban planning.

## Current State of the Research

There are several specific features in dramatic art: awareness that it is being created, that it is being felt, taken notice of, respectively spectator's and actor's awareness of being present. Furthermore there are repetitions, process hic et nunc, impermanency, primary display function and last but not least there is the fact, that for interpreter (actor, performer) his own body is the most important material for creation. From the above mentioned, only the first feature is the most important basis, i.e. spectator's and actor's awareness of being present for taking into account relationship between architecture and theatre.

## Theoretical Background - Scenology

Common interface between architecture and theatre is dealt with in the scientific branch called scenology. According to Prof. Vostry, Czech theatre researcher, scenology which is dealing with scenic situations in general, i.e. "someone is made to watch something". It has two basic axes – specific and non-specific. Specific scenic situation means "actor playing a role" and non-specific scenic situation is used for real daily situations. The latter mentioned is the one to be considered within the ephemeral part of public space.

## Motivation

Present disappearing of image of the cities, the way how we would like to have it, and effort to find a solution for this unpleasant state, lead to various considerations.
For public space, consisting of substantial part (material and spatial part) and non-substantial part (scenic or ephemeral part), the latter mentioned seems to be more important one *(Fig. 1)*.

## Goals

Public space could be symbolically understood as a scene where a number of interactions – social rituals take place. The key question is to define architectural and urbanistic procedures used for urban scene design of public spaces in the cities during their problematic situation today. Image of public spaces should be of communicative, meeting and of „theatre" nature. What kind of role can theatre (which is based on social rituals) play in vitalization of public spaces in more detailed way of understanding?

## Conclusion

If ephemeral part is considered essential for public space design, it is possible to define for this part of public space design principles used in theatre production. In both, similar creative processes are used. It seems that it is possible to design public space as a scenic space, particularly for non-specific scenic situations, with the use of theatre creative processes *(Fig. 2)*. So let us design enjoyment and catharsis of public spaces.

A scene of public space cannot be, by its nature, a theatre scene but this scene of public space could (and should) use elements of theatre namely to support its ephemeral part *(Fig. 3 and Fig. 4)*.
If we try to consider urban design procedure using the theatre point of view, interesting conclusions can be derived. From historical contexts of theatre and urbanism, the analysis of their present situation and especially different and common items defined, it follows that a scene of public space cannot be, by its nature, a theatre scene. The reason is, that there does not exist conscious current relationship of actor-spectator.

[3] Tongji University College of Architecture and Urban Planning 1019942645@qq.com

Abstract: The landscape consists of landscape and appreciation the landscape, landscape design in the neighborhood is to meet the needs of appreciation. Therefore, planning designers and architects should stand in the position of viewing emotion at design time, They should understand what the most viewers want to see and what can touch or fluctuate emotion in the hearts of viewers by strengthening social cohesion. Landscape design in the neighborhood based on the regional culture or emotional tend to make people have a rich emotional resonance. This paper takes Xu Jiahui Park as an example, defining design prototype theory, analyzing from the perspective of regional prototype and emotional prototype , and explorating the park landscape design based on the prototype theory.
Keywords: Design prototype, Local culture, Emotion

## 1. The theory of landscape prototype

### *1.1 The landscape origin*

From ancient time, the generation of outstanding landscape works has its own reasons. The inspiration of creating these works often comes from original artistic which creation the initial impulse "roots". The roots have two means: one is Looking for historical birthplace upwards, the other one is Up to find the source of the feelings. The first emphasizes is that the development of landscape evolution influenced by its areas, all unique to the local climate, geography, culture and other factors which had been hidden in the consciousness of the local residents, The landscape design methods in the application of this phenomenon is called "Landscape Design base on its regional prototype". And the second emphasizes is much more abstract which By creating emotional space, make the viewer's cognitive and emotional resonance. The Emotional was hidden in the audience heart bottom which need to be activated on the works of art by landscape architects (Jin yunfeng, 2005).

### *1.2 Basing on the design of landscape prototype*

The unique features of a local environment always give special characteristics to its inhabitants. On the landscape design of regional prototype can be done by recreating the regional scene. Scene reappearance through landscape design to arouse the people on the traditional consciousness of life and make them feel familiar. Scene reappearance should have full-bodied local atmosphere which ask the landscape designer to have a deeply understand or live experience on the site (Jin yunfeng, 2013). It is also should be continue in the design of the original region about life essence, absorb those local characteristics which can make people able to maintain the healthy development of the ecological balance in the region; To the original region part which hinder the development of itself should use of existing technology to make it perfect. Through combination of retention and development to build a new landscape culture which Implementation inheritance and continuously surpass ourselves.

The prototype theory which based on the emotional space can perform as a form of independent innovation. It is one kind of landscape design based on the rich and colorful emotions, it can Inspire the positive energy of visitor s life. In addition to the physical entity, immaterial culture story can also arouse people's excitement and curiosity, Scenes through one by one emotional together to bring changes of mood (Su long, 2005) .

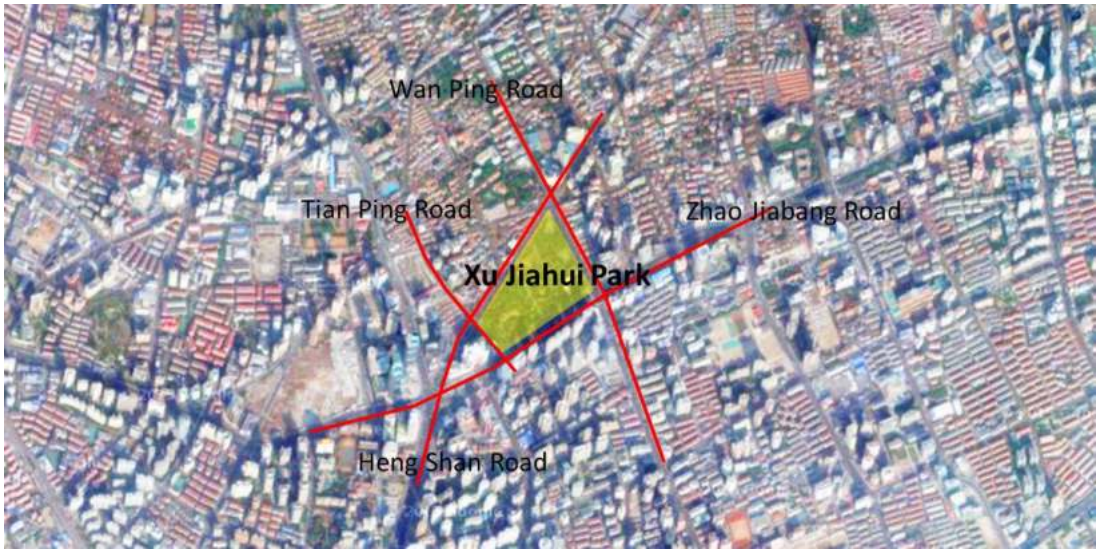

Figure 1. The location of Xujiahui Park

## 2. Analysis of landscape prototype of XUJIAHUI Park

Xujiahui park is adjacent to the largest business district in xujiahui Shanghai. The park is north to Hengshan Road, south to Zhaojiabang Road, West to Tianping Road and East to Wangping Road, covering an area of about 72700 square meters (Figure 1). The base shape of the whole site is like as a trapezium. There are multiple gates organize the stream of people which making it much better integration with surrounding environment and enhance the accumulation ability of the park. Xujiahui Park had been built which improve the regional environment and meet the citizens' leisure activities, is also has strong ecological benefits.

### *2.1 Prototype of Site Region*

#### 2.1.1 Analysis of The Whole Site Region Prototype

Xujiahui Park is like a mini map of Shanghai. It is base on two methods of art symbolic and analogies to tall us a story about Shanghai history. A lot of continuous landscape bridges connect with the History, Nowadays and the future of Shanghai which make visitors who are walking around the park on reading a photo album. So, the best tour way is come from the south entrance, standing on the top of park where getting a whole view, and then, getting a depth experience (Fu zhongxian, 2004) .

The landscape bridge start from the southwest corner near to Zhaojiabang Road and Tianping Road, it show commemoration and admire on national industry in modern times. Walking along the landscape bridge and turn on the northeast direction, a lot of villas which belong to department store had been protected can be seen in there. The villas make visitors close to the history and open

mystical veil of history. And walk along, as you stand on the landscape bridge which bridging upon the park that old map of Shanghai emerge from there. Visitors overlook the whole history on the bridge, all kinds history stories were combined together to arouse visitors sense of history mission. Meanwhile, visitors can also overlook the river system which as a supporter element connect time and space in the park. The river symbolize as Huangpu River which was called as a mother river of Shanghai, dividing the park into two parts to show the different urban texture about Pudong and Puxi in shanghai. The river tell us a continuous story about the development of Shanghai history from industrial age to nowadays. At the end of the bridge is a view of the thinking about future by landscape designer. (Figure 2 Figure 3)

Figure 2. Landscape bridge of Xujiahui Park

Figure 3. River system of Xujiahui Park

Xujiahui Park making the history of Shanghai as a clue and connecting the tradition culture with society, Reappear a view of the location original live in modern landscape. Old and New human landscape were connected by modern technology to achieve symbiosis of old and new space-time, making Shanghai culture inherited. (Figure 4)

Figure 4. Site-plan by hand painting Xujiahui Park

2.1.2 Analysis of partial Site Region Prototype

The landscape architectures are much easier to touch the interest of visitors. And then, there are four cases in the park will be taken to explain how the site region prototype make resonance with visitors.

(1) The memory of Dazhonghua Rubber Factory

Dazhonghua Rubber Factory is a pioneer of China National Industry and had made a great contribution in the history of china rubber industry. It had been stopped to run and relocated in 2000 for the ecological build of Xujiahui district. Most of the buildings were removed except a chimney in the southwest corner of factory to be as a commemoration point. There is a original view of the factory was carved on the bottom of the chimney where base on landscape reappear to record the developmental history of factory. At the moment, the chimney had became as a famous mark of Xujiahui Park, it was also giving an inspiration of environmental protection to people. (Figure 5)

(2) Red building

Red building is located on one side of Hengshan Road. it s as a ruins of Baidai record Company, have a style of period times. The record company which opened the record production in China was built by French, and the record of production in China, it records the evolution of Chinese modern art history. Landscape architects used processing technique to repairing old as before on the Red building. They protected the original red brick wall and extracted the French landscape gardening methods for planning external environment to coordinate the building inside and outside environment. The landscape space where integrate with the modern living environment was built. It satisfies the viewer curiosity of historic buildings.

(3) A Strip Reflecting Pool

Landscape architect use modern way to build a landscape pool which the chimney reflected in. It is also a way make Geographical element Integrated into the Modern landscape. Although the pool look like simple but it Has profound connotation. Changing the water reflection of the sky, Dynamic and static, virtual and real, old and new combination gives the pool of life. (Figure 6)

Figure 5. The entrance of chimney

Figure 6. A Strip Reflecting Pool

(4) Landscape on lake

Four landscape bridge were built upon the lake which significance of the Huangpu River, they are respectively symbolize four Bridges "xupu", "Lupu" and "Nanpu" and "Yangpu" in Shanghai. They are also designed a Yuyuan Garden on the corner of lake. The design of landscape along main veins point brings a kind of homesick feelings bailment.

2.1.3 Analysis on landscape plants of regional prototype

Xujiahui park without adopting enclosed design, fusion of the surrounding environment in the design of urban texture, it faces to the society and open. landscape plant design in the park full respect to regional block texture, because the style is different ways which the park near to. The plants on boundary play an role on closing park and the surrounding environment. Plants design on the Hengshang Road Adopted rules display way on planting for Adapt to the artistic style of it; Plants design near the Zhaojiabang Road is also in harmony with the surrounding roads, uses the natural way for planting. (Figure 7)

Overlooking on a bridge, the map of Shanghai was performed by plants, combination of modern plant and historical residences form, bring the viewer strong visual impact. (Figure 8)

Figure 7. The plants design of walkways

Figure 8. The map of Shanghai made by pants

*2.2 Emotional prototype*

Figure 9. Creative sculpture in Xujiahui park

Figure 10. A Run way

Emotional prototype material selection are not limited to the scope of the area, all of them which shock the viewer inner elements are emotional prototype material, Such as moving plot historical stories, creative sculpture products, novel emotional experience places, etc. The landscape design which based on the emotional have its vitality, it can make busy citizen completely relax in here and get release emotions. (Figure 9)

2.2.1 Atmosphere Build

The lake as the center, axis straight road and waterfront curved road were Combined into the Skeleton of the park, and the Landscape bridges like solid skeleton of space form. The whole park spaces have variety levels which Combined with the primary and secondary, Advancing begets, Strewn at random discretion. Different landscape corridors which String together by the time have different psychological feelings, Stimulate visitor heart from miss the history to the dreams of the future. (Figure 10) Winding corridor water system and time are intertwined, the Running water is sometimes depression soothing and sometimes is actively, making the visitor Sentimentally attached for The passage of time.

Figure 11 Rich levels view Figure 12. Variety of activity space

In each landscape nodes to use of building envelopes, different materials contrast and collage, configuration of the different plants, forming a series of different sizes and rich layers of space. (Figure 11, Figure 12) Different spaces attract different people and Gather a variety of activities; The same spaces at different times will attract different activity groups and rich activities. Bring to different ages viewer an experience which will be much more exquisite and stimulate their inner feeling.

Construction of artistic conception and atmosphere of rendering can t leave away the plant configuration, the plants morphology and flower color directly influence people's deepest joy and sadness. At the major entrance where nearby the Zhangjiabang Road and Tianping Road is fundamental key with Yulan plants, Cooperate with the plum blossom, Chinese flowering crabapple to significance of a feeling of good and strong, give people colorful romantic mood; Nearby one side of the Linping Road, base on red tree to be a key plants, such as maple, maple, and Nantian bamboo. When autumn comes, the Red leaves like fire and yellow leaves like gold, Such a warm color represents happiness.

2.2.2 The Angle of Views

In front of the Xujiahui Park was built, there are just two meters elevation on the site, it is not conducive to build a watch level. In order to form a good viewing Angle, the design would improve the land of northwest corner in the park to make the park surrounded by topography. Gently undulating terrain and plants constitute a gleaming surround close space, obscured the peripheral urban road dust and noise to be a good microclimate in the center area. (Figure 13) The main activity area layout in central of the park, a good landscape views were gotten From the surrounding landscape node static to dynamic center landscape nodes. As the viewer look around the center to the outside is like a place by oneself in the city of the bosom nature, to provide a joyful mood to visitor. (Figure 14)

## 3. The conclusion

Landscape Divided into two parts: Landscape and the viewer of Landscape. When landscape architects begin to design he must be clear about why do the landscape? And who is the viewer? There is no doubt that Landscape design is done for the viewer, and the design process must be standing on the position of the view. Therefore, a good design must be "people-oriented", "based on people's feelings"(The Feelings mentioned here, on the one hand there is a part of the geopolitical foundation, on the other hand is arises spontaneously). Furthermore, the landscape design is by taking advantage of good story with the surface of the earth to touch visitor heart and give visitor ups and downs of emotion.

## Dealing with Urban and Rural Decline: Interplay of Actors and Responsibilities

# Jak DEVELOPMENT OF NOWE WARPNO – IMPLEMENTATION OF A DON T MOVE IMPROVE DEVICE IN A SMALL POLISH TOWN

Katarzyna Krasowska[1]

[1]West Pomeranian University of Technology Szczecin, Faculty of Architecture and Institute of Architecture and Spatial Planning, e-mail : krasowska.katarzyna@gma

Abstract:

Nowe Warpno is a typical example of a town stricken with economic collapse o nevertheless managed to survive due to the attitude of local authorities and re analysis carried out for this rural-urban municipality unveils that it has bee negative occurrence of shrinking towns. Existence of Nowe Warpno has always associated with lake fishery formerly supported by functioning shipyard, com harbours. The crisis of Polish fishery – liquidation of local shipyard, Polish Schengen Area, abolition of duty-free zone on the town grounds caused deteric disappearance of life within Nowe Warpno until the beginning of the 21st cent Strategy of Development supported by efficient local authorities aiming at rev economic development, effective acquirement of regional and EU funding, in addit compensation from Maritime Department reasonably allocated by the authorities, a a decaying village into a tourist destination. Wise management established th richest and best-administered municipalities in Poland. For Nowe Warpno the la from deterioration to averting the crisis . The article depicts endogenous and influenced the success of this small community. Among the positive tendencies a the initiative of inhabitants fighting for development of expansively function actions have a lot in common with the idea originated in a district of Boston:

Keywords:local planning, town revitalisation, european union s funds, local rev small towns

## 1. Introduction

In the time of globalisation, urban centres participate in international investments, inhabitants and tourists. Those cities, which raised a broad symbolic cap battle for creating an attractive touristic product on a global market. The si big, but also small cities. Among this group we can also rate such historical centres Gimignano (7105 residents) and Polish Kazimierz Dolny by the Vistula River Therefore, there are cities which regardless of their scale are globally or over-local to the value of the gathered legacy and compilation of unique features, that nature. There are also cities so far lacking the local, domestic or even global identit small Polish cities, which in the last quarter of a century had to face up to transformation, are peculiarly interesting example. Closing one local industry b turnabout of an economic profile of the city, usually faster than services a developed there. The process of de-industrialization worries the most, due to the co cities and the sequence of negative occurrences such as the unemployment, impo and finally depopulation of small centres, connected with the job-search migration to UE countries. These phenomena cause the shrinkage of small cities and require

organizational potential of theirs authorities and citizens in order to protect maintaining the official, judicial, or health function of the district service further regression or stagnation. Tourism, considered as a leading industry fu important role in the process of the largest post-industrial centres revit significant link to stopping the degradation of small cities.

2. Nowe Warpno – a city with a great history.

Figure Nowe Warpno – location

Nowe Warpno is a classic example of the small town, affected by an economical r It is a least populous urban-rural municipality in Poland situated in Western location). The exact date of town s foundation is arguable, however it probably year. This little city is situated on a cape, which is a part of a Nowowarpie skie Lake from the eastern side. Originally Nowe Warpno laid on th was joined with the dry land by weir. Raising fortifications hasn t been ne defensive conditions of the town. Entirely wooden buildings were put up at fou streets and a marketplace. Uninhabited character of buildings led to many fires Warpno and caused its destruction. Despite historical turbulence associated wit as well as the changing state affiliation, citizens for centuries led a calm l natural environment and season s cycles. According to Wojciech opuch : Existe was connected above all with the lake and bay fishery, as well as with farming and Especially fishings, their processing and sale determined the economic state prince's privilege for the organisation of trade fish fairs gave the city hug activity associated with town s by-water location developed apart from the fis part of the XVI century a shipyard was founded and in the XVIII century seve operated in the city. Apart from a fishing port, a trade port functioned, thro goods were obtained from Wkrza ska Forest. The XIX and XX age brought an in Warpno, as a potential holiday resort. A closeness of the Wkrza ska Forest and tourism development. Even though Nowe Warpno never became a health resort wit other fishing towns set by the Baltic Sea, the tourism started playing a role Many steam ships, which serviced a regular sea-route to Szczecin, made a port Each tourist was able to find a bathing beach, hotels and inns in this town. Ho of tourism didn't affect the fall of fishery s significance. In the 30s Nowe Wa

fishing bay port and a headquarter department of a fishery master. Thanks to th
War has spared Nowe Warpno, it kept its urban planning arrangement and the ma
buildings, along with exceptional monuments such as : Town Hall (Figure 2) and
Assumption of the Virgin Mary. A fishery and a boatbuilding still remained
economy. In spite of restoration and touristic activation projects made in th
monochrome lifestyle has changed in 1996 , when the duty-free border crossing p
Warpno and Altwarp (DE) was opened. The opportunity of cheap alcohol purchase
visitors to Nowe Warpno. However they remained indifferent to city charms by sh
port market. The time period connected with the border trade ended along with
European Union and the "Schengen zone". From this moment on we can observe the
fishery, which is associated with permission to compensational cutter-scrappin
and Nowe Warpno started plunging into the slump, along with vanishing of passer
fishing cutters.

Figure Revitalization of town hall in Nowe Warpno

3. Process of the cities shrinkage.

There s no particular theory explaining the shrinkage of cities. Many asp
cause, that in order to understand its mechanisms, the course and effects,
theoretical concepts. One of attempts of interpretation is a reference to Gunnar Myrd
Process theory (1956) modified by Hokveld (2012) in which the reduction of ci
circle – is both cause and a result of the shrinkage of cities (Figure 3 -
shrinkage). There is no simple solution for stopping this process. The undert
depend on a way a shrinkage-process is perceived by local authorities and o
population s decrease. These strategies can have an adaptive character (plann
shrinkage conditions or can be orientated to re-increase with shrinkage as a

process might also be ignored – no action is being taken. Planning in the time
more difficult than in the increase conditions, therefore a way of managing
shrinking cities is very important. Building the development strategy based o
favouring the improvement of city s social-economic situation is crucial. For
the periods of growth, stagnation and fall. Cities based on one, falling indust
position. Nowe Warpno was set in this situation. The last wave of the stagnatio
connected with fishery s fall. Nowe Warpno was afflicted by a deep crisis
unhesitating actions aiming at the creation of new strategy of social-economic

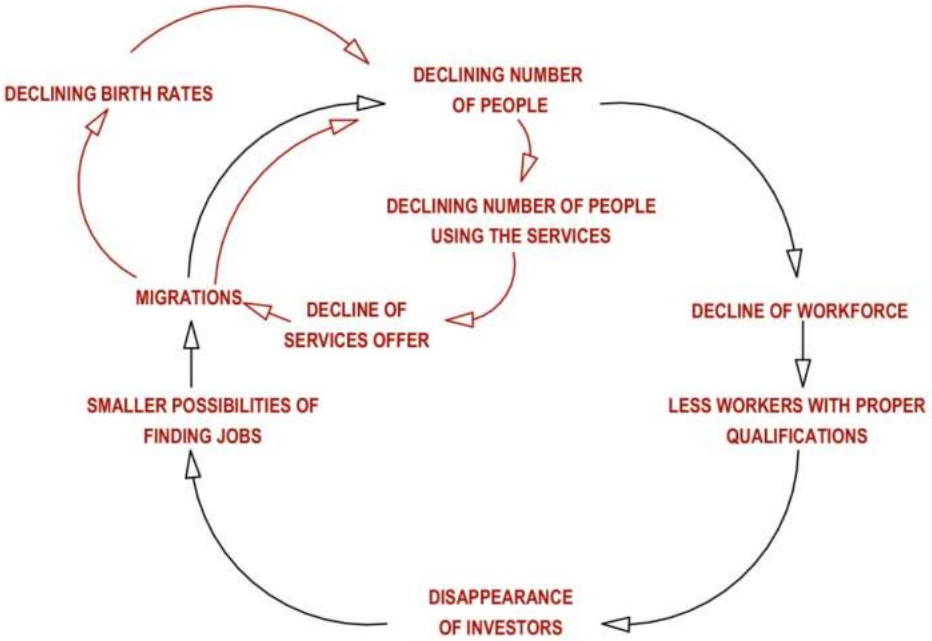

Figure "Vicious Circle" – sherinkage of cities, source: on the base of Hoekveld 2012, s.

4. Social-economic revitalisation of Nowe Warpno.

The revitalization is a method of reviving the degraded municipal compl
accumulated social-economic problems, the effect of which is technical consumpt
land development as well as the environmental degradation. It should consist i
the self-reliance of the local community and the ability to improve (restor
reducing the dependence on the public assistance. It s too often identified as th
buildings or the improvement in the public space, when it is only a part of ac
city. Such actions are rather a symptomatic treatment", effective in places
temporarily suppressed developmental potential. In most of the cases, those act
delete the causes, rather than symptoms of the degradation.

In 2004 a Strategy for Development of Nowe Warpno Community (for years 20
been created. It was later extended to 2007–2020 years. The priorities include
creation and modernisation of the infrastructure for improving the competitiven
strengthening the economic development in the community, enabling personal
development of residents, creating a new quality of life for Nowe Warpno reside
of the touristic and recreational function and exploiting its natural advan

investitions and up to now changes, it s easy to state that strategic aims ar fulfilled, if there s a vast support from the external financing and previously finances.

Recent years of Nowe Warpno pave a road from a shrinkage (fall) to a cr further development . Today's New Warpno present itself as a small dynamicall Wise managing by local authorities focused on the public activation and th development certainly plays a huge part in this process. A number of munici affecting such image of the city.

Amongst major investments, having a huge impact on an actual image of previously fishing, today more of a touristic one – those connected with a tran a greater role ( creating a road from a nearby Dobieszczyn to Nowe Warpno investment with local administration of Police government ). The reconstructio cost over 15 mln zloty. For a touristic Nowe Warpno this road is of a great imp the connection with a central voivod city – Szczecin from an hour up to 40 minu touristic motion, but also increases the attractiveness and worth of recr community.

The municipality also put an emphasis on the cyclists service, so that new bicyc

- road along the ancient railway line No. 424 Swobnica–Sonowo, incising the Tywy v the high hung bridge (length 15.8 km)
- the environmental education path between the newly built district road New Dobieszczyn and the Polish–German border – it leads through Wkrza sk protected by the Natura 2000 project, to a border river My liborka (lengt
- the bicycle route running along an old railway embankment from the Polna Warpno to the route W114 – near a Szczecin Bay (length 3.41 km)

Being involved in a project of the Westpomeranian Sailing Trail Nowe Warp the path marked by the water–leisure touristic potential. Project of the new sa the infrastructure is an extremely needed investment, which without a doubt will city from the waterside. The new sailing port was located on the southern side the development of the water infrastructure Nowe Warpno has an opportunity beneficial location. The city is an only Polish port located on the west coast cross–border character makes the city very attractive for both Polish and Additionally the revaluation of the city conducted in final years builds the s development. However refurbished squares and streets are waiting for their vi yachtsmen. The unique value, in comparison to other trail–cities is Nowe Warpno and still noticeable genius loci of a of fishing settlement. However through th the city shows one enduring principle, the fate of Nowe Warpno is permanently c regardless of the character of this relation. Today the city starts to write the

# Analysis for the Policy of Reorganizing Rural residential patches in China and the Dilemma of Ecological Niche in China s Urban and Rural Areas

Yufeng Yue[1] Weiqiang Wang Jian Li[2]

**Abstract:** *With the rapid economic development and significant urbanization in China, dual-structure phenomenon, caused by the great gap of development level in urban and rural areas, has become increasingly prominent. Compared with the urban areas, the development in terms of social, economic and cultural aspects in rural areas has encountered underlying dilemma. To narrow the gap between urban and rural development, the Ministry of Land and Resources has proposed planning policy for reorganizing rural lands, trying to achieve integration of the population and land resources in agricultural areas and construction of modern intensive rural residential areas to promote the overall development in urban and rural areas, and realize the modernization goals for the benefit of rural areas, agriculture industry and peasants there. This paper is aimed to adopt the research perspective and method of ecological niche theory, establish the ecological niche expansion model and analyze the theory essence of the Reorganization of rural residential patches to summarize the internal change mechanisms of the ecological niche in urban and rural areas during the process of consolidation.* Combined with author s planning and research in Henan P*rovince, Chinese agricultura populous province, the empirical analysis could be conducted to determine the niche development trend in urban and rural areas during the course of the consolidation, so as to propose a value judgment orientation for China rural governance and planning policy development, as well as the discussions on the niche dilemma and path direction of the rural development in China.*

**Key Words:** planning policy, ecological niche theory, reorganization of rural residential patches

## Introduction: the Reorganization of Rural Residential Patches under Urban-rural Dual Structure Background

With the rapid economic development and significant urbanization improvement in China, the social contradiction between urban and rural areas has become increasingly prominent. This has been vividly explained as the dual structure phenomenon to reflect the great difference standard in urban and rural areas. Moreover, it has also led to the severe imbalance in terms of social and economic development in urban and rural areas as well.

To enhance the development from the long-standing malpractice in China s backward rural Chinese Land Administration and Planning Departments have proposed to conduct centralized planning and construction in rural areas through Reorganization of rural residential patches to optimize the land resource construction and explore the social and economic development potentials in rural areas, as well as improvement to the living environment and realization of the mutual development goal for both urban and rural areas.

## Section 1: Theoretical Connotation of Reorganization of Rural Residential Patches

Reorganization of rural residential patches is an important measure to improve rural land use efficiency and intensification, as well as the proper, rational and scientific utilization (Baoxin Qiu, 2003). It is mainly adopted with the engineering technology and land ownership adjustment measure

[1] Yufeng Yue, Department of Urban Planning, Tongji University, yueyufeng1335@gamil.com
[2] Weiqiang Wang & Jian Li, Department of Urban Planning, Tongji University, wwq@tongji

according to the readjustment to the residential land size, internal structure and spatial distribution based on the urban and rural planning.

*1.1 Governance Objective of Reorganization of Rural Residential Patches*

In urban and rural planning, the primary purpose to carry out Reorganization of rural residential patches is to improve the disorder that does not meet the requirement for sustainable development and inefficient land use in rural areas, so that a harmonious living environment could be built up to create conditions to promote the construction of the material and mental civilizations, as well as the development of urban and rural integration. Combined with rural collective land circulation, resource allocation of the collective construction land could be optimized not only to realize rural industrial structure adjustment and upgrading, but also to increase farmers income and emp

*1.2 Governance Measures on Reorganization of Rural Residential Patches*

Consolidation of rural residential patches is actually a kind of action program establishment and feasibility study on rural economic, social, ecological and other aspects of development. The study is consisted of technical feasibility, economic rationality and possible building plan. Through conducting technical analysis and argumentation to the planning program and risk assessment to the potential profit after the implementation of the Reorganization of rural residential patches, a reliable reference could be offered to investment decision to strive to achieve the best effect from the overall benefits of the consolidation of rural residential patches.

## Section 2: Expanded Application of Ecological Niche Theory

From the *dual structure* feature of China's urban and rural perspective, the competition mechanism between urban and rural areas had similarity like the two species competing for the resources (Figure 1) and the differentiation of urban and rural functions led to the differences in development trend and production function in these two aspects, which reached a dynamic equilibrium in resource requirement. The author believes that from the research field of the urban ecology, the Reorganization of rural residential patches enjoys the significant ecological niche feature in changing the long-term harmonious resource competition trend in urban and rural areas, Therefore, the author attempts, from the theoretical perspective of the ecological niche and with the implementation case for the Reorganization of rural residential patches as the basis, to analyze the theoretical mechanism of the ecological niche and potential difficulties aroused from the implementation of this policy.

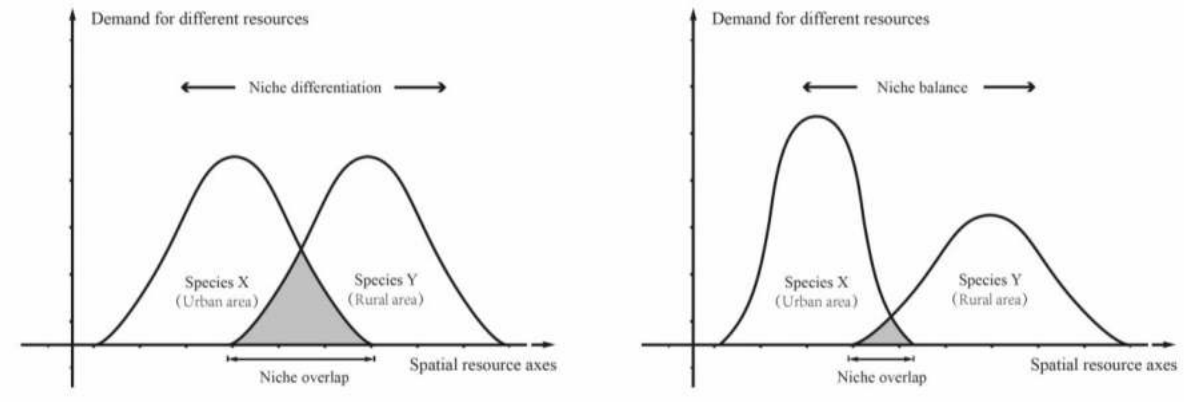

Figure 1. Urban and rural ecological niche expansion model

*2.1 Differentiation and Analysis of Ecological Niche Concept*

Ecological niche, initially put forward by J.Grinnel in 1917, refers to the basic living space that the biotic population occupied. It also mainly refers to the physical space. In general, the ecological niche belongs to the certain qualitative or quantitative description of the relationship between living organisms and the environment (Yuchang Shang, 1988).

It contains two meanings. Firstly, for individual organism or biotic population, it is a matter of the necessity for its survival or a collection of ecological factors or relationships for its use; secondly, for the organism s real living environment, it is a matter of the various ecologi relationship to the suitability of biological species (Rusong Wang, 1988). After eighty years of development, the ecological niche concept and theory has gone beyond the biological category and has penetrated into the field of urban ecology as the research area.

*2.2 Urban Ecological Niche and Rural Ecological Niche*

Urban ecological niche (Rusong Wang, 1988) is defined as a combination to provide people living in urban area with a variety of ecological factors (such as water, food, land, buildings, transportation, etc.) and ecological relationship that can be utilized by people (such as productivity level, environmental capacity, living quality, etc.).

Urban ecological niche is directed to city s special organic *ecological element*. It essentially refers t the urban residents living conditions and the quality of life satisfaction (Xiud the major subject of the city and the urban development is in fact aimed to continuously improve people s living quality. This has become an important issue for urban development on how t the urban ecosystem and establish suitable living and ecological environment.

Furthermore, the concept of urban and rural ecological niche is, during the discussions on the urban and its surrounding countryside s development, the degree of satisfaction from residents and rural areas on their living conditions and quality of life, namely the dynamic trend research on urban ecological element and rural ecological element.

*2.3 Intervention Mechanism of Urban and Rural Ecological Niche*

Urban ecological niche level, to some extent, is set to determine a city s sustainability. The gap between urban and rural ecological niches is a direct reflection of the competition between urban and rural areas. Survival, development, and constant improvement for the quality of life are the instinctive needs for urban and rural residents. From environmental ecological point of view, this instinct is also regarded as the ecological demand. Therefore, the urban and rural ecological niche suitability plays a decisive role for habitability in urban and rural areas.

Predictably, the planning and construction of rural residential patches, from social, economic, ecological and other aspects, could bring impact to urban and rural life appropriateness. This planning and governance policy based on rural development has become an important regulatory tool for the operational mechanism in urban and rural ecological niche. How to efficiently and harmoniously carry out a regional regulatory or the surrounding countryside s niche situation shoul part of the urban ecological planning. The author will also combine the management of urban and rural planning in Xinmi City, Henan Province to conduct the empirical analytic theory for urban and rural ecological niche.

## Section 3: Empirical Analytic Theory of Urban and Rural Ecological Niche

Over the years, population problem has become a major problem for urban development. The proportion of the city population is directly related to city s land use rate and u has also become a crucial constraint to impact the healthy development in social, natural ecological security aspects (Hualou Long, Yansui Liu, Xiuqin Wu,et al, 2009). Take Xinmi City of Henan Province as an example, it is located in Henan, China s most populous provinces and belongs under the jurisdiction of the provincial capital of Zhengzhou. It covers an area of 1,001 square kilometers and the residential population, according to the data in 2010, has reached above 800,000. Xinmi, as the key and centralized construction area called *Zhongyuan urban agglomeration* in central region of China, the regulation of its internal planning and rational development of the population hereby becomes more important.

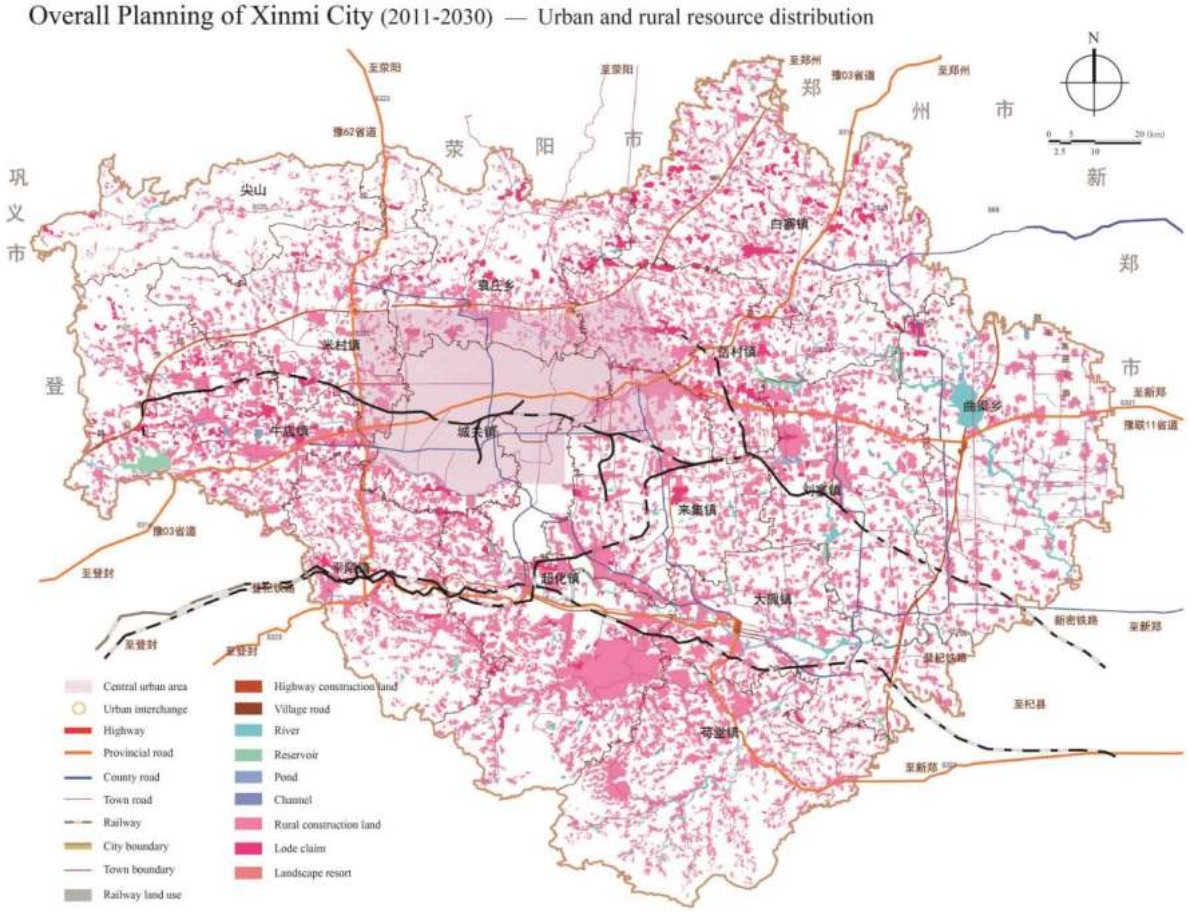

Figure 2. Urban and rural land resources distribution of Xinmi City

The agricultural population reaches 432,000 in Xinmi, representing the city s minimum half of total population in rural areas which has undoubtedly become a major issue for urban development. At present, Henan Province, with implementation of urbanization, industrialization and agricultural modernization as the development goals, is aiming to lead the entire optimization and adjustment of industrial structure and enhance economic vitality to reach the purpose of strengthening the overall competitiveness of the central plains urban cluster. Among them, the fundamental means for the so-called modernization of agriculture is to realize the population migration and the integration of

production resources though new rural residential patches consolidation, plan
(Figure 2).

*3.1 Reorganization of Rural Residential Patches and Planning Implementation in Xinmi City*

*3.1.1 Consolidation Principles for Rural Residential Patches*

As for the current situations, the rural construction in Xinmi is reflected by dense building and disordered layout, which may cause potential safety hazards; village road grade is backward and non-systematical, which could bring inconvenient transport to the external areas, as well as the inadequate infrastructure, outdated municipal facilities and poor living environment. Therefore, the three principles for old villages renovation and new rural construction have be

1) Government-led and prior planning. To ensure that the village renovation could comply with the public interest, realize social justice in area households innovation process innovation beneficiary to the majority of the villagers. Planning Departments are expected to shoulder the inevitable social responsibilities to strive to promote the mutual advancement of the rural special innovation and social reconstruction.

2) Urban-rural integration, one policy for one specific village. Under the guidance of the local policies, the villages at different regions and with various natures should be established by different innovation goals and strategies, so as to effectively carry out peasants survival, relo other issues from planning perspective to achieve comprehensive rural and urban integration.

3) Remove the village and build residential area for nearest settlement. Develop control requirements for land use, building strength, green systems, road traffic, public and municipal infrastructures and others to focus on the innovation of residents lifestyle. Considering rural farmers feelings resettlement should be completed by nearest settlement.

*3.1.2 Thought Analysis of the Consolidation of New Rural Residential Patches*

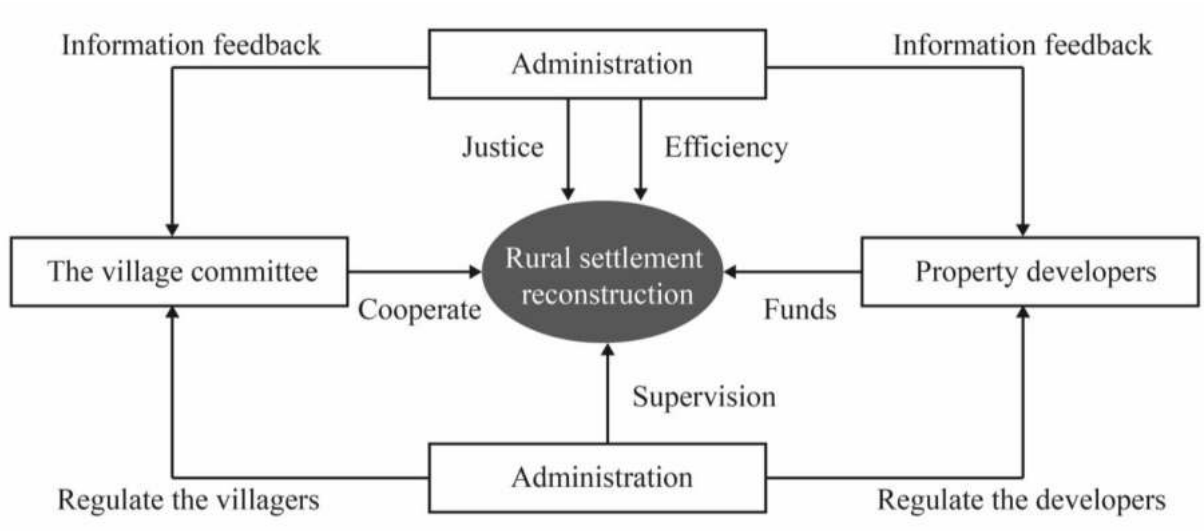

Figure 3. Collaboration mechanism between government - villagers - developers

1) Interest equalization system among the government, villagers and developers for innovation of the physical environment (Yong Liu, Cifang Wu, Zhirong Yang, 2008). Based on government s consideration for the interests of the villagers and development efficiency, farmers and developers could take part in the discussions on village innovation plan and government departments could be designated to monitor the implementation, supervision to standardize the whole process (Figure 3).

2) Diversified mode of function remodeling for village open space innovation. Remodeling can be considered at part of the villages to build up landscape with historical and cultural geographic features; besides, it can be set up as a platform to propagate the local cultural characteristics in Xinmi and plays a role for landscape enrichment to satisfy the cultural, recreational and leisure needs.

*3.1.3 Planning and Construction Overview for Rural Residential Patches*

In overall urban and rural development plan for Xinmi, the rural residential patches consolidation target could be conducted through consolidation of rural residential patches and great efforts for building new rural communities (44 comprehensive rural residential patches). Among these plans, the total population related with the plan reaches 150,000 and there are 3,000 to 5,000 people involved averagely in each community, representing 23 square kilometers for the total construction land.

The major innovation approach is to move and combine the remote areas and natural rural villages where the infrastructure is relatively backward; migrate and combine them into a large-scale village where is distributed along the main highway and with relatively more favorable and economically developed situation. In the meantime, the general idea for urban construction could be integrated to strengthen the construction in culture, education, business and other public service facilities and improve the overall living quality in rural communities (Figure 4).

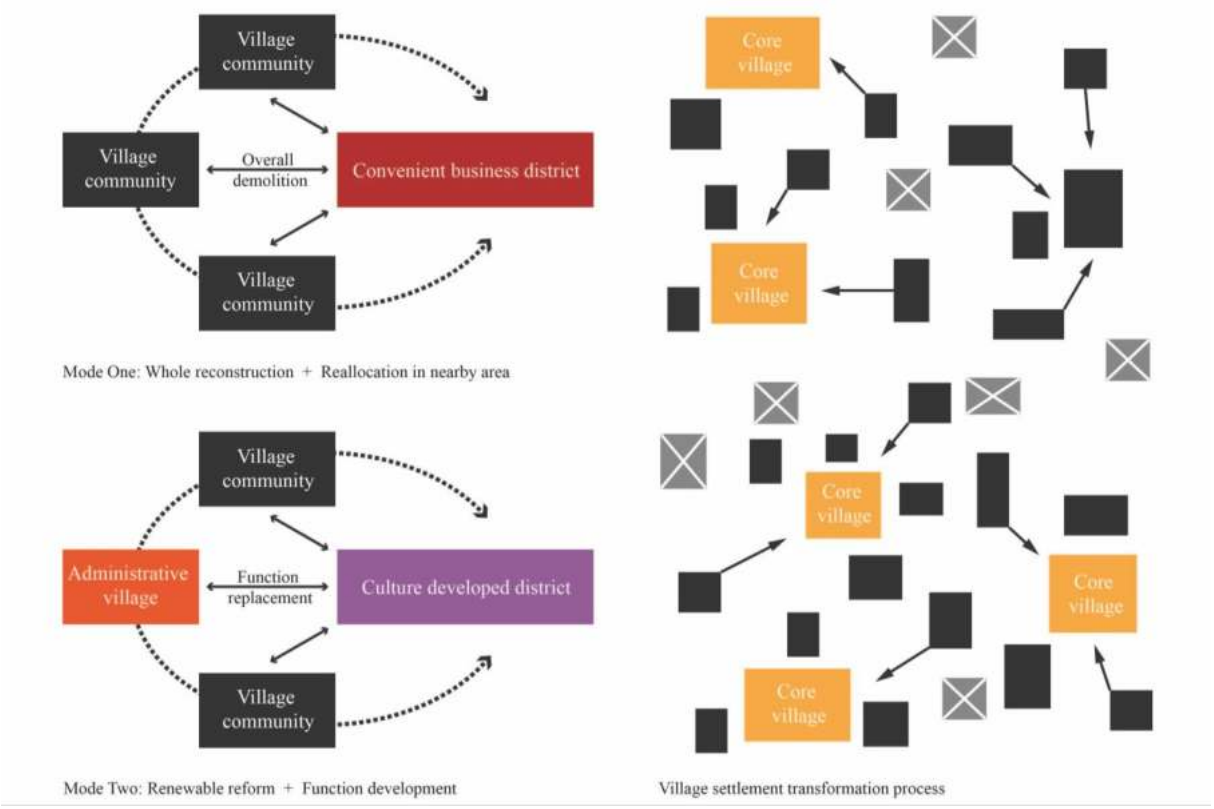

Figure 4. Rural residential renovation patterns

*3.2 Analysis of the Ecological Mechanism of the Rural Residential Patches Construction*

To adopt from analytical perspective of ecology and take ecological niche as an analysis tool to study the migrated population s nature under the rural residential patches consolid provides a main analysis of the level of urban and rural niche in Xinmi rural geographic areas, among which resource niche, environment niche, economic and social niche are included to eventually come out a comprehensive regional population s niche systems, in order to achieve predicting and optimizing the layout of the population.

*3.2.1 Niche Principles for Population Migration*

Regional niche reflects the suitability that the regional status brings to all kinds of economic activity and human life activity. It also reflect the region s nature, function, position, function, po resources and environment s advantages and disadvantages, which could be used attractiveness and centrifugal force to various types of economic activities, occupations and age groups (Xianqiang Mao, Jingshan Yu, Xiurui Guo, 2005). Ecological factors and ecological relationships within urban areas consisting of respective niche which is different from each other and the differences of production and life caused in these areas are known as ecological potential. It is not difficult to see that the movement of the village and combination to the town and city trend in Xinmi, Henan Zhongyuan areas is theoretically a result reflection of chemotaxis principle and balance principle of human production and life activities brought to the urban niche in the following aspects:

1) Seek good niche is a common feature of human production and life activities. Such chemotaxis behavior includes not only the behaviors to adapt the environment, but also includes the behaviors to conduct environment invocation. The result could lead to an urban agglomeration with capital, population and other elements (Rusong Wang, Jing Chen, 2007).

2) Result caused from human s agglomeration into the high niche areas to have over-explored and utilized and thereby reduced the life niche, resulting in a weak niche or even a negative niche and the emergence of the stagnation of the population flow or back-flow (Mingli Chen, 2010). This balance maintains a relatively stable status for population migration between urban and rural areas, cities and communities. Urban ecosystem is always developed toward the direction of succession to reduce the ecological potential.

As to the current situation, these two eco-regulation regular patterns are realistically affecting the village relocation and combination project process. That is, to select new rural settlements, the advantage and disadvantage status of each niche will be taken into account.

*3.2.2 Urban Ecological Essence in Rural Residential Patches Construction and Innovation*

*(1) Niche Analysis*

Through the research on the township and rural settlement in Xinmi, the following findings can be discovered. Firstly, compared with the northern and southeastern mountainous regions, central and northeast hilly areas and towns near Zhengzhou have obvious advantages in business services facilities, culture and education, health care and other aspects; secondly, by analyzing and comparison the current situation in the coal mining towns with the planning model developed in earlier stage, on the

one hand, the original township was developed based on the coal industry and led the upgrade of the related industries, their living quality is further improved accordingly; on the other hand, there are less employment opportunities in the urban areas currently. Compared with the surrounding mining towns with rapid development, the labor demand here is expected to be increased greatly.

From the urban ecological perspective (Yang Liu, Jian Liu, Jiangang Xu, 2008), the living niche in some of the industrially developed towns is now not less than the old town. With the population saturation status of the land for construction in main urban area and the surrounding areas, especially with the bordering Quliang County s industrial construction agglomeration area and the living niche in the surrounding emerging towns will be further improved. However, life potential niche in the main city and surrounding towns will be significantly reduced. According to the chemotaxis principle of the human activity, township s population standing in the rapid development trend and it will conduct internal integration of the population first, namely the merging of the rural communities. This is not only to better mobilize the population resources and advantages, but also to intensively and effectively improve the niche in town areas, resulting in the development of the internal population agglomeration in each township.

On the other hand, due to the improvement of the traffic transportation conditions in the old town, the positive interaction between industry and the community at surrounding residential locations between the mode of production will make life a shift in some rural residents, namely and town flow. Thus, after the merger of rural land, it will be in favor of re-segmentation, development of agricultural modernization, mechanization of agricultural production and efficient labor to further enhance the economic and social niche in rural communities.

*(2) Analysis of Ecological Benefits*

By analyzing the relationship between population agglomeration and urban ecological system, the author found that the city s rapid population agglomeration could effectivel residents living space and enable them to use social traffic transportation for a short distance to go back and forth between communities and towns. Hence, this could effectively relieve the traffic burden for previous difficult trip to city . To make a relatively smooth trip for back and original route could be objectively improved to strengthen government regulation mechanisms to adapt to the future development of the growing traffic.

Obviously, population agglomeration means that the environment they lived has been changed. To adapt this change, it is bound for people to carry out a variety of activities, which the consequences arising from these activities will be responded back to the artificial environment in which new changes are occurred there. Feedback relationship between people and the artificial environment indicates that their individual elements are connected each other and any part of change will cause a chain reaction to the other sectors. Consequently, the entire system reacts and makes changes accordingly. Therefore, population agglomeration is not just a simple problem to only impact on individual, but a significant impact brought to the harmonious development of the whole city s ecosystem.

Firstly, population agglomeration could force the government departments at rural or county level to improve their overall regulatory capacity. From a merge case regarding to the rural residential integration, to achieve *urbanization, industrialization, agricultural modernization* in Xinmi, lag problem to hinder the rural development should be solved as priority. The major problem in rural areas is considered as the problem related with production, culture, education and social security. Integration of the population is essentially the integration of resources and environment. Government, by the most limited administrative resources, is expected to improve the living conditions in rural areas and

enhance the ties with various town centers to make a reasonable and efficient allocation for the nature, economy and social resources.

Secondly, the optimization of the industrial structure of the city will be implemented, namely the integration of the population to drive the booming development of the labor-intensive industries. Under the current situations that high-tech and high value-added industries are not suitable to be developed, push the labor-intensive industries to drive the city s comprehensive industr be transformed from primary industry into the secondary industry or the tertiary industry will be considered as an effective safeguard mechanism, which also functions as a powerful catalyst for urban population s resources regulation.

In the meantime, to improve the social ecological environment also plays a pivotal role. The redistribution of land and natural resources could accelerate agricultural modernization, mechanization and efficiency, which marks the enhancement of urban development and production level. At the same time, from residential patch s perspective for the long-term development of the community, linkage development with township and city, to a large extent, could accelera According to the planning analysis, in the context of the development of the new rural construction and population agglomeration in township in Xinmi, the annual level of urbanization development will reach 2% averagely.

## Conclusion: Analysis of Ecological Niche for Reorganization of Rural Residential Patches

*(1) Regulatory Policy Analysis of the Village Relocation*

Except the limited financial and material resources at this stage, government is also subject to land use conditions in urban areas and is unable to continue expand the population capacity in urban areas. Hence, it is necessary to alleviate the trend of urban agglomeration or outward migration. To achieve this goal, through explore city s internal and textural potentials, subur functionality could be improved. By reducing the urban-rural ecological potential and reduce the floating population in urban areas, the urban infrastructure construction and development pressure could be largely lowered.

It is also worth noting that a single function of land use has a low internal diversity, weak symbiotic relationship and unproductive eco-efficiency. On the other hand, the diversity of the urban environment is a relatively more important symbol than the human environment in countryside. Therefore, the improved villages with strengthened internal diversity will not only improve the single relationship between the internal social culture and life in rural areas, but also promote symbiotic coordination with circular development mode to ensure the continued development in rural communities.

In summary, from the city s ecological regulation perspective, regional intensive huma save space, time and lower utility costs; meanwhile, it can also improve material and energy efficiency. The core theory of village relocation is to promote fundamentally an intensive and efficient ecological construction mode.

*(2) The Niche Dilemma of Rural Development*

However, the load capacity for human activities in urban and rural areas is limit. When population is surpassed a certain proportion, the ecological constraint will appear and urban ecological niche will be

reduced. Similarly, if overextended rural residential patch turns up to cause the mismatch between population and possession resources, this could also cause urban and rural niche imbalance, leading to urban and rural areas further competition for the resources. Village relocation under the governance of the Reorganization of rural residential patches is trying to enhance the niche in rural areas from economic, social and ecological dimensions, so as to change the status to avoid the rural resources from being plundered constantly by the urban development under the tide of urbanization.

Introspection is needed as competition aroused from urban-rural dual structure niche view that rural agglomeration essentially destroyed the original niche trend of urban-rural symbiosis and resulted in their niche overlapping with a deteriorated competitive relationship. In the long run, compared to urban areas, China s vast rural areas could always stand in a weak position for developme use limited resources to conduct centralized development in rural areas and avoid competition for resources between rural and urban areas requires a different route from urban development in rural areas planning. Unfortunately, the current centralized construction method used for rural residential patch, from the perspective of the niche, has encountered plight of homogeneous competition.

## Energy and Space as Resources / Limits for Planning Decisions

# Correlation Studies on Residential Pattern and Carbon Emissions from Residents Transportation: A Case Study on Shanghai Caoyang Xincun[1]

Weiqiang Wang[2] Jian Li Yufeng Yue[3]

***Abstract:*** *Population density is relevant to the residence form characteristics and pattern classification, and the carbon emission from residential transportation is logically correlate with population density, facilities variety and traffic site distance. Existing related research shows that urban form cause influence on transportation and carbon emissions, however, on the part of residential scale, the relative research on spatial form and per capita transportation carbon emission still needs more empirical cases. This paper takes Shanghai Caoyang Xincun as the object, researches on the carbon emission with "3Ds" theory, through the investigation questionnaire to estimate the per capita transportation carbon emission of 54 estates sample. From the comparative analysis of the results, the volume ratio of Caoyang Xincun and population density present positive correlation with transportation carbon emissions per capita, but negative correlation with facilities variety. Considering settlements residents of social economy and traffic facilities layout unbalanced factors of traffic sites and accessibility and negatively correlation with transportation per capita carbon emissions. According to the analysis from the logical correlation between the carbon emission and eight residential patterns in the sample, it is concluded that the diversity of per capita transportation carbon emissions is caused by the superposition of variety of socioeconomic and travel needs of the spatial behaviour main body. Before the judgment of low-carbon estate pattern, the structural characteristics of spatial density and society should be clarified first, then the national conditions, regional development condition; socioeconomic factors need to be combined to guide the development of future residential pattern.*

**Keywords:** residential pattern, traffic carbon emission, caoyang xincun

## 1. Introduction

As the basic unit of the city, residence is the main area of housing, living and consumption that naturally becomes the main source of carbon emissions. China, a rapid developing country, during its nearly 30 years reform and opening-up process, rapidly developed in urbanization and industrialization. According to relative research, it is concluded that by 2020, this country's carbon dioxide emissions will surpass the USA, ranks the first (Claessens) in the world. By 2011, Chinese residential energy consumption had been the country's second largest in the total energy consumption, occupied 23% of the total (total final consumption TFC). At the same time, it was expected that by 2020, Chinese architectural development scale will reach 2.6 billion square meters, residential building will account for 1-1.5 billion of the total. In fact, the Chinese government always in a positive and responsible attitude to response UN's propose to reduce carbon emissions, and adopts various policies and technological innovations to reduce urban carbon emissions. At the same time, a large number of studies to the Chinese cities have also shown (Ma Jin, 2011); Zheng Siqi, 2010) that the residents trip, traffic model choice and carbon footprint is closely related to the residential development pattern. Therefore this study thinks that the optimization of residents form not only takes a long-term and structural effect on energy saving and emission reduction, but also shows an important

planning path to realize low carbon urban development.

## 2.Literature Review

*2.1 Urban Morphology, Transportation and Carbon Emissions*

In terms of urban scale, the city's economic development will inevitably bring the increase of personal income, the expand of housing area and the improvement of car ownership. the understand of relationship between urban morphology and carbon emissions need to be started from the density. For the urban carbon emissions, a large number of research scholars started from the relations of urban structure, land use and transportation (Bourne, 1982; Anderson, et al. 1996), urban morphology influences structurally on residents' daily life behavior, transportation needs and mode, then directly leads to carbon emissions differences. Wahlgren (2007) found that city planning obviously influenced 10% of greenhouse gas (GHGs) on the city scale and 20% the residence scale.

Many researchers agree that if the relationship between urban form and transportation want be confirmed, at first we need to prove that the individual travel choice is due to the factor of urban form rather than other factors, but this would require the time-related inspection to the urban morphology changes impact on traffic behavior. Obviously it is arduous to take continuous monitoring and feedback on individual transportation data as research condition. Based on differences between Chinese and western countries, we need to combine with domestic samples to take further empirical research on the reference of related mature research theories and analysis methods.

The existing studies found that there is negative correlation relationship between urban density and carbon dioxide emissions (Kennedy et al, 2009; Grazi et. Al, 2008), which means the improvement of city density helps to reduce energy consumption and carbon emissions per capita. However, different with the conclusion of the higher urban density, the lower the carbon emissions per capita which is from the large number of research in the Europe and the United States (World Bank, 2010), in China, the "double high" or "double low" residential pattern often corresponds to a larger living space and higher energy consumption. But can this be concluded that there is simple linear growth in per capita transportation carbon emissions with increasing trend of residential volume and expanding of per capita area?

*2.2 The transportation of residential scale and the "3Ds" theory*

At the level of residential scale, transportation-related spatial form researches are mainly from the following three dimensions: Density , Diversity and Design. (Cervero and Kockelman, 1997), that the density has a significant influence on transportation had been confirmed eraly(Levinson, H., 1963), and the impact of built environment on the residents' transportation has become the focus of academic research in recent years. This study argues that the density is not only the strength index of the residential development, but also the guarantee of residents employment and the walking accessibility of service facilities; Residential diversity can mix up land function and the social classes, meanwhile, it can increase the concentration of service facilities; And the distance of residential interior to public transportation sites determines the walking accessibility and convenience degree to the destination. Therefore, the "3Ds" theory of Density, Diversity and Distance to transit is promoted based on the background of present China's fast urbanization and the much higher residential development intensity compared with the density of the European and American countries. This theory shows more pertinency and feasibility on the low carbon oriented residential morphology research.

*2.3 Residential type pattern and carbon emissions*

Residential morphology is closely related to the environmental sustainable development and energy use. Residential density under different urban scales contains different connotation of space development (Tsai, 2005). There exists interaction in factors of housing material form and urban system, land use, functional structure. The classification to the residential morphology and the description to the features can be defined and divided from the perspective of the density (1). Under the constraint of China's population and land resource, the type of residential morphology is more than just the physical space, also expresses the social-evolution logical characteristics of pattern types. Meanwhile, it reflects the residents' daily activities and functional requirements, thus determines the logical correlation between residential pattern types and traffic carbon emissions.

## 3.The object and analysis method

*3.1 the object selection*

Founded in 1951, Shanghai Caoyang Xincun is China's first workers new village. During the historical evolution process of the planned economy to market economy, it gradually formed the social class and the diversification of the spatial structure. Caoyang Xincun covers an area of 2.14 square kilometers, include 200 square meters plus residential construction area, with a total population of 13241 (2010 Shanghai six general statistics), the population density is 62000/km$^2$.

The selection of Caoyang Xincun as a object of correlation of residential density and transportation carbon emissions is based on the following three aspects: First, in terms of physical space, in a certain area, it has formed the low, medium and high density of coexistent residential pattern (figure 1). Secondly, after decades of evolution, it has formed a complete public facilities system and clear grade of service. Finally, its social structure morphology presents characteristics of strata hybridization in professional type and degree of education, etc.

Figure 1. Current spatial texture of Caoyang Xincun

*3.2 The division of data and residential type*

The study selected 54 community and gained basic spatial data through GIS. The per capita transportation carbon emissions are gained through the statistical analysis software based on 54 communities equidistant sampling and recycled questionnaires. Questionnaires are 1500 in total, 1023 valid with effective rate 68.2%. As the Xincun shows multi-gradient and multiple class in density structure, the research summarized eight typical residential pattern from the perspective of typology (table 1).

Table1. Density feature and spatial patterns in Caoyang Xincun

| Development intensity | Characteristic of spatial morphology | Type of model | Characteristic pattern of residential | | | Intensity indicator | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | Typical form of Caoyang Xincun | Typical form of Caoyang Xincun | The serial number of the models | Volume ratio | Building density | Density of population (familys/ha) | Family density (familys/ha) | House area for each inhabitant ($m^2$/people) |
| Low-volume ratio | <3F | Building arrange in line | |  | Type1 | 0.97 | 31.7% | 1343.67 | 297 | 14.97 |
| Middle-volume ratio | 4F-6F | Building arrange in line | |  | Type2 | 1.72 | 38.2% | 2015.75 | 417 | 19.29 |
| | 4F-6F | Building arrange in mix of line and point | | | Type3 | 1.84 | 35.5% | 2210.25 | 436 | 19.18 |
| | 4F-6F | Building arrange in circle | | | Type4 | 2.39 | 36.7% | 816.50 | 355 | 35.58 |
| High-volume ratio | 7F-14F | Building arrange in line | |  | Type5 | 3.07 | 34.2% | 1583.80 | 374 | 39.45 |
| | 7F-14F | Building arrange in circle | | | Type6 | 3.55 | 31.1% | 1192.60 | 260 | 54.87 |
| | >15F | Building arrange in points | |  | Type7 | 4.50 | 29.2% | 1213.80 | 578 | 34.01 |
| | >15F | Building alone | | | Type8 | 4.51 | 29.4% | 823.25 | 346 | 58.32 |

In theory, improving the land plot ratio is the most effective way to increase the population density, but from the analysis of Caoyang Xincun data comparison, it can be found that the low plot ratio

pattern and high plot ratio pattern shows no significant differences in population density. If the higher spatial density carried more population capacity, then the high plot ratio in the sample of this survey cannot simply be understood as high density. On the one hand, the increase of the intensity of the per capita living space is along with residential development increasing, accompanied by the decrease of residential units and the population density, on the other hand, the mixture of residential pattern also reflects social structural differences between residents and family organization.

*3.3 Comparison on residential pattern and per capita residents carbon*

From per capita traffic emission of different residential types, the multilayer residential pattern (pattern two, three, four) and point small high-rise emission are significantly higher than other types, and the determinant low-rise, determinant small high-rise and enclosing type emissions are similar, single high-rise type is the lowest. Therefore, in Caoyang Xincun, the correlations between residential pattern types and per capita residents carbon emissions can not directly explained by the physical form. The difference of per capita transportation carbon emissions is caused due to the facility layout factors. It is not a simply linear corresponding relation between residential morphology and per capita traffic carbon emissions.

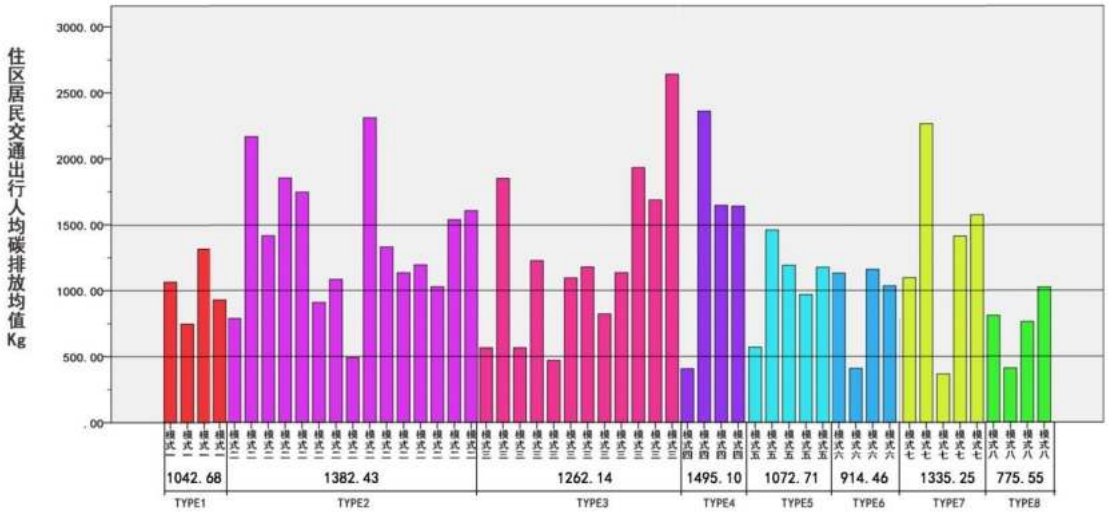

Figure.2 Current spatial texture of Caoyang Xincun

## 4.The correlation studies on per capita traffic carbon emissions based on the 3Ds theory

*4.1 Plot ratio, population density and per capita traffic carbon emissions*

From the comparison curve of different residential pattern plot ratio and per capita traffic emissions (figure 3), it shows that the curve slope is relatively flat in the determinant low-rise, the multi-layer, the mixed and enclosed pattern, and corresponds the volatility change of per capita traffic emissions, but it presents a positive correlation relationship between them. However, when the pattern changes from point high-rise to single high-rise, the mean plot ratio shows little variation, and per capita residential transportation energy consumption suddenly fall a turning point. the above characteristics shows that the strength of residential development in some extent can affect residents' transportation mode, but for high plot ratio estate, its per capita transit emission is slightly lower than the low and medium plot ratio estate, and shows difference distribution of pattern characteristics, mainly caused by

the population density. It could be further validated in the curve comparison of average population density and per capita traffic carbon emissions (figure 4), the change rule of both is quite similar.

Figure.3 Current spatial texture

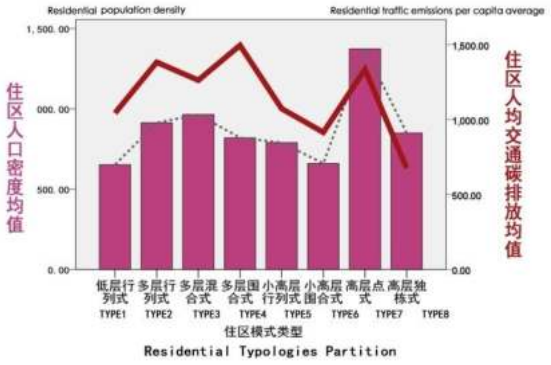

Figure.4 Current spatial texture

*4.2 Facilities diversity and per capita traffic carbon emissions*

From the type and quantity of public service facilities in Caoyang Xincun, its internal supporting facility construction standard is high and variety in types, thus in a certain extent, it reduces using behavioral requirements of external facilities. Caoyang Xincun, meanwhile, also influenced by negative space factors as the cut-off of waterfront and entrance guard settings. For the residents of different residential patterns, the imbalance of the accessibility level of some internal facilities is likely to increase external leisure travel probability. The type, size and accessibility of internal service facilities play a decisive role in maintaining residents' daily life and reduce the motorized transportation.

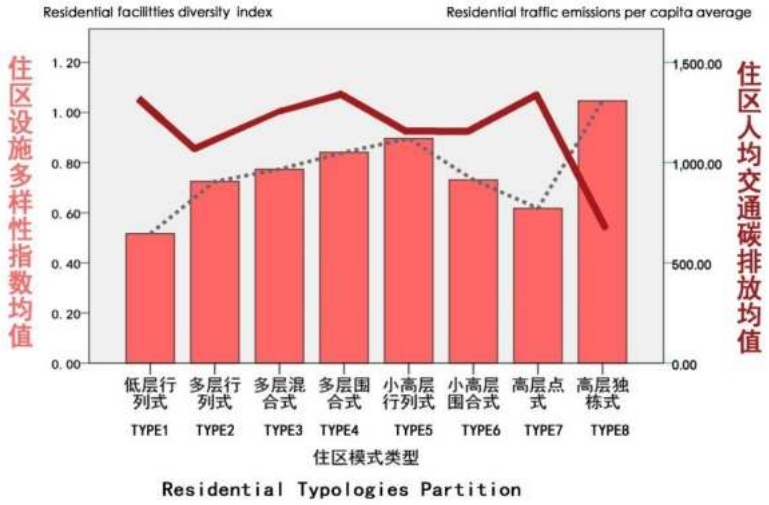

Figure.5 Current spatial texture

The research combined with GIS data takes diversity standardized calculation to the density of service facilities in different types of residential patterns, then obtains the diversity index by cumulative sums of the diversities value of medical, culture, education, business and other service facilities. From the average curve comparison of facilities diversity index from different residential pattern and per capita traffic emissions(figure 5), it shows that the multilayer and determinant small high-rise residential

facilities diversity index are relatively homogenization, but the low-rise and point high-rise pattern is relatively poor. At the same time, it shows negative correlation relationship between facilities diversity and per capita traffic emissions, i.e. the more abundant the surrounding facilities and the more convenient the accessibility, the lower the per capita residential traffic emissions.

*4.3 traffic site accessibility and per capita traffic carbon emissions*

After comprehensive comparison of the average curve of residential public site accessibility index of different pattern types(4) and traffic emissions(figure 6), the positive correlation is shown obviously between the bus site accessibility and per capita traffic emissions, which means that the distance of residence to bus site will have an immediate impact on the decision of taking bus. That is to say, the higher bus site accessibility will reduce the use of private vehicles, and the traffic energy consumption carbon emissions could be reduced by increasing the proportion of residents' public transportation.

Figure.6 Current spatial texture of Caoyang Xincun

In the corresponding relationship between the rail transit site accessibility and per capita traffic carbon emissions (figure 6), the determinant multilayer, mixed, enclosed and determinant small high-rise patterns are positively correlated with carbon emissions, it shows differences with distributions of public transportation site accessibility. It is need to be explained that in Caoyang Xincun, the urban rail transit site is located in the southeast area, so it reduces the accessibility for part of the multilayer and high-rise residential space. In terms of the social structure, the multi-layer mixed residents are mainly migrant workers and private cars takes a higher percentage, thus increases the per capita transportation carbon emissions; And multilayer enclosed and small high-rise determinant patterns are update projects since 2000 with higher commercialization degree, the residents are at high-income levels, the rail transit site accessibility may cause the adoption of other motorized traffic way. In conclusion, under the combined action of the spatial and socio-economic structure factors, the per capita traffic emissions of above three patterns shows no obvious negative correlation with rail transit stations accessibility. If with exclusion of socio-economic factors influence on transportation mode choice, the residential and public transport distance and site accessibility level is negatively related to the per capita traffic emissions.

## 5.Conclusion

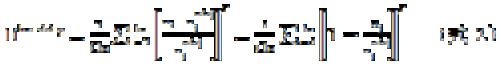
Under the background of global warming and China's economic and social transformation, the theory and empirical researches on relationships between the residential planning pattern and carbon emission characteristics are significant to guide China's practices; With the increasing of people's income and improving of living conditions, the carbon emission effect from residential energy consumption gradually become a core issue of academia and government departments. The study selected Shanghai Caoyang Xincun, from the classification of residential form, divided into high, medium and low density and reflected that the population density of the physical form characteristics and the pattern characteristics of per capita living area. From the correlation analysis of different residential pattern and per capita transportation carbon emissions, residential development intensity and population density was positively correlated with carbon emissions, and negatively correlated with service facilities diversity distribution and traffic site accessibility. The essence of residential pattern types and the carbon emissions is that the density index is spatial significant in development intensity and social structure, meanwhile is related with facility layout, supplement scale and traffic site accessibility. The diversity of per capita transportation carbon emissions is caused by the superposition of variety of spatial socioeconomic and travel needs. Under the background of rapid urbanization in China, the selection of residential pattern types should not be copied simply, the government needs to make quantitative evaluation on residence sustainable development and density characteristics from the angle of carbon emissions ,at the same time also needs to plan appropriate residential density and increase the employment of residential land and accessibility of public service facilities, provide more multiple class affordable housing planning with the goal of implement of low-carbon city development.

## Notes

① From the point of conception, "Type" is the distribution law of things and the abstraction on the co characteristics, but the "Pattern" is the methodology to solve one kind of problem, which concl the ways to analyse and solve certain things and rise to theoretical level.Residence is the mo fundamental and important content in human activities. Residential morphology types covers thr contents as material, economy, and society, and residential pattern is the systemization a structuralization to the residential morphology elements.From residential pattern system, this st thinks that residential pattern includes material and non-material elements. The material eleme include housing, facilities, roads and landscapes, etc., the non-material mainly include the soc relations, humanistic spirit, life style, etc.The density is the important quantitative indicat in residential patterns.

② In quantitative research, the uniform distribution extent description often uses the Simpson in on the different categories of numerical value of the same research object, the index is more u to calculate the concentration degree of economic composition, the formula is expressed as 1 mi the quadratic sum of each object value occupied in the whole structure, as:

When small changes are adopted on the above calculation method that obvious the distance of unif distribution on the objects from different levels, then a new formula is generated as:



In this formula, $D^{facility}$ is for residential facilities diversity measurement index, Cla is for the classification level value of one object, 1 / Cla is defined as the classification quantity wei factor, the smaller the factor value, the more the classification level. Formula in parenthes indicates the average relative distance between each class target value 1 and the actual measured va The smaller value means the smaller distance between the distribution form and the structur distribution target, also means that the greater quantity density of the distribution level of

i type facilities.From this formula, the facilities diversity index parameter value is between 0 1, the value more close to 1 indicates the facilities diversity distribution more uniform.

③ In the public facilities spatial accessibility evaluation method, the geographic information sys analysis platform is an indispensable technical support. With its support, there are lot of evaluat methods, mainly including ratio method, nearest-neighbour distance method, isoline method, grav model method, buffer method, travel cost method, accumulation method based on opportunity, and met based on spatial interaction, etc.This research adopts the potential evaluation model based on sp interaction, the formula is

$$A_i^p \quad {}^{n} \frac{M_j}{D_{ij} V_j}$$

means the spatial accessibility of residential place i to all facilities;means the service ability i facility;means the population scale impact factor;means the travel impedance of i to facilitie (distance or time); represents travel friction coefficient;N means public service facilities quant

## 1. Introduction

*Cities are actually transforming their governmental, economic, social structures. In this complexity, making right policies to guarantee the social justice and the quality of life is really difficult: there is not only a financial problems, in consequence of international crisis, but also a relational problem between people and local institutions. The public government itself to all the utilities and public services for the citizens, and, at the same time, people are losing confidence in the institutions.*
*In this critic context, planners should be the conjunction between people and government, applying good and effective participation methods. In this way, citizens could achieve the capacity to suggest decisions, strategies, local interventions, and in some limited cases they also could support economically their proposals through the civic crowdfunding. The value of this practice is not only financial: in this way we can improve the social cohesion, the sense of community, encouraging the bottom-up processes of requalification, increasing the social justice level. In this way, minorities are protected and the urban management is more democratic and inclusive.*
*The role of planners and local governments is fundamental to coordinate and orientate the bottom-up initiatives: citizens actions could integrate the traditional planning participatory budgeting. At last, a very significant contribute can be represented by the IC technologies: there are many crowdfunding web platforms, local or international, and some of this are dedicated to civic projects.*
*In this perspective, civic crowdfunding could be applied as a valid urban planning practice.*

## 2. Participation processes and bottom-up dynamics in contemporary cities

The complexity and the multiplicity of contemporary European cities require new governance strategies. The public participation to the decision making processes is a fundamental requirement to guarantee the success of the urban projects: we should forget the centralized government idea, and we should adopt a collaborative public-private vision.
The basic principle of civic crowdfunding is not economic, how we could think, but it s a social motivation: citizens who need public spaces or services are starting to make it themselves, because the institutional actors can t or don t want make it. From this point of view, the city is i as a city house (Salzano, 1998). In this vision, the collective financing is an important element to increase the sense of identity of an urban community, and to get stronger the feeling of belonging to the place where the citizens live. Without these elements, the management of the city, mainly when there are many critical and conflictual factors, it s very difficult. If don t consider the importance of public sharing about the urban planning, they objectives; the same is for the urbanists, who should adapt the theoretical principles of the discipline to the fluidity and multiplicity of the real city.
This mechanism works if there is a strong and deep motivation from citizens who live in a city, or in a neighborhood: the sense of identity in a limited urban area is more consolidated than in a whole city, especially when we have a very extended city (Leone, 1999).

The neighborhood is the ideal place where we can apply our survey: it s an i
between the private home and the public city, where there is a particular social balance (de Certeau, Giard, Mayol, 1994). In a neighborhood the feeling of belonging is stronger than the inefficiency of public administration: in fact the citizen are ready to make themselves some maintenance activities, to buy some urban furniture (benches, wastebaskets), although they continue to pay taxes.
It s an ethical question, not only economic or politic: the cultural changes i
also related to the social approach to the urban necessities, no more passive but more active and responsible (Bonafede, Lo Piccolo, 2010a, 2010b, 2011; Lo Piccolo, Thomas, 2009).
The neighborhood is a resistance place: resistance against the extreme globalisation, against the identity s decline (Picone, Schilleci, 2012). It s also a collective place oppo
a material place of relationship, very different from virtual places like social networks. Really, this two relational dimension should be integrated: the ICT could represent an aid to make better the communication between citizens each other or between citizens and public institutions.
The question of communication and confidence between citizens and institutions is essential for the activation of processes bottom-up: when the public institutions don t answer to the ci
requests and needs, the citizen start to organize themselves to solve the common problems. In many cases the civic administration can t guarantee the necessary interventions
of economic resources: the international crisis caused a consistent limitation of the public budget for the welfare, but this is only one of the aspects of the crisis. the main consequence is not financial but cultural: the cities are evolving to a new organization model, more inclusive and participative than traditional government. We can t imagine today an urban c
citizens don t have right to express their opinion about the public decisions,
development, about the valorisation of public spaces and about the services, the shared uses, the social conflict.
Another change of vision is related to the size of the urban projects, and consequently to the relevance that they have in the general economy of the city. The civic crowdfunding is a practice that come from citizens reaction to the lack of public government: some peop
make little reparations or maintenance activities. From a strictly practical point of view, it s
that involve ordinary citizens and not rich businessmen or supranational funding implies the drastic reduction of the available budget for the interventions. However, this is justified by the great symbolic and social value of the projects realized: making something that citizens have required and the same citizens have financed is truly an achievement of right to public space (Lefebvre, 1968). Actually we are living not only a financial crisis but a cultural, social and ethical crisis, about roles, institutions, political balances. People are becoming conscious of their territories: making a shopping mall instead of an equipped area for free time or for children, a public discharge instead of a public park, are political choices not shared with the urban community. As planners we need to make citizenship before to build city.
In some cases the conflict between citizens and public administration could be overcome by joining forces to work to the same objective: the civic crowdfunding could be integrated with the participatory budgeting.
The participatory budgeting was utilized for the first time in Porto Alegre, Brazil, in the 1989 (Allegretti, 2001), and then was utilized internationally as a valid instrument of civic management. It contributes to increase the sense of civic responsibility and the public participation in decision making process. In this way, a part of the budget of the city can be dedicated to a direct management by citizens: this is really a little part of the whole civic budge
alliance between politicians and citizens, and also a public endorsement and contribution to the civic requests.
The idea is very positive but it s difficult to apply in the real contest of the
Italian context, the participatory budgeting has been often replaced by the social budgeting, that is a different thing. In fact the social budgeting is only a public reporting of expenditure incurred by the city for goods and services, made as a final balance and not as a prevision (Viviani, 1999).
Moreover the participatory budgeting isn t regulated by a specific legislation: i
that depends entirely by the will and the commitment of individual persons.
The frequent result of this situation is therefore that the adoption of the participatory budget also is carried out in modalities arbitrarily set by each municipality. In many cases is never taken into

consideration the idea to let citizens participate directly in the management of municipal funds (Rindone, 2013).
We shouldn t forget that civic crowdfunding initiatives started as a bottom-up practices, to overstep the brake generally imposed by public administrations to grant funds for collective projects: then the civic crowdfunding is often a demonstrative instrument to opposition to the governmental approach to the urban questions.

## 3. Civic crowdfunding: how it works

The crowdfunding is a collective financing, born in the contest of arts and creative activities: then it has quickly spread in other contexts, like urban politics and planning. In this way, the crowdfunding takes a public finality and became civic . It works by specific web pl where the promoters can public their projects to collect donations from all the world, by various models of funding. There are specific platforms for particular typology of projects: cultural, urban, about school and education, for humanitarian campaigns (for example a campaign for a whole population who need help because of poverty, of war, of an earthquake, and more), or about animals and environmental protection. The crowdfunding platforms works like a social network: the final objective is claim the attention of people, explaining the reasons and the substance of the project, showing also images, schemes, tables, results, analysis and future prospective to application, to finally reach the amount fixed.
In the fig.1 there is an overview about crowdfunding working: it starts from an idea (in the specific case of civic crowdfunding the idea is related to the city), then it s published c crowdfunding platform, and finally we can reach three options: goal not reached, goal reached or goal exceeded.

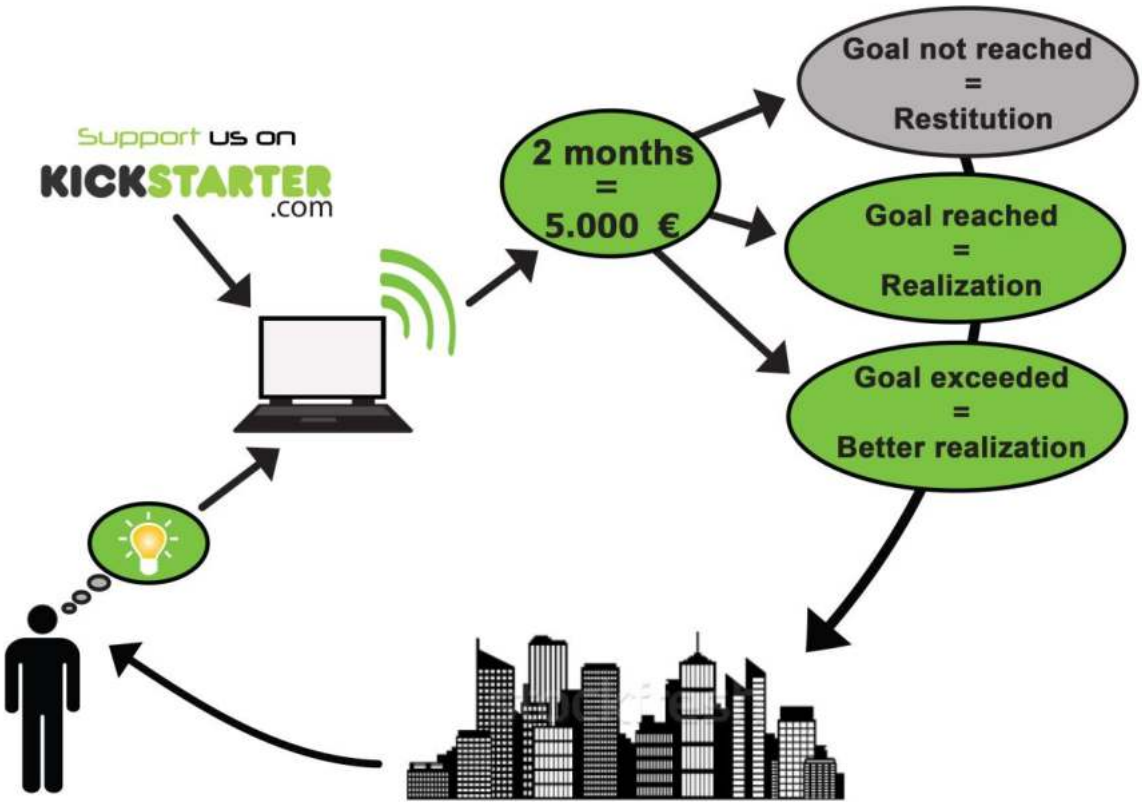

Figure 1. The crowdfunding s working.

Many crowdfunding platforms take a percentage variable according to the type of financing chosen: generally, this percentage is about 4-5% for the typology fixed funding , and about for the typology flexible funding . Some platforms are also intermediate typol

allow different approaches to the crowdfunding campaign. Generally the donations are collected on a PayPal account, and only in a few cases the campaign promoters can collect the donations on their own bank account or by cash.
The IC technologies and the web platform has really many vantages, but also problems.
The vantages are related with the directness and the immediacy of the communication: web is a virtual global place, where is possible communicate with a great amount of people in a click. The easy language, the utilize of cool pictures, the application of apposite marketing strategy to share the project and to increase its relevance by publicity, could be valid instruments to goal the objective. Another vantage is the transparency: all can visualize the amount raised, the time of the campaign, the information and contacts, and all contributors can get back their donation (in the fixed funding model) if the campaign doesn t reach the goal.
However, this mechanism hides some communication risks: the utilize of a marketing strategy could manipulate the public opinion about the project, but the project should take its origin from a common and shared will. Another problem is the digital divide: many people, especially in our application context (Palermo, Italy), aren't able to use computer or other informatics devices or have really difficulties in this operation; some other people, although are able to use ICT, do have confidence in informatics money transfers. There is also a privacy question: people give to the web platform some of their personal data (name, email contact), but if the civic crowdfunding were an institutional funding system they should give all their personal data, because the public institutions can t receive money from unknown persons. This may generate a privacy problem and an overload of the web platform (an ethical and technical problem).
In the fixed funding model the donations are blocked in the donator s credit amount for the project s realization is reached: so the money transfer is made ended successfully. This method is more adapt to project specific, when the promoters know the exact amount that is necessary for realize the project.
In the flexible funding model the donations are really made in every case: all the donations are raised, and the crowdfunding campaign is similar to a traditional fundraising campaign. This method is more adapt for social causes or humanitarian projects.
The time of the crowdfunding campaign is a very important factor: a long lasting campaign (some month) could raise more donations, but it will have a slow rhythm, while a short campaign (60 days max) could count on the emergency effect , a psychological strategy to induce people to support the cause. Some crowdfunding campaigns could have no time limits, like the fundraising for the humanitarian causes or for the promoting and defending of human rights.
The most important crowdfunding platforms in Italy are Produzioni dal Basso (https://www.produzionidalbasso.com), Eppela (http://www.eppela.com/) and De Rev (https://www.derev.com/it/), but there are many local projects really interesting like Laboriusa (http://laboriusa.it/). In the international context the most famous crowdfunding platform are surely Kickstarter (https://www.kickstarter.com/), but there are many recent platforms that are working well, like Indiegogo (https://www.indiegogo.com/). The projects are organized in several categories, especially in the generic web platform, to facilitate the individuation of the projects more interesting; each project is described by a video presentation, and a narrative text that explain the topic and the story of the initiative. Many projects can include the possibility to give rewards as a thank you sign for the contributors: this system are called reward-based , and, how to Alessio Barollo, is the method more adapt to the Italian context (Barollo, Castrataro, 2013).
rewards or perks should be related with the theme of the project, and should be easy to send through postal services. Alternatively, rewards could be an informatics product (a postcard, a little e-book or similar solutions), to send through e-mail. Rewards are a symbolic thank you, and not a product to sell: the whole crowdfunding system are based on the free donation, there isn t a commercial finality. This point is very important in relation to the tax governmental system, and in relation to the control of the money flows: in Italy there isn t a legislation about the crowdfunc (interpreted as a fundraising non-profit activity), so it s very difficult individuate experi follow the same procedure. The only Italian law about crowdfunding is about the equity-based crowdfunding, that is related with the company shares in the business sector: it s a modality very different from the topic of this paper, so we will not discuss it here.

In this way, the transparency and the honesty of the whole operation (publication of materials, crowdfunding campaign s conduction, money flows through PayPal, collection of data) are guaranteed only by individuals campaign promoters and by web platforms, without a systematic institutional control. At the same time, open a bank account specifically for this purpose in Italy it s a problem for a cultural association ( cultural is always non-profit): the control in each moment the money flow and must know the identity of the contributors, in order of a strict law against the money laundering. At this moment a cultural association who want start a civic crowdfunding campaign for the installation of some benches in a neighborhood square, for example, must utilize a PayPal account linked to a personal credit card and not to a bank account. Similarly, there isn t an univocal institutional regulation for the methods and for the participatory budgeting. From an urbanistic point of view, this means that the public participation processes in the Italian urban contexts are severely limited about their application tools: to make really a participation process and to negotiate the choices and the redistribution of the public resources, we need to give people some economic tools to make real the discussion results.

## 4. A practical civic crowdfunding experience within an urban park in Palermo, Italy

The case of study we want to present in this paper is a practical experience of public participation and civic crowdfunding in the city of Palermo, Italy. We want test a methodology and analyse the results from a technical point of view, to understand if this way could be really a public resource for the city.

We have chosen an urban area where the sense of identity and the feeling of belonging are really strong: the place where we have conducted our project is the Uditore Park. This place has a particular story: it was an abandoned land in the middle of the city. Two years ago a group of citizens, with some university professors, constituted independently an association and claimed the use of this land: they realized a park, whit private donations and the collaboration of many people. Many participants to this action was inhabitants of the neighborhood where is situated the park, that is called Uditore-Passo di Rigano (in the 5 district of Palermo). The par of people, who come from all the neighborhood of Palermo, because it s almost t park (the other parks are more peripheral and don t have enough games for children, sports equipment or space for dogs): but the people who live near the park, in that neighborhood, are the principal supporters of the park, and now identify themselves with this.

We needed a strong community who could represent a good substrate for the participation process, and for the civic crowdfunding campaign, so we have chosen the context of this urban park. We have prepared an ideas collection: we have started by the traditional qualitative methods of social analysis like the interviews (Corbetta, 1999), but then we have needed to adapt the strictly formal methods to a new modality, more flexible and near to behaviours of the people. So we have organized some meetings with the people within the park, according with the Uditore Park Association, in some particular occasions like summer events, to know what typology of services or furniture could be necessary in this place from the point of view of the users.

After this first step, we have prepared a box (fig.2) and a list of categorized options: the box was shaped like a little house, with four colours (each one for one specific category). In each colour section there was a slot to insert a ticket (like a vote ) with an idea, or a wish, for have prepared the tickets with some options predefined (these options derived from the first survey), related with sport and free time, games, furniture, other (the ca represented by a blank ticket for a free suggest).

Figure 2. The little house of ideas . A man choses a ticket to write an option.

We went to the park several times with the box, talking with the people and explaining the project, and then we left the box within the park for about one month. At the last, we have counted all the tickets and we have selected the projects more requested for each category: for the sport and free time the multipurpose field , for the games the seesaw , for the furniture the sha We didn t limit to the mathematic count: we have discussed these results in order to technical feasibility and appropriateness, and then we have presented the projects selected to the volunteers of the Uditore Park Association. They told us that was already working to realize a multipurpose field, so finally we have chosen the shade structure as the final project to realize.

At the same time, we have analysed many crowdfunding platforms, to select the platform more adapt to our project. At the last, we have chosen Indiegogo, because is very communicative, has a good graphic style, is very easy to use. The problem is the language (Indiegogo is an American platform, so the instructions are in English, but our supporters are Italians), but we think that the non-verbal (non-written) communication (colours, organization of the elements in the layout of the web page) could be more important than the verbal (written) communication.

We also have learned how PayPal works in this case, relating to a crowdfunding platform: we had to consider also PayPal transfer fees in the total amount we need for realize the project. We have chosen to utilize the PayPal count of the Uditore Park Association.

About the project and the material building of the shade structure, we would like to realize a natural and ecologic structure, similar to the other elements of the park. So we have taken contact with a team of architects who realized the last year a bamboo structure in this park. This team is called LAN (Natural Architecture Laboratory), and this is their website: http://www.lan-architetture.org/. The shade structure will be made of wood and Sicilian reed (Arundo Donax): so we will utilize local materials, helping the local economy.

This is the text we have published in the web platform (https://www.indiegogo.com/projects/viva-l-ombra-al-parco-uditore):

«Hurray the shade! Imagine a wonderful sunny day with a little bit of free time for a walk or other leisurely outdoor activity, but did you ever consider the practicality of a shade structure?

A shade structure:

- offers comfort for resting and allows you to remain outdoors without suffering from heat exposure;

- provides the perfect relaxing spot ideal for reading, chatting, having a picnic or meeting new people;
- offers a meeting space which promotes the importance of socialisation allowing you to rediscover the value of true sharing.

All of the above and more can be achieved under the shade, a totally ecological open structure which respects the environment and is in harmony with nature. Our aim is to greatly improve the site s context.
Who is the project for and where? Palermo s Uditore Park (Italy) is the ideal place in w idea can be realised. The park is a shared urban space, a green heart. It is a part of the city which until recently was disused: now it has been returned to the citizens and it's open to social and intercultural exchanges.
A park, made by local people with flowers, large and small cultural miracles, the place where we want to realise a public resource, a shade ecological structure starting from a bottom-up and innovative experience.
The collaboration with a great number of participants has been worthwhile; from all those who wrote on a note a wish, an idea or a dream for the Uditore Park as well as the users having their input. Now however the time has arrived to bring our proposals to fruition, and for this we need everybody again, including you!
The project originated from the idea of the working group Civic Crowdfundin territory , constituted by: Salvatore Abruscato (territorial planner), Floriana Cane (student architecture), Elena Giannola (architect and PhD in urban and regional planning), Francesco Paolo Riotta (urban planner, masters student of territorial, urban and environmental planning).
Thanks to the collaboration with the Uditore Park Association, we have started the participation process to kick-start the final project being realised. We have produced a collection of ideas in which many people have contributed towards and in the end have selected the shade structure.
The collection of ideas and the relative discussion have been an occasion of confront, dialogue and explain the motivation of each proposal.
The Uditore Park is a space recently returned to the community and is the perfect area for bringing about concrete experiences of urban regeneration and initiatives of environmental protection and enhancement.
A deep sense of community identify and belonging can be most definitely be found here!
The Uditore Park is managed by volunteers who work extremely hard to provide a public service to the city: it s a unique place in Palermo which has great potential.
With this project we can collaborate to utilise it in the best way possible!
Finally we want to say you thank you: you can give a contribution and receive a little gift of thanks in relation to the amount of your donation, such as a special thank yo Facebook/Twitter page, on our official website and on the project s presentatio special bookmark or digital/printed copy of the project s presentation brochure.
Let s get ready to have our shade structure ready for the summer!
Enjoy our park!»

## 5. Results

The experience at this moment is in progress: we can express a partial consideration about the process we conducted until now. The traditional participation methods can t be app the context selected: each region, each city and also each part of one city is different from the others, so with the guide of our technical expertise we had to adapt the traditional survey to the real people, modifying just a little the typology of questions and the modality to present the project in function of the interlocutors (ancient people, children, men or women). Colours and pictures are more expressive than texts, and we had to change our scientific language to explain the project in a way more simple and understandable.
In the precedent steps we had to manage the impetuosity of participants: it was difficult express our identity and our objectives, because in a context where the public administration is lacking, people search other representative entity as of referring points.

We worked in a particular place: it s a public space, but isn t a municipal area ( area is of the Regional Administration); the master plan provides for this area the destination to public offices, but now there is in progress a proposal of variant; many people attend the park, many people identify themselves with the park, but at the same time many peopl park and don t respect the environment and the furniture installed in the park contradictions.

In the transition from the disciplinary context to the real urban context, we have encountered many difficulties and we have spent a lot of time searching the optimal method, the best combination of elements to claim public attention, explain clearly the project and the objective, be short and incisive, change quickly language and expression modality in function of different people. Building this idea, before than building the structure, was a difficult and long lasting operation.

We found some critical points:

- The time is a strategic factor in this process: there is a conflict between the long time of the participation process, and the necessity to a short time of realization, to give a positive feedback to the participants and to take advantage of the period when the subject is much debated;
- The communication is fundamental, but there is a conflict between the technical language and the friendly language, more understandable but less exact;
- The collaboration with any civic association that takes care of the space selected is not always easy and granted;
- The social identity of the urban area selected for the project should be analyzed before planning a civic crowdfunding campaign;
- The public administration should be involved in the process: so the project could have positive effects related with the confidence between citizens and urban government.

Surely, the choice of the web platform, the application of marketing strategy, the advertising of the initiative, are also important points to consider.

We have organized some promoting events in different part of the city: one in a famous co-working space (and also restaurant) in the historical center of Palermo, others in bookshops, cultural centers, and finally within the park. At the end of the crowdfunding step, if we reach the fixed amount (5.000 ), we will organize the building phase with LAN and with some volunteers.

## 6. Conclusions

The civic crowdfunding could be really a strategic resource for the cities: but to apply this practice should be defined some rules more clearly than now. The role of public administration can t b marginal: public institutions and private citizens should collaborate to make a better quality of urban life. The public-private partnership can t be only interpreted as a compromise b public administration, who has the power but hasn t the financial resources, and the who haven t power and want a part of decisional power through financing the Actually the other citizens, who have not power and not enough financial resources, are excluded from the decision making process. The civic crowdfunding can be a valid instrument to build social cohesion, social inclusion, civic conscience, but can t be the unique solution crowdfunding is mainly ethical, and social: is fundamental to lay the foundations for a new citizenship, but to realize materially projects and to create public services we need an amount of money that the crowdfunding alone cannot achieve.

This is not only a financial question, but it s also related with legislative aspect o government: the role of the public administration is especially to give rules, because the public administration is the only one urban actor who can legitimize the bottom-up initiatives. In this way, we have to think in a collaborative vision to cross over the conflict: the city is a complex system, where there aren t only citizens and politicians. The city is really a multidim there are many balances and dynamics and it s very difficult recognize and control these phenomena. For this reason our engagement as urbanists is to enter in this complexity, analysing the potential usefulness of innovative strategies like the civic crowdfunding. We have to think in a multilevel vision: in the contemporary cities we can achieve our objectives only if we operate in

multiple and integrated ways to a unique target. In a fragmented context we have to fragment our action but not our intention.

## Planning across Borders: Transnational, International and Intergovernmental Planning and Spatial Management

# FROM SILOS TO INTEGRATED COLLABORATION: LOCAL POLICY DESIGN AS MEANS TO PROMOTE THE COLLABORATIVE METROPOLITAN GOVERNANCE

Mahesti Okitasari[1]

[1]United Nations University Institute for the Advanced Study of Sustainability and Keio University, okitasari@unu.edu

Keywords: Collaborative governance, policy design, metropolitan

*Achieving integrated collaborative governance of multi-sector stakeholders goes beyond setting independently formulated policies across different domains. It entails taking into account a comprehensive approach among different areas of policy at the formulation and implementation stages. For collaborative metropolitan governance pursued at the city level, integrated collaboration means finding development paths that consider synergies and trade-off applicable for different stakeholders at different level. With the process of designing and administering collaboration varies according to the types of policies and institutions adopted in cities, the success of metropolitan-wide collaborative governance depends on the integrated outlook on local policies and institutional architecture.*

*This paper provides an overview of various local policy designs to administer collaboration, and seek to illustrate the policy framework to promote integrated collaborative governance. Four Indonesian metropolitan regions with a total of 23 member cities are observed as comparative case studies. Detailed examination of local institutional structure is conducted to sketch the local institutionalisation on collaborative activities. Despite the similar setup provided by the central government, the comparison of these cases demonstrates a different scale of operation, structure, and policy instruments. Drawing upon work on power dynamics and social relation, this paper illustrates the linkages between the selection of policy instruments and the institutional structure. Our findings point out that the comprehensive approach through coherence policies positively affects the intergovernmental collaboration, a step toward integrated metropolitan collaborative governance. The cross-sectoral collaboration, on the other hand, is affected in a lesser degree.*

## 1. Introduction

At the city level, the way local governments dealing with urban service provision under the growing pressures and opportunities of urbanization have been front and central since the concern of urbanization is raised. Among other challenges, financing and providing urban public infrastructure have been advocated both as urban and regional issues due to its nature that often reach beyond the administrative boundaries. The proponent of regionalism has been upholding the idea of a regional approach as the potential panacea to provide a wider reach of urban service (Brookings Institution, 2002; Feiock, 2004). In the metropolitan area where most of urban issues take place, achieving integrated planning and provision of urban service calls for integrated collaborative governance of multi-sector stakeholders. This type of collaborative governance takes into account comprehensive approach among different areas of policy, particularly at the formulation and implementation stages. With the politicization of infrastructure provision often found in cities, collaborative approach has been a struggle with each success considered as a major feat.

The notion of collaborative governance at the city level in Indonesian planning process is not novel although not exactly well developed and well expanded either. Prior to the decentralization, collaboration for metropolitan planning was handled by the provincial and/or central government with

less involvement of city level government. Consequently, collaborative metropolitan governance in Indonesia has yet developed a real tradition in comprehensive administration and implementation. In recent years following the decentralization and the push from central government to promote collaboration at city level, research on collaborative governance see increasing values of building knowledge in this area. Looking at the precedent research, this paper found that research on gauging the causal effect of local policies to the working of collaboration in Indonesian cities is considered a new arena of research as the implication remains unknown. Thus, responding to this research gap, this paper will concentrate firstly to understand the implication of local policy design toward the working of collaborative metropolitan governance. Secondly, considering the various types of collaboration implemented, this paper aims to answer whether the process of designing and administering collaboration differs according to the types of policies and institutions adopted in cities and if the success of metropolitan-wide collaborative governance depends on the integrated outlook of local policies.

In order to sufficiently answer the research objectives, this paper undertook an analysis of the local policy design of collaborative governance in four Indonesian metropolitan regions. As cases studies, all cities in four metropolitan region were observed. The metropolitan regions are Jakarta (9 cities), Surabaya (7 cities), Yogyakarta (3 cities), and Denpasar (4 cities). In this paper, the local policy design represents the policy setting developed by local governments that is directly and indirectly affect the working of collaborative activities at the local and regional level. Accordingly, the analysis of the local policy design started with the assumption that the process of collaborative metropolitan governance can or should always be improved depending on local policy selection. This policy selection in turn affects and is influenced by the institutional structure of local governments an interaction between local actors exist in the institutional environment set through local and regional political, social, and cultural characteristics. Thus, our hypothesis was that together institutions and policies create a local platform for local governments to conduct and direct their activities. This paper considered that the linkage between specific collaboration-supportive policy approaches and the extent of collaboration that their adoption entails are crucial to the study. By attempting to address the implication of local policy design on the operation of collaborative governance, a more clarity can be developed on whether the adoption of certain policy approaches affects the collaborative policymaking process at the local level or not. This assumption was largely built upon understanding that policy designs statutes, guidelines, programmes have consequences for the allocation of values in society, and at the same time reflect the culture and values of society itself (Schneider and Ingram, 1990).

This paper is presented in five sections. The introduction covers the background and rationale of the study based on the literature review and observation of Indonesian situation. The second part, the methodology, elaborates the analytical framework used for the analysis, including the parameters suitable for the data availability in Indonesia. The third part presents an overview of Indonesian collaborative metropolitan governance, providing information on the system prior and after the decentralization. The decentralization plays an important role in Indonesian collaborative governance as it changes how collaboration is administered and structured due to the change of authority in local practice. The fourth part brings about the research analysis in three sub-sections; the analysis of the local policy design in observed cities and regions, the analysis of the local institutional structure of collaborative policymaking, and the analysis on the interlinkages between the structure of institutions and the policy initiatives adopted by local governments. The final analysis is aimed to enable further understanding of the internal work of collaborative policymaking, particularly in addressing the causal effect of local policy design on collaborative interaction between actors. The conclusion will close the discussion by providing the implication of local policy design toward the future of Indonesian collaborative metropolitan governance.

## 2. Methodology

### *2.1 Addressing the Local Policy Design*

The primary data used to address the local policy design in this paper is policy instruments adopted in the observed cities. The mapping of policy instruments has largely directed to understand policymaking through the establishment of instrument choice. In order to map different types of policies, this study establishes a policy classification and catalogues policies issued by local governments in their websites, annual reports and development plans in the last 15 years following the decentralization accordingly. Interviews with policymakers were conducted to validate the availability and the status of the policy catalogued. As this research focuses on the local level, all of the policy instruments observed are sponsored solely by local governments to encourage collaborative arrangements in their jurisdictions. Policies issued by higher levels of government are referred in case a policy adoption is observed.

The classification of policy instruments used in this analysis is derived from the sample of the instruments of public policy by Linder and Peters (1989; 1990). Linder and Peters policy instruments were used as they provide a wide variation in instrument appraisal while allow user space to analyze the instruments from an institutional point of view which is a critical important of this paper. Linder and Peters sample of the instruments is divided into seven instruments to accommodate disparities of basic public policy and serves as sampling frames for drawing a stratified sample of instruments. The instruments are: direct provision, regulation, authority, contract, fiscal/tax, subsidy, and exhortation (Table 1). Previous studies that had utilized these instruments for analysis, among others, are McGuire (2000) for local economic development and Holmes (2010) for environmental management.

During the course of cataloguing local policies, this study found that exhortation, financial, and contract related instruments are generally based on the political situation and tend to be short-lived. Exhortation tends to be short lived since it is mostly directed through local program. Table 1 displays the policy mapping of Indonesian cities on collaboration, cataloguing into six major instruments adopted from Linder and Peters (1990). 20 policies currently active since the decentralization of 1999 have been identified.

### *2.2 Analysing the Institutional Structure for Collaborative Policymaking*

The analysis on the institutional structure of collaborative policymaking is directed to explain the structural dimension of local institutions in conducting joint policymaking activities. The analysis, thus, was built upon a hypothetical idea that the state of Indonesian collaborative governance, particularly in building collaborative policymaking, is closely related to and can be explained partly through the extent of the institutional structure of local government interaction with other actors. This paper presume that through the identification of the institutional structure, further analysis on the institutionalisation of collaborative policymaking can be structured.

The study of institutional structure observes a governance architecture from the viewpoint of vertical and horizontal relations which often referred as intergovernmental relations (Rhodes, 1997; Wright, 2000). This paper considers the measurement of vertical and horizontal interaction in the analysis of the institutional structure of collaborative metropolitan governance is built on the basis of the operationalisation of regionalism whereas; vertically, higher interaction between local and provincial governments will result on higher probability of local governments to adopt provincial perspectives in their local policy planning. Similar rationale can be applied to the central-local interaction. Horizontally, the more local governments get involved with other local actors, governmental and nongovernmental, the more they become proactive towards collaboration.

This paper limits itself to analyse the horizontal interaction only, focusing on how the interaction forged among all local actors. The horizontal interaction, thus, is an attempt to explain how local actors interact among interdependent linkages in developing collective platform, bargaining, and determining joint policymaking activities within their allowed capacities. In this paper, the measuring instruments used for the analysis are retracted from the collaborative governance activities survey originally developed by Agranoff and McGuire (2003) to measure the institutional structure of the collaborative governance. Four parameters related to collaborative policymaking are observed as follows; consolidate policy effort, engage/agree in formal partnerships, engage in a joint policymaking, and engage in a joint policy implementation.

To collect the primary data, a structured survey was conducted during two periods (Table 2). The survey targeted chief officers from local governments (city level), working on the Local Development Planning Agency and City Planning, Public Works Agency and/or Collaboration Bureau and are responsible for planning and implementation of collaborative activities. The respondents were interviewed and asked to identify each collaborative policymaking activity their departments (or cities) currently engage with various organisations, including central and provincial government agencies, neighbouring city agencies, state owned enterprises as well as private and civic sector. Additional interviews were carried out with the central government (Ministry of National Development and Planning, Ministry of Public Works and Ministry of Interior) and 6 provincial governments Jakarta, Banten, West Java, Yogyakarta Special Province, East Java, and Bali where observed cities are located. Table 2 presents the data overview.

Table 2. Data collection from questionnaire survey.

| Metropolitan region | No. of local governments | Total respondent/ collected sample | % response rate | Period of survey |

| Yogyakarta | 3 | 6 | 100.00 | * |
| Denpasar | 4 | 5 | 67.50 | ** |

Period of survey: *: October November 2012, **: May June 2013.

## 3. General Overview of Indonesian Collaborative Metropolitan Governance

Indonesian decentralization is often criticized to leave institutional arrangements at subnational levels further fragmented. After the regional autonomy was introduced, the local government, as expected, is reluctant to surrender some of its independence in managing urban development to the regional level government. This local and regional setting created strong push and pull among local and provincial government in most regions practicing regional collaborative governance. While establishing a single authority of metropolitan government is generally shunned by local governments due to strong political tensions among provincial and local governments, the growing need to establish a collaborative framework that can work in a fragmented system remains if not getting stronger. Therefore, owing to this fragmented political landscape, the rebuilding of regional governance becomes increasingly important policy and research agenda in Indonesia (Hudalah et al, 2013).

Figure 1. The transformation of institutional structure of collaborative metropolitan governance in the observed regions.

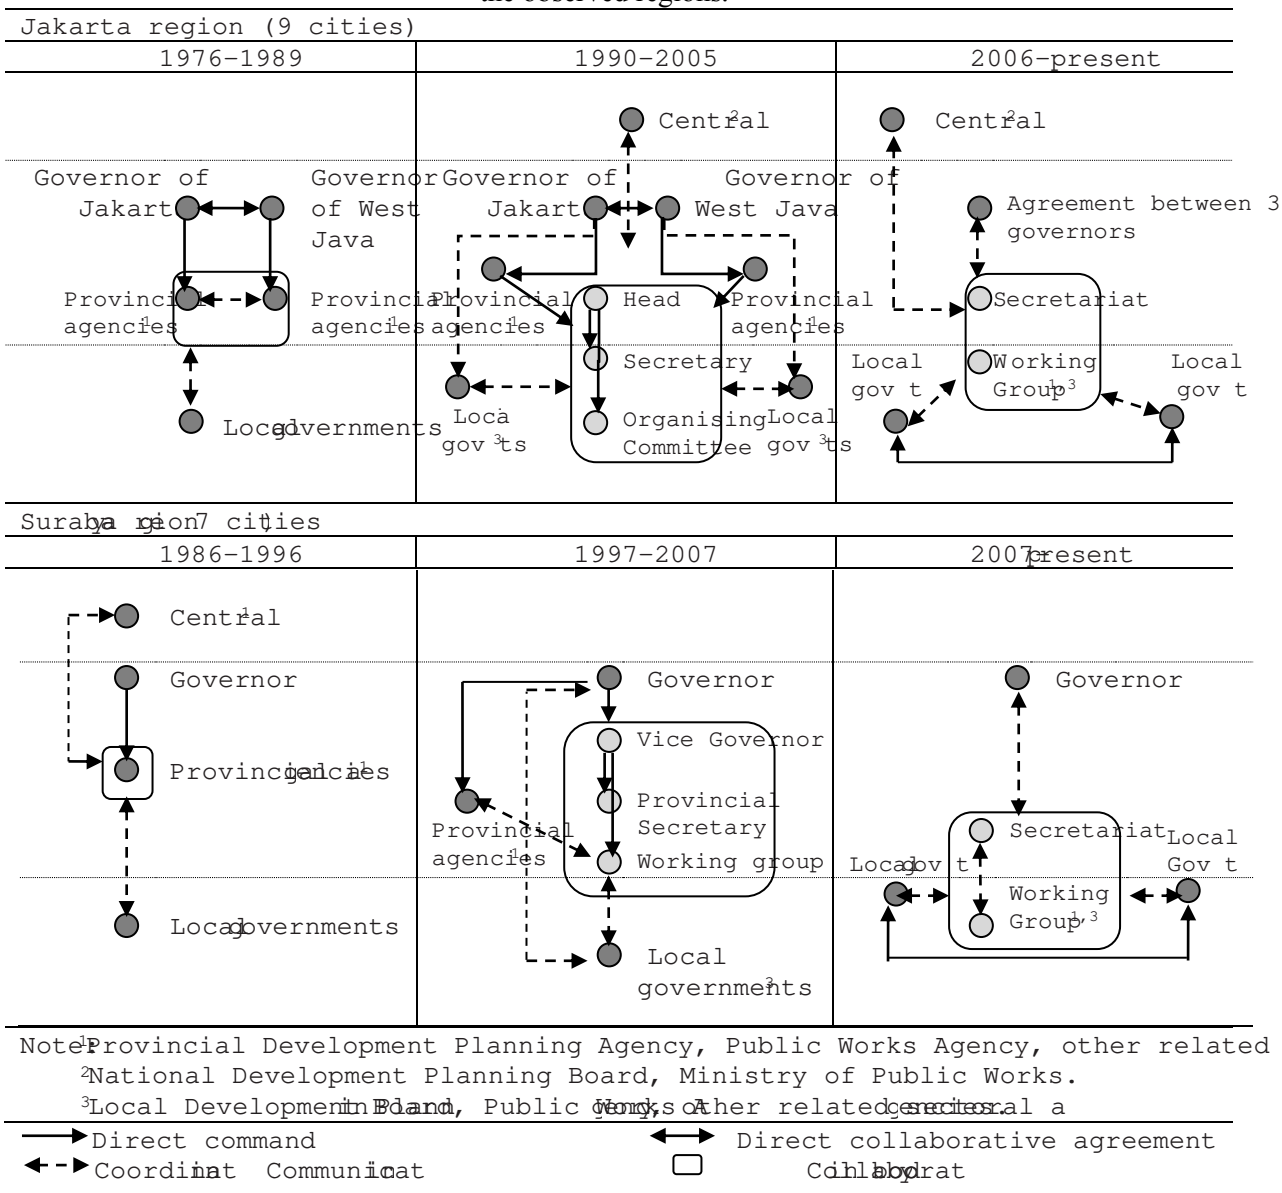

Figure 1. Transformation of institutional structure of collaborative metropolitan governance in the observed regions (cont d).

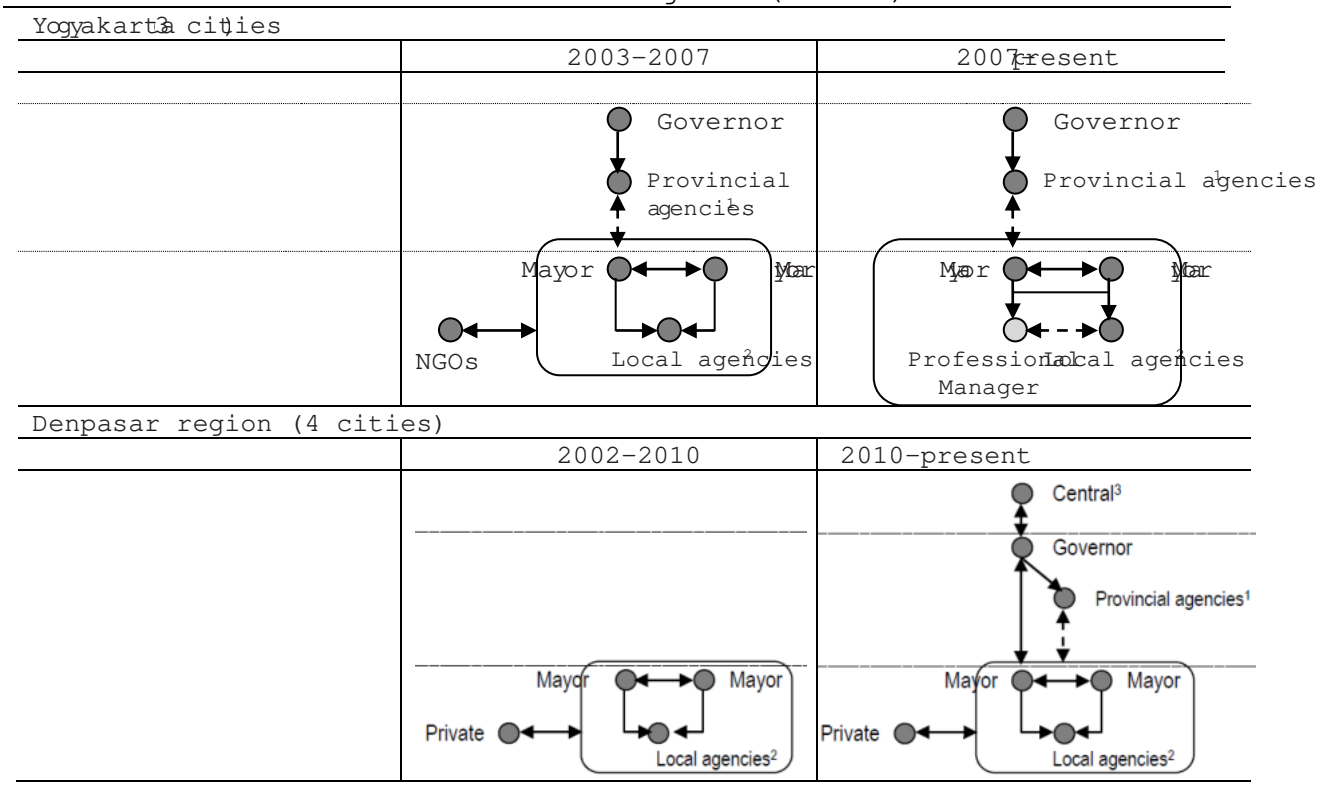

*Source: Author (2014).*

Prior to the decentralization, collaborative metropolitan governance was observed only in Jakarta and Surabaya, very limited to consider the number of urbanized regions. New collaborative metropolitan governance started to emerge again following the enactment of the decentralization law. Various types of collaborative arrangement, range from intergovernmental to contract agreement with the private sector, are experimented in major metropolitan regions. Some of collaborative arrangements were considered thrives, e.g. intergovernmental collaboration in Yogyakarta (see Firman, 2010; Zul Fahmi, 2010) and Denpasar, but others like Jakarta and Surabaya are struggling to set up an arrangement that can successfully plan, coordinate and monitor the implementation of development programs across jurisdictional boundaries.

Generally, collaborative governance between cities in metropolitan regions prior to the decentralization was a provincial issue. Both cases Jakarta and Surabaya were initiated by the provincial government and supported by the central government while local governments mostly acted as the implementing agency. Local governments communicated and coordinated their planning and implementation on a platform established by the provincial government. In this sense, local governments, public and private sectors played a passive role in this system where policies were produced by the higher level of governments and their involvement was limited to the implementation. On the other hand, with the decentralized and de-concentration of power applied to the lower level of government, collaborative governance between local governments in the metropolitan region moved from the provincial to local level. While previously the provincial government has a direct command to the collaborating body as it was established on the provincial level, the new system encourages that the collaborative platform to be developed at the local level (Figure 1). As a result, the local government now yields the autonomous power to decide, whether to collaborate or not.

## 4. Analysis on Indonesian Local Policy Design and Collaborative Governance

### *4.1 The Local Policy Design of Indonesian Collaborative Metropolitan Governance*

Table 3 reveals the percentage of adopted local collaboration-supportive policy instruments in the four observed metropolitan regions. Although the variation is wide among regions, the majority of cities in one region has a similar policy design, with Surabaya as an exception. In four metropolitan regions, three policy instruments are observed in more than 67 percent of cities or two third of a region while the rest of 17 policy instruments range from 16 to 70 percent. This number indicates that common initiatives established by local governments are only a fraction of the observed instruments. The most common policy instrument reported by local government is in-kind transfer, a regulation allowing local government to fund intergovernmental projects through intergovernmental transfer. On average, Jakarta and Yogyakarta have a better inter-city policy coherence than Surabaya in almost all policy instruments observed. In Denpasar case, although the average of policy adopted by local governments is the least among observed regions, the level of policy coherence is higher than Surabaya.

Table 3. Percentage of adopted local collaboration-supportive policy instruments in observed regions.

| Instruments | Jakarta (n=9) | Surabaya (n=7) | Yogyakarta (n=3) | Denpasar (n=4) |
|---|---|---|---|---|
| **Exhortation** | | | | |
| Advocated in Master Plan | 100.0 | 71.4 | 100.0 | 25.0 |
| Advocated in the midterm Development Plan | 77.8 | 71.4 | 66.7 | 50.0 |
| Advocated in the long-term Development Plan | 77.8 | 28.6 | 100.0 | 50.0 |
| Advocated in the Program | 88.9 | 42.8 | 100.0 | 100.0 |
| **Direct provision** | | | | |
| Shared local budget to state enterprise | 88.9 | 100.0 | 66.7 | 75.0 |
| Shared local budget to third parties (private sector/other local government) | 88.9 | 57.2 | 66.7 | 50.0 |
| The budget allocation for managing regional collab. | 77.8 | 57.2 | 100.0 | 100.0 |
| Infrastructure transfer | 77.8 | 42.8 | 0.0 | 0.0 |
| Management of local assets | 100.0 | 85.7 | 66.7 | 75.0 |
| **Fiscal/Subsidy/Tax** | | | | |
| Grants | 77.8 | 71.4 | 66.7 | 50.0 |
| Incentives | 44.4 | 42.8 | 100.0 | 0.0 |
| In-kind transfer | 100.0 | 85.7 | 66.7 | 100.0 |
| **Contract** | | | | |
| Consolidated contract issuance | 77.8 | 42.8 | 100.0 | 100.0 |
| Evaluation scheme | 55.6 | 42.8 | 100.0 | 100.0 |
| Conflict solving | 77.8 | 28.6 | 33.3 | 0.0 |
| **Regulation (for collaboration)** | | | | |
| Regulation covering all sectors | 55.6 | 14.3 | 66.7 | 0.0 |
| Regulating nongovernmental sector only | 55.6 | 14.3 | 33.3 | 0.0 |
| Adopted from higher level (no local regulation) | 1.1 | 71.4 | 33.3 | 100.0 |
| **Authority** | | | | |
| Procedural guideline in collaboration | 88.9 | 0.0 | 100.0 | 0.0 |
| Sub-district and village collaboration | 33.3 | 57.2 | 33.3 | 0.0 |
| Mean | 78.96 | 51.42 | 70.01 | 48.75 |

*Source: Author (2014).*

Further looking at the array of the local policy design across metropolitan regions (Table 4), a wide variation is observed between regions. Generally, metropolitan regions can be divided into two groups; one that has large similarity in their policy instruments and another that has less similarity.

The variation on how regions perceive the importance of collaboration-supportive policies also differs across instruments. In this case, some regions see the importance of advocating and jawboning collaborative activities through their plans while other regions placed their collaborative concern through government provision and public investment related policies or providing comprehensive scheme on fiscal instruments.

The way cities projected their policy instruments from the perspective of fiscal strategies falls into three groups; regions with intergovernmental orientation, regions with cross-sectoral (public private) orientation, and regions which try to accommodate both intergovernmental and cross-sectoral collaboration. Cities with fiscal orientation leaning toward intergovernmental orientation provide fiscal transfer and/or intergovernmental resource sharing scheme through grants and in-kind transfer. The cross-sectoral oriented cities, however, have policy instruments covering private initiatives, incentive for private sector in joint partnership, providing an infrastructure transfer scheme, regulation outlining transfer management of local assets, and other private-sector friendly policies. Surabaya and Denpasar, in particular the core city and large suburbs, issues expansive policies accommodating public private partnership. Cities in Jakarta providing cross-sectoral friendly policies, however, are not limited to the large suburbs only but almost all cities in the region. Whereas cities in Surabaya other than the core city and large suburbs are not familiar with cross-jurisdictional fiscal policies, cities in Yogyakarta are the opposite. Fiscal policy preferences, can be concluded, reflect cities capacity in conducting a certain type of collaboration.

Table 4. Regional comparative policy characteristics based on the local policy design.

| Variable | Jakarta | Surabaya | Yogyakarta | Denpasar |
|---|---|---|---|---|
| Policy coherence | Limited (not in fiscal, contract) | Lack of coherence in all | Coherent in all | Coherent on collaborated sector |
| Advocacy on collaboration | Active | Passive | Active | Active |
| Collaborative policy orientation | Localised | Localised | Region-wide | Region-wide |
| Type of collaborative policy | All cities. Long and short term | Few cities. Limited to mid term | All cities. Long and short term | All cities. Long and short term |
| Fiscal policy orientation | Intergovernmental cross-sectoral | Cross-sectoral | Intergovernmental | Intergovernmental cross-sectoral |
| Regulation | Mostly enacted | Mostly adopted | All enacted | All adopted |

## *4.2 The Institutional Structure of Indonesian Collaborative Policymaking*

The analysis of institutional structure examined the relative importance of collaborative policymaking activity between cities and among participating actors at the local level. It was projected to explain the prominence of local actors at the collaborative platform. Local governments have many ties with different actors and in those ties they create relation with a particular actor through one or many types of activities. There are possibilities that local governments do not create ties with any actors on a certain joint policymaking activity as much as there are chances that they develop ties with a counterpart on all activities. Through the analysis, this study tried to capture the percentage of activity that involves each horizontal actors to represent how the collaborative policymaking is structured from the perspective of local actors. In order to do so, the aggregate of relative involvement of preferred actors chosen by local governments in a particular activity was measured by converting the total number of linkages between local governments and other players within a specific activity into a percentage. Table 5 summarised the findings.

Table 5. The horizontal interaction on the collaborative joint policymaking activities (percentage).

| | OC | D | SOC | CC | REC | PCD | U | NGO |
|---|---|---|---|---|---|---|---|---|
| Jakarta | 32.97 | 0.00 | 20.33 | 6.04 | 9.89 | 13.74 | 8.79 | 8.24 |
| | (1) | | (2) | | (4) | (3) | | |
| Surabaya | 27.85 | 1.27 | 24.05 | 3.80 | 13.92 | 11.39 | 12.66 | 5.06 |

*Source: Author (2014).*

Three different governance structures are observed from the results; intergovernmental, cross-sectoral, and mixed. Cities in Yogyakarta submitted the most intergovernmental results, implying that local governments in the region rely mostly toward their neighbouring cities by devoting their collaborative policymaking activities twice as active compared to the nongovernmental actors. Moreover, whereas the cities in the Yogyakarta regions are the most frequent users of the intergovernmental interaction, they are the least frequent users of the cross-sectoral interaction. The absence of private sector involvement leads to assumption that the Yogyakarta region employs a limited cross-sectoral collaboration and are more focused to develop their intergovernmental structural institutions. As opposite to Yogyakarta, instead of interacting with their neighbouring municipalities, local governments in Surabaya tend to put more focus to form a collaboration with the non-governmental organizations. Not as polarised as Yogyakarta or Surabaya, cities in Jakarta and Denpasar regions are found to be more balanced as they pursued the intergovernmental interaction to some extend and showcase a high cross-sectoral interaction in their policymaking activities.

### *4.3 The Influence of Local Policy Design to the Institutional Structure of Collaborative Policymaking*

In the rational choice institutionalism, the action situation influences participant in which way information is accessible (Ostrom, 1990). Consequently, the action situation varies according to the autonomous degree of participants in controlling their decision. During a decision making process, participants assigned to a situation must choose from possible actions that can affect the desired outcome (Ostrom, 2005). In this paper, the action situation is referred as the local policy design and follow similar characteristics from the rational choice perspective, i.e. it varies according to the set of policy instruments applied by the local entities. A city with a certain local policy design choose to conduct a selective collaborative activity with a specific actor in which affect the overall institutional collaborative structure of the city.

Given the importance of institutions in affecting the structure of a situation and the types of actors who are most likely to come to prominence in a particular type of situation, this paper tried to structure the collaborative governance which local governments engage in repeatedly to establish their local policy platform. Following the characterization of actors interaction analyzed in the previous section, this section addressed the linkage between this actors interaction with the local policy design by gauging the general tendency occurred on a certain condition.

Table 6 summarised the findings through the importance of the status of policy instruments toward the occurrence of collaborative activities. The summary is based on the examination between the characteristics of local policy design with the local institutional structure towards the regional characterization of collaborative governance. The analysis is conducted based on comparative regional observation of multiple occurrence among regions and cities. From the analysis, we found that the collaborative policymaking activities between cities sharing jurisdictional borders and between cities and nongovernmental actors do not require a strong policy coherence among cities in a region. This finding was gathered based on multiple occurrences of joint policymaking as the major collaborative activities among neighbouring cities regardless the status of their policy coherence (e.g. Yogyakarta and Surabaya both see the importance of conducting joint policymaking with neighbouring cities, although the first region has strong policy coherence and the latter has a weaker condition). The corollary is that as the activity focusing on establishing collaborative policymaking, which is considered more planning than implementing, it does not require a strong policy coherence on all instruments as much as implementing or adopting policies. It needs, instead, an active advocacy on collaboration from local governments.

The findings point out the inherent bias toward short-term issues and quick results of the Indonesian planning system as both intergovernmental and cross-sectoral collaborative policymaking prefer a short-term targeting model. This issue roots on the effects of decentralization in which a more decentralized administration and financing make it harder to agree on issues involving trade-off between local goals. Indonesian planning system, and subsequently its policymaking system, interlinks heavily with economics and politics which determine the policy substance and legal and bureaucratic processes which determine the policy implementation . As there is no guarantee that a policy will be implemented fully according to its original intention, the workable policies in Indonesia are often short term to reduce the distortions and noises often observed in the long-term policymaking. Short term targeting model of collaborative intergovernmental policymaking observed in this study stems from local governments demanding less time and energy to expend. Cross-sectoral collaboration is found to be less fussy than the intergovernmental as it is subjected to less political, legal and bureaucratic transaction costs and rather determined largely by the economic variables.

Table 6. Linkage between local policy design and actors interaction in the collaborative policymaking.

| Status of policy instruments | Governmental (neighbouring cities) | Nongovernmental (private and civic sectors) |
|---|---|---|
| Need of strong policy coherence on all instruments | Not related | Not related |
| Need of active advocacy on collaboration | Related | Not related |
| Need of region-wide collaborative policy orientation | Not related | Not related |
| Targeting model of collaborative policy | Short term | Long and/or short term |
| Fiscal policy orientation (Intergovernmental-cross sectoral) | Intergovernmental fiscal policy orientation | Cross-sectoral fiscal policy orientation |
| Status of regulation collaborative partnership (Enacted adopted) | Enactment of independent regulation is not crucial, except in case of Jakarta and Yogyakarta | Enactment of independent regulation is not crucial in Denpasar, yet in other regions cities with private regulation have higher cross-sectoral interaction |

*Source: Author (2014).*

In general, this paper found that the local policy design influences the state of intergovernmental collaborative policymaking more than it structures the cross-sectoral one. The condition of the local policy design directs the local government s behaviour in a way that loose or weak term of advocacy and fiscal orientation will lead local actors to choose nongovernmental actors as a counterpart in conducting collaborative policymaking than pursuing intergovernmental interaction. On the other hand, cross-sectoral collaborative policymaking between a city and nongovernmental actors in its jurisdiction are found not particularly dependable on the type of targeting model of local collaborative policies. Cities in the Surabaya regions which in general remodeling their collaborative programmes through the short term plan (working plan or medium-term development plans) pursue collaboration with nongovernmental actors as actively as cities in the Jakarta region which largely structured their collaborative programmes through both long and short term planning.

The status of regulations is found to create a variation of effects towards horizontal structures, which is predominantly structured according to each region. Enactment of individual regulation specifying code of conduct in collaboration, for example, is not necessary in Denpasar as the region has strong intergovernmental and cross-sectoral collaboration. On the other hand, cities in the Jakarta region, which perform more intergovernmental collaboration are observed to enact separate regulation specifying collaboration rather than adopting from the provincial or central governments. Taking into account power relations among actors, regions with a regional oriented collaborative strategy are generated from strong inter-jurisdiction interaction and, by some extent, closer relations with the higher levels of government. Closer relations with the provincial or central government, either through fiscal or sectoral programmes, can result on higher probability of the higher levels of government projecting their national or provincial plan to the local level. A region like Yogyakarta, for example, enjoys a tight relation with the provincial government in a way that the province can ensure the smooth adoption of the provincial spatial plan to local master plan. On the other hand, policy instrument and power relation also work on reverse, i.e. policy instruments affect the power relations, projecting region-wide collaborative strategy may lead to closer local-provincial or local-central interaction.

## 5. Conclusions

In general, according to the analysis on the institutionalisation of policy instruments, the local policy design through the effects of instruments selection and policy choice affects the state of the intergovernmental collaboration in a city. On the other hand, the correlation between the local policy design and the cross-sectoral collaboration is observed less significant. The variation between sampling cities in the cross-sectoral collaboration is wider than the intergovernmental collaboration. Policy instruments in Indonesian collaborative governance, thus, offer a means of structuring a space of selective cooperation and a space for exchange negotiations and agreements , setting aside an expansive platform with multiple actors, and thereby allow for a sectoral and case by case cooperation rather than ambiguous and metropolitan-wide consensus. Policy instrumentation for cross-sectoral collaboration is built upon a short-term exchanges and the state of power relation between government and nongovernmental actors through the use of authority and regulative instruments. The extent of intergovernmental collaboration, however, is influenced greatly through advocacy and subsidy instruments.

The artisanship of working with rules through instruments is important so as to improve how local policy design operates over time. The institutions where actors operate differently reward or prevent them over time, so that intrinsic and extrinsic motivations are learned and developed. Instruments, from the analysis, we found as a tool to try and change situations to achieve better outcomes. To improve collaborative policymaking with neighbouring cities, as a start, a city needs to actively

advocate collaboration in its local plans and to set their collaborative programme through short term plans. While aligning local collaborative policies toward a region-wide perspective is observed not crucial, but for the long term success of the collaborative governance it is considered necessary. These three rules that structure the local policy design largely require and expect reciprocity and trustworthiness from the regional perspective which is partial to conduct intergovernmental collaboration. Cross-sectoral collaboration, on the other hand, needs different type of rules in which localised perspective on collaboration is acceptable. In conclusion, referring to variation on how local policy design shapes local governments behaviour in conducting collaborative gov to craft rules that attract and encourage actors who share norms as a fundamental requirement needed in the collaborative society.

## Abstract

*There may be higher risk for people during disaster when they are enjoying the varieties of convenient services with urbanization trends. Especially during natural calamities, of which properties are unexpected and rapid, it is more serious for losses of life and property. The shelters in residential districts are the important location which the residents can immediately utilize for safety once natural disaster or emergencies happen. So basing on the common safety interests, there are some responsibilities of all the residents for shelters planning in urban residential districts, which can make shelters be adequately utilized and reduce the losses during disaster. Social cohesion will be needed to realize this objective, which is reflected by the following aspects: firstly making the residents participate in improvement of the shelters planning according to their actual needs; secondly ensuring the facilities in shelters can operate well and the rescue can be effectively utilized. In this paper, the role of social cohesion on shelters planning in urban residential districts, which also included the routing maintenances and improvements of the shelters, was studied by basing on disaster psychology and anthroposociology, and the case study was applied by the in-depth interview and questionnaires. It was found that the more effectiveness of the social cohesion in the shelters planning was bad, and the more roles of the shelters would be played during the disaster and simultaneously the losses could be possibly reduced. Therefore, the social cohesion is important one of the considerations in the shelters planning.*

**Key words:** social cohesion, urban residential districts, shelters planning

## 1 Introduction

The second world conference on disaster reduction (2005), held in Kobe, Hyogo, Japan, suggested that disaster prevention and mitigation in the cities should be paid our attentions, and especially the urban residential districts should be as the elementary unit for disaster mitigation( Li and Lu, 2009).Actually the larger potential risks have arose in modern urban residential districts during the natural calamities (such as earthquake and conflagration) because the high density of population resulted from the increasing density and height of the buildings in urban residential districts. As the vital components of the cities, urban residential districts daily accommodate the majority of population in the cities during some specific time (such as sack time), and there intensively contain amount of the public infrastructures (such as facilities used for electricity and natgas supplies). During the paroxysmal disasters this is prone to result in more casualties and the serious loss of properties compared with other areas, and even it causes serious secondary disasters. So the shelters planning in urban residential districts have became more important for the modern city, especially in China, compared with that in the last century.

However, less residents participated the shelters planning in their urban residential districts, and the most of the existing shelters were not periodically maintained after the construction or used for disaster prevention trainings. This may resulted in that the residents were not familiar with the shelters. After the analysis of the casualties during several earthquakes, it was found that the casualties during escaping to the shelters (such as green lands) were more serious than that caused directly by the disaster. During 5.12 earthquake (Wenchuan) in China, the victims directly put up the tents in street for the refuge, which delayed the arrival of the supplies and relief teams. In a survey for the unban planning (Liu, 2001), a resident said that it was not reasonable for the planning related to his surroundings solely made by whom did not live here. With the analysis (You, 2004) of 10 stricken areas in 9.12 earthquake (Taiwan), it was found that the residents tended to choose the shelters with the following characteristics: being near to their residences; familiar surroundings and neighbors, which made victims feel more belongingness and also contributed to mutual aid. Therefore, the daily life and familiar needs of the residents is the basis of shelters planning in urban residential districts.

Actually the shelters planning is a pattern of the resource allocation, and it is involved with the security interest of the residents. Marx (1956) said that people are fighting for everything to do with their interests. So it is necessary for the residents to participate in the planning, routine maintenances and use training of the shelters, which the social cohesion among the residents plays an important role in. Therefore, the social cohesion should be one of the main considerations for the shelters planning. The case study done by Li (2014) indicated that the level of the social cohesion could be influenced by the public space. However, until now few studies have been conducted to reveal the direct relationship between the social cohesion and the shelters planning in urban residential districts. In this study, the relationship of the social cohesion in the shelters planning was mainly analyzed, and a theoretical model of the shelters planning was proposed, which may further increase the utilization of the shelters during the outburst calamities in future.

## 2 Definition of concepts

### 2.1 Social cohesion

The term Social cohesion was first coined by Emile Durkheim in 1983 (Regina, 200 that it was a characteristic of the social order, which was expressed by the interdependence, mutual loyalty and solidarity among members of society. Subsequently, it has various definition narrated by many scholars, and some governments and organizations have made many efforts for improving its level among their citizens or members. The Social cohesion is a tie among the members of society, and its level can be assessed by the following factors: social relationship, task relation, perceived unity and emotion(Forsyth, 2010). Actually except the expression of social cohesion mentioned above, there also include belongingness, inclusiveness, the participatory, recognition, legality, shared values, shared challenges, equal opportunities and so on.

### 2.2 Urban residential districts

The residential districts are the areas with certain scale, which is divided by the roads or natural boundaries (such as rivers) in city and no main road is throughout, and there are the public greenbelts and the completed infrastructures which can meet the residents daily life. A residential district comprised of several housing clusters is a unit of the resident area. According to <Code of urban residential areas planning & design> (GB50180-93, 2002) in China, the scale of a resident district should range from 2,000 to 4,000 households (approximately 7,000-15,000 residents), and land-use area range from 10,000 to 36,000 square meters.

### 2.3 Calamities of residential districts

The disasters mentioned in this study, which belongs to the urban disasters, likely occur in the residential districts and threaten the security of the residents life and properties. These a of natural and man-made disaster and mainly include earthquakes, floods, severe colds, typhoons, tsunamis, fires, epidemics and the secondary disasters potentially resulted in by them (Liu, 2006).

### 2.4 Shelter

The shelters mentioned in this study, which solely referred to the emergency and temporary refuges rather than the municipal or provincial refuges, are the transitional places before the victims can be transferred to the larger public shelters together. (Design code for urban disasters emergency shelter-exposure draft, 2012, GB xxxxx-2012)

## 3 Research Objectives

The objectives of this study were to (i) explore the roles of the social cohesion in the shelters planning. (ii) Highlight the participation of the residents in shelters planning in order to increase its utilization during the outburst calamities in future. (iii) Establish a theoretical model of the shelters planning oriented by the social cohesion.

## 4 Research methods

A mixed method was design and applied in this study. Firstly, we identified the related literatures by searching the electronic databases of SCI, EI and CNKI, and the following keywords were used in various combinations: social cohesion , residential districts , or shelters planni obtain the real needs of the residents, we respectively made the in-depth interviews with 20 persons from the different resident districts, who are the residents, members of the neighborhood committees, or staffs from the property management companies. Every interview was randomly carried out for approximately half an hour, and the contents of the conversation were not limited before. Finally, the factors selected form the related studies were combined with the topics frequently mentioned in the interviews to design a questionnaire and a total of 200 questionnaires were online distributed.

## 5 Results and discussion

The serious losses of life and property were always caused because the calamities unpredictably and rapidly happened. The comprehensive measures for the disaster protection is one of effective methods to minimize the losses. A shelter in the residential districts is one of the important locations used for the disaster protection, so it is necessary for the immediate and efficient utilization of the shelters during the unexpected disasters, which is directly related to its planning. In this study, whether the social cohesion as one of the considerations is necessary for the shelters planning was investigated, and a theoretical model of the shelters planning oriented by the social cohesion was tried to established, which may be helpful to the related researches and planning.

### 5.1 Baseline of case study

A total of 200 questionnaires were online distributed, and 158 valid questionnaires were identified for the subsequent analysis. The baseline characteristics of case study were provided in Table 1. Briefly, all the respondents were from Chinese mainland and randomly selected without age, gender or education background limits.

Table1. The Baseline Characteristics of Case Study

| Type | Data |
|---|---|
| Gender | Male to female ratio 3:5 |
| Age | Under18:1.90%; 19-30:58.23%; 31-50:37.97%; 50-70:1.90%; Above70: 0% |
| City | About 39 different cities dotted about the country |
| Residence type | 12-30F:20.89%; 7-11F:9.49%; 4-6F:55.70%; the rest:13.92% |
| Housing ownership | Rent:29.11%; Own:70.89% |

## 5.2 Importance of the shelters in resident districts

The various disasters can happen anywhere at any time. More than 70% of the respondents in this survey indicated that they or their friends suffered the disasters (Fig.1). The residential districts are the important one of the functional units in city and are the areas with the dense population. The population mobility in the residential districts always focuses on the special time in daily life. In our surveys, it was found that 74% of the respondents stayed in their home at night and only 7% for all day (Fig.2: a). Simultaneously, the plot ratio are gradually increasing with the increase of population density, which resulted in the reduction of their safe distances. The secondary disasters (such as Stampede) are more easily resulted from the above factors when many panic residents with simultaneously escape for the refuge in the crowed spaces during the disaster. The shelters in resident districts are generally planned as the preferred emergency refuge for the residents during the disasters, and its reasonable planning can partly mitigate the losses and above risks, which is also conductive to the rescues and reconstruction after the disasters.

Figure 2. The Relationship between Residents with Family and Family members.

### 5.3 Existing shelters and awareness of disaster prevention in urban residential districts

The public spaces (such as shelters) in the resident areas, which are the important parts of the urban public spaces, are closely related to residents daily life. However, actually the other urban public spaces were always paid more attention than them, and the resident areas especially resident districts were mistaken for the relatively safe locations. So far, the follow-up of many existing shelters, including the construction, rationality of their utilities, maintenances, improvements of their functions and so on, was infrequently concerned by their planners after accomplishments of their planning.

In this survey, many residents had been trained on the disaster prevention, but nearly a half of the respondents did not know where the shelters were in their resident districts, suggesting that the residents were not familiar with the shelters. 29.41% of the respondents indicated that they were not satisfied with the shelters planning and 21.52% were satisfied(Fig.3); simultaneously, during disaster 68.35% of the respondents intended to refuge in the opened areas outside the resident districts, and 25.95% chose the square in the resident districts for the refuge(Fig.4). In addition, the streets were also chosen by a few respondents for the refuge, which may hamper the recues and evacuations during the disaster. This suggested that the shelters were not regarded as the reliable refuges. If the resident districts were dissatisfied, 44.3%, 17.72% and 8.23% respectively chose to suggest property management companies, neighborhood committees or governments for it, and 7.59% chose to move and 22.15% did not know who should be in charge of it (Fig.5). This indicated that there was not a very definite way for the residents participation in the affairs (such as the affaires related to the sa of the resident districts.

### 5.4 Social cohesion should be as one of the considerations in the shelters planning

The formation of the social cohesion is affected by the complex and diverse factors, which include kinship, traditional or national concepts, class status, social mentality based on the consistency of the realistic interests and so on. For instance, it was founded from this survey that 98.84% of the respondents indicated that they prefer to stay with their family members when the disasters happen (Fig.2:b). In this study, for the concretely reflecting the levels of the social cohesion in the resident districts, it was artificially and simplistically defined and assessed with the following factors in the resident district: the degree of familiarity among the residents, the frequencies and effects of the collective activities, the degree of residents satisfaction for the public spaces, the utilization rate of the public spaces and so on.

In this survey, more than 60% of the respondents, whose age group was from 50 to 70 or less than 18 years old, were familiar with the other residents in their resident districts, but it was less than 10% of the respondents whose age group was from 19 to 50 for it (Fig.6); correspondingly, more than half the respondents indicated that there was never any collective activity held in their resident districts (Fig.7 ). Simultaneously, 46.84% of the respondents had been trained on the disaster prevention and most of the training place were their school or work units rather than resident districts, and the proportions of the respondents trained decreased with age (Fig.8). This may be used to explain that nearly a half of the respondents did not know where the shelters were in their resident districts (Fig.3), and it could result in that the utility rate of the shelters would be low during the disasters. Similarly, the respondents who were the homeowners were more familiar with the other residents and more satisfied with the shelters than the tenants in their resident districts (Fig.9 &Fig.10). The potential utility rate of the shelters is closely related to residents familiarity with them, so the social cohesion will also affect it and should be considered in the shelters planning.

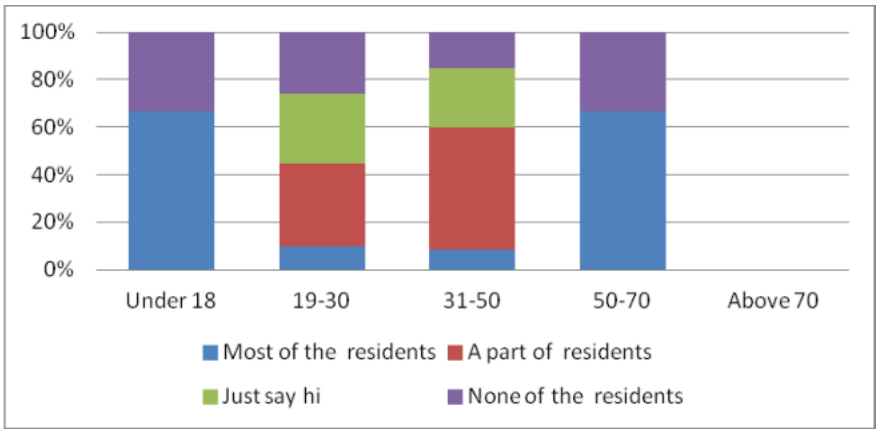

Figure 6. Are you familiar with the other residents in the resident districts?

Figure7. Is there any collective activity held in your resident districts

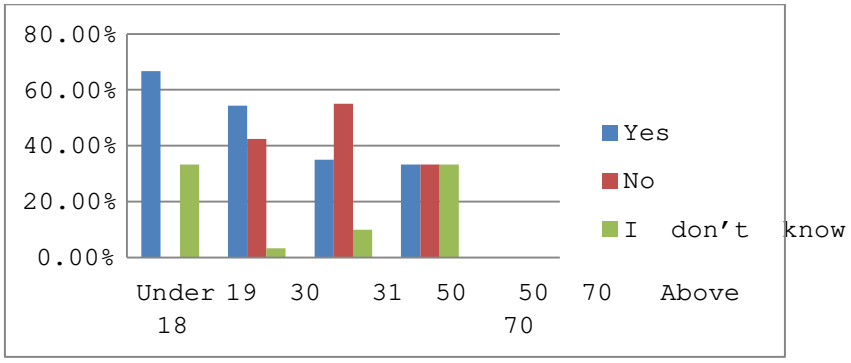

Figure8. Have you attend the survival training course?

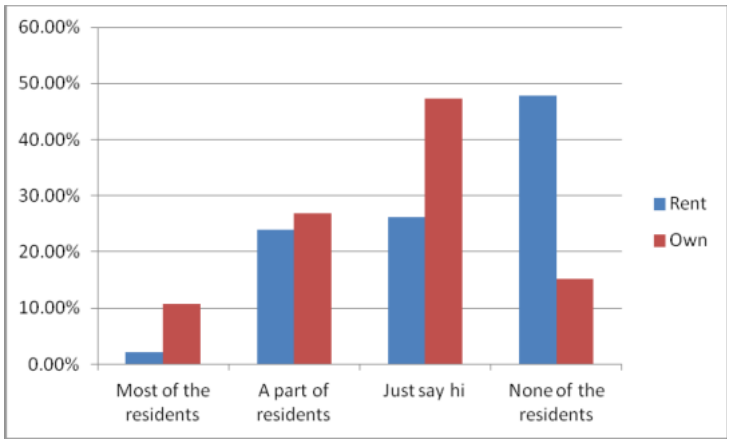

Figure9. Do you familiar with the other residents?

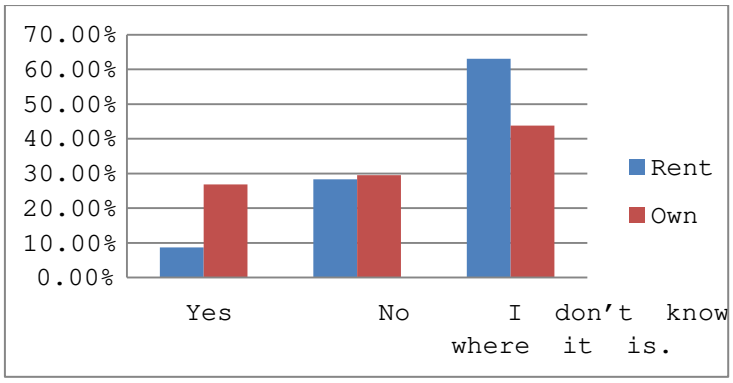

Figure10. Are you satisfied with the shelters?

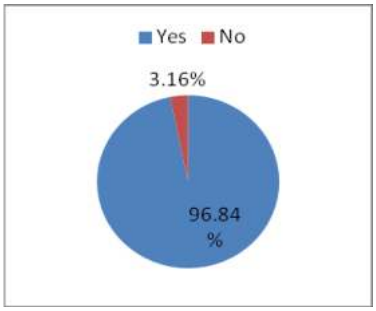
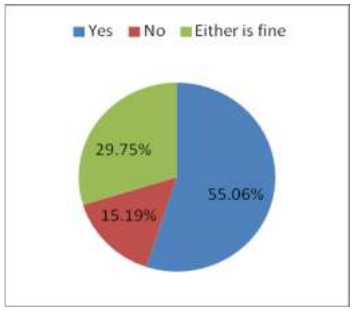
The shelters in the resident districts are planned for and will be mainly utilized by the residents, so it is rational to consider their needs in the shelters planning. The function conservation of the shelters can successfully be realized in daily life and disasters when the planning meets the needs of the residents, which is impossible without the residents opinions. 95.76% of the respondents wou participate in the shelters planning if possible (Fig.11: a). However, it was learned from the in-depth interviews that it was always one-way for the communication between the residents and the managers in the resident districts. The manager generally told the residents what or how they should do rather than comprehended their thoughts or real needs, and the resident seemed to be used to that rather than actively gave their advices. This is consistent with the survey results obtained by Ma (2011). So the enthusiasm of the residents participation weakened by the management mechanism of the residen districts, which could also affect their participation in the following-up maintenances and improvements of the shelters after the constructions. In fact, the effective utilization of the shelters during the disasters is dependent on its following-up maintenances, and the functions of the shelters will be improved with constantly considering and comprehending the needs or habits of the residents in its maintenances. The effective utility of the shelters is related to residents participation in it following-up maintenances, so the social cohesion be certainly considered in the shelters planning.

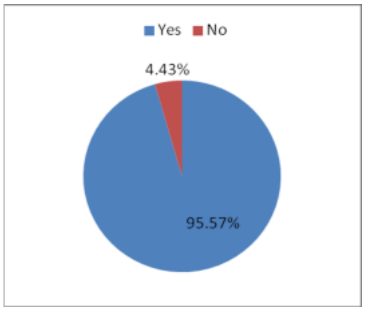
In addition, if the stir-and mutual-rescue can be firstly done among the residents before the recue teams arrival as soon as the disasters occur, the losses will be generally reduced at a great degree. The shelters in resident districts are generally planned as the preferred emergency refuge for this, so the degree of the stir-and mutual-rescue, which the social cohesion plays an important role in, was closely related to the utility rate of the shelters during the disasters. In this survey, more than half of the respondents indicated they would need the helps from others during the disasters (Fig.11: b), and more than 90% of the respondents would like to help others if possible (Fig. 11: c). This suggested that the social cohesion is important one of the considerations in the shelters planning.



a. Would you like to participate in the shelters planning if possible?



b. Do you need the helps from others during the disasters ?



c. Would you like to help others during the disasters if possible?

Figure11: The social cohesion of residents in the disaster.

The density and height of the buildings are gradually increasing with the increase of population density. Although a certain scale of the land are used as the shelters in the resident districts, but with basing on the considerations for the economics and utilization rate of the land, it is impossible to increase their areas without the limitation. So it is necessary to effectively utilize the shelters with the limited spaces during the disasters, which is partly dependent on the participation of its non-planner contributed by the social cohesion. Simultaneously, the various functions of the shelters need to be accepted and embodied by their utilizations among the residents in daily life or disasters, and these are gradually improved with constantly meeting the resident s needs. Therefore, the social cohesion should be considered as an important factor related to the utilization, maintenances and improvements of the shelters in the planning.

### 5.5 How to realize the shelters planning oriented by social cohesion

In this survey, the proportions of the respondents trained in the disaster prevention decreased with age (Fig.8), suggesting that the training had been increasingly paid more attentions. Simultaneously, none of the respondents trained would choose the elevators to escape during the disasters. This suggested that the effect of the training was yielded and the psychological fore-warning system on residents trained had been gradually constructed. The shelters in resident districts are generally planned as the

preferred emergency refuge for the stir-and mutual-rescue of the residents, and the participations of its non-planner (such as disaster prevention trainings), which is contributed by the social cohesion, certainly affect its utilization rate. So it is necessary to consider the residents needs in planning, and these needs are related to the following aspects: age and physical condition of the residents (such as the aged or disable), the locations of the shelters (which is necessary to whether the residents can arrive as soon as the disaster occur and whether it is convenient for the residents in daily life), appropriate functions (such as the differences of the infrastructures between south and north) and so on.

The potential real needs should be collected and summarized with basing on the interests of the majority, and these needs will be combined with other factors and realized in a rational degree by the shelter planner. Subsequently, after the shelters construction the planners should always learn their utilization rate and maintenances from the residents, and the various functions of the shelters will be further optimized according to the reasonable and necessary needs. In other words, the shelters planning in the resident districts should be based on the life experiences of the residents, and it is combined with the professional acknowledges of the planners to be realized. During the above process, the enthusiasm of the non-planners participation is important for the comprehension of their real needs, which is contributed by the social cohesion. In addition, the previous studies done by Guo (2013), Bowers (1996) and Olden-burg(1989) showed that the effective utilizations of the public spaces including the shelters in the resident districts or communities played an important role in and were contributed to the formation of the social cohesion. This means that there are the interactions between the social cohesion and shelters planning in the resident districts. So the shelters should be planned as the public spaces which can allow and attract most of the residents usually participate the group activities in daily life. This can not only promote the residents familiarity with the shelters, but be contributed to the familiarity among the residents, which are important to the utilization, maintenances and improvements of the shelters.

With basing on the results of the above survey and study, a theoretical model of the shelters planning in resident districts oriented by the social cohesion was proposed as the following: the residents participations in the shelter planning embody their needs to enhance their sense of belonging; The high degree of familiarity with the shelters for the residents can increase their utilization rate, and the frequent collective activities in the resident districts can promote the formation of the social cohesion; the social cohesion including the residents sense of belonging is contributed improvements of the shelters; the effective utilization of the shelters is important to the immediate stir-and mutual-rescue as soon as the disasters occur, which can generally reduce the losses at a great degree. Therefore, the more effectiveness of the social cohesion in the shelters planning was had, and the more roles of the shelters would be played during the disaster and simultaneously the losses could be reduced.

## 5.6 Limitation

There were certainly several limitations in this study. Firstly, there the biases of the amount of the different classified respondents, which was resulted from the limited total number of the respondents, and this may resulted in the deviations in the analysis results; Secondly, the current roles of the social cohesion in the shelters planning were only investigated, but the roles were not compared with that in the past for the further confirmation; Thirdly, the relationship between the social cohesion and the

shelters planning was only studied by univariate analysis and the multivariate analysis was not applied. Therefore, a detailed and well-designed study should be performed to further confirm our results.

## 6 Conclusion

In conclusion, our study does support that the social cohesion plays important roles in the planning, maintenances and improvements of the shelters in resident districts, and it should be as important one of the considerations in the shelters planning. The conclusions and recommendations are summarized as follows: the social cohesion is contributed to arouse the enthusiasm of the residents participat the planning, maintenances and improvements of the shelters in daily life, and the group activities in the resident districts (such as disaster prevention trainings) should be frequently held; During the disasters the stir-and mutual-rescue to reduce the losses relays on the effective utilization of the shelters, which the social cohesion also promote; The more effectiveness of the social cohesion in the shelters planning was had, and the more roles of the shelters would be played during the disaster and simultaneously smaller losses may be.

## Transport Planning and Mobility Policies: Available and Affordable Transportation

# I MOVE THEREFORE I CAN . TRANSLATING MOBILITY CAPITALS INTO PLANNING PRACTICE

Giovanni Vecchio

Department of Architecture and Urban Studies (Politecnico di Milano), giovanni.vecchio@polimi.it

Keywords: mobility capitals, mobility practices, mobility policy

**Abstract**

*Aim of the paper is to understand if the construction of mobility capitals, as shaped by planning actions, could be introduced in planning practice and if it could contribute to the orientation of individual and collective travel behaviours towards more sustainable mobility practices. Mobility capitals, that can be framed as the opportunities in the field of movement which are available to individuals, are introduced as a key concept to associate individual aspirations and their reflection on mobility practices, focusing on how individuals differently appropriate the opportunities of movement. Consequently, the potential significance of mobility capitals for mobility planning is discussed through various examples, referred in particular to the now spreading Sustainable Urban Mobility Plans a planning tool developed at the European level which seem to contribute to the construction of mobility capitals with different styles of mobility governance.*

## 1. Introduction

Contemporary urban settings are more and more shaped by mobility practices, which at the same time are crucial to shape individual lives. Relevant in this sense are mobility capitals, that can be framed as the opportunities in the field of movement which are available to individuals. The concept of mobility capital, developed in particular by mobility sociologists, is nevertheless missing attempts of concrete applications in planning.

Aim of the paper is to understand if the construction of mobility capitals, as shaped by planning actions, could be introduced in planning practice and if it could contribute to the orientation of individual and collective travel behaviours towards more sustainable mobility practices. In this way, it could be possible to provide mobility opportunities which would meet more closely individual aims, while providing more generally positive externalities (like lower pollutant emissions or wider access to job occasions). Specific interventions on mobility capitals could in fact provide wider and varied opportunities for movement while reducing the negative externalities related to personal trips.

The paper then introduces mobility capitals as a key concept to associate individual aspirations and their reflection on mobility practices, focusing on how individuals differently appropriate the opportunities of movement. Consequently, the potential significance of mobility capitals for mobility planning is discussed through various examples, referred in particular to the now spreading Sustainable Urban Mobility Plans (SUMP) a planning tool developed at the European level which seem to contribute to the construction of mobility capitals with different styles of mobility governance.

The concept of mobility capitals has not established significant relationships with the current planning practice, maintaining mainly an academic nature. Then, it is not possible to observe ongoing examples of mobility planning practice which explicitly assume mobility capitals as a guiding concept. On the contrary, it is possible to observe if and how some current experience provide potential contributions to the construction of mobility capitals, nurturing specific features which do increase individual and collective opportunities in the field of mobility. In this sense, the recent SUMPs may provide a tentative field for this exploration. The European guidelines shaping them in fact recognise a key role to the achievement of social targets, referr

citizens are offered transport options that enable access to key destinations and services
contribute to enhancing the attractiveness and quality of the urban environmen
for the benefits of citizens, the economy and society as a whole (Wefering e
interest in SUMPs could deepen in particular the reading of those plans which have been considered as best mobility planning practices, like those that since 2012 have received the Sump award (as part of the Do the Right Mix initiative, promoted by the European Commission). Considering the recent nature of this planning tool, the analysis of examples which are already considered as positive experiences allows a preliminary examination of the paper

**2. The relevance of mobility capitals**

Mobility is imposing itself as a category that can frame and arrange into new forms contemporary social life, leading to the definition of a new paradigm for social sciences (Sheller and Urry, 2006). Mobility appears as a fundamental tool to analyse contemporary urban settings, considering the possibility that every individual has to move both from a spatial and a social point of view (Canzler & al, 2008). From academic debate to policy discourse, it is seen as a crucial aspect to understand what already exists and to prefigure future scenarios. The wide recent production of reflections on the issues of mobility seems to reflects such rich influence (as well summarised in Sheller, 2011).

The rich debate reflects a shift in the way mobility is considered. Like any other discipline with a strong (but not exclusive) technical component, also mobility planning has been influenced for long time by the Positivist approach criticised by Donald Schön (1981): an attitude summarised in the concept of problem solving, according to which any given problem has its own solution, specified by technical standards and technology. The approach has characterised a rational form of planning partially abandoned only in the last decades, but is instead still present in the transport field. The planning activity dealing with mobility in fact is oriented by efficiency, with the purpose of favouring existing mobility trends as observed in the given settings. The search for an efficient mobility is reflected in the prevalence of technical tools, like transport modelling and cost-benefit analysis.

Today instead it is more and more necessary to consider mobility from an enlarged perspective, able to take into account also social issues (Martens, 2006). Planning practice has always had social and political reflections, also when dealing with movement: the relationships between subjects and communities are effectively developed also through a specific construction of the territory and its networks (Raffestin, 1983). Nevertheless, in addition to this some current environmental, social and economic issues frame mobility as a fundamental opportunity for any individual, being an essential requisite for the recognition of citizenship rights (Secchi, 2014).

The rise of this social dimension of mobility is conveyed by different approaches that try to deal with it, with a specific attention to overcome existing inequalities among individuals and communities. On the one hand, many have focused on transport-related social exclusion, developing conceptual frameworks and operative tools based on three different features: accessibility, capability and time geography (as in the summary provided in Lucas, 2012). On the other hand, a more purposeful and political approach is related to wider conceptualizations of social justice, framing mobility as a fundamental right to guarantee also civic freedom for every citizen (Sheller, 2014).

Within this rich debate, the perspective we choose to explore in this paper is that of mobility capitals. Considering its current development in fact this approach seems to well focus on the freedom that a person has to lead one kind of life or another, adopting it as a relevant ethical approach even for planning practices. Mobility in facts acts as a tool for differentiation, guarantying to anyone a capital that can be used to pursue one s own aspiratio
as a capital, different are the definitions, such as motility (see for example Kaufmann, 2002), network capital (see Larsen et al, 2006) or potential mobility (Kellermann, 2007); these different definitions anyway share the focus on both individual resources and local ties, opportunities and

endowments. Potential interactions between these principles and the actions in the mobility field are missing, suggesting to take into account the possible practical inflections of a theme discussed mainly from a theoretical perspective up to now, at least. The possible relevance of the topic then is not only academic, but possibly wider: a deeper understanding of the empowering role of mobility and its uses in planning are not just a contribution to an existing debate, but could help the current planning practice. Amongst the others, an approach focused on making individuals and territories capable even through mobility could increase the opportunities available to them and consequently contribute to their development, even in terms of struggling with new opportunities and risks (Donolo, 2005).

## 3. Mobility capitals and practices

Mobility has a relevant influence on contemporary societies, acting as an element of individual differentiation (Litman, 2011) and having as a consequence an increased plurality of urban populations and spatial practices (Pasqui, 2008). Nevertheless, it seems constraining to consider mobility simply as a frame to read contemporary urbanity: could it be possible instead to frame it also as a policy tool (Pucci, 2015)? Aiming at forecasting and influencing future urban scenarios, individual behaviours could have a fundamental role (Urry, 2008). Existing or new mobility practices could generate positive externalities both for individuals and communities: in such a perspective, mobility capitals could become a reference, both to work on individual behaviours (promoting existing virtuous examples and sustaining alternative practices) and to increase individual opportunities (providing access to basic services which are currently inaccessible for specific areas or populations).

The first operational option draws on the fact that, in their multiplicity, mobility practices become the tactical expression of wider strategies, which mobilize different capitals in different ways. Practices are not ended in themselves, since they often have an instrumental value (for example, a movement aims at reaching a certain place, to carry out a certain activity or facilitate a specific interaction) and intercept other dimensions. They also provide occasions for aggregation: according to the situations, mobility becomes the field in which are expressed or from which are originated unexpected occasions for interaction and for the mobilization of capitals. Often the mobility practices convey requests and propose solutions which can intercept the public action, with travel behaviours which express new needs and sometimes propose alternative solutions, being an expression of the multiple trajectories and interests that characterize contemporary mobility. Then, moving from the aim of orientating behaviours, mobility practices can be examined starting from the capitals they mobilize, developing then specific actions to support them. This relationship also seems to anticipate a new way to conceive mobility policy. Traditionally, a mobility demand from the bottom was sided by an offer defined by institutions, that starting from technical analyses developed infrastructures and services for mobility, framing them as a further form of welfare (Secchi, 2005). Contemporary practices instead show more and more examples that from below express a mobility demand which, at the same time, tries to internally develop also part of the offer. The demand-offer dichotomy, as expressed in diverse forms of social engagement, questions also traditional approaches to mobility planning.

The second option focuses instead on the availability of mobility opportunities and on the consequent possibility to use them. While capitals represent a form of potential mobility, which could be appropriated according to individual aims and aspirations, often the provision of mobility opportunities is scarce, compromising even the ability to access basic services. Accessibility to places, goods, services and people becomes then the focus of an approach that can use mobility as a tool to increase the availability of such opportunities. In this sense, mobility is a medium rather than an end, being related to the access that it allows. The focus on basic accessibility seems more suitable where massive interventions on mobility are missing (leading to informal alternatives) or address only specific interests; the Western tradition that has included transport infrastructures and services within a wider definition of welfare somehow reduces the relevance that this specific approach could have in European settings. This approach could anyway act both at a microscale

(with specific interventions on chosen areas) or with a broader perspective (making the capability approach contribute to ongoing planning processes, especially when referring to mobility). Compared to the approach working on individual behaviours, the focus on basic accessibility would consider specific, systematic practices those related to the access to basic services and opportunities like workplaces, schools, market places and social services, which are needed on a daily or regular basis. This approach would then convey a more traditional framing of mobility issues, related to the provision of increased opportunities: its difference would rely on the proposed approach, based on the construction of individual capitals and not simply on the public provision of transport services and infrastructures.

## 4. Mobility capitals and planning

Privileging mobility capitals and the practices using them, planning practice would require specific adaptations to such approach, considering that up to now this has mainly remained within an academic domain. Nowadays, mobility practices reflect the multiplicity of interests, opportunities and need of any individual: occasional trips are growing, in relation to varied activities (leisure, services, accompanying ) and to different periods of the day. The multiplicity of time destinations obstacles the provision of effective alternatives to the use of private cars. Moreover, multiple mobility practices continuously question traditional administrative divisions, defining contingent territories shaped by the temporary presence of urban populations (Pucci, 2013). Such multiplicity is an issue for traditional approaches to the government of mobility, but maybe is also an opportunity bringing potential solutions. Practices may propose claims and produce collective goods, developing policies from the bottom. In the first case, the relevance of practices is in their very existence, since it allows specific forms of spatial appropriation. In the second case instead the focus is on the social production of public goods, so to have commons by social practices rather than by policies (Donolo, 2005, p. 47). Such perspective associates the mul practices with a potential production of collective goods: individuals and communities may contribute to their creation, using existing services in unexpected ways or creating new possibilities for mobility.

An attentive planning approach to mobility may then recognize those contributions from the bottom which could develop interesting features to be considered within mobility policy. Nevertheless, even traditional forms of planning may focus on the production of those features which constitute individual and collective mobility capitals. Preliminarily assuming the features of mobility capitals as exemplified in the concept of motility (for which more operational definitions have been provided), their construction should focus on access to different forms mobility, competence to recognize and make use of access, and appropriation of a particular choice, including the option of non-action (Kaufmann et al, 2004, p. 750). Adopting mo capitals as a reference for planning, existing and new actions can be evaluated according to their contribution to individual and collective capitals, going beyond a simple evaluation of their technical or economical efficiency. Rather than introducing new solutions, the proposed perspective works on how the planning practice is framed: it becomes an activity oriented to guarantee opportunities. To do so, it differently evaluates traditional approaches and becomes more attentive to those proposals and initiatives which may contribute to the provision of such capitals.

As a way to explore the feasibility of such paradigm change, the discussion of some recent European Sustainable Urban Mobilities Plan aims at observing ongoing actions, to consider if and how they already contribute to the construction of these capitals and how. The current mobility planning practice does not consider explicitly the concept of mobility capitals; nevertheless, before proposing devoted actions an attentive analysis of what already exists can explore a different framing, to orientate current actions towards different, and possibly more effective, directions.

## 5. SUMPs and mobility capitals

A tentative recognition of the SUMPs awarded since 2012 as best European plans can provide first elements to support the possible introduction of a mobility capital approach in the planning practice. The short overview of their various plans can refer to the three already mentioned categories that compose mobility capitals (as framed by the motility concept): access, competence and appropriation (Kaufmann et al, 2004). As a preliminary observation, all the examined plans seem to share a similar approach to mobility planning: it is seen as an activity combining projects and policies, trying to reduce the use of private cars and to replace it with more sustainable alternatives from public transport to cycling. The focus on sustainability, mainly seen as an environmental target, leads to a shared emphasis on some widespread current planning principles, referring to land use-transport connection, promotion of active mobility, integration among different transport modes. As a consequence, the plans tend to privilege similar actions and most of them seem to foster individual and collective access, with a minor emphasis on competence and appropriation.

As for access, it is constrained by options and conditions. The options refer means of transportation and communication available, and the entire range of services and equipment accessible at a given time. The conditions refer to the accessibility of the options in terms of location-specific cost, logistics and other constraints (Kaufmann et al, tends then to include the majority of the actions proposed in the examined plans, especially those increasing the opportunities for movement. A first action in this sense is the integration of existing transport networks, combining different transport services, offering common titles of use and providing interchanges. The action combines service planning and fare policy: for example, the German city of Dresden has promoted the networking of all transport modes by intermodal and multimodal transfer points, while the compatriot city of Bremen has improved the integration of transport network across its region. In addition to these overall approaches, integration is pursued also via smaller specific infrastructures, like park and ride structures or bicycle stations (as in Dresden). All these elements facilitate the use of the networks, making easier to access them and take advantage of their various parts.

A further element increasing access is the provision of specific services and infrastructures that are missing or incomplete. Apart from the expansion of public transport and cycle networks (which are almost commonplaces of sustainable mobility planning and can be found almost in any place, at least as guidelines), some plans have fostered the diffusion of new sharing services, focusing on cars. Both car pooling and car sharing have then been introduced as a way to provide new connections that can more effectively serve specific relations in specific times of the day, when alternative services are not available: even if their sustainability can be questioned, shared cars do increase the opportunities for access, especially for places and hours with poor services.

The previously mentioned actions somehow intervene on the options, including means of transportation, services and equipments; the focus on public spaces instead seems to work on the conditions of accessibility, privileging interventions on the locations. The Belgian city of Ghent offers a traditional approach to the theme, focusing on the extension of pedestrian areas and proposing the reduction of cut-through traffic in the historic centre; the measure in itself reduces specific quotes of accessibility, preventing car drivers to use the central roads, but also guarantees wider opportunities of use for non motorists, increasing the available areas and the possible usages of these public spaces. Instead, the Basque city of Vitoria has promoted a diffused use of the superblocks, urban cells of different dimensions from which motorised vehicles are prevented to enter. Traffic is concentrated on the bordering roads, while the inner streets are left to active forms of mobility from cycling to walking; also public transport is redesigned accordingly. In this way, the quality of urban space is increased and specific forms of mobility become more attractive from the improved public transport to the safer cycling.

Moving to competences, this is maybe the most difficult field of action for current mobility planning. Our attitudes to mobility are influenced by previous experiences that are part of our mobility biographies, so that a sedimentation of experiences and opportunities continuously shapes

the individual competencies for mobility. Various communication and civic education initiatives addressing specific categories (children in particular) work on the construction of individual competences, while interventions on the legibility of networks reduce the level of complexity in the use of transport services. Among the most recent SUMPs, the plan of Dresden provides a small example in this sense, having worked on the adjustment of public transport schedules: an integrated system, with regular passages and interchanges, provides an easier understanding for its users and requires then a lower level of competencies in order to be used. In other cases, inbetween competence and appropriation, some cities have developed devoted marketing initiatives: for example, the Slovenian town of Ljutomer has introduced a day of active mobilit use of cycling and walking also as modal choice for everyday trips.

Considering appropriation, the discussed measures imply the effective possibility to rely on a given service, choosing to use it or not. A first example is that of operative traffic information, as those provided in Dresden: ongoing road works, traffic conditions and parking possibilities are communicated on real time, offering the information that allow to know which is the most convenient modal alternative in a specific moment of the day. This action intervenes providing updated information, allowing then the appropriation of a modal alternative in a precise moment; it does not have the structural consequences that can obtain actions focused on fostering individual and collective competencies, since it allows the appropriation of something that can be already used. A second approach is that of providing incentives for specific categories, fostering the use of existing services which may prevent some citizen groups from their uses. The French city of Strasbourg has intervened both creating special facilitations for disabled people, both providing fare incentives for financially disadvantaged families. In this way, services that already exist and could be potentially used become more usable also to those categories that are currently experimenting restrictions to access, due to physical or economic reasons. In general, also the actions for appropriation are difficult to define, since external interventions can privilege one modal choice or another, but the final decision on how to move is in charge of each individual.

It must be also noted that all the examined plans share a specific attention to stakeholder involvement and participatory planning processes. While not being directly related to the provision of further opportunities for mobility, this can be framed as an aspect that fosters both competence and appropriation. On the one hand, participatory processes help to increase knowledge of existing transport alternatives and more general mobility issues, expanding the perspectives of everyday urban experiences. On the other hand, appropriation is potentially fostered, admitting that participatory processes allow a better knowledge of different mobility alternatives and increase the familiarity of individuals and communities to them.

## 6. Conclusions

From the short overview on the awarded European SUMPs, what emerges is the potential space for a mobility capital approach even within the current planning practice. The overall attention to sustainability in fact provides some elements that contribute to the construction of individual and collective capitals. Most of the actions contribute to access, working on the offer of mobility services and, indirectly, on the quality of public spaces (which can facilitate specific forms of active mobility). Devoted measures, like incentives and promotional initiatives, provide elements facilitating the appropriation of mobility. Competences instead are almost completely absent from current mobility planning, without structural marketing or educational initiative which may shape the individual ability to use one or another modal choice.

The current planning practice seems then to provide a partial contribution to the construction of mobility capitals. It is relevant to notice that most of the examined plans have been developed in medium-sized cities, mainly located in Central Europe: the results of this preliminary overview are then influenced by the focus on relatively small cities where the principles of sustainable mobility planning have been in use since long time. It would be interesting to conduct a similar analysis on completely different areas, less sensitive to the issues of sustainability or less influenced by

consistent planning traditions; more simply, also a study of more complex metropolitan areas and urban regions could potentially provide different results on how mobility capitals are currently constructed throughout these different settings.

In general, a potential space for a further attention to mobility capitals appears. The European guidelines on SUMPs recognise specific social objectives that mobility planning should pursue, while the dominant planning paradigms tend to privilege actions that are environmentally sustainable (considering also that it is easier to measure their impacts and benefits); as a consequence, the social benefits of mobility plans are very specific (with precise categories receiving the positive externalities of some actions) or too generic (without any possibility to quantify the positive consequences of specific interventions, especially if generally benefitting the whole community). Instead, a focus on mobility capitals could guarantee specific references for their construction (referring to the three categories of access, competence and appropriation, and eventually to further, more precise categorisations), and at the same time could also provide wider occasions to consider and support those everyday mobility practices which contribute to the pursuit of wider collective aims.

The paper then aims to suggest a different, and potentially fruitful perspective for mobility planning, trying to give more relevance to the social dimensions of mobility. Its starting concepts require further research, in order to be expanded and even adapted to the peculiarities of the planning practice: considering the various definitions provided for mobility capitals and their scarce planning uses, it becomes necessary to understand at which conditions a mainly sociological concept could be transferred (and become usable) within the current mobility planning practice. Nevertheless, a reference to mobility capitals can give more relevance to individual attitudes and behaviours, making mobility opportunities more effective thanks to a closer connection to the ways in which they are used. More importantly, framing mobility from a capability perspective may allow to consider the wider uses of mobility, taking into account also the activities and the social relations to which it can contribute.

## Culture, Entertainment, Tourism and Planning: Panacea or Threat?

# Planning Coordination Mechanism of Scenic Spots and City Area Contradiction——Case Study of Dengfeng, Henan, China

Hua Shao

Shanghai Tongji Urban Planning & Design Institute, nicole116@163.com

Key Words: Contradictions, The synergistic mechanisms, Scenic spot and city area

## 1. Introduction

Dengfeng is located in the central of Henan province of China. World Cultural Heritage The Centre of Heaven and Earth , the Songshan Scenic Area and the world famous Shaolin Temple are located in Dengfeng. The rapid development of economy and city expansion brings to the contradiction of scenic spot and city area, culture tourism and Real estate development, high rise building and city style. Therefore, it is reference significant to explore the synergistic mechanisms of scenic spot and city area under the participation of local government, enterprise planners and citizen.

In order to exploring the reasons of contradictions between scenic spot and city area, cultural tourism and city development in the process of rapid urbanization of China, it is important to research the synergistic mechanisms of typical case in the micro and macro bilinear logic view in the interception of certain historical span. It is argues that keeping the flexible adaptability of micro system relative to macro system (the national or regional scale) is the key to stable local elements, guide the coordination of scenic spot and city area and inverse configuration. The synergistic mechanisms of scenic spot and city area, which consist by the transition space of basic control line, height zoning and cultural infiltration, could form a bidirectional djustment path and elements allocation pattern which aims to optimize small unit. city unit development mode leads to the reshape of scenic spot and city blending area, but it also brings with a certain degree of inner closed tend, which deeply influences the formation of new relationship of scenic spot and city area. At last, it reclaims that China should transfer from the macro guide system to micro innovation system when deal with the relationship of scenic spot and city area, to enhance the ability of independent regional development organization and effective allocation of elements.

## 2. Transformation of urban development mode in the rapid urbanization trend

Urbanization level is a significant symbol of a country s industrial modernization level. Seen from the world development history ever since the industrial revolution, if a country shall realize the modernization successfully, it shall not only promote the industrialization, but also enhance the urbanization synchronously. Ever since the reform and opening-up in China, the urbanization develops stably, and in 2014, the proportion of urban population in the total population reached 54.77%. However,

generally, the urbanization and industrialization level in China still lacks behind, and it is far behind that in developed countries and even lower than the average world level. According to the statistics, the urbanization rate of developed countries has already been close to or higher than 80%, and the urbanization rate of our surrounding countries like Malaysia, the Philippines, etc. which have similar per capita income, is also above 60%. The low urbanization rate prevents the domestic demand from expanding, and impacts the upgrading of industrial structure, which is also a significant reason for the inconsistent regional economic development. Consequently, the acceleration of urbanization process is an important part of the adjustment of economic structure.

In the grand urbanization development trend, the urban culture, ecology and landscape construction shall be fully learnt. It is proposed in New National Urbanization Planning (2014-2020) that it shall pay attention to human-oriented and quality-stressed urbanization path, and avoid the wrong mode of weighing amount and neglecting quality, and sacrificing environment for economic growth in the past rapid expansion period. Aiming at the problems of occupying scenic sports for the urban expansion and declining service ability, the National Tourism Administration proposed the cancelation of 44 A-level scenic spots in April 2015, and put forward the reorganization requirements for some 5A scenic sports. In this general background, many cities begin to transform the development thoughts and reformulate the urban planning and scenic spot planning, and study the coordinated scenic-city planning and management mechanism.

## 3 Changes in scenic-city relation in Dengfeng in the rapid urbanization period

Dengfeng, located in the middle of Henan Province, has center of the heave world cultural heritage, Songshan Mountain and World-famous Shaolin Temple. In recent decade, the economy grows rapidly and urban scale expands constantly. Profit from the major projects, such as Music Shaolin Grand Ceremony and key projects of Shaolin Temple, the tertiary industry in Dengfeng enjoys great development, and especially, the tourism value and tourists are nearly doubled. According to the statistics, the annual tourists increased to 9.58 million in 2013 from the 6. 7 million in 2009 in Dengfeng, and the total tourism income developed to 6.2 billion in 2013 from 3.6 billion in 2009. It could be said that in the past decade, the city and scenic spot developed rapidly, but there were distinctions in the development subjects. The emphasis of urban development shall be in the population, industry and land expansion, while the key of the development of the scenic sport shall be the promotion of service and supporting facilities, as well as the way of dealing with the huge passenger flow in peak time.

Table 1 Changes of major indicators in the past decade in Dengfeng

| Classification of indicators | | 2001 | 2013 | Growth rate |
|---|---|---|---|---|
| Economic indicators | Gross domestic product of the city (0.1 billion Yuan) | 52.2 | 450.9 | 8.63 |
| | Per Capita GDP (Yuan) | 9818 | 65978 | 6.72 |
| | Total value of agricultural output (0.1 billion Yuan) | 7.7 | 21.8 | 2.83 |

| | | | | |
|---|---|---|---|---|
| | Total industrial output value (0.1 billion Yuan) | 98 | 1019 | 10.4 |
| | Local financial revenue (0.1 billion Yuan) | 1.91 | 27.1 | 14.18 |
| Urban scale | Urban population (10000 People) | 10.7 | 19.3 | 1.8 |
| | Urban size (square kilometers) | 11.35 | 23.13 | 2.03 |

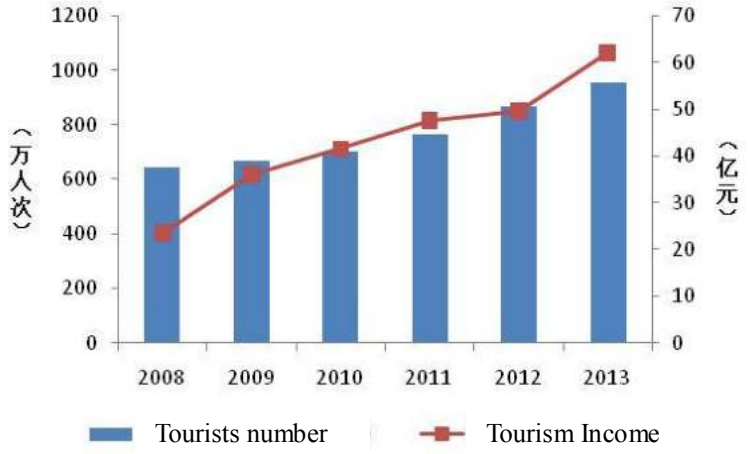

Fig. 1 Changes in tourists received and general tourist income in Dengfeng from 2008 to 2013

Dengfeng has eight scenic spots, including Shaoshishan Scenic Spot, Shaolin Temple Scenic Spot, Fawang Temple Scenic Spot, Songyang Academy Scenic Spot, Taishishan Scenic Spot, Luya Cliff Scenic Spot, Zhongyue Temple Scenic Spot and Guanxingtai Scenic Spot. Fengdeng is surrounded by the scenic spots, with close boundaries. At the early stage of the rapid urban expansion in Dengfeng, there was also the impact of cultural tourism project, industrial project and real estate development on the ecological environment and scenic spot, especially the constant emergences of high-rise buildings. In the old city transformation process, many traditional buildings were torn down, and the tourists and residents were doubted at the urban scape. Therefore, with the common participation of local government, planner, residents and enterprise, the achievement in the exploration of scenic-city planning coordinated mechanism based on the concept of scenic city will be of certain referential significance.

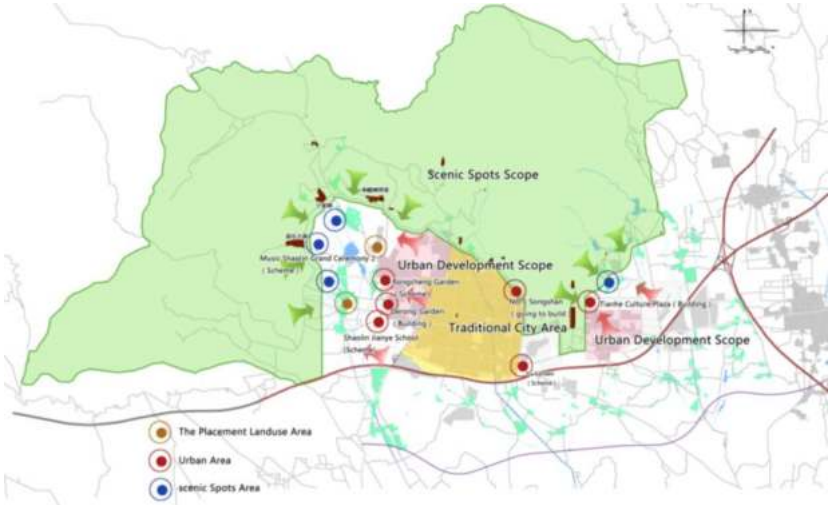

Fig. 2 space of scenic spots and Dengfeng city

## 4 Processing of scenic-city relation with the concept of scenic city

The scenic city theory has abundant details of traditional culture, and inheriting the traditional philosophic concept, as an eco-city theory with Chinese characteristics. According to the artistic conception of traditional Chinese landscape painting, artificial environment is one of the significant elements of the composition. Especially, the single architecture and architectural complex with historical or regional features usually become the theme and spirit of the painting. Therefore, respecting the urban context and continuing the historical features shall be the important links of the construction of scenic city.

In the Chinese history, attention shall be paid to the concept of geomancy, as w requirements on drinking water, disaster prevention and war prevention, etc. in the building of a city, and it had the tradition of building the city near the mountain and by the water, which created a batch of historic cities with remarkable landscape features. Historic city, town and village shall stick to the principle of overall maintain the traditional street textures and spatial scale, instead of changing the natural landscape and environment relying on the traditional patterns and historica [1] The protection of historic culture shall also integrate the thinking of scenic city.

Currently, the scenic spot planning and overall urban planning compiled for most cities may be detached in the compilation time and coordination. And the planning of scenic spot is usually limited within the protection range, and there is a lack of effective control over the surrounding natural environment. Therefore, the specific measures and methods of implementing the landscape and historic culture from the coordination of scenic-city relationship, especially in the planning of some small towns, may be of great significance for the protection of scarce resource, shaping of urban features, as well as the coordination of development and construction.

## 5 Planning strategy based on the concept of scenic city

### *5.1 Investigating the landscape environment and historical culture, and clarifying the protection object*

Before the compilation and implementation of the planning, it shall balance the urban development power and requirements on the landscape environmental protection. The legal, immovable, and non-renewable mountains, waters and historic sites with particular significance shall be protected strictly, and general resources shall also be applied in classification after full demonstration. In this period, it must pay attention to the connections between the objects, investigate and confirm the surrounding environment, important sights and overlook landscapes [2].

### *5.2 Paying attention to the coordination between protection and development, and highlighting the thematic features*

At present and in the future, the force of urban population and industrial concentration is still strong [3]. When creating the scenic city with historic features, it can dredge the population and industry by constructing new urban areas, thus to alleviate the historic protection pressure. Confirm the differential development mode of the new and old urban areas gradually, and encourage the functional updating and multi-element combined utilization in controllable condition.

*5.3 Controlling the development capacity and construction intensity, and promoting the sustainable development of the city and environment*

Scenic city shall conduct the practical control over the overall urban environment, and realize the sustainable use and constant optimization of landscape, as well as the organic integration of the economic benefit, social benefit and economic benefit [4]. It must carry out scientific measurement of the environmental carrying capacity and resource capacity, control the development capacity, construction intensity and architectural height reasonably, and guarantee the coordination between the urban development and landscape environment.

## 6 Collaborative mechanism of planning based on the scenic-city coordination

In the legal planning system, the control of the urban natural landscape and environment is realized with the overall planning which are the main documents for the planning management department to carry out the planning and construction management. Consequently, in order to implement the concept of scenic city and historic protection, it must propos the measures and methods from the perspective of the overall planning. Combining the above analysis, the author proposes the scenic-city planning mode from the perspective of the overall planning (Fig. 1). It mainly puts forward four aspects of contents,

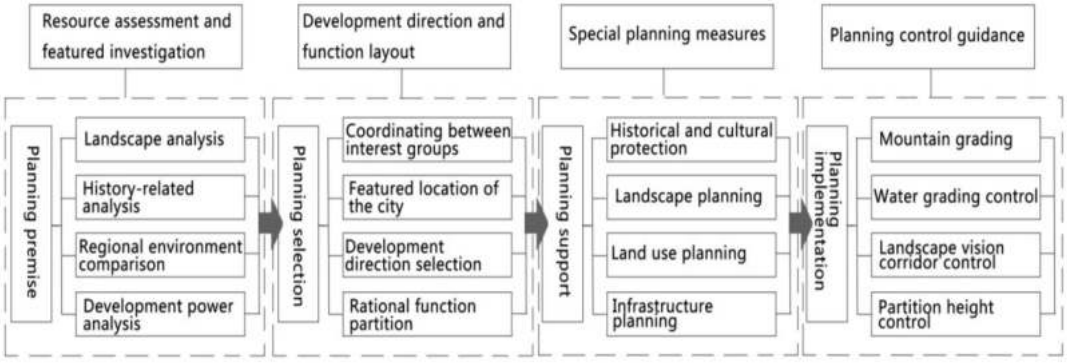

Fig. 3 Collaborative mechanism of planning based on scenic-city coordination

including the resource evaluation and feature investigation, development direction and functional layout, special planning measures and planning control guidance, as well as the staged integration of overall planning.

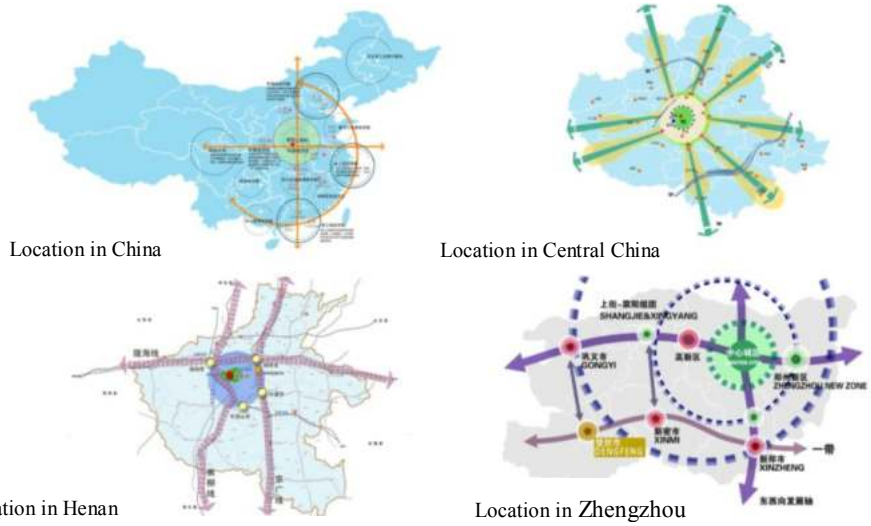

Fig. 4 Zone bit of Dengfeng

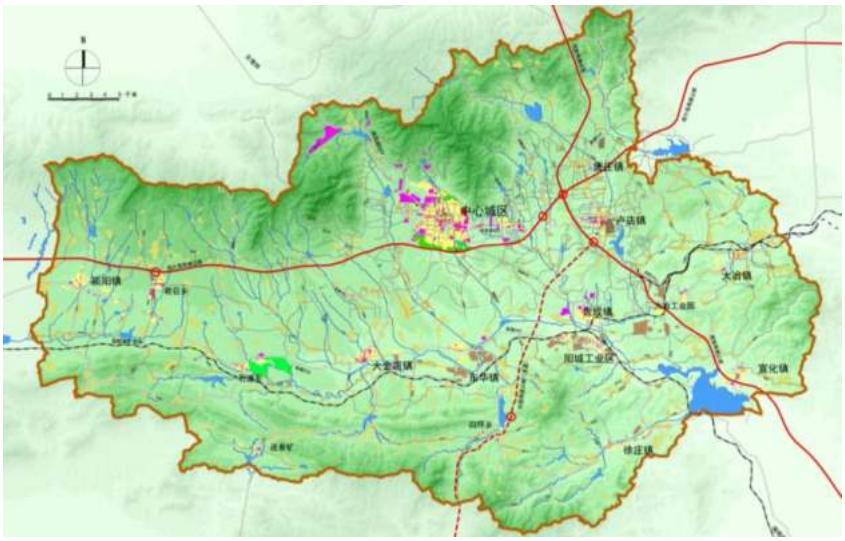

Fig. 5 Land status

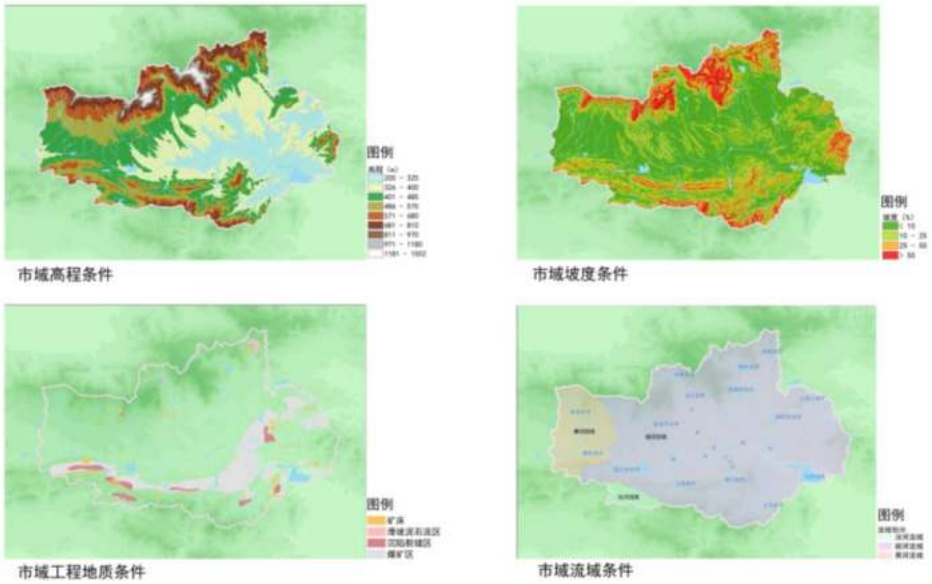

Fig. 6 Comprehensive assessment of land use

## 7 Planning practice based on scenic-city coordination in Dengfeng

### *7.1 Analysis of the landscape environment and historic culture*

The integrated mountain-city feature in Dengfeng is quite outstanding. The northern Songshan Mountain is not only one of the five mountains, a national-level scenic spot, but also a significant part of the historic city pattern. The historical architectural complex in center of the heaven and earth includes 11 outstanding historical buildings, including Shadows Measuring Platform, Star Observation Platform, Songyue Pagoda, three Watchtowers (Taishi Watchtower, Shaoshi Watchtower and Qimu Watchtower), Zhongyue Temple, Songyang Academy, Huishan Temple, Shaolin Temple Architectural Complex (including Changzhuyuan, Talin and Chuzu an), etc. It passed the del the 34th conference of the World Heritage Committee UNESCO, and being listed in the World Heritage List successfully, becoming the 39th world heritage.

There are numerous cultural relics and historic sites, which are especially concentrated in the south foot of Songshan Mountain, covering the dwellings, ancient streets, entrance building, temple, ancient pagoda, ancient tomb, ancient stele, ancient sites, etc. in which, multi-period features were quite significant. Before planning, it mainly started from the artistic carriers and historical remaining, including the contents, ancient poetries, books and paintings, and the landscape and historical sites that shall be protected with emphasis shall be confirmed for guiding the development direction, through the comprehensive analysis of the popularity, particularity, landscape value and preservation integrity.

### *7.2 Spatial structure planning of bottom line control*

(1) Urban expansion power and development direction analysis

Seen from the zone location, Dengfeng is in the suburbs of Zhengzhou, Henan, Central China, as the core economic region of the Central Plains, as well as the key area of industrial development and population integration. Seen from the urban coordination, Zhengzhou will construct the metropolitan area pattern, and require Dengfeng to develop the urban world history cultural tourism city. Seen from the tourism development, Dengfeng is a significant part of the golden tourist route Kaifeng Z Dengfeng (Songshan) - Luoyang , and it shall still be improved and perfected i tourist reception facilities and scenic spot construction. Therefore, Dengfeng must coordinate the relation between protection and development, and expand the development thought based on the continuity of historical context, stick to the ecology red line and historic culture landscape protection line strictly, and shape the featured scenic-city space integrating the landscape and historical cultural protection.

(2) Delimiting the basic control line

The overall planning of Dengfeng mainly alleviate the pressure of old city protection with the urban cluster in the east and south of the city, strengthen the population and industrial

concentration in the new city, and intensify the historical protection and tourism development in the old city. The urban clusters are mainly separated by the water system and greenbelt. In the cluster, it mainly plans the garden and greenbelt by relying on the landscape, thus to form the overall spatial structure of surrounding by r water, as well as gardens . Industrial parks shall be constructed at a certa the old city, for avoiding the damages to the historic culture and landscape environment. (Fig. 5 and Fig. 6)

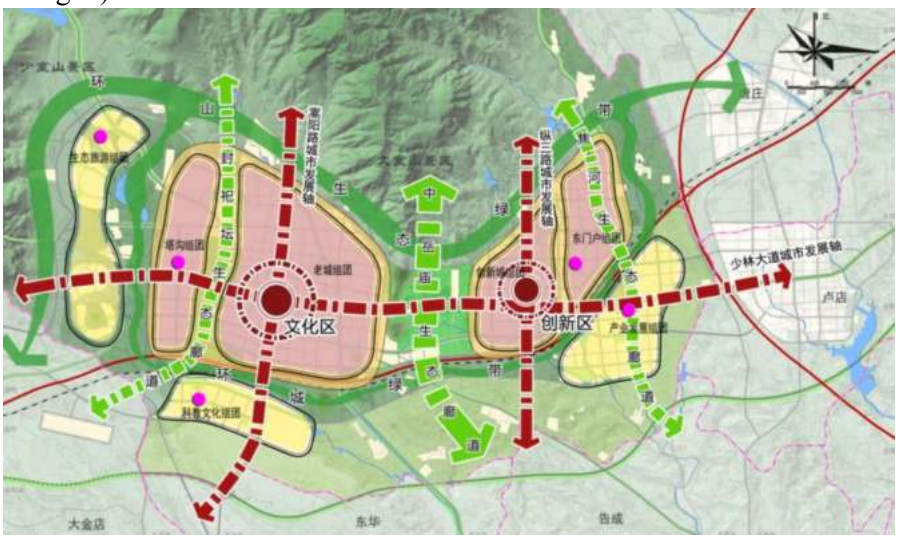

Fig. 7 Planning structure

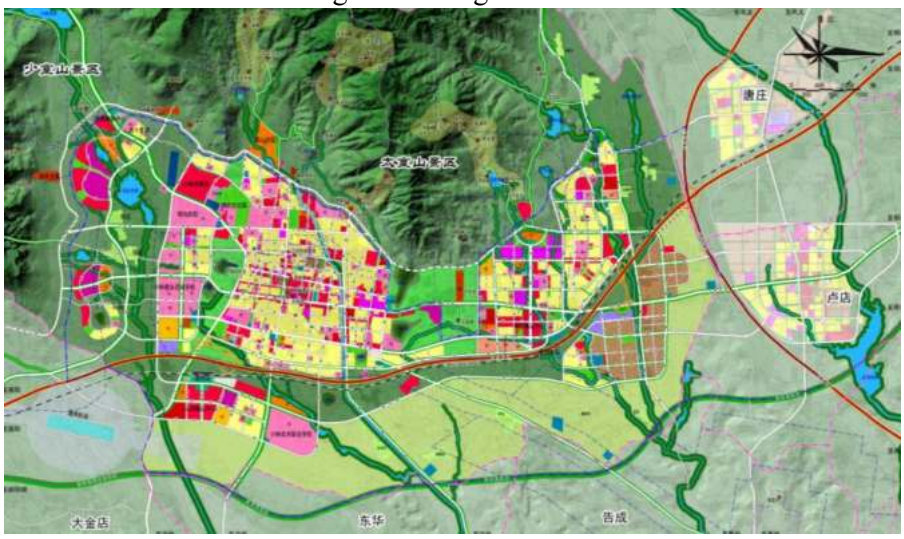

Fig. 8 Landuse

Designate the boundary of construction land and non-construction land in the urban planning area, control the urban growth range, and protect the landscape and rural ecological environment (Fig. 7 and Fig. 8)

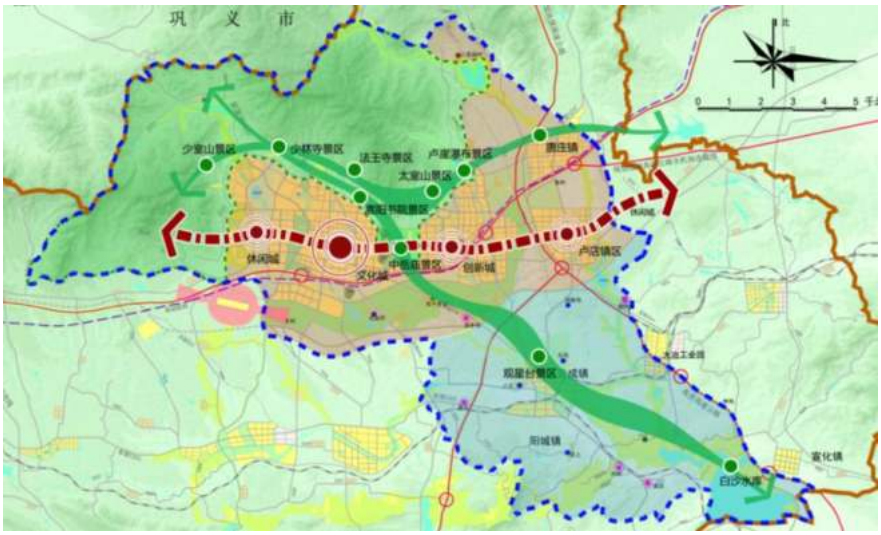

Fig. 9 Eco-space structure in urban planning area

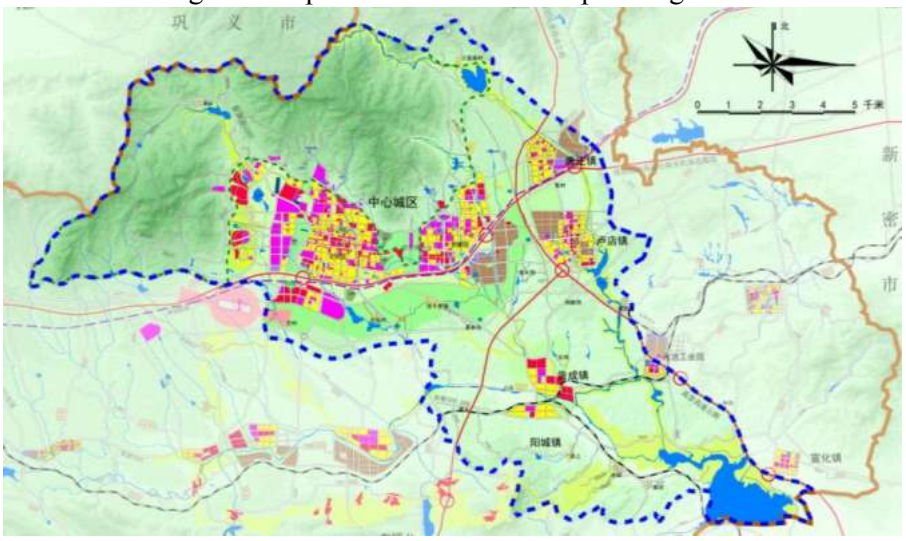

Fig. 10 Landuse of urban planning area

*7.3 Coordinating transition space*

Form the recreational transition zone between the city and Songshan Mountain with the current round-the-mountain roads, and expand several places of public space for forming the leisure nodes of tourism.

Form several places of the slow public place by making use of the features of distributed tourist sites. Highlight the recreational traveling atmosphere of the entire Dengfeng through the urban travel and leisure zone. Distribute several important tourist facilities cluster, and perfect the supporting service system in Dengfeng.

Control the surrounding areas of Mazhuang Reservoir between the urban area and landscape, the west and north side takes the boundary of landscape as the boundary, to Epo- Fengjitan Suogudui Urban ecological greenbelt in the east, and Zhengshao Highway in the south. Plan and develop the functional cluster dominated by the ecological travel and leisure functions. It shall strictly control that the construction land shall not

exceed 1/3 of the total, and reserve large stretches of forest and farmland. The unit development gives rise to the re-shaping of local element and environment in the scenic-city integration region, with certain inside closure inclination, which has great impact on the formation of new scenic-city relation.

*7.4 Strict height partition*

The following elements shall be considered for determining the architecture height: guaranteeing the overall style and feature of the city, especially the smoothness of the visual corridor. Combining the building function layout of blocks, the architecture height shall be adjusted according to the natures of the function. Considering the operability of the planning management, the same plot employs unified architecture height for control.

Designate the architectural height control line in Dengfeng. It is in the buffer control region of Songshan Mountain in the north. The limit height of the building in core tourism service region is 12 meter, while the architectural height in the north of Shaolin Avenue shall be less than 18 meters, and that in the south of Shaolin Avenue shall be less than 3 meters. The urban construction shall be controlled according to such height, and those memorial and landmark architectures exceeding the height shall receive special procedures or examination and approval.

*7.5 Landscape features with cultural penetration*

Guarantee the integrality and uniqueness of the urban spatial form, and keep the coordination between the natural landscape and human landscape.

The planning shall follow the goal of ecological tourist city and national-level historic city, highlight and strengthen the mountain, river and city urban landscape organize the roads, architectures, architectures and greening space rationally, integrate the urban environment, natural environment and humanity history environment, and form the harmonious and unique featured tourist city and landscape.

Starting from the landscape components, including nature, humanity and city, carry out the contrast analysis by combining relevant cases. The overall positioning of the future urban landscape in Dengfeng is determined as Mountain-foot city cultural city famous tourist city . Focusing on such a positioning, the future urban landscape sh the following nine strategies: highlighting the mountain, water loving, integrating green, inheriting history, carrying forward Zen culture, displaying the spirit of the time, protecting the traditional feature block, constructing ecological livable city, and improving the traveling experience and service.

## 8 Conclusion

At present, the urbanization accelerates in China, but hind the economic globalization and planning standardization, the appealing for counter-urbanization, ecologicalization and

humanistic transformation keeps raising [6]. The overall planning of Dengfeng carries out the thinking of landscape city and protection of history and culture. In the small urban planning, it shall continue the traditional art and culture of China, respect the urban context and landscape, establish the planning system, guide the featured development of the city, and provide good references for shaping the featured and attractive small towns. The disposal of scenic-city relation shall transform from the macroscopic system supply to the scenic-city coordinated microcosmic system, and enhance the autonomous organization of development and effective allocation of element. However, there are still many problems requiring more studies and exploration, for instance, the problem between history protection and urban construction, problem between traditional landscape and modern landscape, problem between waterfront development and disaster prevention, which are also the problems that would certainly be confronted in the rapid urbanization process.

Keywords: nature reserve, urban fringe, landscape design

***Abstract***
*This paper explores the process of cultivation of specific areas within Bratislava urban landscape located in close proximity to protected areas of Little Carpathians included in the Natura 2000 BA project towards Restoration of NATURA 2000 sites in cross-border Bratislava capital region. However, the concept of landscape management of contact zones of urban and natural structures is not reflected in the project and existing policies. Therefore, responsibility for decision making and sustainability of these areas are fuzzy and divided between many actors with conflicting interests, such as residents and vacationers, environmentalists, municipalities, developers and activists. Hence, the emergent need is to cultivate these spaces - to develop their relations into deeper levels of understanding, participation and sharing by visionary planning, innovative design and sensitive management in the complexity.*
*The output of the research is the framework of development measures for sustainable development and cultivation of the urban fringe natural areas developed by author in cooperation with NGOs Daphne and BROZ - the Natura 2000 BA partners. Using field research, analyzing historical and existing characteristics of the sites, by the participation of residents and visitors, and consulting with experts, the concept of landscape plan was developed. Segments of the plan designed in detail respect both the interests of nature and also human requirements - democratic, accessible places with more opportunities for sociability. This paper contributes to the debates on practical examples of managing various interests in specific locations, characterized by fuzzy relations between natural and urban aspects.*

## 1. Introduction

Urban fringe, where rural and urban environments intertwine and where the most intense growth and change happen (Friedberger, 2000), is under constant pressure. Urban fringe natural areas (UFNA) are facing various challenges arising largely from dynamics of contemporary human lifestyle and needs, dealing with process of urbanization and also from alterations in relationship between people and nature. Particularly significant is the problem of urban sprawl in contact zones of densely urban and highly protected natural structures (Gažová, 2006; Arnberger et al., 2013). The new development on the border of such contrast environments is related also to disharmony of relations, territorial conflicts and fuzzy division of responsibilities between diverse actors with conflicting interests, such as residents and vacationers, environmentalists, municipalities, developers and activists.

Protected areas within the borders of urban areas are very valuable since they provide many ecosystem services - the benefits people obtain from ecosystems and nature (Millennium Ecosystem Assessment, 2005). UFNA in conservation are biodiversity hot spots, producing drinking water, regulating hot summer temperatures, providing wildlife viewing, recreational, spiritual and eco-tourism opportunities and wellbeing for their visitors and residents of the locality (Daniel et al., 2012). At the same time,

they constantly suffer from high recreation use pressures because of their attractiveness (Arnberger et al., 2013).

This paper focuses on the important case of the UFNA – the area Devínska Kobyla. The case study Devínska Kobyla is unique massif belonging to the protected mountains Little Carpathians. This area is significant in several aspects: by the location on the edge of Bratislava city whole surrounded by its urban areas and separated by two rivers Danube and Morava from Austria. Due to unique landscape character and rare flora is the locality of Devínska Kobyla highly protected. Its natural areas are involved in the Natura 2000 BA project - Restoration of NATURA 2000 sites in cross-border Bratislava capital region by LIFE Programme. However, the Devínska Kobyla areas are intensively used settings and the pressure of human needs for recreation with lack of complex established infrastructure causes degradation of the landscape.

Subsequently, it is highly important to deal with the conflict resolutions in such areas, since fuzzy relations and conflicting interests can impact negatively the natural resources and consequently the quality of the resident well-being and the visitor experiences.
There are many positive examples of landscape design, planning and management of protected areas in close proximity to large city. Such important previous study is focused on Donau-Auen National Park in Vienna, where effectiveness of buffer zones is deeply investigated (Gál, 2013; Arnberger et al., 2013).

However, the previous studies differ considerably from this study mainly due to the character of transition zones between urban environment and protected nature. The focused case Devínska Kobyla is characterized particularly by direct bordering of the protected nature with housing developments, with almost any buffer zones. Furthermore, contribution of this study is also deep emphasis on human needs and requests on natural environment, since the studies from similar cases mainly focus on demands of the protected nature.

## 2. Literature review

### 2.1 Cultivation of urban landscape

The process of cultivation is elucidated and defined briefly in this paragraph. Currently, cultivation is still predominantly connected with agriculture field; even if in the connection with urban landscape (May and Rogerson, 1995; DeLind, 2002, Diogo et al., 2010). Although despite of that the expression of "cultivation" fits exactly to the main objective of the study; improvement of fuzzy management in the contact zones of contrasting environments towards sustainable and resilient by appropriate planning and design. Cultivation process is grasped and shaped as the complex concept responding to current challenges of the studied areas.

Generally, the meaning of cultivation is according to Oxford Dictionaries defined as;

- "The action of cultivating land, or the state of being cultivated", where cultivating means process of improving, developing and promoting into growth

While in Oxford Advanced Learner's Dictionary definition is;

- "The deliberate development of a particular relationship, quality or skill"
- "The preparation and use of land for growing plants or crops"

In connection with landscape, cultivation is defined as the process based on human existence, when things are growing and it is possible to show up the core ability of culture. Then developing spatial

opportunities lead to multitude of possibilities, expanding knowledge, innovation, valuing beauty, perception, enriching experiences (Marques, 2014).

Hence, the concept of cultivation in the specific areas of Bratislava urban fringe is understood as the process, when conflicting interests and complex relations of actors in both environments are taken in account and developed into higher, deeper or richer levels of understanding, participation and sharing. And so the fuzzy relations between urban and natural structures are harmonized, such as relationship between people and nature.

## 3. Research objectives

Whereas the relations in these areas are fuzzy, many problems occur. The landscape suffers from the conflicting interests of many various actors. Underestimation results to unsatisfactory compromises or to severe neglecting of some interest groups, heading to physical and philosophical decay, deviating from sustainability and resilience of the environment.

The question of arises whether is possible to plan, manage and design effective infrastructure for recreation with attractive entrance spaces which will satisfy the demands of various users and concurrently will help to protect the nature of Devínska Kobyla, despite very tight buffer zones.
Thus, this research aims to identify the optimal planning and designing measures and management options useful for answering fuzzy conflicting relations between natural and urban aspects towards sustainability of the landscape.
The proposed output is the framework of development measures and the landscape design concept for cultivation of the UFNA "Devínska Kobyla".

## 4. Core construct - Urban vs. natural relations

### 4.1 Cultivating harmony in the urban fringe of Bratislava

To achieve relevant approach to cultivation, the core construct was developed on the basis of the most important characteristics of the area. This process involves many layers, aspects and specifics in the case study Devínska Kobyla. The research should be complex, noticing enough attention to all of aspects, so then is possible to avoid negative impact at the natural resources, at the quality of the recreation and quality of living environment for residents in the locality. However, the limits resulting from nature conservation should serve as fundamental mantinels for planning process, while the conservation of the natural and historic values is the priority in the area.
The uniqueness and strengths of the locality bring a lot of opportunities for whole Bratislava region, but it also entails some challenges; majority of the most important and brief relevant proposals for solutions are outlined below.

#### 4.1.1 Management of recreation in contact zones - infrastructure for recreation, entrances and buffer zones

In the contact zones – specific areas where is occurring direct contact of settlement and nature, there the relations of city and protected nature intertwined and emerging conflicts then lead to degradation of the environment. The recreation use pressure makes the situation much more alarming.
Thus, linking, structuring and hierarchization of the system of natural environment from the core entrance zones and urban recreation areas are essential (Gažová, 2006). Subsequently, areas of major intervention of city to the country would become the core areas of interest for the urban dwellers. Although the buffer zones practically not exist, the main recreational areas and points of interest should

be defined within the infrastructure for the recreation. Defined structure of the connected trails and nodes helps to clearer spatial fuzziness.

Further, satisfactory quality of particular recreational areas, urban green spaces and interest points should be managed, since their design and program significantly influence well-being of visitors during their recreation. Hence, the research should focus also on human requirements and needs - democratic, accessible places with more opportunities for sociability (Thompson, 2002).

### 4.1.2 Protection of the nature by motivational approaches

Learning landscape design – cultivating the positive relationship to nature

Next important challenge in the area is the lack of awareness of the importance for nature conservation by some visitors and especially local dwellers. The issue of increasing respect for nature and cultivation of the positive relationship should be underpinned by creative peaceful means. Whereas there is demonstrated high contribution of early childhood education to sustainable society (Herbert, 2008; Didonet, 2008), to cultivate human values is very effective from the earliest age.
Appropriate solution then could be planning and design of interactive learning parks – Nature Play areas, emphasizing the need to introduce nature to children by inspiring, interactive and playful way. Initiator of such areas in Oregon - landscape architect Mathis (2013) states that the intent behind Nature Play Areas is to provide creative, free form play spaces that spark children's connection to, and love of nature. Obviously, planning the interconnected infrastructure of educational trails is also a proven and widely used method for improving environmental awareness of human society.

Figures 1 and 2 - Learning landscape design in Devínska Kobyla applicated by Daphne NGO

Sustainable grazing management

The locality of Devínska Kobyla is protected mainly because of occurrence of unique xerothermic grasslands that spread through human agricultural activities (Senko, 2010). It is therefore essential to find the ways of sustainable maintenance of these plant communities, since the expansion of invasive tree species is rapid and almost uncontrolled.
To suppress the overgrowing of rare grassland and ensuring regular removal of biomass is suitable to apply the management of traditional grazing and mowing (Dúbravková et al., 2011). Application of grazing also increases the attractiveness of the site and naturally adopts people to appreciate the values of

nature. At the same time, further benefit is utilization of goat milk for production and sale of desired organic food.

## 5. Methodology

### 5.1 Case study Devínska Kobyla

The case study area is defined on the western slopes of the robust mountain Devínska Kobyla, part of the massif of Little Carpathians, while its whole area belongs to the Little Carpathians Protected Landscape Area. The wooded mountain is located in the northern part of Bratislava, the capital city of Slovakia, with a population of about 0,5 Mio. This massif is surrounded from all sides by neighborhoods of Bratislava. The area of focused segment is almost 400 ha, while the urban areas of the city districts Devín and Devínska Nová Ves extend into the study area. The highly protected National Nature Reserve Devínska Kobyla occupies most of the study area, containing unique protected paleontological sandstone Sandberg. The area is managed by organization Urban forests in Bratislava, involved in the Natura 2000 BA project - Restoration of NATURA 2000 sites in cross-border Bratislava capital region by LIFE Programme, lasting 2012-2017.
Locality is unique for an incomparable landscape character, rare protected steppe flora, significant geological, topographic and singular paleontological structures and beautiful views of the landscape from steep slopes and for historic and cultural wealth.

#### 5.1.1 Data collection methods and approaches

In first phase, the basic and deeper research about Devínska Kobyla area was necessary; for understanding the conditions, potentials and limits of the territory. It was conducted from Sept. 2013 to May 2014 on the basis of field survey and mapping, then literature and documentations survey on various aspects of landscape country and also by meetings and consultations with experts; environmentalists, stakeholders from NGOs Daphne and BROZ participating on Natura 2000 BA project in the area, stakeholders from local government and by interviewing the public.
In next phase, data from the survey were analyzed in the complex context – using also historic plans. Analyses of land-use, relief, functions, legislative, dendrologic, visual and compositional relationships were included.
In third phase the qualitative research with the users of area was conducted. The knowledge and views from the “experts of the locality” – the users and residents were obtained. Data were collected by method of individual interviews with random representative sample of the public across study area Devínska Kobyla.

#### 5.1.2 Sampling

Locality of survey was conducted mainly on routes leading to the "main entrances" to Devínska Kobyla, especially in the district Devínska Nová Ves, where are the most significant conflict zones between natural and urban environments.

A total sample of respondents involved in the survey was 51; respondents were chosen randomly, trying for varied and representative sample (Figure 3).

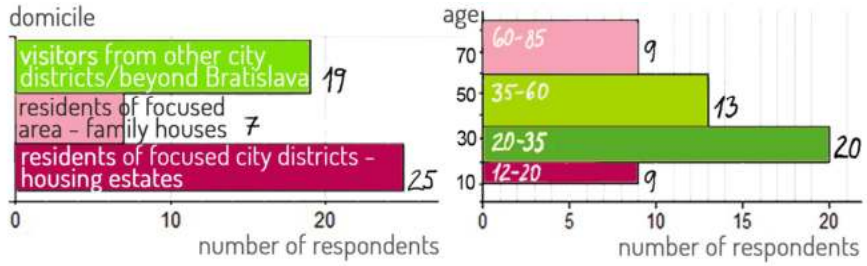

Figure 3 – Basic pattern of respondents – structure of domicile and age structure

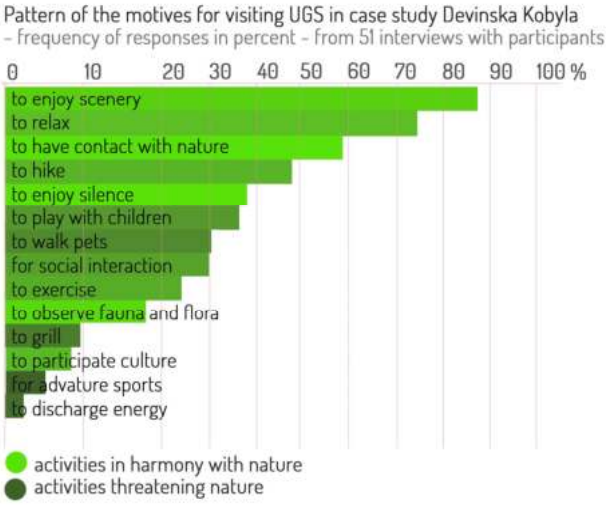

Figure 4 – Pattern of the motives for visiting the natural areas in case study Devínska Kobyla

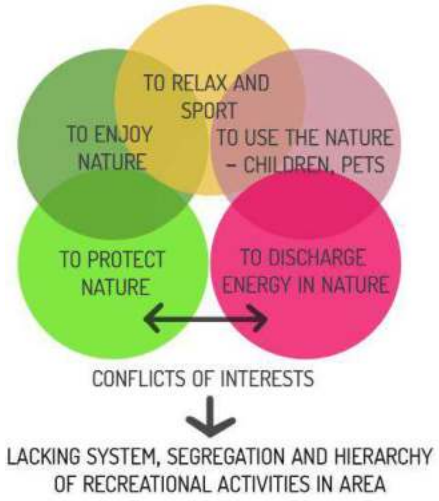

Figure 5 – Conflicts of interests in the locality

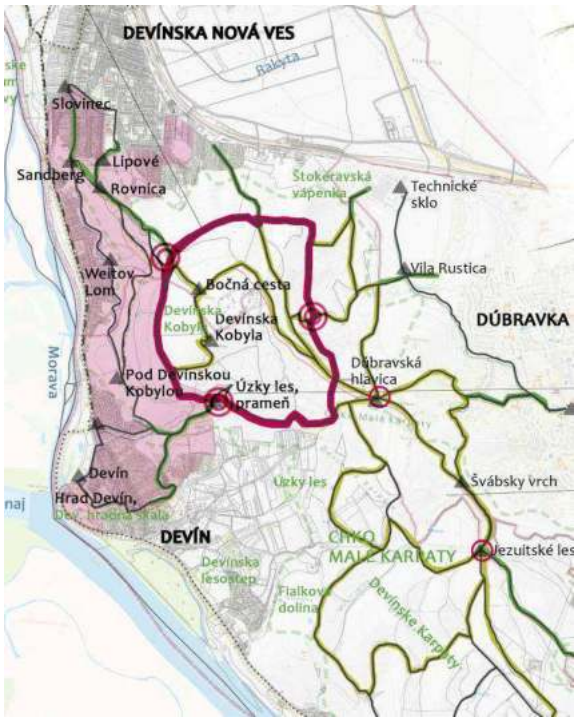
## 6. Discussion of results

By synthesis of complex knowledge from previous stages of the research was developed the design concept for the landscape plan, applicable in practice. Whereas the focus of Natura 2000 BA project aims on measures beneficial for natural aspects of the locality, the output of the research significantly addresses the measures improving recreational infrastructure in the locality, although by respecting the nature – whereas conservation is the priority among conflicting interests.

Cultivation plan for sustainable management of Devínska Kobyla locality is designed across multiple scales to complex design concept; from the overall design of the infrastructure of routes and trails and its hierarchization, mutually connected to the principal interconnecting sports circuit, to the detailed design of various recreational spaces, points of interest and interactive stops.

Since in the transparent recreational infrastructure of Devínska Kobyla is cumulated the main pressure of visitors, the Nature Reserve Devínska Kobyla is protected from the degradation of lively activities. These activities are transferred to peripheral buffer zones in the contact with urban zones and also inside the forested massif, beyond of the highest protected Nature Reserve with unique grasslands. Furthermore, by the network of trails, the city districts surrounding the massif are mutually interconnected. In the strategic crossroads, where the main sports circuit intersects the other trails from

the districts, hubs for recreation are designed. Particular recreational spaces are according to their hierarchy equipped with several components for rest and recreation, accessible and attractive for various visitors.



Figur. 5.The connection of trails to systematic infrastructure for recreation; main sports circuit

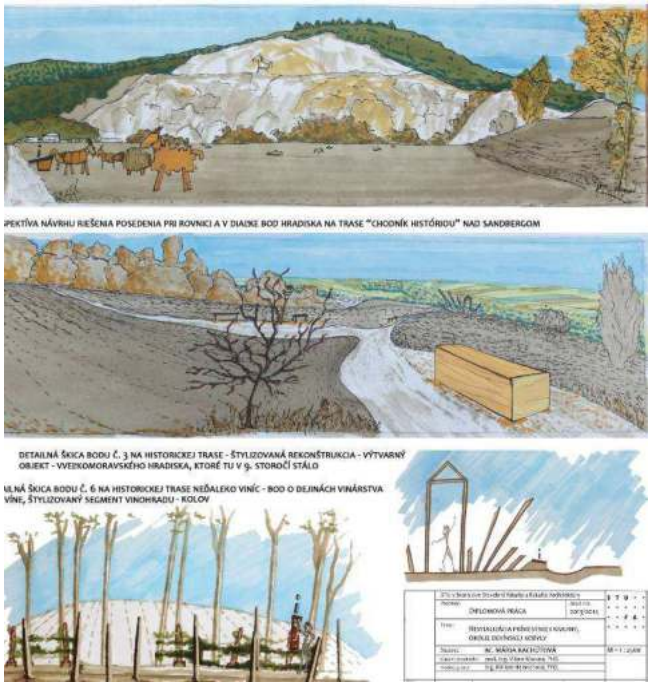


Figure 6. Sketches of the educational and recreational areas and nodes - interactive point on the trails

The core philosophy of the design concept for cultivation of Devínska Kobyla UFNA is based on the very nature of the locality. The concept "From fairy tale to fairy tale" indicates tremendous wealth and uniqueness of the Devinska Kobyla.
Particular stories about different layers of the area are introduced by individual segments, creating the mosaic of the complex history of the locality.

1. Three main interactive trails in the Nature Reserve Devínska Kobyla introduce specific aspects of Devínska Kobyla. These trails and their themes are: “The Story of Nature”, “The Path of History” and the sports “Circuit Kobyla”.
2. Interactive hubs and points of interests at these trails have learning, informative and recreational character with the character of Nature Play areas – inspired by Learning landscape design.
3. Navigation element in the form of a mare reference to the name of locality - Devínska Kobyla (kobyla in Slovak = mare). Land-art elements are incorporated in the whole locality, made out in the form of sculptures, statues, playground components. These navigation elements highlight the identity of the site and unite the locality into a unified whole. They also elevate the artistic value of the site, creating the art libretto.

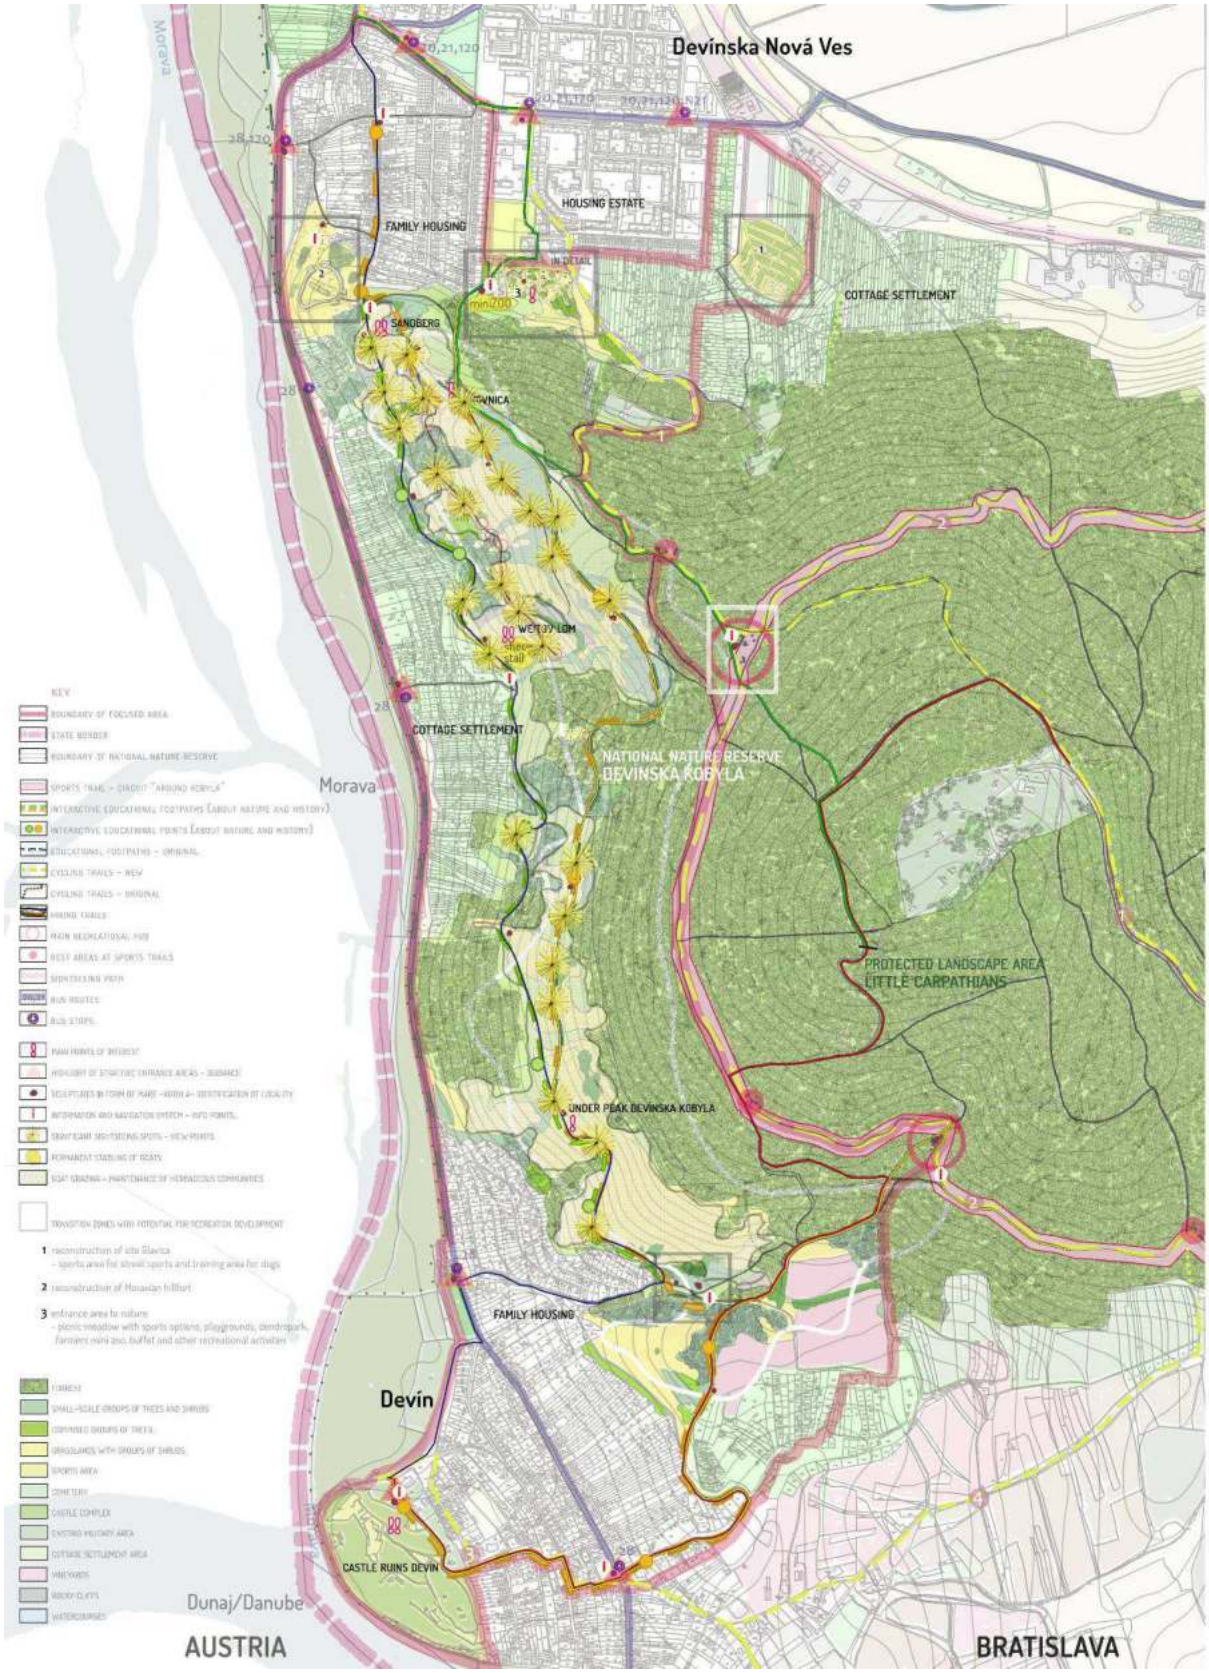

Figure 7. Complex plan of development measures in Devínska Kobyla

The protected grasslands are proposed to be maintained by sustainable grazing management in accordance of the intention of LIFE project, managed by BROZ and Daphne NGOs. Children from the urban areas are attracted by present goats and sheep, serving as the magnet for the visitors. Hence, the visitors learn about the need of conservation and the uniqueness of the locality also by this way.

The main recreational spaces and entrances to the Nature Reserve are located in the peripheral zones of the urban areas, as their inhabitants visit the natural environment most frequently. Each of the spaces provides other forms of activities, answering also on the need of lively recreational activities as downhill, skating and dog exercises.

## 8. Conclusion

The study solves the area of Devínska Kobyla by set objectives. The resulting output answers to the conflicts of nature and the city by proposing facilities for recreation in accordance with the protected landscape by management and design measures.
Methodology and creative approaches in the process of development could contribute to solving similar territories with spatial fuzziness, where the great pressure of urbanization on highly protected nature negatively impact the landscape and where residents and visitors have a high demand for recreational use of the environment.
The research has not solved the policies and governance of the locality more in details, next phase of research propose to focus on this issue.
The paper contributes to the debates on practical examples of synchronizing various interests in specific locations with fuzzy relations between natural and urban aspects in general.

This contribution is result of the project implementation: SPECTRA+No.26240120002 supported by the Research&Development Operational Programme funded by the ERDF and VEGA No.2/0038/14.

## Smart Approaches to Responsible-minded Planning Practice

# THE ROLE OF VISUAL REPRESENTATIONS IN URBAN PLANNING

Burcu Akinci
Vienna University of Technology, office@burcuakinci.com

*Representations inform our capacity*
*and our need to imagine the city*
*(James Donald, 2000, p.53).*

Visual representations in its all different forms help us to understand our cities, make it available for analysis. They help us to make useful conceptual shortcuts in our understanding in order to have a glimpse of what s happening in our cities.

This research focuses on visuals as representations of cities. These visuals may be a single spatial representation as a map or a sketch, or it may be in form of a visual metaphor (for example Blue Banana, European Bunch of Grapes, London Green Belt, the finger model of Copenhagen etc. ) or a complex set of images.

Throughout the history, the urban planning discipline has looked at visual representations in various different ways, giving little to no attention on them at all (Jarvis 1994; Neuman 1996, 2000; Faludi 1996; Dühr 2007).

Since the notion of planning through debate (Healey, 1992) they are acce communication tools which shape attention (Forester 1989), therefore shape the discourse (Kunzmann 1996; Healey 1997, 2006; Forester 1999). On the other hand, they are object to treacherous vision (Shields, 1996) which allows manipulations (Pickels 1992; Neuman 1996; recognized that representations may focus on certain parts while inevitably neglecting others (Harvey 1996). Since the visual representations of spaces, like cartographical maps, are not accepted as objective and scientifically informed instruments only, they as well are object to communicative distortions (D hr, 2007). That s why it is believed by some theoreticians that it is proba abstain visual representations (Eeten and Roe, 2000) because they can lead to serious conflict (Zonneveld, 2000) through their biased perspective of reality (Crampton, 2001).

Despite the recognized consensus-building purpose of representations; growing chaos, complexity and fuzzy reasoning hinders their effective outcomes (Forester, 1999; Healey, 2007; Innes and Booher, 2010; Neuman, 2010). Growing complexity makes planning messier, their outcomes sketchier (Neuman, 2012) and their discourse more abstract. On the other hand how can we make planning interesting and understandable without using visual representations (Zech, 2013)?

Nevertheless discourse helps finding meaning in complexity and it can create unquestioned knowledge that requires unconventional creative thinking. Visual representations in all its different forms help us to understand the urban complexity.

The web has become a new opinion space today, a virtual but de facto public space (Shields, 2013). It is re-wiring our way of thinking, how we perceive our cities and how we respond to changes.

But we face a great challenge, besides the obvious complexity of our cities;

phenomenon. We are producing an enormous diversity of data, from governments to city councils to institutions. It is getting incredibly difficult to make sense of all these data, how to analyse it, how to see through it, how to communicate it, how to visualize it.

The open-ness of the virtual public space makes cities more inclusive, enabling its citizens and different organizations to actively take part in it. Open data initiatives and institutions are actively encouraging their smart citizens to use the urban data and make meaning out of

Urban and regional areas need to be represented collectively, not only from certain perspectives or in certain forms. If we can have a glimpse of what s happening, then we might hav intervene, to plan, to design and sometimes to resist (Mitchell, 1996).

To empirically analyse this hypothesis UCIT (www.ucit.or.at) is created, it is an open source project consisting of open source solutions. Here, the purpose was to present urban data in an interesting way to the media and public, just by creating an application which shows the urban data with its time-space character. We need to re-examine the city, keep it open to further critical analysis and show the urban data in different ways from different perspectives which in turn may reveal unperceived knowledge and spur creative thinking.

# Smart Solutions For Healthcare System
## Cases From China

Jiaying LIN

Tongji University, Shanghai, China
jiaying_lin@yeah.net

Abstract
In the digital age, the structure of global economy has been transformed; the he
also changed. By reviewing the history and statistical data of China healthc
evaluating them in a global realm, this paper reveals the fact that medical sys
China still falls behind the world average level, which doesn t coordinate wit
urbanization development. The main reasons are deficiency of financial expen
institutions and health care workers, which is hard to be improved within a sho
local governments have adopted Smart Healthcare System to meet the people s der
care. Cases include Smart healthcare card, new health insurance policy and the
were introduced, Following by the review However, this paper also indicates t
these smart methods, and presents a holistic medical service system-planning f
predictive urban planning to responsive urban governance, the whole process of
system could be realized by big data analysis and local legislation establishmer
planning decisions more rational and feasible.

Keywords: smart cities, healthcare, China

## 1. Introduction

Since China implemented reform and opening policy in the late 1970s, China ha
general adoption of the market principle. Financial reform has also been made
system toward a free market system. National healthcare for all the people was c
of health facilities were encouraged to support their operations rely on us
governments continued to take control of the prices and hospitals. These finar
organizational policies were not coordinated. These uncoordinated policies
problems in the system. Market-based financing created more unequal access t
between the rich and poor. Irrational classification system of public healthcar
management caused inefficiency, waste and poor quality of health care.

In the 21st century, despite the fact that China has higher income, better
advanced medical equipment, due to negative effects raised by urbanization, ind
globalization, Chinese public health system has encountered greater difficulties
are more and more unsatisfied with the low efficiency and the high expenses

healthcare service. Then another reform in healthcare system was raised in 20
decided to recover the national healthcare insurance for all the people.

To examine China s Health care condition from a holistic perspective, data f
countries to developed countries were collected to compare with China. Four majo
chosen, including health care expenditure per capita, health expenditure propor
physicians per 1,000 people and hospital beds per 1,000 people.

1.1 Healthcare expenditure

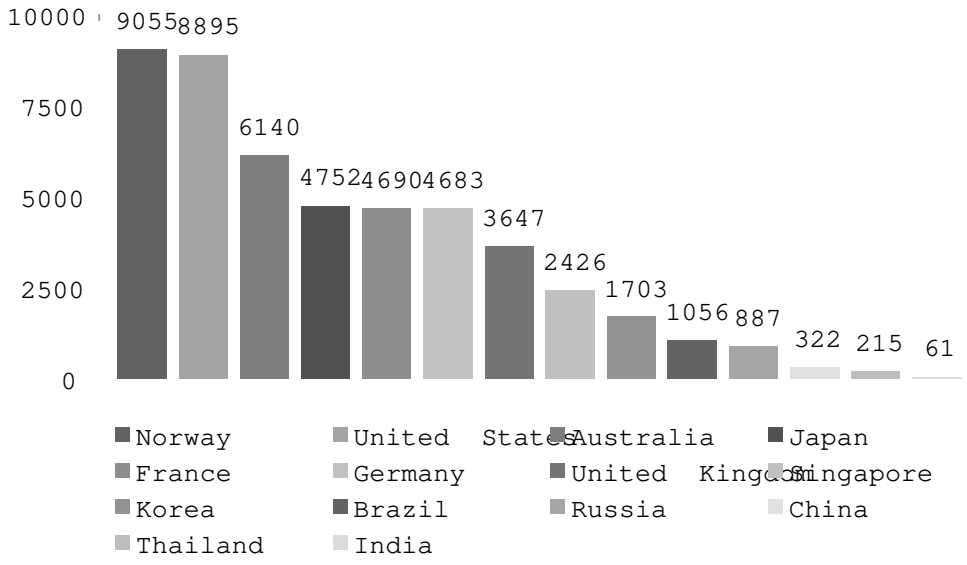

Figure 1. Health Expenditure Per Capita in 2012 (current US$)
(Resouce: World Bank Open Data)

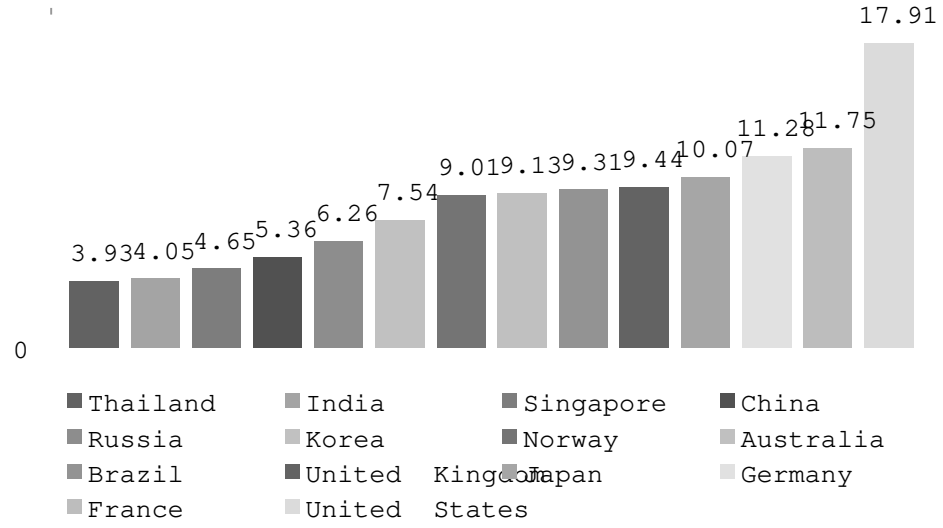

Figure 2. Health expenditure % of GDP in 2012(current US$)
(Resource: Chinese Health and Family Planning Statistical Yearbook)

China ranked 118 in health expenditure per capita in 247 countries and regio
Although China is better than Asian countries like India and Thailand, but it st
developed countries quite a lot, for example the index of Norway is almost 30 ti

Besides, despite the fact that China has experience rapid growth in economy, it
health expenditure portion of GDP. The reason may be Chinese macro-health pol
health care financing and delivery toward a free market system in the1980s.

## 1.2 Healthcare facilities

When it comes to the index of physicians and hospital beds per 1000 people, alt
of China are not advanced in the world, the latter could be compared with that
the former is one of the last in the main countries.

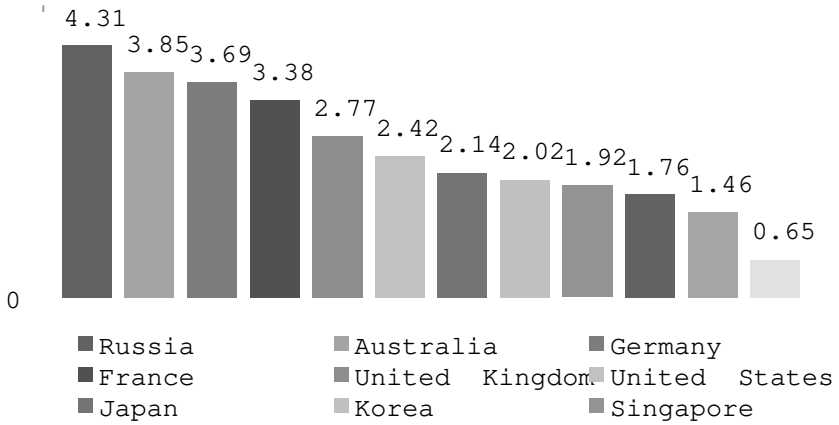

Figure 3. Physicians per 1,000 people in 2012
(Resource: World Bank Open Data)

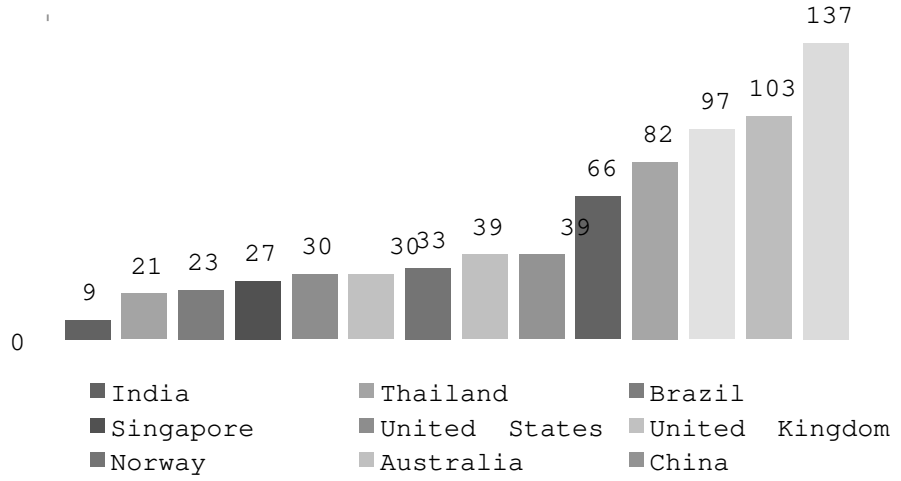

Figure 4. Hospital beds per 1,000 people in 2012
(Resource: World Bank Open Data)

Comparing the conditions of economic development and healthcare development, obvious that healthcare service still fall behind the economic and urbanization

To conclude, the hardware condition is generally better than the software condit seen from the rank of the number of health care institutions, hospital beds and reflects the fact that China paid more attention on hardware construction, but i of workforce in health care.

The reason could be as follows: firstly, China is still a developing country, government were still going to infrastructure construction projects, but not y medical workers. Secondly, since China changed the financing policy in health was invested in the income of medical workers, therefore people working in thi adequate to provide qualified service. Thirdly, the whole system is free marke could go to hospitals whenever and wherever they want, therefore, there s alw workers in the general hospitals, but not much patients were treated in commu institutes.

## 2 Smart Healthcare

For several decades, China is experiencing rapid urbanization from 26% in 1990 end of 2014, but still less than other mid-level developing countries such as M urban) or developed nations like the United States (80 percent). Chinese governm further urbanization to support economic development. But pollution, housing a traffic congestion are already heavy burdens, so it s urgent for cities to fi creating a better life for migrants.

## Abstract

*Historically there have always been two different genealogies of public space (Rowe,1981; Sennett,1997 Trachana, 2014). On the one hand there have been spaces created by human societies over time, based on evolution, empirical knowledge, daily life and the real needs of communication and exchange among citizens. These are places full of life that persist over centuries in our cities (De Certeau, 1999). On the other hand, there are instant spaces, planned, designed, and imposed from above. These spaces are governed by a geometric, abstract and symbolic order. They are regulated or regulatory spaces that impose certain patterns of use and behavior that have prevailed from the Renaissance and Baroque to modern and contemporary times in terms of urbanism. Today the effectiveness and professionalism in urban design that local administrations and economic powers have promoted and always justified by the common good, is being questioned.*

*The main issue addressed here is how some practices that are being spread nowadays, can be justified. This paper is a critical review of different urban actions that are taking place in Europe (with special emphasis in the case of Spain) and Latin America, and that are an alternative to the public sector in urban planning. Some of the most common actions are the occupation of empty sites, urban gardens, ephemeral transformations of public space for social and recreational uses, and other practices that generally respond to citizens´s real needs in depressed neighborhoods and impoverished urban areas. These practices constitute effective responses with little means adapted to the current socio-economic situation that imply austerity in public resources and an optimization in the use of technological tools within easy reach by both, professionals and citizens. They are made possible by the network connectivity resulting in collective actions in the physical space. The new models of performance have not only begun to be supported by the public sector but have been adopted and are actually promoted by them.*

## 1. Introduction

In this paper we deal with some alternative processes to those that control the government and the usual promoters. These are processes managed by the citizens, through their associations and groups formed by interdisciplinary professionals. The latter belong to a new generation of professionals who investigate new forms of intervention in the city. They also seek career opportunities in Spain and in many European countries where the public sector has significantly reduced their budgets for building work and improvements in their neighbourhoods. Many of these new initiatives have emerged from the economic and social crisis and replace the institutions and where they fail to intervene or make mistakes. They are acting on the micro-scale level of the city with limited resources but they often have a great impact as they stimulate responsible communities in opposition to governmental institutions which in turn are stimulated by these initiatives. These are formulas based on citizen participation and the use of new technological tools and social networking. There are many categories such as urban art, ephemeral occupations of public space, urban gardens and community gardens, occupied plots and vacant areas that are reclaimed for social and recreational uses, obsolete industrial

areas and other waste and degraded spaces creatively reused. We call these interventions soft urbanism (Trachana, 2012) and in other places we have also referred to them as hybrid spaces, as they have as a main characteristic, the ability to integrate people within its creation, through their opinions by the use of networks and also by their physical participation *in situ* (Trachana, Martín Castillejos, 2014). These are non-business like interventions and focus instead on the enjoyment of the citizens and for the citizens.

The Madrid urban action group called *estoesunaplaza* ("this is a square") provides through a methodological manual of urban action that has been developed and that indicates the basic issues to consider before starting an intervention strategy on an urban site. The group recommends the setting up of a good multidisciplinary team to develop a strategy of action in order to convince, attract and get the different elements required to carry out the action, and above all, to get the necessary support and public sponsorship. For them, a workshop, an exhibition or a party are highly social events, either artistic or cultural (without seeming merely commercial-promotional) that leave their mark in the liberated space, and can mobilize expectations and get institutional or financial support. The creative process finally takes place when all the elements are gathered together as it requires people, action and dissemination, policy and administration. The participation in the process of the people for whom the space is intended, is absolutely essential, so that they can feel their involvement in the creation of the space, calling it their own and providing a continuity in time. Without people, neighbors or groups involved, an urban action would not make sense (Moradiellos, 2009).

## 2.Conceptual framework

The historical city has produced spaces where the conditions of everyday life have been altered and where extraordinary rituals take and have taken place. History reveals how a city, when planned as a whole unit or when arisen from synergies over time, forges a structure consisting of a series of architectural events and unique collective spaces, with artistic will that clearly differs from the typical production processes, i.e, the reproduction of stereo-types. It is the leisure activity spaces that are the essential fields of expression, of confrontation and cultural production, this is one of the diverse forms of expression of the material and spiritual existence of human beings. In their essence, these spaces are public. They are spaces that give energy and help develop the daily and community life. The elements that shape these spaces sometimes express the world of ideas, discourses and utopias of the city. But its meaning cannot be reduced to its layout, design, architectural construction, forms of occupation and planned use. They depend, fundamentally, on their interpretation and the spontaneous use given to them. Their use can, therefore, be outside the forecasts and planned programs.

In these spaces, then, freedom of expression, participation and the exercise of citizenship are accomplished. In general terms, today, they have little or no interest at all for the economic powers, and the developers of urban space. It is not surprising, therefore, the low profile with which they are developed in the emerging city given their zero economic profitability as their essence is enjoyment, not productivity. It is not that today's cities lack social and recreational spaces, but they are built, occupied, regulated and managed without having the concept of public space. They don t form the part of the budgets and components of civic identity. Leisure spaces developed by institutions, trading companies or a consortium of both, often privately exploited, do not exactly respond to the natural impulses of spontaneous individuals and collective activities that arise from complete freedom (Trachana, 2014).

The theoretical approach to the areas of reference are derived from the Situationi Situationists advocated the construction of situations or isolated events and fragmented urban projects as opposed to the objective and unitary character that urban planning sought to give to the city s image aimed at the 'society of the spectators' (Debord, 1967 and 1988). The Situationist *dérive* consisted of the non-productive experimental use of urban space. The city would have spaces dedicated to games and the well being of the people. This idea was certainly indebted to the spirit of Laugier and shared with the Romanticism and the Baroque in the daring adventures and discovery of spaces as the result of travel and the assimilation of cultures. The new conceptions of art today are connected to action,

participation, involvement and commitment with reality and with the collective. Art is no longer conceived as an isolated work but has been brought out of the galleries in the street to provide us with a stronger and more intense perception of reality (Perniola, 2002, p.17). This idea of contemporary art that emanates from the Situationist notion, conceives the city as a collective of dynamic art works. It has the potential of a total artwork place or an environment all inspired and carried out by and for t community without being distracted from everyday life.

The concept of "place", on the other hand, involves the inter-communication as opposed to the non-places or places lacking in communication (Augé, 1994). In these places the memory of ephemeris manifests itself, the historical and social identity is reaffirmed by repeated civic events and religious rituals. They are places of significant density, complexity and up-to-date in that they continue being live scenarios of society. They are, therefore, structural or primary elements of the city (Rossi, 1971). Since ancient times these areas have been regulated, i.e. generated architectural types and have been part of the management of the city. Today they continue being direct references for the creation of new urban spaces. In these structures one would have to add those little shaped and sometimes ephemeral or improvised some sectors of modern society can promote, those that may arise from the bases as demand for living space. But would, above all, reclaim quality spaces from the hands of the professionals who are ready to investigate, experiment and work in collaboration with those more sensitive sectors of citizens and administration. The public space project would integrate social and cultural needs with solutions to the environmental problems, re-introduce nature to the urban areas, recover the degraded and wasted areas and preserve the festivals, games and traditional rituals in their original places for celebration.

In different regions of the world, ancestral formulas of popular occasions and games have survived and continue to captivate popular appeal. Some are carried out in spaces that are especially prepared and others in popular multi-purpose plazas. They acquire all their meaning and sense thanks to their ability to convene the people to the evocation and memory that constitutes the hallmark of the people. In these scenarios the identity, nationalism and regionalism are updated and revived through the architectural buildings. But the majority of times it is the streets and the open spaces in the city, the undefined spaces, which temporarily absorb these popular occasions. It is the very people of the city who make up the social spaces and not the defined spaces which shape the society.

The construction of spaces for festivities, games and rituals in society reflect their historical and fabled identity, built as a decisive and inescapable condition of life both individual and collectively. In Spain, for example, the games of rural origin, the processions of Holy Week and bullfighting itself constitute a mnemonic persistence of which, however, form part of the formal strategies and operational modes of certain politics and powers that be.

In the first decades of the twentieth century, the architectural avant gards advocated the disintegration of the street and all highly organised public space, promising in exchange an area of freedom and enjoyment close to nature where the border between the private and the public would be abolished. The free area as a spatial continuum could only facilitate the demands for freedom, nature and free spirit . The naturalist space, free and unlimited was considered superior to any structured space. The claim for free time was associated to this concept of free space of the modern society: leisure, sport, health, closeness to nature. But, as it turned out it was just a fantasy embedded in the modern city that started to fade and be recognized that the ideal of free space and its indiscriminate neutrality or equalised uniformity was barely attainable and not even desirable (Colin Rowe, 1981).

But this debate had already been surpassed in the second half of the twentieth century when the principles of the modern city went into crisis for having surrendered to the interests of real estate speculation and for having produced effects of uniformity, monotony and low spatial quality. The critical platform that addressed these phenomena counted with the Situationist movement among its different components, which started a new way of seeing and experiencing urban life. Instead of being prisoners of a daily routine (voiced by modern rationalism under the terms of work, rest, move' with the subsequent zoning of the city), the Situationist proposed creating situations as specific emotional

moments of life, deliberately constructed for collective organization. Guy Debord (1957) considered urban transformation as the possibility for an orderly intervention on all the complex and interacting factors of the material part of life and behavior involved. The concept of a unitary urbanism would integrate all the arts and techniques as a means by which they contribute to a comprehensive composition of the environment. It can be said that the Situationist utopia becomes a possibility today thanks to a connectivity that encourages citizen activism that is spread by the social networks.

In the ideological basis of such interventions underlies the wish to please that is always associated with personal pleasure from the aim of creating a space for the enjoyment of a group, diluting the personal into the collective. As opposed to the typical interventions where personal projection prevails over architectural design, originality and innovation, this is rather, intelligent management by the people. It's not about occupying space selfishly but about opening moments of freedom and leisure in urban areas that lack space for recreational and socialization activities. The areas are redefined to escape the 'totalitarian' control of the star designer projects that public today. It is about trying to find the formulas in which people become involved and participate in creating public space, so that they can take it over and give it a temporal continuity. Without people the intervention would have no sense or life. Many spaces designed by prestigious authors in fact fail because they stop considering people, to be there for the people, as they have the ambitious aim, for it to become an event for a society of spectators .

We have, nevertheless, historical forerunners who think of the architecture of the public space for everyday life and present needs, which responded effectively to the special circumstances of each place and have been approached by several very good architects in the past. Let´s remember how Aldo Van Eyck of the municipal services of the city of Amsterdam, transformed vacant lots and residual spaces in playgrounds. After the destruction of half of the city as a result of air bombardments during the Second World War, he transformed these areas with scarce resources and a lot of ingenuity. When the financial crisis knocked down many buildings in Manhattan, the Green Guerillas in New York devoted themselves to the creation of urban gardens. Lina Bobardi, in the 70's, did some work to transform the heart of Bahía (a degraded environment and closely linked to very active popular uses). They were focused on rescuing popular traditions and local building knowledge that also involved the revaluation of popular cultures. From the 90's on there is an awareness in several European cities that urban spaces are not dead places but 'areas of opportunity'. Residual areas could accommodate emerging ways of life, that are an alternative to those proposed by the city council and then the creative reuse of degraded industrial areas could begin. We have enough examples of projects that cross the frontiers between formal and informal works and where the architectural discipline breaks its barriers. The new parks in the Ruhr valley in Germany where the mining and steel industries were abandoned are good examples.

Thus, against the typical transformations of squares and open spaces in urban centers and historic districts by the local administration, where there is, generally, total disconnection between citizens, future users (mostly neighbours), architects and authorities, today we can see several initiatives that are starting to develop. Nowadays, opportunities for direct action, formulas to act autonomously, that are independent from political programs and where professionals can get out of usual commissions and become involved in more daring ones are produced continuously. Moreover, when the economic crisis has truncated the public works, the young professionals have the ability to see new project opportunities, to detect new needs, to look for different promoters and to seek solutions to urban problems. Thus, interdisciplinary professional groups have been created displacing the personal ego in order to carry out different activities where the focus is no longer on specific and stellar works that become an emblem for institutions and capital. They are professionals who identify the final users and meet up with them using the new technology and innovative marketing tools.

Further, the ineffectiveness of the reconfiguration processes or the restoration of public spaces, always conceived from the point of view of the interests of economic and political elites, is more than clearly demonstrated. More positive forms of intervention necessarily involve interdisciplinary processes that imply the participation of local intelligence by conversing with professionals who coordinate them.

More than ever we can say that today what is needed is not so much in new initiatives, but rather, to add value to what already exists, by transforming, enhancing their own characteristics and inventing new possibilities of appropriation. In this sense, we have an increasing number of examples of good professional interventions in given situations designed to be effectively functional, sustainable, natural and popular.

## 3.Emerging tendencies of informal spaces

There are numerous examples of necessary spaces for pleasure, urban transformations that are able to offer a temporary use such as *container city*, or the widespread urban vegetable gardens, the creative management of social spaces such as the Tabacalera Building Madrid or a gym created under a highway in Sao Paulo by the ex-boxer Nilson Garrido and his wife Cora Oliveira. Other unusual places have been brought about outside the conventional channels to mitigate social problems like unemployment, leisure, poverty, drugs and crime. There are also practices of dissent concerning temporary occupations devised from the ingenuity, the recycling and the parasitic actions. The "a-legality" in which they move, the survival practices and the marginality with their flexible mechanisms in order to stay within the city; the city with an economic crisis must develop new mechanisms of spatial configuration through recycling, the inclusion of residual spaces, etc.

The running of the contemporary city with regard to the dynamics of community life extends well beyond entertainment, tourism or consumerism in the new networks (ephemeral, changeable, transformable) of collectively used spaces, residual spaces that are temporarily activated by the people who occupy them, acquiring a collective meaning. The city is inhabited by practices that do not leave permanent traces, which appear and disappear, such as the Plaça dels Angels in front of the MACBA in Barcelona, which is activated by the presence of groups practising skateboarding or the Plaza de Colón in Madrid used in a similar way for different sports. With small behavior patterns like these new relationships with the public arise and new dimensions of life that transform, in their own way, the usual features that are involved in the public space.

Meanwhile, the contemporary urbanism still poses a dichotomy between the planned and the unplanned city. And the informal, that appears to be the problematic and is seen as a visual disorder, has however, an aspect full of life, that reveals itself as an enormous interaction of social energy. For this reason and facing exclusion (in its many codes that contemporary cities have developed) we would have to assess the emerging forms of urban intervention assimilating natural tendencies, and reversible, ephemeral and sustainable actions; such as the inclusion of, the reuse and recycling of spaces and disposable elements and materials; the spontaneity with which citizens generate and regenerate living spaces aside from the power and the production systems; the communal living and citizenship generate and the knowledge transferred to the academy and the institutions involved.

*Container city*, for example, constitutes one of London's architectural oddities. It is a conception of flexible spaces that are adapted to different lifestyles. Containers can become a very flexible method of modular construction, very strong, very quick and economical from the structural point of view. They are easily adaptable and transformable with regards to their image. They can be reversibly dismantled and remounted releasing the occupied ground for other purposes when required. Today with this method, they have created several units of affordable rooms, low cost youth residences, social and cultural centers, lecture halls, offices, artist studios, workshops, medical facilities, and all kinds of habitats. Some of them are self-built and others are part of the innovations of architectural design.

Other notable examples of informal occupation are the wagenplatz in Berlin constituted by trailer-dwellings that colonize different empty plots formed after the fall of the wall. The wagenplatz or bauwagenplatz, urban settlements consisting mainly of trailers, cars and site offices are communities that originated in Germany in the years after the end of World War II, due to the housing shortage. Currently several of them remain in Germany and other countries like the Netherlands or Switzerland.

Their rise began in the 80s, from the movements of occupation as an alternative way of living to the capitalist s system. There is as much a variety of wagenplatzs as settlements. installed directly on occupied land, others that rent the ground after years of negotiations, or even those that offer a service to the community in exchange for its use. In any case, they serve as a reference for physical spaces where resistance and counterculture are defended day after day by means of everyday acts such as the preparation of food for the community, the exchange of second-hand clothes, cleanups, etc., besides collaborating actively in the anti-fascist struggles, against real estate speculation or racism.

These ways of understanding the urban phenomenon are presented as an alternative to the excessive planning that supports the fact that politics resembles surveillance and that justifies a neoliberal state control that empowers corporate forces to exercise repression in the name of the public good. In the impoverished economies prevailing today, to use bland urbanism or to use self-built, ephemeral, fast, lightweight, removable, strictly functionalist and why not, effective aesthetic formulas, is to answer to the needs that many people have in whatever part of the world that depends on them. That makes us wonder what can be done and what is still not being done.

The informal appropriation of urban spaces for temporary uses, we believe, is an extremely important aspect for the future of urban space. The different formations with a casual connotation such as spontaneous occupations with recreational activities, the organization of parties or trade activities, markets or spontaneous malls have arisen in slums. This is where legal activities mix with illegal and others have been accepted by the state and its system of formal organization. In most cases, the obsession for security has transformed the paradigm of temporary into a real strategy of control and repression, which is exactly the opposite for which they were originally destined.

There are also architectural and artistic interventions in the cities which are sensitive to the anthropic, by trying to respond to immediate needs and improve the people s spirits. Gordo Anarchitects, the Stalker group, Lacaton and Vassal architecture, among others, give us a glimpse of their principal ethical behavior and aesthetic criteria that reflect a willingness to conceive natural, uninhibited and positive responses, even at low-cost but no less strategic in the current situation. The traditional conceptions of form/design are surpassed by a certain informality and openness of a multiple interaction with the users, the environment and with time itself.

Many paradigms of alternative urban actions have been placed in European cities as well as in other continents (Martín Castillejos, 2014), carried out in multidisciplinary ways and with the participation of academics and students who are facing the new social and economic situation with new ideas and new techniques. The peculiar mode of action of the Basurama group, whose office is a website, has been spread across the four continents with a different approach towards the waste that surrounds us and towards recycling in general through workshops and urban actions. Worth noting is the work of L'Atelier d'Architecture Autogérée (AAA) that is developing urban community gardens in Paris with the support of local authorities.

The so called open source communities develop online collaborative design methods that atte cut costs and experiment with recyclable or biodegradable materials and components, formulas of self-build, etc. Other projects try to recover the artistry of the urban voids by focusing on the urban dynamics through architecture, urbanism and art, taking into account the perspective of citizen participation, collective intelligence, urban revitalization and public space. This is precisely what groups like PKMN, Studio Bijari, Bruit du Frigo, Esterni, Supersudaca, Raumlabor ..., etc. do. These are groups that develop urban activities as a way of instantly intervening in the cities and workshops as a direct experience and who seek political provocation through their critical interventions. All these groups and many others investigate new ways to build civic spaces with reduced, ecological and sustainable resources using ICTs as a *leitmotif* (Trachana, 2014 p.218)

The Roman group Stalker was named like that, in their attempt to find another way of doing architecture, to address the transformations of space and to interact with these transformations in a city

of the future, chaotic, labyrinthine, multi-ethnic and multicultural. In recent years, they have investigated marginal issues, the residual spaces, the non-places that are, according to them, the genuine places to investigate, create, build; to understand the city of the future and to change it. The Campo Boario, in the very historical center of Rome, is an example of the new phenomenon of where these emerging places are appearing, and although marginal they have not been forced to the outskirts. In the Campo Boario, the Stalker acted without having a project in mind. Stripped of prejudices and preconceptions, just by watching, they understood "what the thing was, that was going on there," and how they could, somehow, wrap up this situation, "making it go from a form of degradation to something interesting". They collaborated with the transient Kurdish immigrant community and local artists and students to organize events at Campo Boario, including Kurdish festivals, workshops and competitions for the site and other art exhibitions and performances. It was not a topic that they could resolve in terms of form; their approach was not presenting an architectural or urban project, they operated through a "a work of woven relationships," by trying to get the di were coexisting in the same space, to get along together. This took place through a playful approach where they act as artists who organized the Campo Boario Games: Global Game , Boario Lunch and a number of playful actions that were carried out so that the participants could forget their everyday problems and get involved in the game as an artistic performance that spoke about themselves. In addition to the physical transformation of the space the Stalker distinguish a mental one through a modification that makes reference to a new perception of the space.

Specifically in Spain we can find several collectives. There are about 50 in total, among others, recetasurbanas.net, straddle3.net, caldodecultivo.com, estonoesunsolar.com, etc. stand out. These groups have managed to make vacant lots, temporary buildings, civic participation, employment plans emerge from the legal vacuum; all of them are a series of actions that change the rules of the game through a new logic to undertake projects. They all seek to renew the concept of public space in the public domain. Architects, engineers, landscapers and workers consider their work as "opportunities for learning and cooperation" with an ideology willing to provide the means to get to see a change in their cities. Beyond design (most of the time there is no time to draw plans), they are responsible for the construction of projects.

The intervention carried out on the municipal site in Doctor Fourquet Street in Madrid was the fruit of two years of intense collective work by the Milanese Esterni Group and the following institutions in Madrid: la Casa Encendida, COAM (Colegio Oficial de Arquitectos de Madrid) and the Central District Council. They were able to make a square for the neighborhood residents, with its trees, its garden, its allotment, its square for exchanging goods, its stage for performances, its football field and its silent disco. Today there is a complete and complex project of joint management of the space with the 300 residents who signed the petition to the Council in order to be able to keep on using this space during the time that is available. The authors of this intervention have been encouraging citizen creativity to initiate more interventions on potential urban sites or to present proposals and program ideas for the 'urbanaccion2' competition, which has been launched together with the Competition Office of the COAM. The group thinks that the more ideas people put on the table, the better the cities where we live will become.

Other references in Spain are: Andrés Jaque with his so-called Office of Innovation Policy. It is a platform for experimentation and generic research that develops projects, interventions, performances, exhibitions, critical reflection on architecture and the city. In those projects, certain aims and uses are pursued in order to transform everyday life. According to Jaque, the idea is to subvert the "modern project" in order to create situations (following the Situationist manner) and encourage people to enjoy them. The final goal is "that architecture fosters situations instead of making situations depend on the spaces that architecture imposes."

Urban ecosystem is a group that works in Spain and abroad holding workshops and doing projects. The Ecobulevar of Vallecas in Madrid, designed by them consists on some artifacts (artificial trees) that aim to improve environmental comfort, promote social exchange and design a more sustainable public space. They create, therefore, a space of a more social character between traffic lanes with very

few resources. The materials used are mostly recycled; they also use alternative sources of energy and air conditioning systems by using passive cooling techniques commonly used in the agricultural industry. Being aware of the fact that the best reconditioning of the public space would consist of sufficiently dense and good sized trees, material that would need about fifteen or twenty years to properly show itself, they opted for an "emergency" performance that serves as the seed for a regenerative process of the public space. The three pavilions or air shafts function as temporary for multiple activities chosen by their users. Installed in the non-city will only be used until the inactivity has been corrected and the trees have grown. Sufficient time allowed, these devices should be removed, leaving the premises they occupied as clearings. The goal in the Vallecas project was to create an atmosphere that invited and promoted activity in an urban public space. It is not part of a marketing strategy, creating reconditioned environments in which the citizen plays an active part in the public space.

Santiago Cirugeda, from 'Urban Recipes' (www.recetasurbanas.net) addresses issues such as ephemeral architecture, recycling, strategies of occupation and urban intervention with the incorporation of prosthesis for existing buildings or public participation in decision-making processes on urban issues. He takes advantage of legal vacuums to carry out alternative solutions for the benefit of the community. By means of interventions that investigate the legal frameworks that govern the city, he develops protocols to be used by groups or citizens, both to improve urban fragments, as well as carrying out individual projects that resolve housing problems. In particular, many of the "urban recipes" that he proposes as "subversive" and "revolutionary" take advantage of the regulations that allow the temporary installation of items such as tanks and furniture in public spaces that have not been equipped by the administration and also scaffolding and roof constructions to create extensions and finding habitable solutions in available spaces after getting the neighbours´ agreement. He defines himself as a social architect. His work developed with many groups that work on the urban field (hackers, planners, activists, architects, etc ...), has achieved the creation of a network called "Collective Architectures", that uses as working and information tools, both face to face meetings and digital platforms.

Hackitectura architects are from Seville and they define themselves as "architects, programmers and artists designing in the convergence of physical and digital space." Their research is about the different ways of hybridization between the network (cyborg) culture and "open source" communities. Zoohaus is a multidisciplinary work platform made up of individuals and collectives and born in Madrid in 2007. It functions as a network depending on the availability of its members to be more flexible when planning a job or responding to a request. It develops all kinds of projects that focus on urban dynamics through the fields of architecture, urbanism and art, from the perspective of citizen participation, collective intelligence, urban revitalization and public space.

In Latin America, Carlos Teixeira is a Brazilian architect who complements its commercial architecture with projects of artistic recovery of urban spaces using public cultural funds. The Bijari Studio is a studio in Sao Paulo interested in political provocation through critical interventions in urbanism and the occupation of abandoned buildings. Supersudaca is a collective of architects located in five Latin American countries whose research is based on new formulas related to the "sudaca" territory and tourism. Raumlabor builds civic spaces with very scarce means. The list goes on but shows concerns widely shared today by young architects and other professionals.

Public institutions, that are increasingly becoming more involved in alternative projects of this type, are seconded by corporate institutions. The municipality of Zaragoza, for example, has promoted the occupation of twenty sites in less than two years. They have been carried out by the Esonoesunsolar group creating parks, orchards, social spaces with sports fields, playgrounds and other activities, and have become in such a way, a municipal employment plan. The Madrid College of Architects, COAM, has promoted the creation of Madrid Think Tank', a platform-open-lab for ne which the participation of companies, administrations, institutions and individuals is sought with the aim of building a collective urban project for Madrid thereby improving the city and quality of life

of its inhabitants. Through public calls for ideas they intend to propel innovative initiatives that foster citizens participation.

## 4.Implications of ICT in new configurations of public space

The new paradigms of transformation of the urban space that we observe today are imaginative, open and implemented by technological processes; they start on the network and are verified in situ. So, the development of these projects implies the participation of different entities that act from below, from the baselines of citizenship, instead of being directed from above, from the governments and professionals. These are projects that are usually tackled from different disciplines and not only from the point of view of urbanism and architecture, and that use new technologies as a catalyst. The new trends in the design of the urban environment that are not exclusively architectural, point towards new learning based on sensitive perception, with the induction and the imagination of citizens who act as interpreters and managers of information generated and shared with technological tools and telematic means that they choose or design themselves.

The new technological tools for everyday use come with great spontaneity and ease which enables the development of expressive and communicative skills not only by those with expertise in the architectural design of the environment but also by all citizens. In such a way, a new generation of public space projects is emerging thanks to the connectivity in the virtual environment that stimulates the creativity of citizens. So, instead of remaining passive confronting the world, they are no longer willing to adapt themselves, in one way or the other, to the external circumstances. The new active inhabitants of the city can now imagine that they are creating and recreating the conditions of their environment and of their own lives.

We refer, therefore, to the citizen´s ability to take initiatives and undertake unconventional projects, sometimes in conjunction with professionals that act outside the usual regulations; or react to urban planning in order to rectify mistakes that the public administration is unable to solve or where architects and planners are making a mistake, by demanding changes and introducing reforms. Thanks to the resources available for communication and citizen interaction as a common denominator, the emerging trends in the design of the public spaces affect not only the external transformation of places but the people that inhabit them**.**

As Juan Freire (2010) says, we are witnessing a process of "hybridization" that is modifying, our individual identities as much as the community and territorial ones. The distinction between physical space and virtual communities is being updated. Internet, which has contributed to the development of global networks, is now beginning to have a significant influence at local levels. Digital technologies are radically changing the way in which we organize and interact with our environment. The telematic means of communication and interaction increase the citizen´s options for participating, constituting an open and dynamic tool that is constantly being updated.

Development of skills and creative abilities point towards more realistic guidelines, as well being more imaginative and innovative in the design of the Environment. These are capable of regenerating the architecture and building sector in crisis from a more anthropological than aesthetic perspective. The traditional architect educated in the responsibility of designing and constructing their work, can nowadays, assume much broader and diverse tasks recovering a more humanistic and global view of the architectural space as an experiential space.

In fact, the classical paradigms of modern architecture are reviewed from a wider point of view. So we are seeing a shift "towards strategy" in opposition to an interest in the pure expression of the architectural project that requires new procedures and tools both theoretical and practical, more adequate to their time. We are at the crossroads of new *poietics* that break with conventions in order to establish new educational and cultural habits and explore new proposals by claiming reflection and lifetime commitments.

Models of collective management of the convivial space are taking place on the internet, from where they are extending in situ. New communication and relationship dynamics, able to improve the cohesion of communities are developed on the internet. They are presented as an alternative "place" for social relationships, differing from the "traditional" ones. Digital relationships call face to face relationships and on the net the perspective of community as a "place" is generated. We can then speak of a hybrid identity of spaces which are digital and, at the same time, produce face to face relationships. We can speak of "territorial activation from the digital culture . The new "hybrid spaces" emerge from the integration of digital technologies in the physical space. They are configured as places where the free exchange of information is guaranteed and where management transparency is encouraged. With the design of these public spaces, a key role to restore the vitality of these places is given to society by returning to these places the vitality that they seem to have lost (Di Siena, 2011).

The *Campo de la Cebada* Project in Madrid, for example, is a neighborhood initiative to temporarily reactivate the urban space that occupies the site (the previous plot of the demolished La Latina sports center) in the Central District of Madrid. The project consists of the generation of dynamic neighborhood meetings with collective interests for the development of participatory, recreational, cultural, educational, non-consumptive activities, necessary for the community. The *Campo de la Cebada* is a space, historically unique in the center of the city that has been made available so that people can play, skate, cycle, run, meet ... This initiative has neighbors who come from different professional, sociological and ideological backgrounds. It is planned as a temporary alternative to revitalise a closed and abandoned site, only during the time that the works planned for reuse are not carried out, and it is expected to have to wait for some years before that happens. It is a space where priority is given to the human relationships rather than the projects themselves. The project is open to all constructive proposals and initiatives in line with the demands and the parish´s needs that are key to the design process where the neighbours maintain a constant dialogue with the respective institutions.

The result is a strange structure that is a mixture of architecture, self-construction, self-management and where something is inaugurated every day. The content is constantly changing as it is not just a physical construction but the construction of an environment where the neighbors provide their services for free. The place becomes, therefore, an educational and cultural field, an area of social construction and a space to perform all kinds of projects with the active participation of people. It already has multiple facilities and all kinds of events and festivals are organized. 'Edumeet', for example, consists of informal meetings every 15 days, in which there are debates on education, learning and culture and a horizontal structure is maintained. Communicating and sharing is more important than authorship. The fact that these meetings take place in the *Campo de la Cebada* prevents the space from determining their identity and authorship. The announcements, dissemination, communication and interaction obviously happens through the net. Certainly such spaces are initially constituted as a digital entity. (http://elcampodecebada.org/).

The hybrid paradigms mentioned before, created outside the established channels of architecture and urbanism are beginning to have an extreme interest in urban areas. These new generation spaces are almost always created on the border between the need and the creativity of their "users". This innovation gives priority to the creation of social life and political culture rather than the physical construction of the space. Most of the time, the creation of these spaces is alien to the cultural policies, moreover, it acts in substitution of them, because they do not exist.

The group Ecosistema urbano provides another example of how to carry out projects of a hybrid nature. 'Dreamhamar' is a project among others that have been conducted in a workshop format where they have promoted the process of citizen participation through the network to redesign Stortorget Square in Hamar, Norway. The Hamar commune has chosen a pioneering approach for the construction of the new square. Instead of giving the citizens of Hamar a finished space, they have chosen to participate in a process of collective reflection that will determine the new configuration of Stortorget. The architects created a design process in the network -Think Tank- in order to share with the Hamar citizens the way they saw their city and the way in which they imagined their square. All

the residents in Hedmark were invited to participate in on-site workshops so that they could say how they wanted this main space to be. (http://ecosistemaurbano.org/).

Digital technology, on the other hand, is being adopted to encourage feedback between citizens and institutions, even though these platforms still work in a precarious way bilaterally. Nevertheless, they have information and provide services electronically, saving time and energy for citizens. There are, in fact, a wide range of public and private, local, national and European level initiatives (for more information see Trachana, 2013, pp. 45-46). But nevertheless, there still exists much work to be done in order to develop the potential of ICT in the transformation of cities. Today we speak of the "open source city", an expression that makes reference to the free access to urban information which public administrations provide for the citizens, and we also speak of smart cities that through digital technologies offer a diversity of advanced services related to street lighting, traffic, pollution, waste, etc. But the truth is that the transformation of the urban reality is more in the hands of citizens than that of the technology itself as a product, a mere consumable and business object. It depends on the Citizens creativity as it continues to find new solutions to new and old probl are feasible due to the infinite possibilities of choice. We understand creativity as the ability that citizens have as individuals to capture and transform reality, by generating and expressing new ideas. According to Florida (2009), as long as the citizens acquire the ability to make this become their way of life, one can envisage that new possibilities to create and recreate the living environment that will emerge, and that should improve people´s living conditions and coexistence.

## 5.Final implications as a conclusion or the creative essence of a city

Therefore, we can see how a new concept of the city starts being clearly described on the horizon. In contrast to the stable city like a monumental and representative image, a new urban condition is emerging. The urban condition is a continuous flow that cannot materialize or stop, it cannot be planned. We are referring to the practices of mobilized citizens; a sphere of and for practices, and specific knowledge that serves a unique organization of coexistence based on perceptual and sensitive values, movement, change and instability as raw material; the citizens´ knowledge and participation allows them to organize the self-build of their living spaces. In such a way, returned to the citizens, sensitized and motivated into action by seeking pleasure in working together. (Lefefbre, 1978; Delgado, 2007)

With that, the need and urgency to plan cities should not be questioned. We should not accept the withdrawal of the public administration nor the permissiveness of speculation by the fiercest of liberalism that despoils and makes the city a mere business; that converts their spaces into consumer products; that stimulates ownership but restricts appropriation; which considers the urban utility as an obstacle for good urban marketing and as a source of uneasiness for any form of political power. Urban use, is incapable of being planned, it is only possible to keep an eye on these spaces where urban life passes by contemplating all the unforeseen events. The happenings, the ways to escape and the possibilities of emancipation; the "minimal relationships" that can achieve a high level of intensity, the latent 'placing', a possibility of place or a city. The return to the naturalist spirit already permeates a methodological change in all the disciplines that study and act in the urban sphere.

This eagerness to capture what happens to our senses should be translated in a stronger interest in the environmental conditions and the practices that build an anthropological space. The naturalistic or positivist observation that seemed to have been buried under the pretentious methods of 'high design' based on abstract concepts and under the tyranny of a speech that prevents access to the things themselves, it should be guided by common sense processes, collaborative and sustainable development among sensitive professionals and motivated citizens, committed to the common cause which is that of urban space.

In opposition to an urban planning that is a predictor of continuous regularit are those molded to the real needs and everyday, free and spontaneous citizens practices. The configuration of space through instituted planning is systematically based on models that are based on

mimetic behavior. The 'spatialization' of social experience involves the creation of identity because the individual and collective identity is expressed in terms of space. Each 'spatialization' involves identification and the identification is made possible from the 'spatialization' (Stavridis, 2003, p.59). The neoliberal and globalized tactics transform besides the production of space, each intervention in the urban space, experience and relationship in the space in an commercial relationship. The control of the space expressed as under the official authority regulations for public spaces as much as under the rehabilitation of degraded areas, with the perspective of its transformation int and the management of these urban pockets; such is the vision that prevails over other perspectives.

With the practices that escape this control a doctrine for a more creative and more intensive use of urban space (Florida 2009) is being spread and a new urban practice, a 'soft and flexible urbanism', of local and particular rules is emerging. A pro-active and creative citizens body, able to create and recreate their own life and their own living space, is taking shape, thus keeping the Situationist philosophy (Debord, 1967; Constant, 1974) alive. This is certainly, an optimistic reading for the future, possibly the only one that can be made of megacities focusing on the urban space that remains outside the controls of regulation: the residual spaces, the vague terrain significance, as characterized by Solá Morales (2002) and particularly in the daily and spontaneous processes of intervention and transformation of urban space.

The significant changes that are occurring in the management mechanisms and in the proper design of urban space mainly consider mutant factors of the environment: communication, mobility, everyday uses, activities, perceptions ... against the objectives, quantitative or statistical data. Against permanent structures, representative public spaces, monuments, major infrastructure and equipments, etc., focus on the minimal, informal and irregular practices, the individual and collective experiences that escape any systematization.

The urban and constructive paralysis that is a consequence of the economic crisis is another reason that leads us to a new 'sensitive urban planning' that intercedes with the consequences of excesses (hyper-consumption of resources and territory) and the surplus of unemployed and unoccupied; an alternative urbanism to the planning that has provoked endless extensions of empty apartments to the outskirts of the city (Spanish case), the reduced population in the center of traditional downtowns in the cities and their transformation into theme parks; the fragmentation of cities by the globalization processes that marginalize the poor (informal part with their own laws) and separate the exclusive wealthy (formal part controlled by the government); a conservative planning facing the radical destruction and replacement of obsolete industrial areas that erase the traces of the material culture of industrialization.

In this new situation Constant´s forecast seems to have been proved, according to which, as a result of the increasing technology and automation, leisure time would be increased to the point that citizens would be exempt from work, although this occurs today under the most dramatic form of unemployment and lack of occupation. The newbabylons became nomads because a stable habitat and stable relationships were a consequence of a stable occupation. Losing this condition (of a permanent job), they would use their time to build their environment creatively. This raises the challenge, now more than ever, to focus on the creative essence of the city as a permanent change, overlapping of vital processes, of incessant flow of people from diverse backgrounds and cultures, changing representations of life along with goods. It is urgent to rescue the positive values of the informal part of the city. This interest responds to the fact that it is in the city where the new and more committed art developments germinate, where lies an immense creative potential, spaces where intense dynamic exchanges can take place, spaces of communication and of freedom, to fight out the differences and where the individual human being can change from a *homo faber* to a creative human being (*ludens*). In these areas, a dialectic between order and disorder takes place. These are ambiguous spaces in a universe dominated by the rigidity of formality and legality. In this ambiguity we can see how wisdom and an ethical clarity lie, that makes it possible to mix things up and confuse them.

# Waterfront Space Utilization in Coastal Metropolitans: An Empirical Study Based on Quantitative Analysis

Sicheng WANG[1], Lingling TANG[2], Lingyu KONG[2], Jing HAN[2]

[1]A1 Tongji University, yingzaofashi@foxmail.com
[2]A2 & A3 Tongji University, 451859689@qq.com

## Abstract:

For most coastal metropolitans, the waterfront areas provide various valuable resources, However, reasonable arrangement and utilization of different resources, scientific distribution of diverse functions and efficient management of various urban elements with the limited space are major difficulties for urban planners. This study chooses 14 famous coastal cities over the world as the research objects, to conduct a quantitative analysis. Researchers have demarcated a 10-km$^2$ waterfront area (10-kilometer-long coast, 1-kilometer-wide outspread urban space) in each case city with a screenshot software based on Google Earth, then marked different components on the map with different colours, and calculated the ratios of buildings and lands with different functions. Moreover, this study has elaborately analysed the qualities, functions and heights of buildings through the open-source platform Openstreetmap and Geographic Information System, for answering three questions: (1)the proportions and percentages of various types of lands; (2) the types, forms and heights of constructions and buildings; (3)the organization of road net system. The result of the study has concluded key elements of coastal-waterfront space planning, utilization and management.

Keywords: coastal metropolitans, waterfront spaces, quantitative analysis,

## 1 Introduction

### *1.1 Waterfront Space: the Revitalizing Engine of Coastal Metropolitans*

Waterfront space of a city refers to the urban land or dockland district which is alongside a body of water. Giovinazzi (2008) suggested that the waterfront should not be considered as a line, but should be more correctly envisaged as a network of places, functions, additions and hinges between the coast and the city[1] Compared with most inland cities, coastal metropolitans usually have much more longer and broader waterfront area, which is a substantial proportion of urban space. Nowadays, coastal cities and its waterfront spaces have played a significantly important role in the process of global urbaniza 21 , which was published on UNCED Earth Summit of Rio de Janeiro in 1992, st Sixty percent of the world s population already lives in coastal areas, whi cities with populations above 2.5 million are located along the world coasts in the Chapter

1 Giovinazzi, O., 2008. Waterfront planning: a window of opportunities for post-disaster reconstruction. 4th international i-Rec conference, Christchurch 30 April-2 May 2008.

17 Protection of the Foreshore[2] For most coastal metropolitans, waterfront areas have various valuable treasures, such as sightseeing, resort, biological, cultural, business and other public activities etc. As A.C. Moore said, a waterfront is a significant resource ad a challenging opportunity for a city, chance to be an escape for the pressure-cooker of crowded city life, a chance to be a bright breathing edge of city living.[3]

In the ancient ages, the utilization of sea and coasts was limited. Waterfront areas of coastal cities were always only used as ports, wharfs, fishery industry facilities or manufacturing factories. The urban centres and downtowns of those cities were usually not adjacent to their coasts or seashores. However, after the Second World War, the functions of sightseeing, residence, commerce, entertainment and other various functions besides transportation and industries had been developed in waterfront areas of coastal cities all over the world. In 1964, the government of Baltimore, a major metropolitan of the U.S. State of Maryland which is located in the east coast of America, operated an ambitious plan to re-use the maritime waterfront for tertiary facilities, middle-class and tourist settlements, therefore rejecting the conventional organisation based on manufacturing plants and traditional residential buildings.[4] Since that time, coastal-waterfront spaces have become a kind of public resources for the residents and tourists of cities. As Jauhiainen (1995) mentioned, waterfront redevelopment became a widely spread and largely accepted tool against urban dereliction of inner city areas close to water in North America. This development stared in the 1960s in the United States and about a decade later it spread to Europe where it was a key factor in inner city redevelopment during the 1980s and 1990s.[5] Today, coastal waterfront has become the stage of newly-emerging industries such as tourism, hotel and resort, real estate, MICE (meetings, incentives, conferences and exhibitions) as well as other public services projects. Those industries and projects make the engine that revitalize the coastal city.

### *1.2 Question: How do we make use of coastal urban waterfront?*

Since urban coastal waterfront area provides a large amount resources and opportunities which can be used for various functions, we are facing to a major question that how we can distribute, arrange and manage those different functions in limited space. What are the proportions and percentages of each kind of land? Are there any waterfront space use models in coastal metropolitans? In this paper, we have raised three questions about the utilization of coastal-waterfront space: (1) ratios of various types of land; (2) ratios of various types of constructions and buildings; (3) the organization of road net system. For these targets, we

have designed this research which focuses on case study and empirical research based upon quantitative analysis.

## 2 Case Study

### *2.1 Overview of 14 Coastal Metropolitans*

This study chooses 14 coastal metropolitans which have various characteristics and are located in 9 countries as the research case cities. We demarcates a 10-km$^2$ waterfront area in each case city as our survey sample. Then we compare and analyse these samples quantitatively in terms of the function categories of land use, building density and road traffic density etc. Through the comparison and analysis, we finally conclude key elements of planning and the model of coastal-waterfront space utilization.

As the table 1, the chosen cities are New York City, Los Angeles, Seattle, Baltimore, San Francisco, Barcelona, Benidorm, Fukuoka, Busan, Lisbon, Rio de Janeiro, Rotterdam, Marseilles and Vancouver. They are located in Continents of Asia (2), North America (6), South America (1) and Europe (5) (see Figure 1). In summary, every city of 14 chosen coastal metropolitans is of great importance in the aspects of economy, policy and culture in its region or country. Meanwhile, all of them are adjacent to sea, ocean or great lake, and each of them has huge and continuous body of water, long shoreline and port or harbour. Therefore, these 14 cities are the suitable cases of typical coastal metropolitans.

Figure 1. 14 Case cities on the World Map

Table 1. Case Cities and Their Locations, Characteristics, Population and Adjacent Waterbody

| Nr. | City | Country | Characteristic | Population(million) | Sea/Ocean/lake |
|---|---|---|---|---|---|

| | | | | | |
|---|---|---|---|---|---|
| 1 | New York City | U.S.A | The largest city of the United States. | 19.7 | Atlantic Ocean |
| 2 | Los Angeles | U.S.A | The second largest city of the United States, the largest port of the United States. | 3.9 | Pacific Ocean |
| 3 | Seattle | U.S.A | The largest city of North-western U.S. | 0.6 | Pacific Ocean |
| 4 | Baltimore | U.S.A | The largest city in the U.S. state of Maryland. | 0.6 | Atlantic Ocean |
| 5 | San Francisco | U.S.A | The second largest city in the U.S. state of California | 0.9 | Pacific Ocean |
| 6 | Barcelona | Spain | The second largest city of Spain, the largest port of Spain. | 1.6 | Mediterranean Sea |
| 7 | Benidorm | Spain | The famous tourism destination of Spain. | 0.07 | Mediterranean Sea |
| 8 | Fukuoka | Japan | The capital city of Fukuoka Prefecture and is situated on the northern shore of the island of Kyushu in Japan. | 1.5 | Pacific Ocean |
| 9 | Busan | Korea | The second largest city of South Korea, the largest port of South Korea. | 3.5 | Pacific Ocean |
| 10 | Lisbon | Portugal | Capital city and the largest port of Portugal. | 2.7 | Atlantic Ocean |
| 11 | Rio de Janeiro | Brazil | The second largest city in Brazil, the sixth largest city in the Americas and the world's thirty-fifth largest city by population. | 6.5 | Atlantic Ocean |
| 12 | Rotterdam | Netherlands | The largest port of Europe | 1.0 | North Sea |
| 13 | Marseilles | France | The second largest city of France, the largest port of France. | 0.9 | Mediterranean Sea |
| 14 | Vancouver | Canada | The third largest city of Canada, the largest port of West Canada. | 2.3 | Pacific Ocean |

### *2.2 Study Methodologies*

In this study, we cut out the satellite image of each case city with a screenshot software based on Google Earth, a virtual globe, map and geographical information program (see Figure 2).[6]

6 http://en.wikipedia.org/wiki/Google_Earth

According to the 14 satellite maps we demarcated a 10-km$^2$ waterfront area (10-kilometer-long coast, 1-kilometer-wide outspread urban space) in each case city. On the maps, we mark different functional lands and main buildings with different colours. With the marked maps of the case cities, we can divide and distinguish the different components of the waterfront spaces, and calculated the ratios of lands and buildings with different functions (see Figure 3). Through the database of the open-source website Openstreetmap, we can estimate the heights buildings in the research areas. Meanwhile, we use Openstreetmap, Autodesk CAD and Geographic Information System to calculate the road traffic density of the coastal space of each case city.

Figure 2. The Satellite Images of 14 Case Cities and Their Waterfront Area

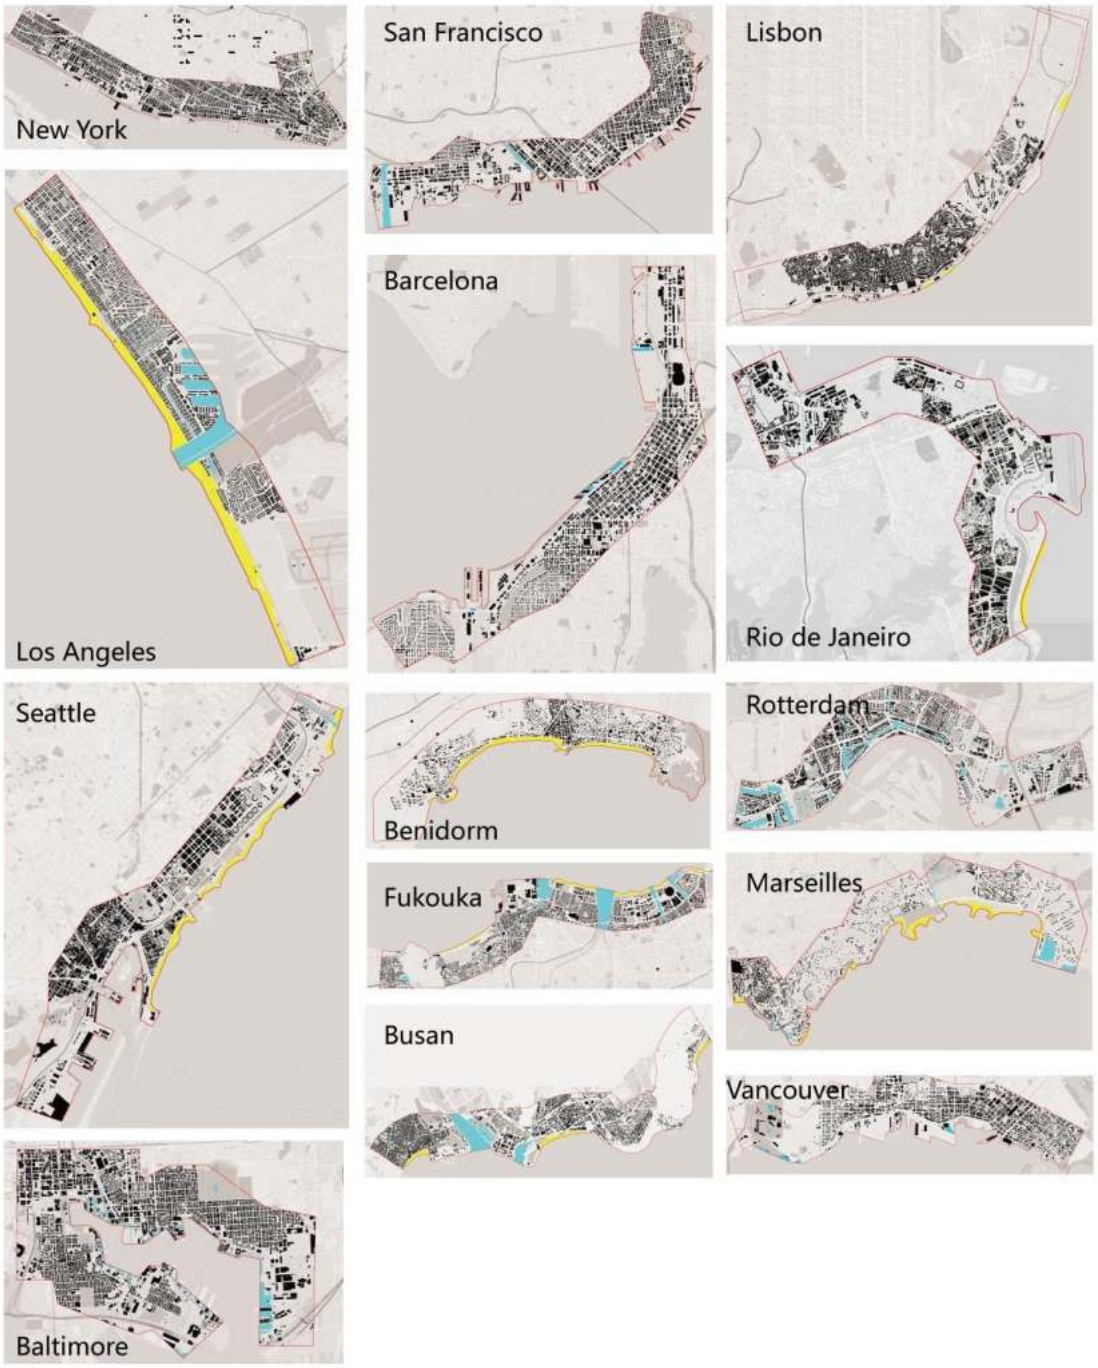

Figure 3. The Marked Maps Which Distinguished Different Components of the Coastal Area of the Case Cities.

### *2.3 Analysis on Land Use*

The pie charts in below Figure 4 show the land use ratios of waterfront areas of 14 case cities. The red parts of the charts refer to the lands used for buildings. The green parts refer to the lands used for roads and green spaces. The orange parts refer to sand beaches. The blue parts refer to water bodies.

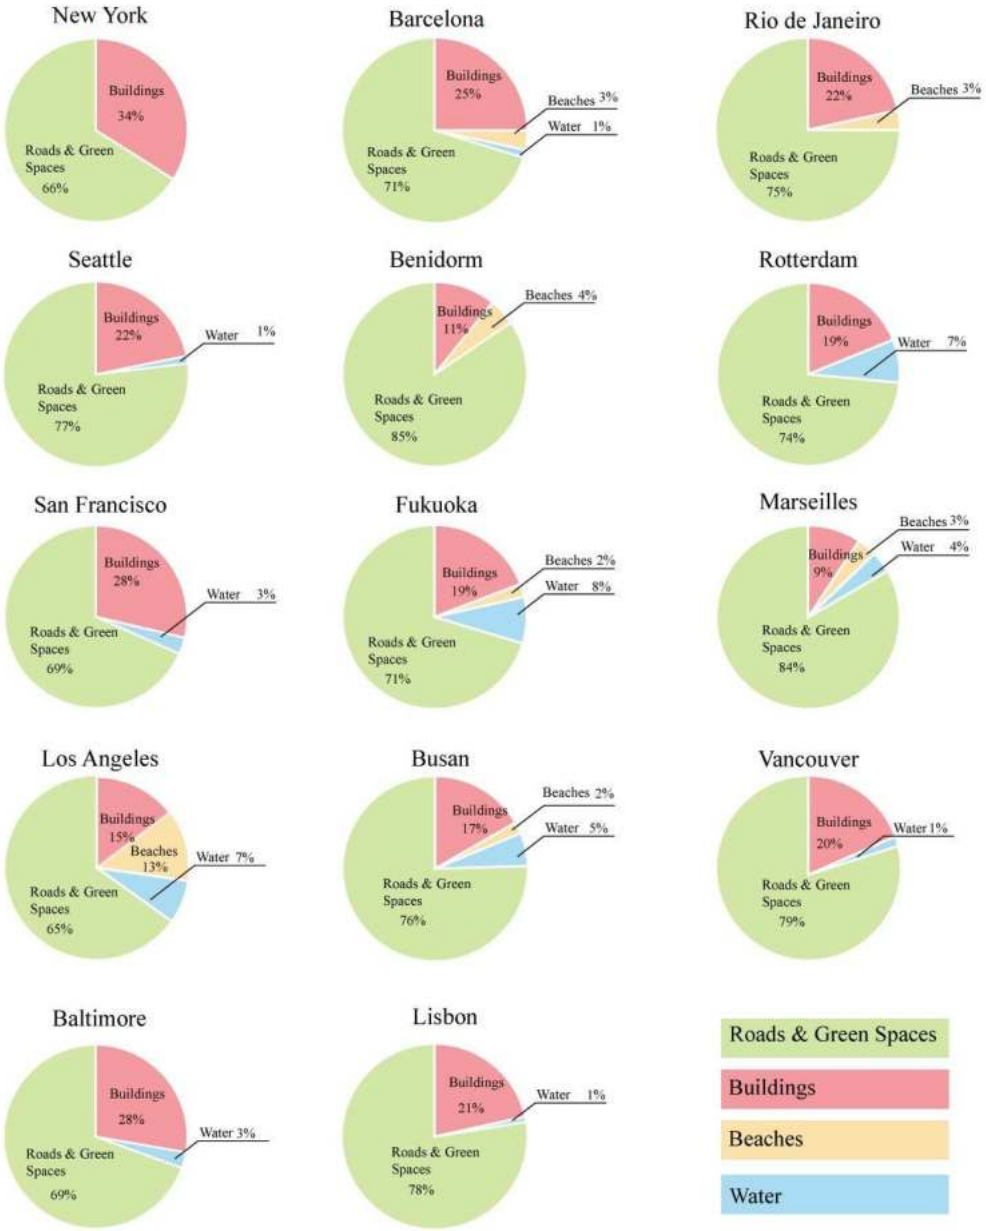

Figure 4. The Pie Charts about Land Use Ratios of the Waterfront Areas of the Case Cities

Generally speaking, the most lands of waterfront areas are used for roads and green spaces, which cover about three-fourth (74.2%) of all in average. The lands used for buildings occupy about one-fifth (20.7%) of all in average. The lands used as sand beaches cover about 2.1% in average. Besides, the small water bodies (such as rivers, small lakes or pools) occupy some 2.9% in average (See Figure 5).

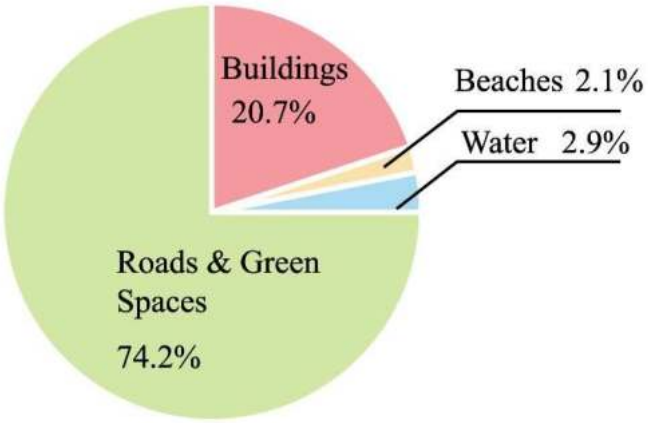

Figure 5. Average values of the percentages of different lands

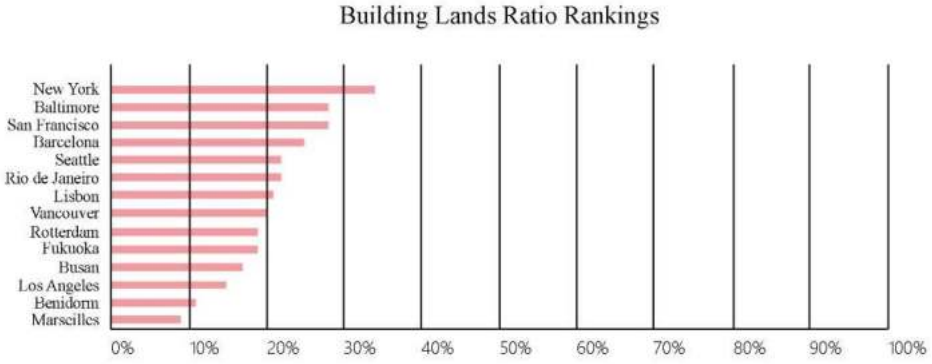
As we see in the charts, in all 14 case cities the top three cities with highest ratio of buildings are New York City (34%), Baltimore (28%) and San Francisco (28%) (See the rankings of different types of lands in figure 6). And their rankings of roads and green spaces are relatively low. Except these three cities, all the case cities lands for buildings are l the whole waterfront areas. And this ratio is less than one-third even in New York City, the global commercial centre, financial centre, cultural centre, transportation hub and a world-class comprehensive metropolitan which has the most population in 14 cases. These statistics demonstrate that a large amount of outdoor open spaces and public facilities are necessary and the most important components of waterfront areas of coastal cities.



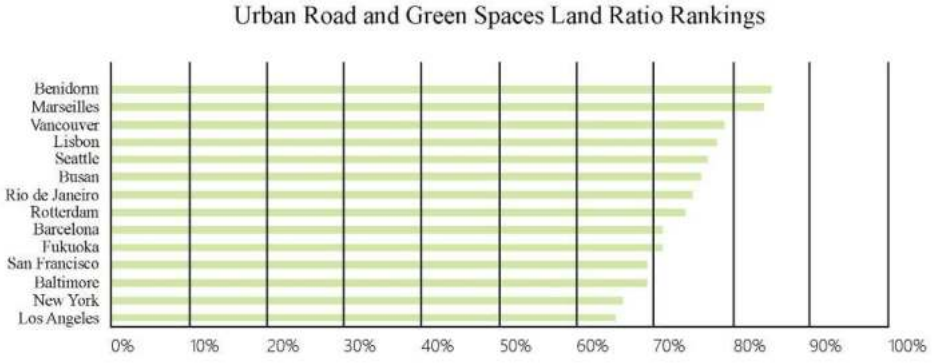


Figure 6. Building Land Ratios Rankings and Urban Road & Green Space Ratio Rankings

*2.4 Analysis on Buildings*

Through the planar shapes of the buildings on the satellite maps and the building information data come from the open-source platform Openstreetmap , we can estimate the heights the buildings on the waterfront areas of 14 case cities. We classify those buildings as low-rise buildings, multi-story buildings and high-rise buildings. Their percentages of each type of buildings of 14 case cities are shown in the figure 7.

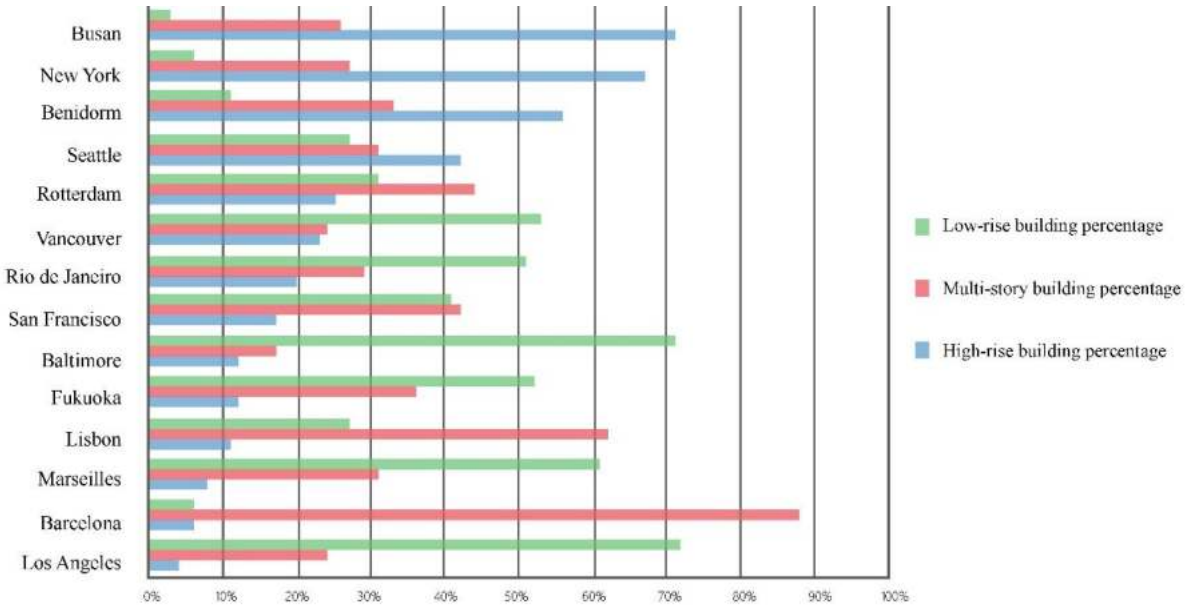

Figure 7. Percentage of Each Type of Buildings of 14 Case Cities

*2.4.1 High-rise buildings*

As we see in the Figure 8, among 14 case cities, Busan, New York City and Benidorm have relatively high percentages of high-rise buildings. Their percentages are 72%, 71%, 67% and 56%, which are all above 50%. Among them, Busan is the most important industrial centre in South Korea. New York City is the most populous city in the United States and the centre of the New York City metropolitan area, one of the most populous urban agglomerations in the world and a global power city.[7] Benidorm is the new town which is regarded as a vital seaport and an attractive tourism and resort city located in the Mediterranean coast. Benidorm is known for its hotel industry, beaches and skyscrapers.[8] In fact, it has the most high-rise buildings per capita in the world.[9]

7 Wikipedia. Benidorm. [online] Available at: <http://en.wikipedia.org/wiki/New_York_City> [Accessed 10 May 2015].

8 Wikipedia. New York City. [online] Available at: <http://en.wikipedia.org/wiki/Benidorm> [Accessed 10 May 2015].

9 Burdett, R. and Sudjic, D., 2008. The Endless City. London: Phaidon Press Ltd.

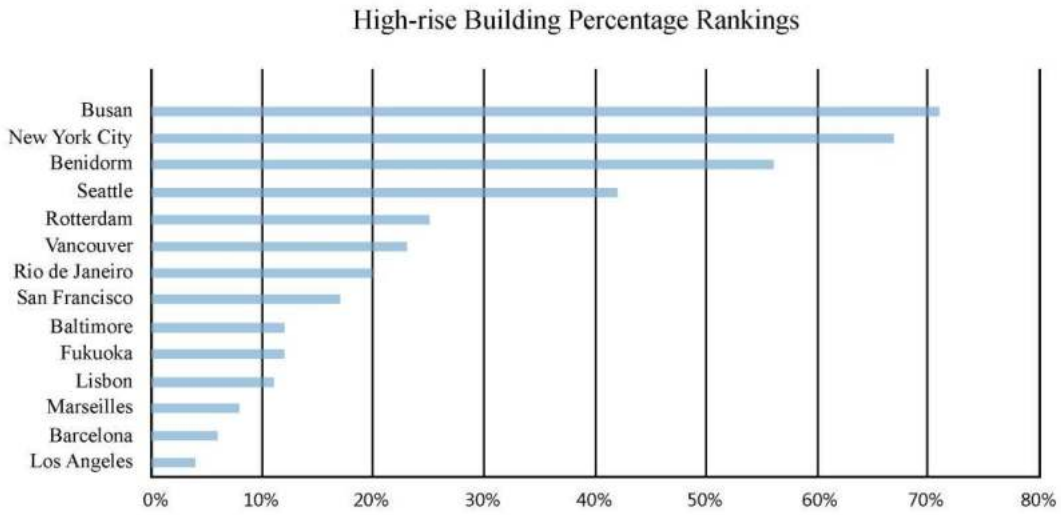

Figure 8. High-rise Building Percentage Rankings

*2.4.2 Multi-story buildings*

As we see in the Figure 9, Barcelona has the highest percentage of multi-story buildings. One reason might be the terrain of the city. It is located in the hilly region where multi-story buildings are more adaptive. Another reason is that the historic communities and architectures. As an ancient coastal city whose old down town is very close to the seashore, Barcelona has a large number of old building in the waterfront area, and most of those buildings are multi-story. Lastly, compared with other cities, Barcelona s coastal areas have mor communities, and the dwelling houses are almost multi-story.

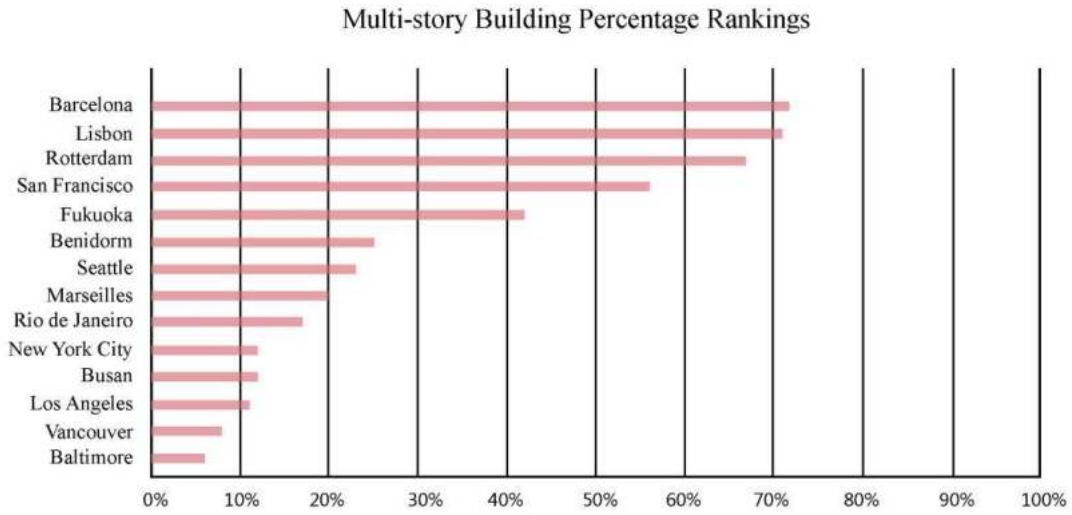

Figure 9. Multi-story Building Percentage Rankings

*2.3.3 Low-rise buildings*

As we see in the Figure 10, Los Angeles, Baltimore and Marseilles are in the top rank of the percentage of low-rise buildings. Their percentages are 72%, 71% and 61% in all the buildings

of the coastal areas.

Los Angeles has the highest percentage of low-rise buildings. That is because that Los Angeles is located in the seismic zone and earthquake disasters happen frequently. For instance, more than 2500 buildings were damaged in the 1994 Northridge earthquake. Therefore, single story buildings and low-story buildings are the main types of the architectures in coastal area of Los Angeles.

Baltimore ranks second in this percentage. Frequent natural calamities is also the main reason. Since 1980, 56 known hurricanes, tropical storms and tropical depressions have affected the U.S. state of Maryland, which state Baltimore is located in.[10] Hurricane Isabel submerged the whole Inner Harbour, the historic seaport, tourist attraction, and landmark of the city of Baltimore. Low-rise buildings are more easily preserved in severe weather.
Hence, natural conditions and geologic hazards are nonnegligible factor in the planning and design for the waterfront areas of coastal cities, which always are the frontlines of the disasters and the ecological sensitive areas as well.

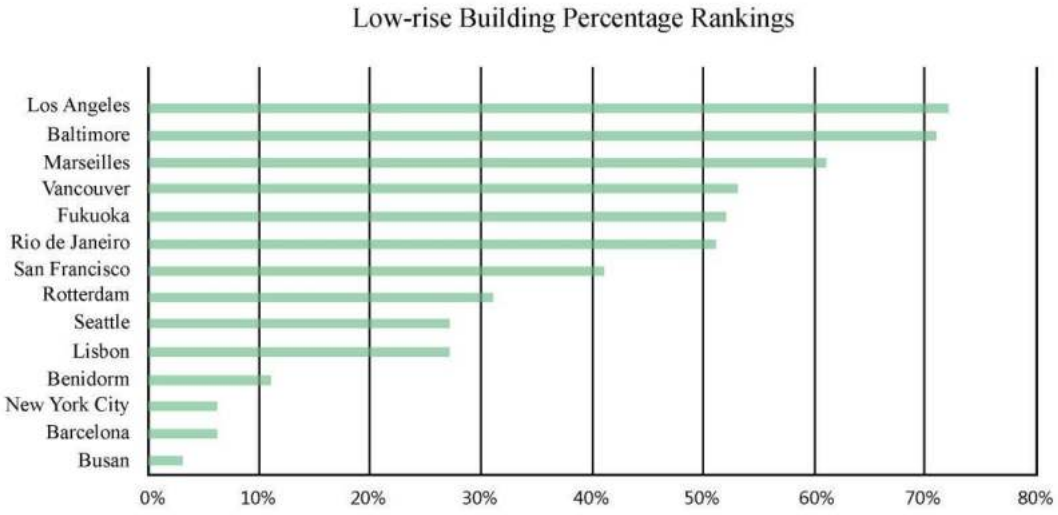

Figure 10. Low-rise Building Percentage Rankings

### *2.5 Analysis on linear density of road net*

We exported data of networks of roads within all the study areas of 14 case cities through the open-source platform Openstreetmap . These data are in the file format of OSM. Via the geographic information system ArcGIS, we parsed these data files and turned them to DWG files which can be analysed in Autodesk CAD. By the analysis of Autodesk CAD, we finally educe the linear density of the networks of roads in the research areas of 14 case cities (See Table 2. The List of the Linear Density of Road Net and the Figure 12. Linear Density of Road Net Rankings) .

10 Wikipedia. List of Maryland Hurricanes. [online] Available at: <http://en.wikipedia.org/wiki/List_of_Maryland_hurricanes_(1980%E2%80%93present)> [Accessed 10 May 2015].

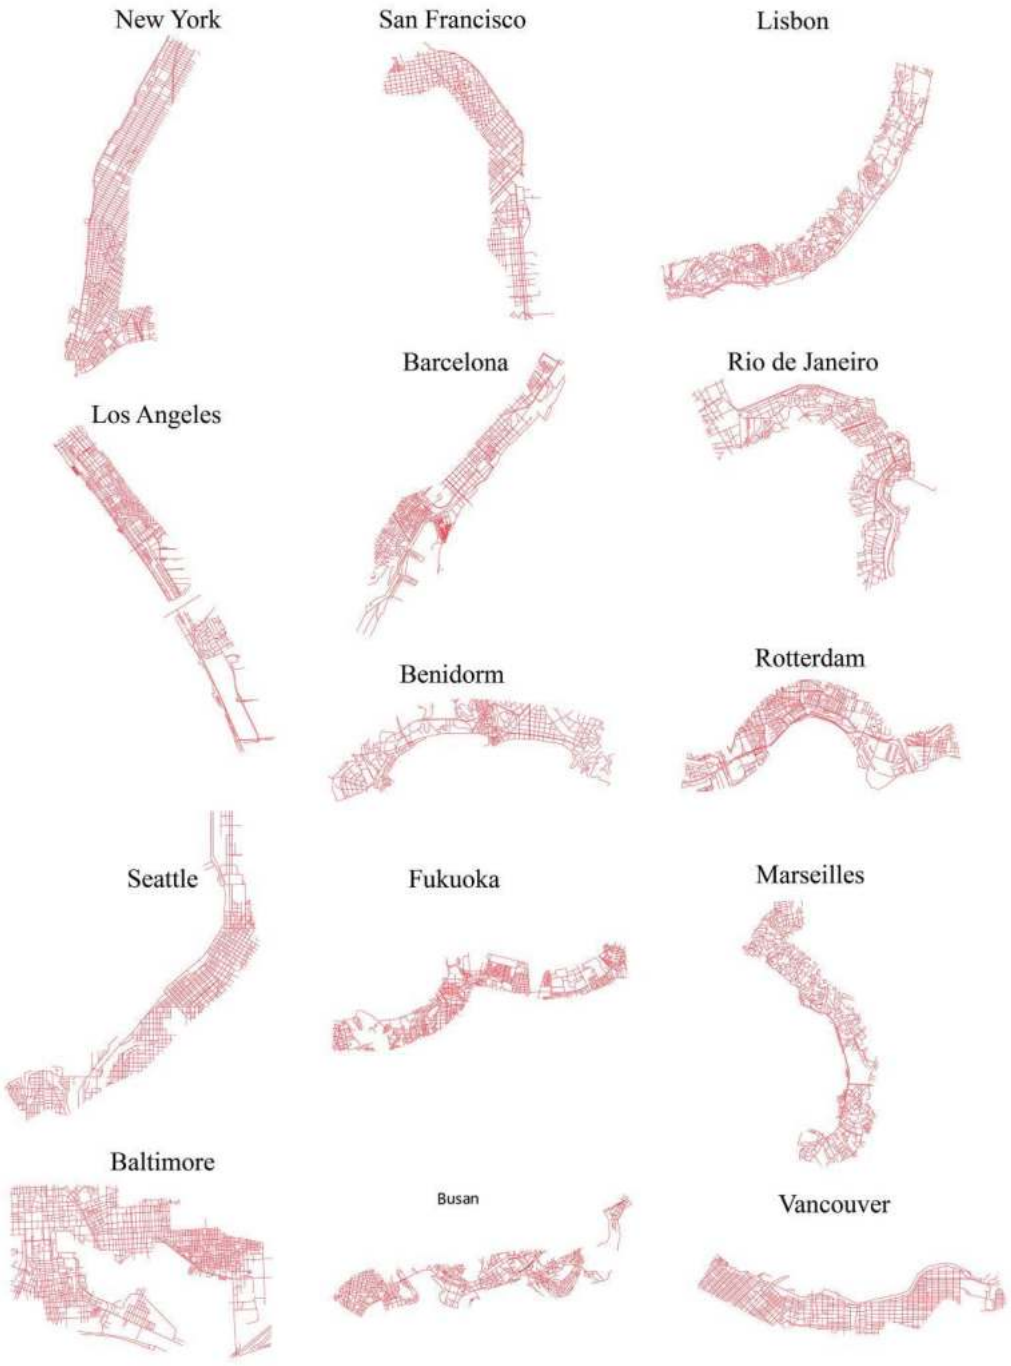

Figure 11. The Road Networks of 14 Case Cities

Table 2. The List of the Linear Density of Road Net of Each Case City

| Nr. | City | Linear Density of Road Net km/km$^2$ |
|---|---|---|
| 1 | New York City | 19.8 |

| | | |
|---|---|---|
| 2 | Los Angeles | 13.8 |
| 3 | Seattle | 14.2 |
| 4 | Baltimore | 21.4 |
| 5 | San Francisco | 15.7 |
| 6 | Barcelona | 16.9 |
| 7 | Benidorm | 12.2 |
| 8 | Fukuoka | 17.8 |
| 9 | Busan | 14.4 |
| 10 | Lisbon | 16.3 |
| 11 | Rio de Janeiro | 15.8 |
| 12 | Rotterdam | 17.7 |
| 13 | Marseilles | 14.6 |
| 14 | Vancouver | 14.7 |

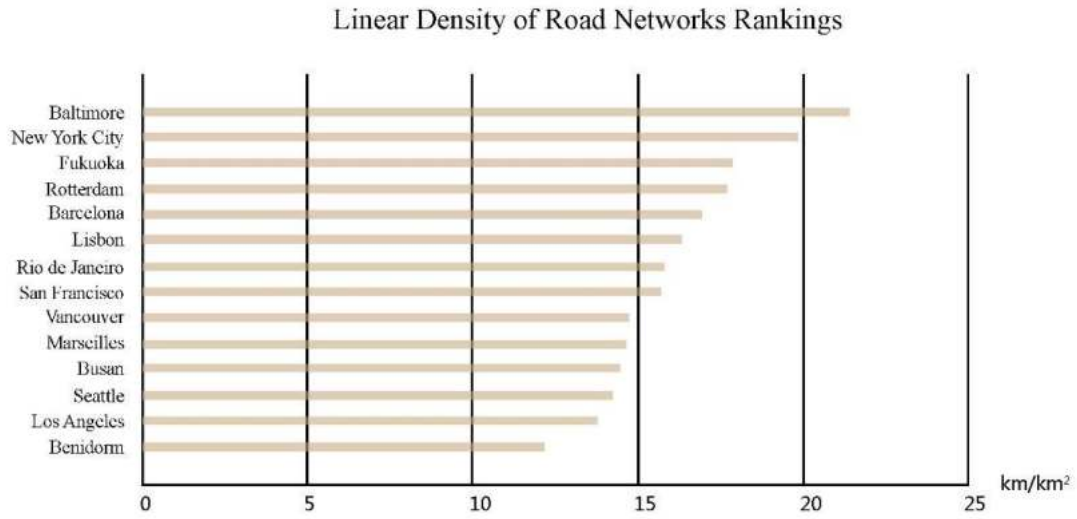

Figure 12. Linear Density of Road Net Rankings

As we see in the figure above, all case cities linear density of road net are ex and the average linear density of the 10-km$^2$ waterfront areas 14 case cities is about 16 km/km$^2$, which means that all the waterfront areas in those cities have relatively good accessibility. Among them, Baltimore ranks the first in the road networks linear density, which is about 21 km/km$^2$, and New York City has the second highest linear density of road networks, which is close to 20 km/km$^2$. While Benidorm has the lowest road networks linear density. Compared with each percentage of building lands of case cities (New York City and Baltimore rank in the top and Benidorm ranks in the bottom), we can conclude that there is interrelated between building density and the linear density of road networks.

## 3 Conclusions

Through the case study and empirical research based upon quantitative analysis, we discover several regular phenomena about the waterfront space use in coastal metropolitan.

### *3.1 Land Use Division and building density*

As we found in the case study, roads and green lands occupy the largest proportion of the coastal waterfront space (about 74% in average), while the lands of buildings averaged in one-fifth. The largest building density is about one-third of the whole area (New York City). This phenomenon tells us the importance and heavy demand of outdoor public activities in coastal-waterfront areas. Therefore, we must balance the scale of open space and indoor construction with rigid control over the construction quantity, avoiding to misappropriate the green lands and other public infrastructures by blind expansion of buildings.

### *3.2 Type and Height of the Building*

In the case analysis, we can see that the types and heights of the buildings vary in different cities. There are three decisive factors for this phenomenon. The first one is the functional role and development orientation of the coastal-waterfront area as well as the city. For example, Busan, New York City and Seattle are the industrial centres, commercial centres and transportation hubs in their regions, while Benidorm is a well-known tourism and resort destination which is famous for its beach sceneries and coastal landscape. In other words, in all of those cities, the density of population is comparatively high in the waterfront area, since a large number of people live, work, communicate or travel in this area. Hence, the proportions of high-rise buildings in those cities are much higher than the proportions of other cities. The second reason is the natural environmental conditions, including terrain condition, geologic condition and natural disasters etc. For example, the regions of Barcelona, Marseilles and San Francisco are hilly and uneven, thus skyscrapers are not proper for the terrain of those places. Another instance is Los Angeles and Baltimore, these two cities often encounter severe natural catastrophes, like earthquakes and hurricanes. The threads come from nature force them abandoning high-rise buildings. The third reason is the historical background of the city. Old cities which have long history, and whose old downtown are near the waterfront areas, always have higher percentage of low-rise buildings and multi-story buildings.

When we plan a new coastal city s waterfront, we much synthetically consider the functions and development orientation, natural environmental condition and history background of this city, for design and arrange the forms and heights of the new-constructed buildings.

### *3.3 Organization of the traffic and road networks*

In our research, the linear density of the case cities are relatively high. The average value is 16.1 km/km$^2$, and the highest value is 21.4 km/km$^2$. In all the case cities of different types and scales, dense roads guarantee the connectivity, openness, publicity and accessibility of the

coastal-water areas. All case cities have special promenades in their water front. In fact, the cities with higher building density, always have correspondingly higher linear density of road net (like New York City and Baltimore). This phenomenon shows that even in high building density cities, most buildings in the coastal-waterfront areas are not private properties. When we plan or design for the urban coastal waterfront area, it is required to ensure the accessibility and necessary to increase the linear density of branch road net.
