In both Taiwan and UK, there is a history of more than a century of planning. In Taiwan, the first planning commission was established in 1897; in the UK, the first act to deal with town planning was 1909. In both, planning is a highly politicised activity, which often attracts negative opinion when controls are implemented (Chen and Shih, 2010). There is an emergent lack of trust in government (Askew, 2006); and in Taiwan too, many communities distrust their local and central governments. For example, there were many protests in 2014 in Taiwan about trade agreements with China and then later, as the movement gained support, the opening of a new nuclear power station in Taiwan, when the so called 'Sunshine Movement' occupied the parliament for several weeks (Bloomburg, 2015). Enforcement is controversial, especially in Taiwan, although the UK has a well-established enforcement system, which underpins the very nature of development control. Illegal building in rural and urban areas in Taiwan is prevalent. In both countries, economic development is of utmost importance - lengthy planning processes are seen as delays to vital investment. Adams and Watkins (2014) argue that good planning contributes to economic development, rather than detracting from it, and this message is a vital one for planners to make to governments where planning is under attack.

It is this attack on the values of planning that has prompted many to question whether or not the systems are working properly. Such assaults do not necessarily refer to the public interest in their criticism on planning, but demonstrate a desire for an unregulated approach, which allows a market more freedom to proceed with development, it maintains is vital in the interests of economic growth.

How does this play out in Taiwan and the UK?

## 2. Taiwan

Taiwan has had a very early start of mixing these two systems in the 1970s when the Regional Planning Act (RPA) enacted in 1975. These apply differently to urban and rural areas. The RPA set up a clear rule for a discretionary system in rural areas, which occupy approximate 80 per cent of the land in the whole country. Any new development occurring in rural areas has to involve different levels of planning permission procedures depending on the context and scale of the development project. It serves a clear purpose to guide developments allocated to urban areas where zoning plans are laid out deliberately, and it aims to sustain the natural environment as usual for as long as possible. (Chen and Shih, 2010) However, the good intention has failed due to the poor enforcement and conflict which occur between property rights and development rights. One such example of this is in the Ali Mountain area, where indigenous peoples have strong property rights, and have actively engaged in making their own plans. (see for example, research project on reservoir planning by NCKU, 2013).

As in the urban area, although the plan-led zoning system has provided certainty to developers, the delay of the every 3-5 year review procedure usually results in the criticism of an out-dated plan, let alone the well-known flaws of rigidity and inflexibility. Hence, attempts have been made such as introducing the idea of "floating zoning" and "overlay zoning" in the Tainan Science-based Industrial Park Special District in 2009 in order to bring flexibility to the current conformance systems. (Chung & Hsu, 2013) Nevertheless, introducing flexibility also brought up the debates of lacking principles and worries of challenging the entire statutory system. It is obvious that how to achieve the delicate yet controversial balance between the conformance and performance is the difficult task for planners in both Taiwan and England. Hence, this paper will start with discussing the role and functions of planning system in the future world in react with foreseeable challenges i.e. climate change followed by debating the need for mixture of two systems from property right perspectives.

## 3. Taiwan: the future challenges and the changing role of the planning system

There is no doubt that no matter under what system, the planning system should regulate the development and seek to optimize the public interest. Planning involves making decisions about the future of cities, towns and countryside. It also includes considering the sustainable needs of future communities. The role of planning system also should include control safeguard, guidance provision and protection of the character and amenity of certain areas for the benefit of the public as a whole. Hence, because of the comprehensiveness and multi-function of planning system, it is always expected to deliver a scenario that could please everyone or balance most interests of public and individuals. Nevertheless, the role of planning system per se has contradicted with the value theory. For instance, the zoning plan-led system is always considered questionable from the property right perspectives. The concept of sustainability in the 1990s had brought the dilemma between environment-led planning and demand-led planning to the surface. (Owens, 1994) It was then that the role of planning system has started to be challenged by new circumstances constantly and seek for more tools to deal with the ever-changing environment.

To this day, although Taiwan had an early start to practise both discretionary and zoning systems in rural and urban areas separately for 30 years, how to balance the need for developments and threats of climate change has triggered some further changes in the current planning systems. Taiwan is a small island with total land coverage of 36000 $km^2$ at the Pacific Rim. It was ranked as the number one country of high risk to natural disaster by the World Bank in 2005 with more than 73 per cent of its total area exposed to three or more hazards. (Dilley et al., 2005) (Table 1) Considering the high risk of natural disasters, more rigid controls and enforcements over developments in the mountain and environmental sensitive areas are urged in the rural planning system due to the large land coverage. Hence, starting with the amendment of the Regional Planning Act in 2000 after the notorious 911 earthquake attack in 1998, each city and county has had to propose a plan-led regional plan with clear regulations, instructions development capacity cap for future developments happened in both rural and urban areas. So far, almost 22 cities/counties in Taiwan have

finished their regional plans with much stronger control over the potential developments on one hand, and introduced some discretionary guidance such as urban design guidance in the urban area to provide necessary flexibility for individual cases on the other hand. The table shows the vulnerability of Taiwan in relation to other nations.

**Table 1 Countries most exposed to multiple hazards in 2005**

*a) Three or more hazards (top 15 based on land area)*

| *Country* | *Percent of Total Area Exposed* | *Percent of Population Exposed* | *Max. Number of Hazards* | *Country* | *Percent of Total Area Exposed* | *Percent of Population Exposed* | *Max. Number of Hazards* |
|---|---|---|---|---|---|---|---|
| Taiwan, China | 73.1 | 73.1 | 4 | Vietnam | 8.2 | 5.1 | 3 |
| Costa Rica | 36.8 | 41.1 | 4 | Solomon Islands | 7.0 | 4.9 | 3 |
| Vanuatu | 28.8 | 20.5 | 3 | Nepal | 5.3 | 2.6 | 3 |
| Philippines | 22.3 | 36.4 | 5 | El Salvador | 5.1 | 5.2 | 3 |
| Guatemala | 21.3 | 40.8 | 5 | Tajikistan | 5.0 | 1.0 | 3 |
| Ecuador | 13.9 | 23.9 | 5 | Panama | 4.4 | 2.9 | 3 |
| Chile | 12.9 | 54.0 | 4 | Nicaragua | 3.0 | 22.2 | 3 |
| Japan | 10.5 | 15.3 | 4 | | | | |

Source: Dilley, M., Chen, R.S., Deichmann, U., Lerner-Lam, A.L., Arnold, M., Agwe, J., Buys, P., Kjekstad, O., Lyon, B., Yetman, G., (2005) Nature Disaster Hotspots- A Global Risk Analysis, The World Bank Hazard Management Unit, Washington, D.C.

Also, several new changes made in the long-delayed National Planning Act (draft) not only re-organize the future planning system to be more strategic and performance-oriented in order to respond to issues such as climate change, sustainability, healthy, and environmental justice but also recognize the concept of 'dual planning theory'. (Sager, 2013) It embraces the importance of social factors in the planning process. The latest vision of the National Planning Act (draft) clearly regulated the need for more public participation in the planning decision making process. By acknowledging the necessity of a bottom-up approach in the formal planning procedure, the Taiwan government is trying to offer a more conceptual tool that is less value-laden and normative in the current zoning systems. By doing so, the attempts are to break the distinct divide between zoning land use plan in the urban area and discretionary planning permission system in the rural area used to practice in Taiwan in the past 30 years. Of course, given the nature of civil law system in Taiwan, the legal-binding planning and land use control will still play dominant role in the future to provide a stable control base.

## 4. United Kingdom[1]

In the United Kingdom, there have been numerous changes to the planning system in the past twenty years. The basis of the UK planning system is the 1947 Town and Country Planning Act which remains the basis for all legislation, despite numerous changes to details since

[1] The UK has four devolved nations, each of which has a planning system that contains different details, with separately named statutes. However, the principle of discretion in the planning prevails, so where legislation is discussed, it is that legislation for England.

then. Importantly, the pioneering act nationalised development rights, and introduced the requirement for planning permission for all development. Each development was to be considered on its merits, with primary consideration given to policy or any statutory development plan prepared by the planning authority. The absence of plans in the local area would result in decisions being made based upon national policy statements, government statements in parliament, emergent policy at whatever level, and other material considerations, arising out of consultation with a variety of bodies, including environmental bodies and communities.

In 2004, the UK introduced a system of spatial planning (Nadin, 2007), but application of an integrated system that came so obviously from Europe proved difficult to implement in the UK. Whist this promoted a strategic planning approach, it did not suggest that European zoning systems should be part of a new approach to planning in the UK. The complexity which accompanied its roll out was the beginning of further changes in the planning system, and led eventually to two major events in the history of planning in the UK. The first was the Conservative Party's manifesto for the 2010 election, known as 'Open Source Planning', which promised de-regulation of the planning system. The second was the abolition of the regional level of planning in England, which was introduced through the Localism Act 2011, which also promoted neighbourhood planning. In fact, simplifying regulation is a common aim of all governments of all political persuasion (Baldwin, 2005; Baldwin, Cave and Lodge, 2011), most recently exemplified by the current UK government in its attempts to reduce regulation. This has largely been led by the UK Treasury, which perpetuates the idea that over-regulated environments and planning in general delay investment and delay economic recovery.

In fact, despite this effort and the words of successive government, de-regulation has not been achieved and what has occurred has been a considerable complication of the planning system in all the devolved nations, who continue to make changes to the system and to their statutes. Regulations are highly centralised in the UK, and in recent years, they have become in part impenetrable, with strong requirements for specific and expert knowledge in the private and public sectors to interpret them. However what these two events have achieved is a further dissatisfaction with planning in the UK, opening the way for developers to question the very nature of the planning system itself. They seek a more liberal system which in they assume will speed up the delivery of decisions on development and permits.

One issue for the UK planning system is the statute which grants development to minor developments. This is known as the permitted development regime, granted under a statute of 1995 called the General Permitted Development Order. This order, which has been amended many times since 1995, was looked at in 2008 under a government commissioned investigation, known as the Killian-Pretty Report, which was charged with simplifying the regime of permitted development. Recommendations were made to the permitted development rights (PDR) to supposedly simplify them. These particularly referred to householder rights for minor developments such as home extensions, garden sheds, garages

etc. Many planners and householders at the time of the change said they were more complicated than before.

A further layer of complexity was introduced which invited a half way house between seeking planning permission and having the rights to develop. This system is known as the 'prior approval' system and it particularly applied to agricultural developments in the countryside and, more significantly, to mobile phone masts. The relaxation of permits was to encourage the roll out of mobile technology to improve business and communications. Such changes required considerable amounts of paperwork, but there was a perception that planning permission was not needed, so it created bad feeling amongst communities and a good feeling amongst the industry, who thought they were avoiding the bureaucratic procedures.

Although experts told the government that the prior approval system did not work, (Askew, 2006), many more uses of land have been brought into this system, which is very complex and requires complicated procedures. One such use is a relaxation in 2014 of the change of use from offices to residential use, as the government considers that this might assist in the housing shortage by allowing the use of out-dated office space for housing. It is causing a decline in vital office space in some areas, such as in Central London for example, where 13,000 new housing units have been provided, but with a vacancy rate of just 4.9% in London, there is a shortage of commercial office space.

In addition, to the housing issue, the application to build a fifth terminal at London Heathrow Airport took several years for a decision to be made. This gave planning permission a very poor reputation and it was said that the planning system was holding up important economic development and growth. In reality of course, it was the political situation that was holding up development as no government wanted to be associated with granting permission for controversial applications such as an expansion of an airport, or the erection of a nuclear power station. As a result of this caution, a vast amount of assessments are required by local authorities when a planning application is submitted, resulting in time delays, but its contribution the final decision is doubtful.

The issue of housing is creating more problems in the UK. It is said that approximately 250,000 new houses per annum are needed to catch up on the gap created by the lack of affordable, public housing built since 1980 (Shelter, 2013; JFR, 2014)). The main issue for London is affordable housing, with prices rising above levels ever known, for example in Kensington and Chelsea the average house price is £1.2million (data.london, 2014) while the national average is just £178,000 (Land Registry, 2015). So the major question for government and local authorities is where to build houses, particularly in London, where land values have risen by 47% in the past five years, and only 2.3% in the rest of the UK (Knight Frank, 2014).

And so back to the production of plans. Prior to the Localism Act of 2011, regional spatial strategies allocated housing target numbers for each region and local plans had to comply with the housing figures and allocate sufficient land accordingly. House builders offered

even higher figures than local authority predictions stated and there were long and drawn out discussions about housing requirements for each area. The government knew that this was unpopular with local communities and also with house builders who wanted a more liberal regime for obtaining planning permission for houses. In particular, they wanted to build on green field sites, where possible. The 1997 – 2010 government had a strong policy that at least 60% of all new housing had to be on brown field land, and this is more expensive to develop.

In 2011, the new government introduced the idea that there would be local plans and neighbourhood plans and that each local authority must produce 5 year housing land supply. In the absence of this controversial decision, the government would deliberate on the applications for housing, based upon its own very general policies contained with the National Planning Policy Framework, which is brief and very general. It is difficult to not comply with it, it is so lacking in detail. This has been a gift to house builders who do not want to negotiate with local authorities if they can go straight to government for a decision. The government has also given the rights to neighbourhoods to create their own plans under the Localism Act, under the hope that communities might allocate land and welcome housing in their area. So far, this has not happened. Out of thousands of potential neighbourhood plans, only 140 have been made.

In addition, where land has been allocated for housing (successfully through an adopted statutory local plan), the house builders have argued that there is no necessity to go through the procedure for applying for planning permission under the discretionary rules. They argue that the designated land should in effect, grant planning permission in principle, and all they would then have to do would be to submit for details of design, siting, massing, access etc. They are arguing, in effect, for a sort of zoning system in certain circumstances in the UK.

So far, this has been resisted, as it would change the entire way in which planning permission is granted for development in the UK. It would not allow for changes in circumstances; local plans might be out of date; the house builders might continue to sit on and bank land until the market is right. Further calls for this system massively under-estimate the inflexibility of the zoning system. The fact is that the main difference between the zoning and the discretionary system is the point at which the decision is made. Where it takes a very long time to determine a planning application, it takes potentially longer to produce the legally binding zoning plan, and an inordinately long time to amend it when situations change. The table of performance and conformance illustrates when this can happen (see above).

## 5. To mix or not to mix, that's the question.

It is clear that both the Taiwan system, statutory zoning plan system and the UK system, discretionary planning system, are trying to adapt some essences or tools from the other planning system for different reasons with same goal of a more efficient and adaptive planning performance. The real argument that we are raising here is how far could each system go pragmatically. For the zoning system, how to set up performance standards without losing the refined and clear-cut planning instruction would be the greatest challenge.

For the discretionary system, how to provide a set of regulations that are realistic yet preserving flexibility and keep the nature of policy-oriented system is still debatable. As Mastop and Faludi's (1997) concern, it is very difficult to evaluate strategic plans. In a plan-led system, conformance between a plan and final outcomes is the ultimate test of effectiveness. However, for development-led system, it would be more difficult to foresee the overall effectiveness even with the policy goal set up in the beginning. Especially both Taiwan and the UK are islands that face the unpredictable climate change environment more than those continental countries.

The other question we want to raise is could all these changes really help to serve a better town and country planning function for future needs?

## 6. Conclusions and next stages of research

The next stage of the research will look further into some detailed case studies of where the two systems have been used in both countries. The research will also study some other countries where the debate rages – Canada and Australia perhaps, where zoning is being questioned as an efficient method of meeting the flexibility that development demands. Furthermore, in the UK, enforcement plays an important role in the management of development and in Taiwan, property rights are important, but less so in England, where development rights have been nationalised since 1947. Rights of the individual might assume greater importance in Taiwan where the public interest is not emphasised in the way it is in England. In examining these complex regulations, it might be concluded that the performance versus conformance model of planning might not be as clear cut as suggested in some of the literature. Certainty or flexibility cannot be dismissed as the preserve of one system over another – each offers a mixture of the two, and further research will examine this in relation to Taiwan and England

Keywords: Enforcement, system inadequacy, public interest, social justice

**Abstract**

Enforcement matters are frequently high-profile, and yet there has been relatively little practice/academic discussion and debate in comparison with many other areas of planning. Drawing partly upon recent research undertaken by the University of the West of England, Bristol, this paper investigates and concludes upon the vulnerable position of planning enforcement in England today and the potential impact of this upon the provision of a fair, just, ethical, pro-active, robust, effective, efficient, and delivery enabled planning approach.

As the backbone of the planning system enforcement supports and underpins; it ensures adherence to policy and regulation and plays an important role in the effective delivery of post-decision project management. It also provides the certainty and legitimacy required for effective governmental intervention into development delivery and place shaping. And yet today, despite the optimism brought about through spatial planning, planning enforcement is at risk of becoming a victim of the state of the profession in the current political and economic climate.

This paper will specifically explore enforcement within the context of planning's role in the successful management of the built and natural environment, the balancing of public interest and matters of social justice, and the adequacy of the current and potential legal mechanisms necessary for the operation of a fit for purpose planning system. The work will consider the risks facing planning enforcement and the associated implications upon the wider planning system, society and the environment.

## 1. Introduction

The modern English planning system has its roots firmly in the welfare reforms of the mid – late 19th century. The Industrial Revolution had resulted in the rapid growth of densely populated urban areas, the majority of which offered extremely poor living conditions and little, if any, form of sanitation. Nonetheless, a flood of economically driven migration to England's burgeoning industrial towns saw the country's population reject a traditional agricultural existence, creating a new (urban) working class (Rydin 1993).

The exceptionally high mortality rates, spread of disease and squalor prevalent in these new industrial centres led to increasing pressure on the ruling political class for fundamental welfare reform. Resultantly, the second half of the 19th century saw a stream of state interventions in the form of new legislation, which was to eventually lead to the first planning act, 'The Housing, Town Planning etc. Act 1909'.

In effect, the welfare reforms of the 19th century represented a movement to affect social justice. These were reformations borne out of the basic human instinct to protect and nurture. It is this guttural and emotional response to society's most challenging problems, which is largely absent from the current planning system. Issues of social justice, related to human emotion and a sense of fairness, do still resonate, however, within the sphere of planning enforcement (hereafter referred to as enforcement).

The historic treatment of enforcement, as a discipline somehow removed from forward planning and development management has acted to insulate the activity from ideologies that have transformed planning into a system for facilitating economic growth. The position of enforcement is therefore unique within planning. It is the only truly remaining vehicle for the delivery of the form of social justice from which the system originally grew.

**2. Planning, enforcement and social justice**

The history of planning is often told as a simple, linear journey in which the vision of delivering social justice was aborted in the face of harsh environmental impacts and political philosophies following the end of the Second World War. The timing of this abandonment could not have been more ironic, given the utopian vision of the 1947 Act. Nonetheless, in the decades that followed, the theories and politics that shaped the English planning system became discernibly less people-centric. This shift can be traced, in part, to the rise of a neo-liberal approach to socio-economic politics that have dominated the policies of successive British governments. This has transformed the purpose of planning into a means of wealth creation, both for the individual and the nation, and has led to the commoditising of planning, whereby decisions are made on economic grounds, as opposed to imparting any value led judgement. (Taylor 1980).

As the planning system has continued to evolve, new terms such as place shaping and sustainability have come to define its objectives. At the same time, the premise of delivering social justice has all but vanished from the agenda. This is surprising, given that planning has at its disposal many of the tools necessary to help address some of the most challenging and debilitating issues facing society. Tackling wealth and health inequalities, facilitating equality of opportunity and combating the threat of climate change, are issues that should be central to the planning objective. To which extent they are, is open to conjecture based upon the current direction of travel. This raises two very fundamental issues; to what extent is social justice a conscious consideration for key actors in the planning system and who or what are the barriers that prevent its delivery?

Through its pursuit of wealth creation the idea of place has come to dominate the planning landscape, often to the detriment of people. There is perhaps no better example of this than the revanchist tide that has washed over many of England's major city centers transforming them into shopping, leisure and entertainment destinations for out of town day trippers (Macleod, G 2002). In some cases these areas are within a stone's throw from several of the poorest and most deprived areas in the country. Furthermore, it is now approaching half a century since the Skeffington Report was published, providing evidence, if it were needed, that a clear disconnection between people and planning does exist (Ellis, H and Henderson, K. 2014).

Despite planning's changing relationship with people enforcement has remained the one area in which issues of social justice, equality and fairness, have been ever present. It is often the impact of unauthorised development upon a citizen's sense of well-being and their perceptions of justice that lead them to complain in the first instance. These concerns relate not only to the most basic and vital aspects of social justice but also the human condition. How enforcement has found itself in this space, however, is more through chance than design.

**3. The absence of control**

The reason for a robust enforcement regime can perhaps best be demonstrated by the story of the 'Plotlanders' movement. In the first four decades of the twentieth century a 'perfect storm' developed that led to a movement characterised by unauthorised development and driven by a quest for arcadia (Hardy, D and Ward, C. 1984).

The economic, social and environmental change witnessed in the run up to, during and after the First World War resulted in a growing quest for home ownership, and increased demand for housing post-war, and a demand for better quality housing. Transport enabled 'commuting' was also developing, as was the ability to 'escape' from the urban centres and working life on holidays and day-trips. In parallel, land ownership was becoming increasingly fragmented with the decline of Country Estates and the declining fortunes of farms. Importantly, all of this existed within a context of legislative weaknesses.

The manner in which this quest for arcadia manifested itself was in a series of unauthorised settlements which flowered mainly along the south and south east coast, and up the Thames Estuary. The name 'plotland' comes from the nature of the development activity; land, typically sold off by farmers and estates and of low quality, was purchased by speculators and resold on a plot by plot basis. These plotlands varied significantly in scale, quality, provision of infrastructure and degree of permanence but all had in common the fact that they were unauthorised. Despite strong opposition from some quarters of society to their existence, the fact was that legislation was weak and the ability of local authorities to remove these developments was limited.

It was only the advent of the Second World War and the subsequent post-war legislation that ultimately led to either the loss or consolidation of the plotlands and for some their evolution into legitimate settlements, albeit ones with a very unique character, appearance and ethos.

**4. Emergence and consolidation of an enforcement system**

Development such as the plotlands were wholly incompatible with the new plan led system of the post-war planning landscape. This new planning system included provisions to ensure that such developments could be controlled; the introduction of universal control made certain that all new 'development' would require permission. In addition, some legal powers existed to address unauthorised development that was undertaken although these were actually quite limited. The planning system that emerged was also designed to manage change through that system, rather than respond to changes that took place outside of it.

With regards to enforcement it was not until the 1990 Town and Country Planning Act that interest and recognition in its importance was truly ignited. That act established greater powers for local planning authorities to tackle unauthorised development and in doing so helped to raise the profile of enforcement. This was underscored by the publication of Planning Policy Guidance 18 in 1991, which among other things alerted LPAs to the consequences of failing to take appropriate action in cases where a harmful breach of planning control had been identified.

The noughties saw further and progressive change for enforcement. The emergence of spatial planning and the development management approach, courtesy of the Planning and Compulsory Purchase Act 2004, brought about a more holistic appreciation of the activity of planning. The development management approach particularly placed greater emphasis on the significance of project management skills and the desire to create a robust system and processes that would facilitate clarity, certainty, public and developer confidence, and deliverability (Shepherd, A. Britnell S. 2013). This succeeded in bringing enforcement into the centre ground of the planning discussion, due to its ability to assist the delivery of an end to end management of development.

In 2011 the Localism Act provided additional new powers for enforcement, including Enforcement Orders, to address issues of concealed breaches of planning control, and the ability for local planning authorities to refuse to consider planning applications for development against which an Enforcement Notice had already been served. These changes appeared to set the scene for a greater appreciation of enforcement, as a discipline in its own right, and within the delivery of a collaborative and solution orientated approach to development. However that has not materialised and the reasons for this may be found in the historic treatment of, and value placed upon, enforcement.

## 5. Still the 'Cinderella Service'?

In 2008 the Planning Advisory Service published "Case Study: A Stitch in Time", which highlighted the history of planning enforcement as a 'Cinderella service' that had not received adequate resources or attention. The report also pointed to the vital role that enforcement has in underpinning the whole planning system, within facilitating the development management approach and its positive impact on communities and the built environment.

That enforcement plays a vital role in the planning system cannot reasonably be disputed. It supports the entire system, including the policies and decisions made by local planning authorities. However, the economic and political climate of the past 5 years has already seen degradation in the role of the enforcement officer, as a planning professional, and the profile of enforcement as a professional activity. At some local planning authorities the enforcement service has been subsumed into a wider, generic enforcement team (Britnell, S et al 2014). While no doubt driven by essential financial considerations, these moves are threatening to undermine the positive changes that have been made in enforcement, specifically over the last decade.

The historic perception of enforcement, as a cost negative activity, is likely to play a key role in how local planning authorities choose to deliver planning services over the coming years. It is vital therefore that the success of enforcement is not measured on the balance sheet, but in terms of its ability to deliver social justice, and provide robust protection for the built and natural environment. There is a strong body of local, national and international evidence suggesting that social disturbance and environmental damage are realistic consequences of failing to properly manage development. Such circumstances have resulted in substandard living conditions and environments that fail to deliver social justice, from the extremes of illegal 'shanty towns' to the removal of a prominent and protected tree.

Perversely, it is the historic lack of interest and neglect of enforcement that now presents local planning authorities with the opportunity to deliver innovative and pro-active services. Paragraph 207 of the National Planning Policy Framework (NPPF), the only paragraph dedicated to enforcement, is less prescriptive in its requirements than it is of the forward planning and development management activities. This allows local planning authorities the chance to shape enforcement services in a way that is not afforded to the other planning disciplines. Critically, if local planning authorities can demonstrate the ability of enforcement to close the planning loop, by informing policy and facilitating an end to end approach to development, it may finally achieve parity with the much vaulted other members of the planning trinity.

## 6. The wider context

The current wider planning landscape is one of constant flux. While changes to regulations and policy affect all professionals within the planning system, it is the enforcement officer, always at the coal face, who is often the first to notice how they are played out on the ground. Keeping abreast of new policies, guidance and processes presents a huge professional and intellectual challenge. Failure to interpret and implement these matters correctly may lead to potentially expensive legal disputes, and could damage the profile of the planning department as a whole.

Despite the obvious challenges the changes imparted upon the planning system in recent years have been all too frequent and fragmented. While the NPPF initially promised consolidation, raising hopes of a period of much needed stability, the intervening years have seen a continuation, if not an acceleration, in changes. It is important to note also that these changes represent some of the most fundamental to the planning system in decades and have been implemented against the backdrop of austerity and biting local authority funding cuts. Not only have local planning authorities reduced staffing levels during this time but they will have also lost senior, experienced officers, who otherwise could have provided a steady hand through this period.

The changes to the General Permitted Development Order (GPDO) demonstrate the complexities of a scattered, incremental approach to regulation and policy. The GPDO now includes a number of new and complex procedures, including Prior Notifications, for issues as disparate as larger than normally permitted domestic extensions, to the conversion of agricultural buildings to residential dwellings. These permitted development rights are subject to a variety of convoluted and voluminous limitations and conditions, presented in a language and structure that is likely to be alien to all but seasoned planning professionals.

If the intention of amending the GPDO was to relieve pressure on local planning authorities, cut red tape and breathe confidence into the development sector, the recent changes appear to have done little to achieve this. They are only likely to result in precious local planning authority resources being expended in responding to queries, which if given concise and accessible regulations, there would simply be no need. Where development is carried out erroneously because of the difficulty in interpreting the regulations, it is likely to be the enforcement officer who is tasked with resolving any issues.

Changes have also been made to the Use Classes Order, the nature of which threatens to undermine the established plan led approach of the planning system, and the ability of local planning authorities to properly forward plan their areas. While Prior Approval processes attached to some permitted changes do provide local planning authorities with opportunities to consider, on limited grounds, the impacts of such development, the uncertainty over future uses is likely to impinge on the ability of authorities to robustly assess the future requirements of an area. Furthermore, local planning authorities who have already produced and adopted Core Strategies or Local Plans risk seeing years of meticulous planning undermined by these changes.

In addition to regulatory changes, the debate regarding devolution of political and economic powers to English cities, including mooted concessions over planning, is introducing a new dynamic that is yet to be played out. While this represents a clear synergy with the localism agenda and can only support the argument that decisions affecting local people should be made at the local level, any suggestion of further fragmentation of the planning system is a very real and fundamental concern.

**7. Conclusions**

The notion of the human condition is all but absent from the policies that guide the current planning system. Yet underlying key planning notions such as sustainability and place making is the fundamental experience of human existence. For enforcement, the historic view that it is the lesser activity in the planning trinity continues to cause damaging impacts to the profession. Still, addressing clear and harmful breaches of planning control resonates strongly with the notions of fairness and justice that sit behind the origins of the planning system. These issues present a dichotomy for the planning system, which is only likely to be resolved by a fundamental re-alignment that reconnects planning with citizens on a human level.

Changes to regulation, policy and processes continue at pace and the cacophony of constant upheaval in the planning system is threatening to undermine the recent advances in the profile and appreciation of enforcement. There is real concern that this hitherto forgotten service may once again be cast aside. It is vital in these circumstances that the voice of enforcement continues to be heard and that the drive for a progressive and innovative enforcement service is not lost in the noise.

Despite the warning signs the threat to enforcement services from the current political and economic climate has already been played out in some authorities; and with further potential cuts on the horizon, it is a scene set to be repeated over the coming years. Recent research (Britnell, S et al 2014) however, suggests that enforcement is not quite the financial burden it has always been perceived. Some local planning authorities point to the income generated through retrospective planning applications associated with enforcement cases and there does appear to be scope for charging for post-decision monitoring of planning permissions.

It is likely to be the case however that most enforcement services are run at a financial loss. Should that be true, it is a small price to pay for ensuring that the principles and operation of the entire planning system are protected.

While it is clearly hyperbole to suggest that enforcement alone can create a better society, its unique position within the planning regime does enable it to deliver social justice in a most direct and visible form. Furthermore, a planning system that dares to operate without a stable, robust and fully supported enforcement base runs the risk of facilitating both social and environmental harm. To avoid this, the planning system needs to refocus its meaning, from one primarily concerned with wealth creation to a return to the social visions of the original welfare reforms from which it emerged. And enforcement, for so long maligned, may just provide its vital starting point.

# When POPS Travels: The Transnational Transfer of Incentive Zoning Policy and Its Implementation in Taiwan

Hsiu-Tzu Chang[1], Chia-Hui Lo[2]

[1] Assistant Professor, Department of Urban Planning, National Cheng Kung University, hsiutzuchang@mail.ncku.edu.tw
[2] Master Candidate, Department of Urban Planning, National Cheng Kung University, sally5128369@gmail.com

Keywords: Incentive Zoning, Privately Owned Public Space, Open Space Provision

*POPS, as known for "Privately Owned Public Spaces", are amenity space built by private developers in exchange for additional floor area through incentive zoning ordinance. As part of 1961 New York City Zoning Resolution, their successes have drawn practitioners from local and aboard. In Taiwan, the concept of incentive zoning was first adopted in the capital city Taipei and later applied to all urbanized areas in Taiwan in 1984. Different from the original concept of "zoning" incentive with particular designated area in mind, the Taiwanese adaptation has been implemented as part of the building codes with site constraints only. What is the impact when the ordinance administered in the domain of building regulations rather than planning? Does the provision of open spaces serve in areas in need and who should hold accountable? These answers become fuzzy when the incentive zoning policy meets varying local conditions and morphological patterns. This paper takes Tainan City as a case study to examine the policy implementation in a historical yet less-densely built city. The POPS produced in lately 3 years are compiles from the building permit record system. To understand their spatial patterns at different scales, the distributions of POPS are identified in GIS and overplayed with existing socio-economic-physical variables. The types of open space, their patterns and use are examined through site visits and statistical analysis. This paper wishes to demonstrate the local adaptation of a transnational policy and develops a deeper understanding of its potential impacts.*

## 1. Introduction

In view of the demand of urban public space and the creation of open space by private sector, the first implementation of incentive zoning regulation began in New York City in 1961. In exchange for additional floor area, private developers can provide and maintain an amenity place for public use, which so-called Privately Owned Public Space (abbreviated as "POPS"). Incentive zoning add flexibility to the traditional rigid zoning regulations, and the provision of open space drawing practitioners from local and aboard.

In Taiwan, the concept of incentive zoning was first adopted in Taipei, the capital city, and later applied to all urbanized areas in Taiwan in 1984. Different from the original concept of "zoning" incentive with particular designated area in mind, the Taiwanese adaptation has been implemented as part of the building codes with the constraints of condition of sites only. What is the impact when the ordinance administered in the domain of building regulations than planning? Does the providing of open spaces in areas where the shortage happens and who should hold accountable? These answers become fuzzy when the incentive zoning policy meets varying local conditions and morphological patterns.

The problem of incentive regulation gradually happened (Shie, 2006). Due to the dispute about the openness of the POPS, residential area was excluded from the eligible application list in 1999 in

Taipei zoning regulations in consideration the difficulties of management. However, except for Taipei City, other cities in Taiwan still adopted in building code until now, in which condition of site is the main factor of the decision whether POPS bonus is applicable instead of planning. The doubts of benefits supplied by POPS still exist, and how its impact on urban open space is still unknown.

In the past, incentive regulations are mostly analysed in capital cities or big cities. For consideration the difference between the social and substantial environment, this research investigate the phenomenon in the secondary city—Tainan by using the building application information in past three years. To understand their spatial patterns at different scales, the distributions of POPS are identified in GIS and overlaid with existing substantial space map. By analysing the location and typology of POPS, this paper aims to demonstrate the local adaptation of a transnational policy and develops a deeper understanding of its potential impacts.

## 2. Institutionalisation of Market-oriented Policies in POPS

Since the 1970s, the globally interconnected crises of Keynesian Fordism and East Asian developmentalism have given rise to increasing neoliberalisation (Jessop, 2002). Neoliberal scholars claim that state should vigorously reduce authority, induce a shift to market-oriented economies (Brenner & Theodore, 2002). Neoliberalism emphasis on reinventing governance, and government must guide development and release authority. With globalization and the growing power of multinational enterprise, national government become gradually powerless to control the condition of economy and society, turning national development competition into urban or regional competition. Increasingly, urban policy in modern societies has a competitive character: It seeks to achieve the highest utility of socioeconomic progress and attract private capital investment. In a situation of devolution of nation-state administrative power, cities are bound to become more entrepreneurial, more market-oriented and more international with a view to participation in global networks (Nijkamp et al., 2002).

Influenced by liberalization and privatization of urban policy caused by the emergence of the neoliberalism, environment of urban political structure and governance mechanism is generally formed to being friendlier to developers and the alliance of real estate. However, these enterprise are profit-driven, causing urban growth coalition often trumps public-oriented planning actions. Neoliberalism brings conflicts and paradox of urban reconstruction, creating challenges of socioeconomic polarization, uneven geographical development and gentrification (Brenner et al. 2012, Jessop 2002, Pickvance 2012).

Public sector and private sector have already realized that both of them can't afford the responsibility of social operation by their own, wherefore to seek new cooperation relationship under the trend of neoliberalism (Wu, 1996). At the same time, due to fiscally strained of government and popularization of privatization, the public sector has to cooperate with the third-party to achieve public goals. The number of planning practices where collaboration models applied has rapidly increasing. In particular, public-private partnership solutions have become popular in the areas of infrastructure provision (for example, parking facilities), affordable housing constructions, and urban redevelopment and revitalisation projects.

Public-private partnerships (abbreviated as PPPs) become a popular strategy and rhetoric in the context of neoliberalism. PPP provide a unique perspective on the collaborative and network aspects of public management. PPPs can be defined as 'co-operation between public and private actors with a durable character in which actors develop mutual products and/or services and in which risk, costs, and benefits been shared' (Klijn and Teisman, 2003). PPPs put spirit of business management into

administrative system, making public sector more efficient, marketability, and entrepreneurial. It's not only a pure mutual relationship, but also a win-win game of integral resources. The essence of PPPs are privatization and economic decentralization, may result in the malady of local policies controlled by enterprise, causing private sector gain profit with cost put upon the citizens.

Policies are not physical objects that can be transferred with their content intact (McCann, 2011). Since neoliberal governance is improvisational and produces locally unique forms of urban governance wherever it takes hold, there is an identified need for informed case studies on how 'actually existing neoliberalism' is produced in situated settings (Brenner and Theodore, 2002) Evidence of neoliberalisation in Taiwan is increasing, ranging from relaxation of regulations on land supply and planning procedures to provide public goods by the private sector. We focus on examining how a series of 'keenly negotiating, processual, and space-mobilizing constructions' (Wilson, 2004: 780) have driven incentive zoning mechanism as a deregulated, market-based policy. The aim of this research is to discover whether quality of substantial amount of POPS achieve the original goals of the policy, and the adaptation of incentive zoning policy in Taiwanese practice through investigating its implementation in Tainan City.

## 3. Spatial Influence of the Policy

Floor area control, or floor area ratio (FAR) is part of the zoning regulations. The main purpose is to control the intensity and distribution of urban development, ensuring the quality of living environment and the provision of public facilities. However, due to rapid urban development and fiscal crisis of the local government, problems such as lacking of urban public facilities, difficulties of promoting public infrastructure, and low quality of public facilities is becoming more serious.

To solve the shortage of public services provided by the public sector, governments increasingly tend to improve the urban environment by public-private partnership mechanisms, where " incentive zoning" is one of the solutions for the shortage of open space provision in traditional "land use planning" (Yang, 2007). The mechanism of incentive zoning encourages private sector to provide open space in exchange with extra floor area space of their development projects.

### *3.1 Policy and the provision of POPS in the United States*

As the originator of incentive zoning regulations, New York City implemented open space bonus FAR policy in 1961. The program encouraged private developers to provide spaces for the public by allowing extra floor space in certain districts. In the New York City, the policy of POPS was influential to the cityscape, especially in the commercial districts. During the past five decades, the incentive mechanism of POPS has created 85 acres of public open space in the boroughs of Manhattan, Brooklyn and Queens (Schmidt et al., 2011). The open spaces provided by POPS in New York City are claimed to be beneficial and influential to citizens' daily life.

As part of 1961 New York City Zoning Resolution, their successes have drawn practitioners from local and aboard. With the extensive application of incentive zoning, many local governments realized that the mechanism has to consider comprehensively. To make the incentive policies complement one another in a city, local governments should quantify the goals of policies, ensuring the necessity of incentive, arrange the priority and making differences of inducement (Yang, 2007).

Using incentive mechanism without consideration of the overall effect will cause the zoning regulations be destroyed, resulting in the chaos of urban function and the disorder of real estate market, which used to happened in Seattle and Portland (Yang, 2007). Therefore, many local

governments in the United Stated set goals of each incentive mechanism, with the development location been decided and the standard of FAR bonus been designed purposely. The priority be reorganized based on the political target each year, and the total amount of incentive zoning will also be regulated. Government will rectify relative regulations regularly to ensure each policy reach the targets.

### *3.2 Policy and the public space in Japan*

Basically, the planning system in Japan followed that of the Western countries. These zoning regulations are used to deal with reconstruction after disasters, such as earthquake (Liu, 2009). Unlike the United State, incentive mechanism in POPS isn't only applicable in commercial districts, but also in residential and industrial area as well (Gao, 2001). Japanese POPS is implemented in two regulatory system: both zoning and building code regulations.

The urban population rapidly growth in the late 1950s, caused deterioration of urban environment, especially in commercial area. To prevent the further deterioration, Japanese government modified zoning regulation, setting a new zone where the density regulation is flexible. The FAR bonus will be implemented in this new zone if the open spaces created during development. Although this new regulation considerate the location of FAR bonus and surrounding area from the view of overall urban development, the decisions are practically made by governments, causing questioning of legitimacy due to the absence of public participation (Chen, 1995).

The further expansion of FAR bonus into the building code system was to stimulate the real estate market in Japan in 1970s. The Japanese government modified building codes in 1970, allowing development site exceed certain size to be eligible for gaining FAR bonus of the provision of open space, traffic and safety can be accommodated in the project. The incentive in the building code system has being adapted more often than zoning in Japan due to its greater flexibility. Yet the regulation broadens FAR only with limited site constraints, without considerations surrounding land use and capacity of public facilities. The provision of POPS were distributed unevenly and caused serious burden of public facilities in some areas (Chen, 1995).

.

### *3.3 Policy and the public space in Taiwan*

The planning and regulatory system in Taiwan was highly influence by Japan and the United States due to the colonial governance and post-World war II assistance respectively. Due to the colonial governance by Japan, Taiwanese incentive mechanism was at first significantly influenced by Japanese regulations, especially in the building code system. With the aid from the State during the post WWII, the planning system and zoning concept becomes the core of land use planning in Taiwan. Influence from both countries result in a hybrid-nature in the development control system in Taiwan. When a new policy is about to propose, we often see a strong tendency of looking after two country's models among scholars and officials to find a proper balance in between.

Taiwanese incentive mechanism was first implemented in Taipei City in 1983. As capital of Taiwan, urban planning in Taipei started in 19 century during the era of Japanese colonization. To coordinate the demand of urban construction and development, Taipei City first adopted FAR control in 1967, and then, to complement the shortcoming of zoning, the government introduced the mechanism of urban design deliberation and incentive zoning, aiming to improve the rigidity of zoning and to a create better urban environment. The initial goals of the policy adoption in Taipei City were as followed: encourage integration of site and overall development, provide urban public open space,

give flexibility of building design, promote disaster prevention function, and regenerate old downtowns etc..

Similar to that of Japan, incentive mechanism was first introduced in zoning regulations in 1983 in Taipei City and later integrated into part of the national building code in 1984. As part of the building codes, the FAR bonus is applicable to anywhere in every cities with restrictions of site area. The key restrictions of FAR bonus applicable site are street-width (greater than 8 meters) and minimum size of site (1,000 square meters in commercially-zoned area and 1,500 square for residential). According to the regulations, open spaces are specified as a space for pedestrian passage and leisure function for public at certain size. Type of open space includes 'pedestrian space' and 'plaza', where different incentive coefficients are given to calculate the extra FAR bonus gain from the open space provision.

The problem of the lack of management of incentive regulation has gradually emerged. Due to the social dispute about the accessibility of the POPS in the residential projects, 'residential zone' was excluded from the applicable list in 1999 in Taipei's zoning regulations (Shie, 2006). However, incentive mechanism of POPS still applied everywhere through building code system in other Taiwanese cities until now. As the result, the locations of the POPS are then determined by the site conditions and less concerned about the overall provision of public space to meet the planning and social goal. This pattern bring up our main questions of inquiry: What are the patterns of distribution of these POPS with the spatial constraints by building codes? Are these POPS located in the area in need?

## 4. Data and Methodology

This paper takes Tainan City as a case study to examine the policy implementation in a historical yet less-densely built city. The study area covers the developed centre of Tainan, consisting of East Dist., West Central Dist., North Dist., South Dist. and Anping Dist.. There are 53 building permit applications involved in POPS from May 2012 to March 2015 being analysed in this study. The data is compiled from the building permits issued by Department of Buildings Management of Tainan Public Works Bureau. This study synthesized and analysed the information of these 53 cases, including the administrative area, zoning, the developed merchandises, the type and area of POPS, quantity of FAR bonus and whether its applied TDR.

The empirical analyses are divided into two steps. We first mapped the 53 projects sites applied for POPS by geocoding each project and overlay with the figure-ground of existing city to see its geographic distribution. Second, we investigated the planned and current states of public open space in each district to compare their differences and to identify the districts in need of POPS in supplementing open space provision. By comparing the two we intend to identify if there is a spatial mismatched pattern in provision of POPS as a neoliberal policy. By these two steps of analysis, this study examines the preliminary effects of POPS policy in Tainan, Taiwan.

## 5. POPS Analysis—Empirical Study in Tainan City

### *5.1 The Distribution of POPS in Tainan*

There are a total of 53 projects applied for open space FAR bonus in the past three years, and in total account for a provision of 7.07 acres of new POPS in Tainan. Among these projects, 18 cases are located in Anping Dist., 13 cases in West Central Dist., 12 cases in South Dist. and the rest of them distributed in two other districts. As the number mentioned above, the area amount of POPS in Anping Dist. is the largest (2.33 acres), followed by South Dist. (1.96 acres) and West Central Dist.

(1.34 acres). The research measure the area of POPS in each cases, finding that the average area of area per case in East Dist. is the largest (2,252 square meters in each case), while the average area of POPS in North Dist. is the smallest (634 square meters in each case).

Table 1. Projects with provision of POPS in District in Tainan between 2012-2014

| Administrative district | population | Number of New Projects | Number of projects applied TDR | Area of POPS ($M^2$) | Average area of POPS per person ($M^2$) | FAR Bonus by POPS ($M^2$) | Potential increased residents by POPS floor bonus |
|---|---|---|---|---|---|---|---|
| West Central Dist. | 78,064 | 13 | 10 | 13,388.13 | 0.172 | 30,406.55 | 278 |
| North Dist. | 132,459 | 5 | 5 | 3,170.50 | 0.024 | 6,689.93 | 69 |
| Anping Dist. | 64,745 | 18 | 16 | 23,331.26 | 0.360 | 45,345.22 | 440 |
| East Dist. | 190,360 | 5 | 0 | 11,257.89 | 0.059 | 14,625.81 | 108 |
| South Dist. | 125,650 | 12 | 12 | 19,592.00 | 0.156 | 24,310.53 | 445 |
| Total | 591,278 | 53 | 43 | 70,739.78 | 0.154 | 121,378.04 | 1,340 |

The actual distribution of the POPS showed a much evident pattern as compared to the aggregated data presented by administrative district. In the figure below, we identified the spatial distributions of POPS in GIS and overlay it with figure ground map of Tainan. Most of the 53 POPS are located in or near the periphery of the cities where more vacant space available, instead of located in earlier developed area near the core of the city.

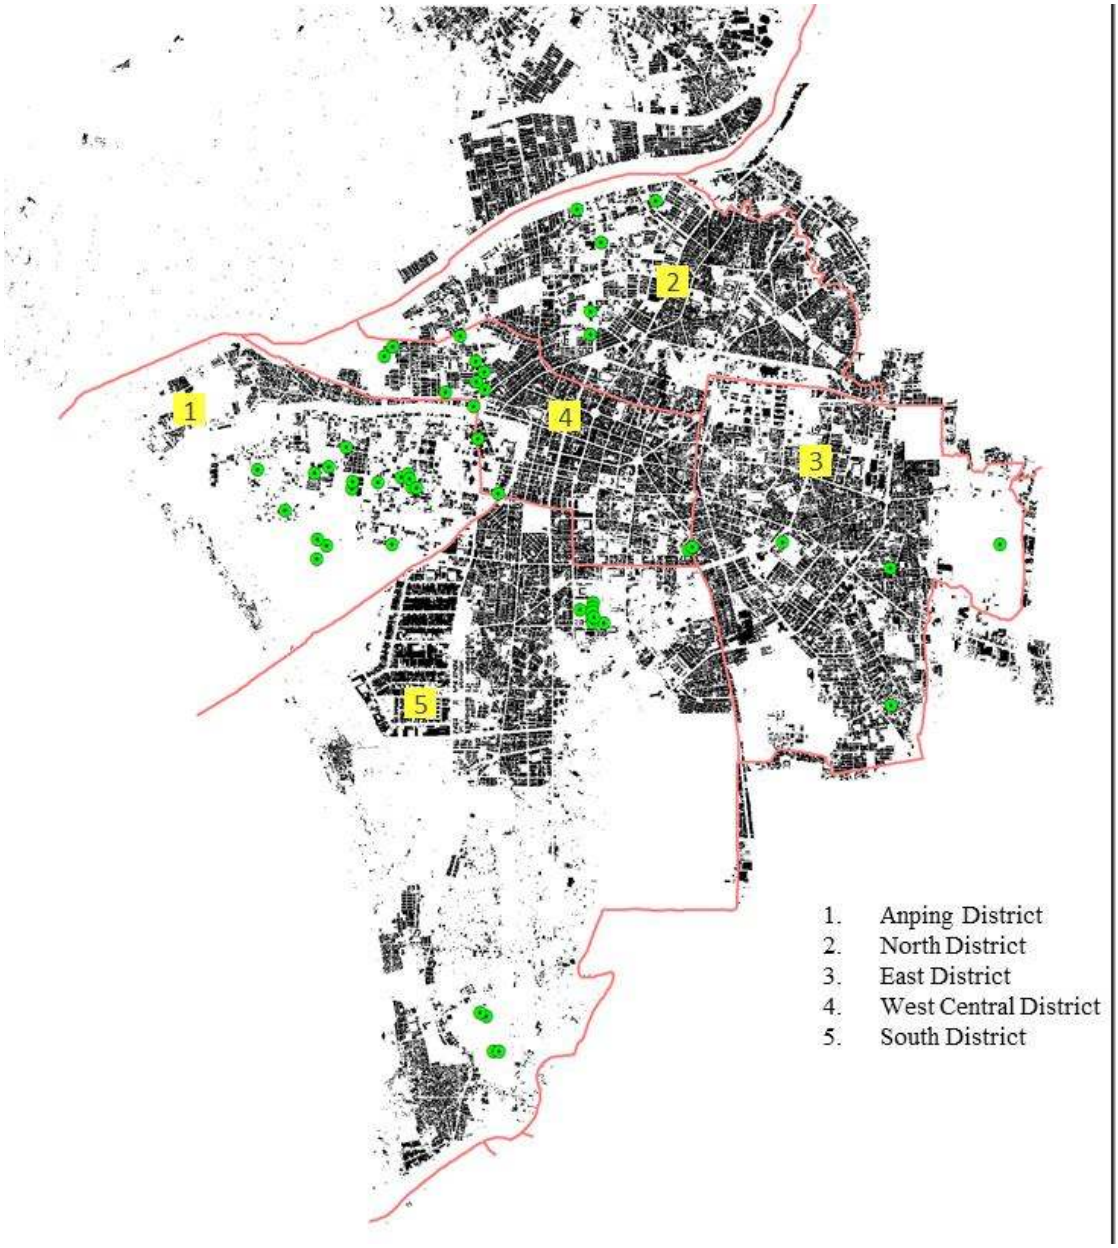

Figure 1. Location of Projects with Provision of POPS

We further analyse the distributions of POPS based on zoning and the primarily land use of each project. From the zoning perspective, more than 70% (39 cases) are located in residential zone and 30% are located in commercial zone. However, the publicness of POPS may differ by its primary land use. We examine the details and found out only 2 out of 51 cases are commercial properties (hotels). The rest are 25 mixed-use projects with residential plus ground commercials, and with the rest are purely-residential properties. The publicness of private-owned public space usually decreases from commercial to residential. In the case of Tainan, the POPS in commercial properties are less likely to be friendly or accessible for public with hotel uses. The one are more likely to open for public are those mixed-use projects, which account for only about 50% of the total POPS cases.

### *5.2 The mismatched of the provision of POPS and the Needed Area for Open Space*

As one of the oldest city in Taiwan, Tainan City was colonized by different nationalities (such as Dutch, China and Japan) since seventeen century. It used to be the center of colonial government, making itself transformed from undeveloped region into a city. With the construction of commercial harbour and the government buildings, West Central Dist. was developed earliest in Tainan City. With urban development and expansion of the city, areas such as East district, North Dist. South Dist. And Anping district have been incorporate as part of urban area from its earlier rural conditions.

The initial goal of the POPS is to improve the overall urban environment by provide public space for the area in need. To measure its effectiveness of POPS in Tainan, we further examine the allocation of existing public-owned public space. What we included in the open space calculation are park, green space, playground and plaza. We found out that the overall provision of open space in Tainan City is unevenly distributed and highly correlated with its history of development. Older area on average has less open space than newer area. Geographically, the amounts of urban open space provided in central district are less than other surrounding districts.

Viewing the average open space per resident in each district, the amount of service level of West Central Dist. is the lowest, followed by East Dist. and North Dist. The newest development areas, including Anping Dist. and South Dist., share the largest amount of open space per residents on average. The open space each resident shared in South Dist. (9.25 square meters per resident) is five times greater than in West Central Dist. (1.61 square meters per resident).

Table 2. Provision of Public-Owned Open Space by District in Tainan

| Administrative district | Population in prediction | Population in reality | Total area (acres) | Planned open space (acres) | Area of open space per resident (planned) ($m^2$/person) | area of open space per resident (current) ($m^2$/person) |
|---|---|---|---|---|---|---|
| West Central Dist. | 107,600 | 78,064 | 628.87 | 17.28 | 1.61 | 2.21 |
| North Dist. | 177,050 | 132,459 | 985.48 | 70.92 | 4.01 | 5.35 |
| Anping Dist. | 96,500 | 64,745 | 603.98 | 44.02 | 4.56 | 6.80 |
| East Dist. | 243,200 | 190,360 | 1,430.54 | 80.49 | 3.31 | 4.23 |
| South Dist. | 160,000 | 125,650 | 2,714.92 | 147.98 | 9.25 | 11.78 |
| Total | 784,350 | 591,278 | 6,363.79 | 360.69 | 4.60 | 6.10 |

If POPS play an important role for supplementing of public-owned open space, we should see the old center receive the largest amount of POPS. Comparing Table 1 and Table 2, it is evident that POPS in West Central District do not sufficiently supplement the lack of public space in this area. While Anping and South districts where the greater amount of open space on average are received also get more POPS on average than the city center.

### *5.3 The analyses and impact of POPS*

POPS does not take place in the right location and right property in Tainan. Due to the existing saturation of downtown, there are rarely large-area undeveloped site in West Central Dist. and East Dist.. Requirement of scale of site are in building code regulation is a possible key factor causing the

lacking of POPS in the right place. Urban fringe or other sites without land assembling issues are preferable sites for tall building development that applied for POPS incentive FAR bonus. In addition, these spaces are mostly privatized place for residential properties. Compare to the Capital City Taipei, the population density in Tainan is a lot less, about 1/10 of that in Taipei. The commercial developments primary take place on the street-level retails, with very little commercial real estate on office development. As the result, most of the tall building developers prefer residential properties because of its marketability in real estate market. Compare to the general application of other countries in commercial area and offices, whether the public benefits and accessibility of POPS are in line with the expectation may become an issue in the future study.

POPS are not free meal. Each comes in exchange of floor area space for additional development in each project. These 53 cases in total applied for about 121,000 square meters of bonus floor area for the open space it provided for public use. This extra space could accommodate at most extra 6,086 living units and 16,000 residents. In addition, the research also discovers that about 80% of these POPS cases are also the receiving site of transfer development rights (TDR). The total amount of extra FAR these projects applied is able to accommodate about 2,840 additional residents, adding about 17.5% more of new residential population that does not included in the land use planning. The additional residents come with the floor area bonus which may influence the carrying capacity and lower the service standard of public facilities in each district.

## 6. Conclusion

Policies are not physical objects that can be transferred with their content intact (Therdore, 2010), instead, imported policies are stripped down to their administrative or methodological 'essence' and then re-embedded into local contexts (Peck and Theodore, 2001: 435). Through the Taiwanese experience, the study discover that the regulations consisting of different spirits of the United States and colonial government make site condition become the main factor which decides whether incentive of open space is applicable. Practically, the locations where POPS happens are not the location where the demands are strongest, which disobey the original goals of the regulation, since the development location can't be decided by spatial planning and the public goods provided by market without management.

This situation of POPS in Tainan responding to the real exist neoliberal marketed-oriented public policy in cities. The observation is a powerful indicator that real estate capital fully exploits market-oriented POPS policy in pursuit of profit, causing provision of POPS didn't set in the demand location where the public services is difficult being provided by public sector. The development of POPS didn't reach the initial policy goal, which is providing urban open space in poor public service region and promote urban regeneration in old downtown by public-private partnership.

In conclusion, the incentive mechanism of POPS has been significantly diverted from its original utility as open space provision in commercial area in New York City. This research investigates the impact of locally adapted POPS in Taiwan, verifying that urban development under neoliberalism become more uneven, inhomogeneous and polarization. The neoliberal effects identified in our analysis contribute empirical depth to the scholarship on urban policy mobility, which remains theory and process-oriented.

# Transient and Informal: Negotiating Temporary Use in Portland, Chicago and Detroit

**Matthew F Gebhardt**[1]

[1] Assistant Professor of Urban Studies & Planning and Real Estate Development, Portland State University, mfg@pdx.edu

***Abstract***

*Using the framework of the Tragedy of the Anticommons and informality this paper explores how some actors have attempted to navigate the complicated tangle of intersecting and contradictory property rights and regulatory regimes in the US and ambiguous position of temporary uses within these spaces. Using this framework, three examples – food carts in Portland, Oregon, neighborhood markets in Chicago, Illinois, and pop-up shops in Detroit, Michigan – are used to highlight specific challenges faced in trying to negotiate informality and the complicated task of navigating local land use regulations, retail markets and political environments to successfully create viable activities that contribute to revitalization.*

*The paper demonstrates that temporary uses can be valuable contributors to revitalization and emphasizes the importance of for providing an avenue within planning for temporary uses. However, these cases also reveal some of the potential drawbacks of temporary uses including entrenchment of these uses frustrating attempts to develop permanent uses (Portland), cooptation of temporary uses crowding out small entrepreneurs (Chicago) and transition of temporary uses to permanent uses requiring substantial time and skill (Detroit). They also reinforce that the process of formalizing informal uses can be a new avenue for the exercise of power and the reallocation of resources.*

## 1. Introduction

Over the past ten years, there has been a growing interest in the potential for temporary uses as a flexible response to vacant lots and storefronts and a tool for encouraging revitalization. This paper attempts to expand understanding of the temporary uses by using the framework and literature of the Tragedy of the Anticommons and informality to explore how temporary uses have emerged as a potential solution to the tangled array of overlapping property rights and regulatory regimes that have limited the redevelopment, rehabilitation or reuse of underutilized properties.

This paper begins with an explanation of the concept of the anticommons and an analysis of underuse and stalled revitalization using this lens. Particular emphasis is placed on the underlying logic of US planning and regulatory regimes in both hindering the development of temporary uses and providing spaces for their creation. This framework is then used to examine how actors have attempted to navigate the ambiguous position of temporary uses within local planning regimes through the presentation of three examples: food carts in Portland, Oregon, pop-up retail in Chicago, Illinois, and pop-up shops in Detroit, Michigan. These examples are used to highlight specific challenges faced in trying to negotiate the complicated task of navigating local land use regulations, retail markets and political environments and informality to successfully create viable activities that contribute to revitalization.

## 2. The Tragedy of the Anticommons

The concept of the anticommons was developed by Michael Heller in 1998, building on a concept introduced by Frank Michelman in 1982. Conceptually, the Tragedy of the Anticommons was described as symmetrical tragedy to the Tragedy of the Commons. The Tragedy of the Commons scenario describes a situation where too many actors hold the right to use a particular resource and lack the right to exclude others with the same right from using that resource. Behaving rationally, each individual actor will maximize their use of the shared resource even if this results in overuse of the resource to the point of its destruction (Hardin 1968). Typically cited examples of tragedy of the commons scenarios are overgrazing, overfishing or climate change (Heller 2008). In contrast, an anticommons exists where every individual in a society has the right to exclude all others from the use of a given resource; that resource can only be used only with unanimous consent of all members of the society. As a result, the resource is prone to underuse, sometimes to the point of being unused altogether (Heller 1998).

As a thought experiment, the Tragedy of the Anticommons was fascinating, but not terribly useful as it was nearly impossible to identify a real-world example of this type of anticommons. Building off this initial concept, Heller (1998, 2008) elaborated a situation where not everyone, but instead a limited number of actors possess the right of exclusion. In effect, no actors have privilege of use, each actor requires the cooperation or permission of others to use the resource. Using the case of post-Communist Russia, Heller used the anticommons to explain the proliferation of both empty storefronts and informal street kiosks. In this case, four main actors possessed overlapping rights to commercial storefronts: owners, users, investors and regulators. Without the cooperation of each actor, the storefront would remain empty. In contrast, operating an informal street kiosk was comparatively simple as it only required the assent of only two actors (Heller 1998).

Heller's original (1998) and more recent (2008, 2013) analysis of the problem of anticommons has focused primarily on property rights, that "wasteful underuse can arise when ownership rights and regulatory controls are too fragmented" (Heller 2013, 10). Others have emphasized the problem of coordinating and assembling those rights (Schulz, Parisi, and Depoorter 2003, Fennell 2009). Fennell (2009) describes the anticommons as being primarily a problem of assembly. Assembling the fragmentary rights held by different actors into a single whole requires incurring transaction costs (often

from simply finding out with whom one must negotiate) and overcoming strategic holdout behavior. The more actors that are involved in this process, the more difficult it becomes as "misreadings and miscalculations become more likely…and mundane transaction costs associated with identifying and communicating with the other parties rise as well" (Fennell 2009, 14).

## 3. Anticommons, Planning and Real Estate Development

The literature on the anticommons suggests, and I argue here, that real estate development is particularly vulnerable to this dilemma as it is more prevalent in situations where vertical exclusionary rights exist, where there are few substitute goods, where projection of future value is difficult and where goods are "lumpy" (Schulz, Parisi, and Depoorter 2003, Fennell 2009). Each of these is present in real estate development. Real estate development in the US often requires navigating multiple layers of hierarchical, sequential review and permitting often involving multiple levels of government, increasing transaction costs and coordination difficulties. As each individual property is essentially unique and the exact same building on a different parcel is not a perfect substitute, real estate is particularly prone to strategic holdout behavior.[2] Real estate typically has a very long usable life compared to other goods, potentially lasting through multiple economic cycles and multiple changes in consumer preference making miscalculations of its most efficient use and potential value more likely. Finally, while certain financial instruments can spread the return on a real estate development out over a longer period of time, real estate development is inherently lumpy, potentially increasing holdout behavior.

My argument here is that, while Heller's example was of post-Communist Russia, the situation occurring in many US cities with regard to redevelopment can be described as an anticommons scenario. The abundance of vacant lots, abandoned buildings and empty storefronts in some locations may not be simply the result of a lack of market demand for goods, services or real estate. Instead, an anticommons exists where the participation of too many actors is necessary to successfully redevelop, reuse or revitalize these properties. Property owners and government regulators both have direct rights to exclude, while financiers and users may possess actual or defacto rights of exclusion. "Strategic" positioning by these actors and high transaction costs associated with assembling their cooperation may prove too substantial a barrier. This argument is implicit in much of the literature on temporary uses that advocates using temporary uses where permanent development is infeasible or "the realisation of the future function is delayed for various possible reasons, including planning processes, financial complications or unexpected technical issues" (De Smet 2013, 2).

As with Heller's original case, the successful execution of a real estate redevelopment in the US typically requires the cooperation of property owners, investors, regulators and users. The interests and behavior of each can impede redevelopment. Property owners will seek to maximize the rent they can extract from a property. In doing so, they may misread the market, overvaluing their property and/or setting rents too high for users, particularly new, start-up businesses. Based on these assumptions, they may choose to hold out with the hope that they will eventually be able to secure their asking price/rent. This problem was particularly pronounced during the recent Great Recession when many property owners retained unrealistic expectations about their properties based on the previous market. Property owners may also be constrained in their ability to vary their expectations by equity partners or an existing mortgage that requires a specific return. In many cases the desire to bring in a tenant to glean some rent was overridden by the need to generate a specific net operating income and a fear of extending a long-term lease cutting off the ability to sign a more lucrative tenant.

[2] This is essentially the argument made to support the use of eminent domain to facilitate redevelopment in the US, a practice most recently upheld by the US Supreme Court in 2006 in *Kelo v. City of New London*.

While they are not always involved, most redevelopment projects in the US require the participation of lenders and/or equity partners, giving them real or defacto rights of exclusion. Lenders and equity partners will demand certain benchmarks be met in order to extend financing, benchmarks that may be difficult to meet in redevelopment projects, particularly those in weak markets. Lenders or equity partners may also be most familiar with specific markets and/or product types and less willing to extend financing to projects outside their ken. Adding to the level of difficulty, lending standards in the US tightened during the Great Recession and individual lenders judgment about the suitability of a project was restricted, making it more difficult to undertake a redevelopment of a vacant site or renovation of an outmoded space. Lenders are also often involved in financing the users of redevelopment sites. New, start-up businesses may be seeking to enter a new market unfamiliar to lenders and may lack the proven track record to secure the necessary financing to start their business. In both cases, the transaction costs associated with identify, negotiating and securing financing may be prohibitive.

Users may also possess real or defacto rights of exclusion. They may demand certain types of spaces or they may only be capable of paying only a certain level of rent. These may not match those required by the property owner. Users may also have long-term leases that afford them veto power over redevelopment proposals. Users without leases might also make claims on the space, citing squatters rights or using popular appeals to support their claims.

Planners and regulators can also complicate the ability to quickly or easily revitalize vacant space. Regulations including zoning and building codes are designed to promote order and efficiency and to protect health and safety. Obtaining approval to redevelop or rehabilitate a property involves processing fees, document requirements, staff reviews and on-site inspections which can impose substantial transaction costs. In simple cases, it may only be necessary to seek a Certificate of Occupancy verifying a user is allowed to occupy a space. However, redevelopment of a site, substantial renovations or tenant improvements, or a change in use[3] can trigger a more comprehensive review. As previously mentioned, the approval process is often multi-layered with applicants needing to satisfy multiple regulators reviewing the proposals compliance typically in sequence (i.e., zoning approval is required before seeking building approval). In many cases, additional reviews such as environmental reviews are required or public incentives are sought which may involve interaction with an additional level of government or quasi-governmental agency. In many cases, the specific actors within these agencies tasked with reviewing proposals do not have the authority to deviate from the specific standards set forth in plans and codes. Finally, plans and regulations in the US tend to focus on the long-term use of a site. These long-term projections can lead to miscalculations or disagreements about the most efficient or equitable use resulting in holdout behavior.

## 4. Anticommons, Informality, and Temporary Use

The role of plans and regulations in creating an anticommons situation bears additional exploration, particularly as it relates to temporary uses. The literature on temporary uses includes extensive discussions of how these uses can provide solutions to many of the problems presented above. Temporary retail can allow both businesses and property owners to test the viability of the relationship. It provides the property owner with cash flow from a vacant property or storefront without having to invest in significant tenant improvements or impede the opportunity to secure a more lucrative permanent user. It allows the business owner the opportunity to demonstrate the market for the business

[3] Change in use reviews are required for changes from one use class to another such as from office to retail, but may also be triggered by changes within a category if the uses are not considered sufficiently similar. For example, a change in use review would not be required for a change from a millinery to a flower shop, but would be for a change from a bank to a boutique or from retail to restaurant.

to justify sales forecasts and lending requests. Filling vacant spaces can also help create a brand and image for a neighborhood and build community, building a market for businesses and raising property values. They can temporarily activate a space and create visible changes in an underutilized building, lot or block while increase foot traffic and eyes on the street, increasing perceptions of safety (Temel and Hydn 2006, Overmeyer 2007, Oswalt, Overmeyer, and Misselwitz 2009, Blumner 2006). In essence, temporary uses temporarily resolve an anticommons by providing incentives to avoid strategic holdout behavior (e.g., property owners holding out for the most lucrative user) and reducing transaction costs (e.g., legal costs associated with lease negotiations).

Conversely, public sector plans and regulations and bureaucratic inflexibility in applying these regulations are often cited as being as much an impediment to temporary uses as permanent. One group advocating for more temporary and interim uses in Cleveland acknowledges that actors might find it simpler to act illegally than to try to conform to plans and codes, encouraging actors to "do your best to follow all the rules and keep everything by the book, but you make compromises and take short-cuts when absolutely necessary" (Pop Up City 2014, 1). It is not surprising that public sector regulation would prove to be the key veto preventing temporary uses as in using this to address an anticommons, public sector actors face an awkward problem. While there certainly are benefits to the public sector from allowing temporary uses, doing so undermines a fundamental justification for the plans and codes they are enforcing.

The most common types of plans and regulations governing real estate development in the US, comprehensive plans, zoning ordinances and building codes, are all predicated on identifying long-term, permanent uses for sites. Comprehensive plans present a community's vision of where their town will be and what it will look like 20, 30 or even 50 years in the future. The long-term nature of these plans serves several purposes. First, comprehensive plans are intended to provide a guide for capital improvements expenditures. The long time frame of these plans is intended to better match the time horizons for large capital improvement projects and to insure that capital expenditures are made in a way that best supports future growth. Second, it provides a guide for property owners, investors, business and residents on intended future growth allowing them to calibrate their own plans and investments to match. Zoning ordinances, like the plans on which they are (usually) based, present a snapshot of the pattern of permanent uses that are desired, or at least acceptable. Both also represent significant built consensus. Building codes are also designed around insuring the safety of permanent buildings and improvements.

When temporary or transient uses are addressed, the regulations governing them are more often than not designed to discourage or prevent these activities as undesirable impediments to reaching the desired end state. Many zoning codes contain no specific protocols for temporary uses. Others contain provisions only for specific temporary uses such as construction staging areas or seasonal Christmas tree sales. And when addressed, local codes, as Portland's Zoning Code does, will often explicitly state that temporary uses have "no inherent rights within the zone in which they locate" (Portland Zoning Code 2012, 296-1).

The problem facing public sector regulators is that public sector plans and regulations are not intended to promote temporary uses or facilitate immediate, flexible responses to changes in demand. Rather, they are to provide certainty. Allowing alternative uses of sites, even temporarily, undermines one of the most important bases upon which the plans and regulations are built. Comprehensive plans and zoning ordinances are inflexible and, unless regularly monitored and updated, largely static instruments that are not responsive to short-term changes. Yet part of their strength comes precisely from this lack of flexibility. Early arguments in favor of zoning made this case explicitly,

> "With a city entirely zoned, they [realtors] could assure purchasers of residential property that their neighborhoods would never be encroached upon by business, while on the other hand, zoning would give business property a touch of monopoly value. Accordingly the signs went up on vacant lots: "zoned for business," or "zoned for apartments," with the definite implication that such action on the part of the public authorities had resulted in giving the property a higher and more assured value than it would otherwise have"

Changing plans or regulations or granting exceptions too often would undermine this confidence and devalue the consensus represented by a plan. Returning to the anticommons framework, planners and regulators have a very strong incentive to engage in strategic holdout behavior and not encourage temporary or long-term uses that deviate from the agreed to permanent use.

This dilemma may explain why observers of temporary uses have noted a tendency for temporary uses to seek out informal spaces and solutions. While some temporary uses have engaged in illegal activities, many have sought out the "spaces of exception" created by regulatory regimes (Roy 2005, Porter 2011). A widely cited example of this is Park(ing) Day where groups pay parking meters and then temporarily turn the parking spaces into miniature parks. While turning a parking space into a park is not strictly permitted, neither is it specifically prohibited. The silence of most plans and zoning ordinances on temporary uses creates an opportunity (and challenge) by situating them in an ambiguous position. They are not the permanent uses formally allowed to exist, but they are not specifically excluded either. Rather, they are informal uses that exist outside the bounds of, or within the unregulated spaces created by, the normal planning regime.

Many temporary uses exist, at least initially, in these informal spaces. This position is often seen as a challenge requiring revision to local plans and policies to formalize. Formalization of these informal uses is typically dictated by powerful interests (Gebhardt 2013). Returning to Heller (1998, 641),

> "existing rights-holders, including local government agencies and the private actors who have invested in reliance on the current property regime, may cling tenaciously to their rights. Many now have plausible claims that their rights have vested, and redefining rights to bundle them more sensibly would amount to a compensable taking of their property."

The tendency toward informality also appears in the solutions that have been devised and advocated to respond to the constraints imposed by planning and regulatory regimes. Rather than deviations from existing plans and regulations, solutions focus on lowering transaction costs through informal activities and policies such as dedicated staff to provide technical support and facilitate permit applications, permitting and licensing templates, site inventories of spaces for temporary use, and informal coordination across government departments and agencies (Blumner 2006, Overmeyer 2007, Haydn and Temel 2006).

## 5. Case Studies

The following section presents three case studies that each highlight an aspect of temporary uses and their relationship to the anticommons and informality. The first case, food carts in Portland, Oregon, examines the ambiguous and informal space often occupied by temporary uses and the ways in which allowing these uses can lead to their entrenchment. The second case, pop-up retail in Chicago, Illinois, discusses the potential role of large institutional actors in facilitating temporary uses and the ramifications of introducing these actors as an intermediary. The last case, pop-up retail in Detroit, Michigan, explores the emergence of an active program to use temporary uses to revitalize neighborhood commercial districts and the difficulties of translating between the temporary and the permanent.

### *5.1 Food Carts in Portland, Oregon*

Unlike many cities, Portland has long allowed street vending and street food. Hot dog carts, catering trucks and coffee carts were fairly common activities by the mid-1990s. All foodservice businesses in Portland were and are regulated by the Multnomah County Environmental Health Department. Food carts must obtain a license from this department and are subject to semi-annual inspections. Up until 1997, mobile food vendors were not allowed to prepare food on-board. Instead, food had to be prepared at a commissary to which the mobile unit had to return every evening. Rule changes in 1997 allowed food to be prepared on-board and units to remain parked in a single location provided they remained capable of moving. These changes, and the relatively low cost of obtaining a license, facilitated growth in licensed mobile food vendors in the County from under 100 in 1997 to over 300 in 2000 and nearly 800 in 2013 (Multnomah County Health Department 2014).

While these rule changes allowed more freedom for food carts to operate, they initially occupied a legally ambiguous state under City of Portland codes. Food carts operating in the public right-of-way are regulated by the Portland Bureau of Transportation and are subject to elaborate and detailed rules regarding location, design, and hours of operation (Portland Municipal Code Section 17.26). However, no such regulations existed to govern food carts operating on private property. These food carts occupied an informal space left by the regulatory regime as they were neither explicitly allowed, nor explicitly prohibited by Portland's codes or regulations.

Interest in food carts swelled during the Great Recession amongst both entrepreneurs (many of whom had lost and/or were unable to find employment) looking to start an inexpensive business and property owners searching for a way to secure some return on underused property. This growing interest put pressure on the city planners to develop a formal approach for regulating the operation of food carts on private property. Rather than create a new ordinance and set of regulations, city planners chose to reinterpret existing code. Food carts would be allowed to operate on private property in non-residential zones. As long as they were less than 16 feet in length and had a working axle and wheels allowing them to be moved at any point, they were considered commercial vehicles and were exempt from most zoning and building codes. Food carts could not have any permanent structures – awnings or canopies could not touch the ground – and had to be fully self-contained – they could not have plumbing facilities. Carts with electrical service needed to pass an electrical inspection and were allowed a single A-board sign that needed to be approved under the sign ordinance (signs on the carts themselves were exempt) (City of Portland 2014). In addition, these policies are generally enforced on a complaint basis meaning that, if no one complains about an infraction such as the addition of permanent structures to a food cart, the City will generally overlook them.

As a result of the regulatory regime adopted by the city, Portland's food carts have clustered into food cart pods on private parcels throughout the city. This spatial arrangement is quite different from other major US cities and has contributed to the positive regard. Portland's food carts are now widely known for creating highly eclectic environments both aesthetically and gastronomically. Low barriers to entry are touted for allowing small entrepreneurs entry into the market and for encouraging experimentation. Portland's food cart pods each have their own identity which is often associated with the neighborhood within which they reside. Downtown pods typically lack amenities, while many neighborhood pods have tents, seating and restrooms. The pods have created activity on numerous formerly vacant lots or along the edges of parking lots[4]. While estimates of the total impact vary, food carts have also had a positive effect on tourism.

[4] This is enhanced by Portland's general walkability. Portland's city blocks measure 200 feet by 200 feet, approximately one-quarter the size of a block in most other US cities.

The development of food cart pods on private property has allowed the development of a unique food cart culture marked by diversity and longevity. While the long-term, stationary nature of Portland's food carts is an important element of their success, this has also resulted in the entrenchment of these temporary uses. Portland's real estate market has recovered from the Great Recession and there is significant demand for land for development.[5] Over the last year development proposals were announced for two long-running food cart pods. The resulting outpouring of support led to the rescinding of one of the proposals. The property owner of a third pod received an unsolicited bid for his property, but rejected it in favor of keeping the food cart pod. One of the first and best-known of these pods is located on a prominent parking lot near the center of downtown. While this parking lot has long been identified as a prime development site and falls within an area with the most permissive zoning in the city, the owner of the parking lot has expressed no interest in developing it further. The guaranteed return from the food carts and the potential negative reaction to the carts removal outweighs any potential return from a new development.

### *5.2 Pop-Up Retail in Chicago*

The Hyde Park neighborhood of Chicago has long been regarded as an island of relative affluence amongst a sea of poverty. Located on the south side of Chicago in the heart of what used to be known as the black belt (Burgess 1925), the neighborhood is home to two large institutions, the University of Chicago and the Museum of Science and Industry, and managed to retain a strong black middle class presence while surrounding neighborhoods did not. However, despite a potentially strong retail market, the neighborhood experienced a long period of commercial decline. Redevelopment under Urban Renewal altered the fabric of some commercial streets and perceptions of the south side as a poor retail market were applied to Hyde Park uncritically. Thus, while there was a market for retail development in the neighborhood, up until very recently, it has been largely underserved resulting in considerable leakage as residents and workers left to shop in other neighborhoods (South East Chicago Commission 2000).

In 2000, the City of Chicago and the University of Chicago began working together to address the dearth of commercial development. Targeting 53rd Street, an historic commercial street, the produced a revitalization plan and designated the area a tax increment financing (TIF) district with the vision of creating "a cohesive and vibrant mixed-use commercial district that provides a comprehensive range of commercial and retail uses" (City of Chicago 2001, 1). The plans called for working to expand and improve existing businesses, create an identity for the area, and address the need for parking and access. The City and University held multiple visioning sessions between 2007 and 2009 and conducted a survey of the University student body to determine the type of retail development desired.

Representatives of the University have been vocal about their interest in revitalizing the street to enhance "the quality of life for students and faculty who are used to the kinds of amenities you find in places like New York, Boston and Palo Alto" (Sharoff 2012). As a result, the University played a key role in implementing the plan by aggressively acquiring property along 53rd Street including the former Harper Theatre in 2002 and Harper Court shopping center[6] in 2008. These properties were redeveloped into a 600,000 square foot mixed-use project completed in 2013 that was intended to serve as a catalyst to

[5] The development of infill sites in Portland is strongly encouraged by the city and regional planning frameworks and the urban growth boundary that restricts the supply of ready greenfield sites.

[6] Harper Court shopping center was initially developed as a relocation site for small, neighborhood businesses displaced by Urban Renewal. It was largely financed by the University of Chicago and Archdiocese of Chicago and featured subsidized rents.

drive revitalization. The retail space in this project has largely been filled with regional and national chains, but rents have been too high for small retailers (Urban Land Institute 2012, Cholke 2013).

In addition to the Harper Court redevelopment project, the University has also purchased or negotiated long-term master leases for many of the other buildings along 53rd Street. Many of the previous tenants have been relocated or not had their lease renewed (Cholke 2013). The University has used these retail spaces to temporarily bring apparel, home goods and toy stores to the commercial district as pop-up shops. The stated reasons for using pop-up shops are to allow small retailers to test their concepts in the neighborhood and to provide local residents a wider variety of choices. It is also explicitly aimed at A a consistent issue identified through a variety of reports, analyses and meetings that few retailers have been willing to be pioneers where there is limited familiarity with the customer base. The pop-up shops serve to demonstrate a market for the types of retailers that had been identified as both retail types missing from the neighborhood and those that are difficult to attract (Sharoff 2012).

Currently, the third set of pop-up stores is finishing their run. The University closely screens and recruits the retailers that operate the pop-up shops. All of the pop-ups selected by the University are small retailers that have already had success in other neighborhoods in Chicago. In addition to identifying and recruiting the pop-up retailers, the University also provides funds to set up the space, covers insurance for the space and facilitates all necessary approvals. All three of the current group of retailers already operate successful stores in affluent north side neighborhoods. Thus far, the pop-up stores have been successful with operators stating that it was a "perfect way to get my feet wet" and "great because you can kind of test the waters" (Bishku-Aykul 2014). One of the pop-up retailers has transitioned to permanent businesses in the neighborhood (closing their existing shop on the north side), and another expressed interest but was unable to break their current lease (Cholke 2014). The pop-up retailers also help fulfill the University's commitments to both the neighborhood and the City that they made as part of securing development approvals to bring in local businesses that serve the neighborhood residents as well as the University community.

### *5.3 Pop-up Retail in Detroit, MI*

Pop-up retail has become popular in Detroit over the past several years as a potential solution for few proven markets, shrinking market base, and high retail vacancy rates. Temporary retail uses have emerged as a way to demonstrate market demand, increase vitality, create an identity and cultivate entrepreneurs.

A variety of neighborhood actors have worked as facilitators of temporary retail including business improvement districts, neighborhood organizations, and community development corporations focused on commercial development. In addition, a program citywide program called REVOLVE has been started by the Detroit Economic Growth Corporation, an organization working to promote neighborhood economic development. This program is specifically aimed at using temporary, pop-up spaces to recruit new businesses, encourage public and private investment, and change the image and narrative of neighborhood business districts (Revolve Detroit 2014, 9). They recruit, vet and link potential businesses and properties in target neighborhoods. They assist start-up businesses with training, support and funding. They provide a checklist for potential pop-up businesses that explicitly identifies costs and processing times for required tasks including business licensing, permitting and lease negotiations (Revolve Detroit 2014, 27-30). Also provided is contact information for permitting, insurance and equipment rentals as well as sample lease agreements.

One example of the use of pop-up retail spaces is the Chalmers Square redevelopment in the Jefferson-Chalmers retail district near the boundary of Detroit and Gross Pointe. Chalmers Square was a

redevelopment project that renovated three vacant, historic buildings into a mixed-use building with 47 affordable apartments and 17,000 square feet of retail space. The project was put together over a ten year period by the local business association who facilitated transfer of buildings from City ownership to the private developer and completion of Phase 1 site assessment. While the residential units were absorbed fairly quickly, the retail component did not (Jefferson East Business Association 2013).

The Jefferson East Business Association, working with the property owner and the American Institute of Architects, developed a plan to open the spaces for pop-up retail. Seven pop-up retailers were recruited to fill the five storefronts to operate on a temporary basis during the annual Jazz on Jefferson music festival. The event was dubbed June on Jefferson and ran through June and July 2013 (Clark 2014).

One of the pop-up retailers that operated during the event chose to transition from a temporary to permanent use. The Coffee and (_) shop selling coffee and whatever baked goods the owner felt like making that day. The site lacked kitchen facilities. The owner baked the goods at a separate location and brought them to the shop. The shop attracted a strong neighborhood following, but closed at the end of its pre-determined temporary run. After a short hiatus, the owner decided to attempt to open a permanent business in the temporary location and was allowed to reopen her temporary business while undertaking the necessary work to prepare the space and acquire the necessary approvals (Trudeau 2013).

Despite having support of the Business Association and a cooperative City staff, the process has lasted over a year. Initially, the City was going to force her to close the shop while she pursued her permanent Certificate of Occupancy at the expiration of the Temporary Certificate of Occupancy. After the intervention of the Business Association, she was able to stay open during the process (with only a brief closure to finish construction). It took months of work to comply with historic preservation, building and sign permit requirements (Trudeau 2013, Trudeau 2014, and Revolve Detroit 2014).

Revolve Detroit uses this case as an example of the difficulties of transitioning from temporary to permanent use. The lessons learned from this particular case are instructive. They note the significant difference between planning for and executing a temporary use and a permanent use. Additional due diligence is necessary to understand the existing space and what level of investment and approval will be necessary to maintain a permanent business in that location (Revolve Detroit 2014). Designing, financing and building a permanent space requires knowledge and expertise well above that needed to cobble together a temporary space. Interior space, fixtures, furniture, and signage that might have previously been borrowed or rented, one of the hallmarks of temporary uses, must now be bought or built. Permits for permanent uses are considerably more expensive than those for temporary uses. The level of scrutiny applied to permanent uses by the local authority is also much higher. Permanent uses must meet all city codes including zoning, structural, mechanical, plumbing, and electrical.

While temporary uses may be allowed to operate in spaces not intended for that type of use (for example, the coffee shop occupying a retail space without a kitchen), permanent uses may not. Changes in use, even those that may not require a zoning amendment such as a change from a retail to a restaurant use, may trigger an additional review resulting in added time and cost. Even without a change in use, becoming permanent will require obtaining a Certificate of Occupancy. Technical assistance on a variety of subjects including business operations, access to capital, legal assistance and local authority approvals are very often necessary to insure a successful transition from temporary to permanent. Lease negotiations can also be time consuming and complicated.

## 6. Conclusions

In the case of food carts in Portland, food cart operators were able to identify and occupy an informal space within the regulatory regime by locating their carts on private property. Supportive property owners and politicians provided space for planners in Portland to formalize this arrangement by permissive interpretation of existing ordinances and codes, navigating a narrow path between upholding existing plans and codes while facilitating the temporary use of vacant lots and parking lots. While this maneuver is widely regarded as successful, as Portland's food cart pods have gained local and international acclaim, they have also become deeply entrenched. The strong claim asserted by the food cart operators to the sites they now occupy has created a new anticommons, albeit one that might not be particularly tragic. However, it does serve as a cautionary note.

The Chicago pop-up retail establishments demonstrate the potential value provided by temporary uses for efforts to revitalize struggling commercial districts. The temporary uses in this case were employed in conjunction with a broad revitalization strategy that also included a large, catalytic redevelopment project. They filled an important role in this larger strategy by providing space for small businesses and for recruiting specific types of retail businesses identified as lacking in the neighborhood, satisfying neighborhood resident demands. The pop-up shops served as a demonstration of the potential of the market to support these types of businesses. In this case, the anticommons was overcome by a single, powerful actor, the University of Chicago, absorbing the transaction costs and using its power to assemble the necessary rights. A hefty endowment and strong bond rating rendered investor veto meaningless and deep ties with the City eased permitting issues. However, in doing so, it displaced existing local businesses that were deemed less desirable. This type of cooptation of temporary uses to serve the needs of powerful actors does not fit easily into the narrative that is often told about temporary uses. Yet with the growing popularity of temporary uses, it would not be surprising to see this strategy adopted more widely.

Finally, the Detroit case vividly illustrates the use of temporary use to activate vacant retail space and reads like an example of best practice. Part of a larger citywide effort to use pop-up retail to attract small entrepreneurs and investors to struggling commercial districts, the June on Jefferson event achieved multiple ends. It filled Chalmers Square's empty retail spaces temporarily providing the property owner with a short term return and the business operators with an opportunity to test the market and their concepts. The event also raised the profile of the commercial district citywide. The process was facilitated by a citywide non-profit and a neighborhood business association working with a receptive city government which lowered the transaction costs for the actors involved. The event also resulted in a best case scenario with one of the pop-up retailers deciding to transition to a permanent use. However, the process of transitioning was very difficult with the regulatory regime creating particularly significant barriers. The transition took much longer and was much more costly than anticipated. This demonstrates that, while temporary uses may provide a short-term solution to an anticommons, they do not necessarily resolve it.

The three cases presented above further illustrate that temporary uses may be valuable contributors to revitalization and emphasizes the importance of for providing an avenue within planning for temporary uses. They demonstrate the ability of temporary uses to provide a short-term solution to the anticommons. However, these cases also reveal some of the potential drawbacks of temporary uses including entrenchment, cooptation and transition. All three cases illuminate the role that powerful actors can and do play in sanctioning and enabling temporary uses.

# The integration types of agricultural space in urban community scale: The case study of Hamburg, Germany

Qiao HUANG [1]
[1] Bauhaus University, Weimar, Germany / Tongji University, Shanghai, China
evelineqq0224@gmail.com

**Keywords:** Urban agriculture, special integration model, Hamburg

*Faced with agriculture recession, food crisis and a series of environmental problems caused by urbanization, the introduction of urban agriculture and promotion of shifting city-model from a consumer to producer is one effective strategy to achieve sustainable urban development.*

*Urban community is a certain self-organization and could reflect differences in different social factors. It's a good space for urban agriculture and an appropriate platform to carry out agricultural activities. This paper studied the integration model of agricultural space in urban community scale by choosing a representative city, Hamburg, Germany, as empirical objects. We aimed to explore the integration models of agriculture in urban community, figure out the features of spatial layouts in different models and analyze on participants in corresponding communities.*

*With literature review and field research to obtain one-hand and second-hand information, firstly we collected the types of agricultural space in communities of Hamburg, then analyzed and compared representatives for each type in terms of agricultural space layout model and participation of people, etc. Descriptive statistics is the key method used for collected materials.*

*Conclusively, it has found that in the city of Hamburg, community-scale spatial patterns of agriculture include the residential community, enterprise organization, city park and commercial-business community. Different types have their own emphases according to space layout, including horizontal, vertical, green roofs, etc., corresponding with different integration models and specific functions. Meanwhile, demographic structures of the participants, forms of participation and interaction modes vary based on the types of agricultural space.*

## 1. Introduction

The city has experienced a transition from an agricultural society to an industrial society and till today, an information age. Along with the rapid development of industrialization and urbanization, urban area expanded rapidly with a massive rural-to-urban influx. A lot of energy and natural resources were devoured, while agricultural civilization was considered a laggard civilization that hindered urban development, and had been gradually squeezed out. Urban and rural areas became more and more alienated. Their developments showed increasingly imbalance as well, which exacerbated the deterioration of the above crisis, and posed great challenge to sustainable development.

Most recently, information bloom enhanced human being's living standards significantly. Population issue, food security, energy shortages, environmental degradation and other practical issues received more attention. Urban and rural areas relationship and their partnership on development have been reviewed. Urban agriculture is to make agricultural production, supply and consumption concentrated in urban area. It will help improve the self-sufficiency of cities, and to a large extend, ease the food, energy, environment pressure and other issues, promote the change from consumer aptitude to production aptitude which is more flexible and resilient.

## 1.1 Definition of urban agriculture

Urban agriculture first appeared in developed countries across Europe, America and Japan at the first half of the twentieth century. Then it was spread and developed rapidly in other developed countries and regions. In late 20th century it has been widely introduced to the developing world. Compared with conventional agriculture, urban agriculture is a brand new concept. From the dependency of agriculture and urban development, urban agriculture is not a specific form of agriculture, but a concept which emphasize the synchrony and synergy of agricultural and urban development (Cai, Yang, 2008).

### 1.1.1 Concept of urban agriculture

The concept of urban agriculture has yet to form a unified conclusion worldwide, but the connotation of urban agriculture has basically reached a consensus. First, the spatial layout of urban agriculture mainly involves inner-city and suburban areas. Second, the carrying out of urban agriculture is to fulfill urban demands, including several aspects of the production, ecological, landscape in essence. I defined herein for urban agriculture: it is a new type of modern agriculture locates in the city center or suburban areas, focusing on integrating production, life and ecology to serve the city in a better way.

### 1.1.2 Functions of urban agriculture

As a new type of modern agriculture, urban agriculture has a couple of new features. From city demand fulfillment perspective, besides economy function, we're developing more functions of urban agriculture such as ecological function and social function, thus full functionality agriculture.

In conclusion of various definitions of urban agriculture functions, although the expression is different, but the essence is consistent, namely: it has many functions simultaneously, economic, ecological and social cultural. It provides high quality agricultural products for urban residents and meanwhile provides a large number of job opportunities. It helps improve the ecological environment of the city to a large extent. It also fulfills increasing residential spirit demand and reflects educational value.

### 1.1.3 Types of urban agriculture

According to the layout of spatial location, urban agriculture can be divided into two forms –suburban agriculture and inner-city agriculture (Mougeot, 2000). Suburban areas are less restricted by land. So there is more macro-level large urban farm, such as ecological agriculture garden, allotment garden, leisure farms. Inside-city areas are impacted by the built environment. So it appears in the forms of mid-level residential community, such as small business farm, agriculture theme parks and micro-level presence as roof gardens, squares farm, vertical farms.

## 1.2 Research background

From early 20th century to recently, studies of urban agriculture has become a research field addressing economic, social and environmental issues, involving interdisciplinary research in the field of agricultural science, economics, geography, architecture planning, sociology, ecology, and many other disciplines. Based on theoretical research, urban agriculture practice was also carried out adapting to local conditions, and became a hot topic of urban construction and development worldwide. Based on different extend of economic and social development, climate condition, agricultural infrastructure, urban agriculture development pattern differs from countries to adapt to their own characteristics.

There are mainly three patterns: first is the economic function-based model, represented by massive urban agriculture along Atlantic coast in US and highly intensive agriculture in Israel. This model strengthens people's initiative and weakens the natural environment initiative in ecological economic system. Second category is social ecologic function -based model, represented by European cities, such as Germany's garden city, UK’s Forest City. This model emphasizes harmony between human and natural environment, requiring government’s issuance of laws, regulations and policies to regulate the development of urban agriculture. Last category is economic and social ecological function-mode, represented by Japan. This model emphasizes the use of advanced science and farming techniques. Agriculture resides in urban ecological environment, so as to provide certain amount of agricultural products and perfect public goods (Li, Xu, Wang, 2006).

While developing countries (South America, Asia, and Africa) place urban agriculture to alleviate the country's economic pressure, improve the urban environment and enhance the quality of life, make urban self-sufficiency and promote the steady development of the city.

## 1.3 Research issue and objectives

### 1.3.1 Research object and scope

Current research on urban agriculture has penetrated multidisciplinary field. This article is based on architectural planning aspect, covering agriculture and urban spatial integration model research and

discussion, focusing on selected representative on urban agriculture activities in the German city Hamburg as empirical study.

Urban Community is at certain level self-organized and could reflect differences in different social elements and it is also a good platform to create urban agricultural space and carry out agricultural activities (Gao, 2012). Therefore the scope of this article is limited to urban built-up area.

#### 1.3.2 Research objectives and significance

In this paper, the study on community level spatial pattern of agricultural research of Hamburg, is to explore the following three points: 1) What're the integration models of agriculture in urban communities; 2) characteristics in different modes, including integrated form, special layouts and agricultural function; 3) community corresponding analysis, including forms of participation and interaction models vary based on the type of agricultural space. May hope this paper provide a reference value of urban agriculture activities undertaken in the context of urban built-up areas through empirical research on the practical level.

### 1.4 Methodology

In this paper, the writer used literature review and field research to obtain one-hand and second-hand information about urban community agriculture space. Literature review is mainly used in previous study, with a view of urban agriculture concept, function types, and the development process to get comprehensive understanding. And then analyze and compare representatives for each type in terms of agricultural space layout model and participation of people.

Field research focused on study subjects. Firstly understand the types of hamburger community agriculture space, then for different types trying to select one representative agricultural space to analyze and compare layout mode and participation status. In the field survey, the writer collected data and information through pictures, interviews, follow-up feedbacks. And descriptive statistics is the key method for collected materials.

## 2. Case study

### 2.1 Overall introduction of Hamburg

As one of Europe's great ports, Hamburg is located in the northern part of Germany, which is the second-largest city of this country, home to 1.8 million people within its city limits and 4.3 million in the metropolitan region (Braunstein). It is made up of seven boroughs, which are Altona, Bergedorf, Eimsbuttel, Hamburg-Mitte, Hamburg-Nord, Hamburg and Wandsbek, accompany with almost 2500 bridges spanning the canals and waterways (Figure 1).

Figure 1. The location of Hamburg in Germany and the distributions of its boroughs
*Source:* http://en.wikipedia.org/wiki/Hamburg

Hamburg has served as a trading hub for centuries, and in modern times as a major industrial center in Germany. Still, Hamburg is impressively green when compared with most cities of similar size, with over 16.7% of forests, recreation and green spaces in urban area. In 2011, it gained the prestigious European Green Capital mainly for its achievement of high environmental standard, further ambitious goals for environmental improvement and sustainable development.

In those further specific planning, there is one called A Green Network, 'will connect parks, recreational areas, playgrounds, gardens and cemeteries through green paths' (European Commission, 2011, p23). The plan aims to form a green link from the outskirts to the city center with two inner loops and several landscaped axes together (Figure 2). It is a great opportunity to combine different types and scales of green lands and public spaces into a greener network in order to make the city more sustainable and resilient. Urban agriculture spaces are also as public greenery lands included in the green network which helps to have a more potential development of its own and better connection with other urban public spaces.

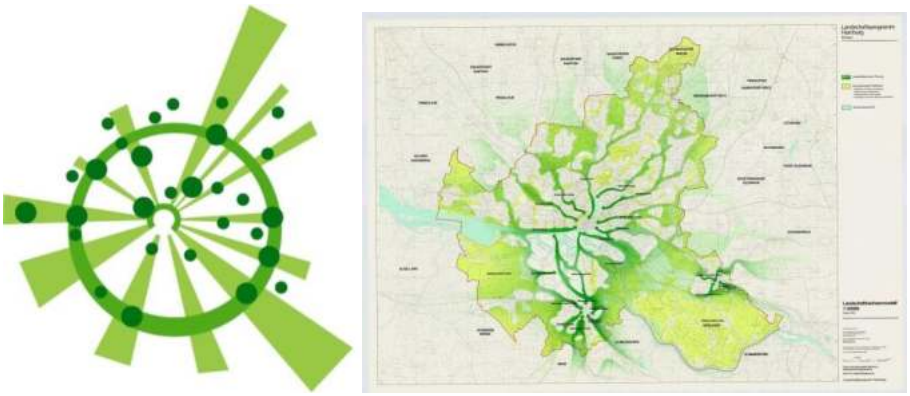

Figure 2. The green network plan of Hamburg
*Source:* http://www.hamburg.de/gruenes-netz/

### 2.2 Basic information of urban agriculture in Hamburg

Urban agriculture has a long history and successful experience in the development of Germany. In the early 20th century, the first form of urban agriculture, "allotment garden" appeared in Germany, and after 100 years of development and improvement, the current urban agriculture works vigorously with a set of ecological, social and economic functions. Its main purposes are: 1) to enhance the ecological and environmental quality of the city, 2) to create entertainment, farming experience and learning platform for education, 3) to provide healthy and safe green fruits and vegetables.

As Germany's second largest city, the urban agriculture in Hamburg has a relatively long history. Especially in recent years, with emphasis on the ecological environment of the city and the pursuit of sustainable development, the development of urban agriculture is in great esteem by the government and positive response of the public to form a government -NGO- citizens system, including the top-down and bottom-up implemented in two forms.

Among them, the government for the development of agriculture and urban agriculture enacted The Hamburger Agricultural Development Program 2015-2020, which clearly referred that urban agriculture is an important part of the Hamburg economic policy, and will promote the development of urban agriculture through a series of measures to protect its space, function, technology and other aspects (Meinecke, 2015). In addition, several projects are with the government's guidance and assistance.

Furthermore, NGO has played a very important role at the launching of urban agriculture, currently there are several civil society organizations in Hamburg as CSA Hamburg, LGH (Landesbund der Gartenfreunde in Hamburg EV) and so on, who design, build urban agriculture space and organize unregularly activities to attract public members to participate, better play the role of urban agriculture. Meanwhile, the Hamburg public enthusiasm for urban agriculture is also very high that urban agriculture activities carried out by the growing number of people spontaneously, such as moving farm, street gardens, etc.

## 2.3 Study on agriculture spaces in urban community scale

### 2.3.1 Urban community and integration of urban agriculture spaces

The word “community” is derived from old Latin, which was firstly applied by Ferdinand Tönnies, Germany’s sociologist, in his famous work “Community and Society” (1887). One broad definition which incorporates all the different forms of community is “a group or network of persons who are connected (objectively) to each other by relatively durable social relations that extend beyond immediate genealogical ties, and who mutually define that relationship (subjectively) as important to their social identity and social practice.” (Anonymous, n.d.). This shows that there are several characteristics of community, be: 1) in certain geographic region, 2) having a certain number of

population, 3) common interests and consciousness among residents, 4) with relatively intimate social interaction. In this paper, the concept of community keeps the same as previously mentioned.

According to the degree of intervention, agriculture and urban space integrated model is divided into the following four categories: reservation, insertion, substitution and reconstruction. Among them, the reservation refers to keep some existing agricultural space in the city; insertion means, full use of idle space into agricultural space when maintaining the original function of urban space; substitution means partial function replacement in the urban space to convert other space function into agricultural function; while reconstruction refers to building new urban space systems and space unit.

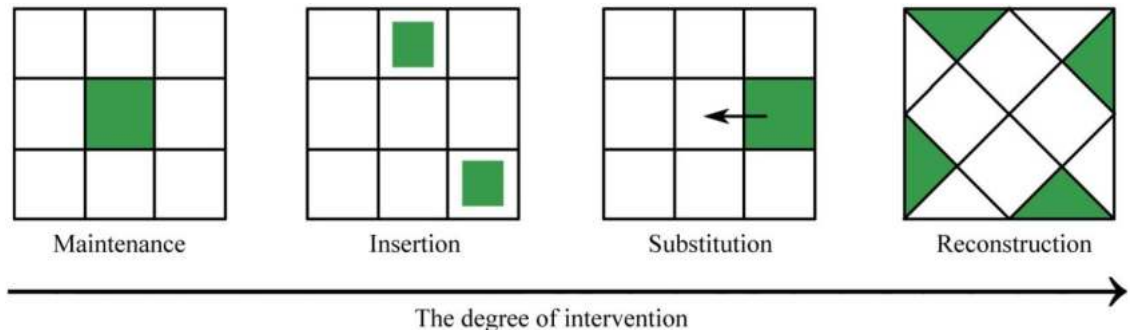

Figure 3. The integration modes of urban agriculture
*Source:* writer's own drawing

From the reservation to the reconstruction, the degree of intervention in the agricultural space to the city enhances gradually. Wherein the reconstruction as a subversive space construction, will form a new city structure, so it is more in the planning and construction of a new city but has greater difficulty in the city has been built. The other three modes are easier to integrate in the space within the city and suburbs, with a strong operational.

### 2.3.2 Types of urban community agriculture

According to the relationship with the land, the space for urban agriculture may include urban green space, city squares, buildings, etc. Taking into account the compatibility of urban agricultural production and urban construction land as well as the community connotation, the paper divides the basic unit of urban agriculture in the community level into four types: residential areas, parks, enterprise organizations (schools, hospitals, units, etc.) and commercial business districts.

With the Collection of information from literatures as well as field research, the current agricultural space in the city of Hamburg includes the following four types:

**A. Allotment Garden (Kleingarten)**
Allotment garden originated from Germany in nineteenth-century. It means the farmer or a specific organization offer the land and help the plant management, then urban residents rent and participate in

farming, harvesting their products which owned to them. Currently in Hamburg inner city, allotment gardens are mainly by certain NGOs planning and organization, to provide the public different locations in the city for the planting and harvesting of crops. One representative NGO is the LGH (Landesbund der Gartenfreunde in Hamburg E.V.). Now it has already have almost 1400 hectare lands, 33000 allotment gardens in 9 districts all over the city, managed by the club members (LGH, n.d.).

**B. Community Garden (Gemeinschuftsgarten)**

Community gardens is a very famous type of urban agriculture in Hamburg in nowadays that there are some different forms, like stationary farmland, moving garden, roof agriculture and so on, which provide fresh produce and plants as well as satisfying labor, neighborhood improvement, sense of community and connection to the environment (Hannah, Oh, 2000). To some extent the community garden is related to the allotment garden, but the existing forms of it are more flexible and abundant.

**C. Intercultural Garden (Interkulturelle Gärten)**

Intercultural garden is a characteristic type of urban agriculture in Germany. It firstly grew up as a project of the German Association of Intercultural Gardens (Interkulturelle Gärten e. V.), and the goal is a further intercultural competence and racial integration among refugees, immigrants and natives. The intercultural garden consists of planting vegetables and fruits as well as public space for community events and activities.

**D. Professional Garden**

Compared with the types of urban agriculture above, professional garden is a comprehensive concept. It includes the gardens especially for culture and education, the gardens owned by certain organizations, such as school agriculture, company agriculture etc. Now in Hamburg this type of urban agriculture is having a rapid development that it offers the agricultural experience to wider range and more citizens.

Corresponding to urban community, the urban agriculture space mainly includes community-scale in meso-level and scale of buildings and spaces in micro-level. It should be noted that, in the paper, private gardens and other private space are not included. When matching the four types of community agriculture basic unit and the types of urban agriculture in different scales, there is a table to show the proper agriculture forms in different communities (Table 1).

Table 1. The characteristics of different community agriculture

| | Residential community | enterprise organizations | City parks | commercial and business area |
|---|---|---|---|---|
| Allotment garden | √ | — | √ | — |
| Community garden | √ | √ | √ | o |
| Intercultural garden | √ | o | — | — |
| Professional garden | √ | √ | o | — |

| | | | | |
|---|---|---|---|---|
| Roof farm | √ | √ | — | √ |
| Vertical farm | — | o | — | √ |
| Street garden | — | — | — | √ |
| Square farm | √ | — | — | √ |

### 2.3.3 Research on different types of community agriculture in spatial layouts

According to the basic four types of urban community agriculture, the writer has selected several representative cases of urban agriculture in Hamburg that own to different types in order to study on and compare the characteristics of integration models, spatial layouts and the space functions in different community agriculture types.

**A. Urban agriculture in residential community**

The residential community is the most common form for urban agriculture in the city. Closely related to people's daily life, residential agriculture offers a public space which is attractive to the residents for participating and experiencing.

- **Gartendeck**

The Gartendeck is an urban agriculture project in Hamburg St. Pauli, working as a temporary roof garden on a parking deck. The roof area offers 1000 sqm for flexible agricultural spaces, like around 650 baker boxes and a container. This garden offers green vegetables planting, herbs growing, and also there are three beehives and a worm box.

This residential community garden is a moving farm that every week it has regular opening time to welcome all the residents in neighborhoods coming by and participating in. As the self-organized community center, it offers a rent-free and use-free space for neighborhood meetings, sociocultural facilities, collective gardens etc. to improve the integration and communication among residents and help shape new forms of urban community with locally food production. The integration model of it is insertion, which means to turn the fallow land into productive green (Figure 4).

Figure 4. The location and image of Gartendeck
*Source:* http://www.gartendeck.de/

- **Keimzelle**

The Keimzelle is located in Hamburg as a small social garden since May 2011. In the garden, variety of vegetables and herbs are grown as well as fruits to offer the residents a natural environment with plants and insects that not as likely to find in a big city. Everyone can use the site jointly, whether for gardening, a meeting or just a short break.

This site lies in the road turning as a green plaza before, then turned its function to the urban agricultural space. The integration model of this form is substitution that actually the garden is still a greenery in the city but add the social and economic functions in accompany with the environmental one. The cultivation forms in the garden include the stationary land and mobile boxes, which offer the participants more chances to join in the urban agriculture activities to take over the design of their living and working environment and especially a part of the food production back into their own hands (Figure 5).

Figure 5. The location and image of Keimzelle
*Source:* http://keimzelle.rindermarkthalle.de/

The above urban gardens are two typical examples in residential community in Hamburg, and with the information the writer has searched and the field research in the city, there are some more types of community agriculture in residential areas, such as the allotment garden, cultural and educational garden, etc. The main integration models are insertion and substitution with both stationary and flexible spatial layouts in relatively small sites.

**B. Urban agriculture in school**

As one of the representative types of enterprise organizations, the school is a proper subject to implement the urban agriculture that offer the students knowledge and practical experience about the agriculture. Hamburg is paying attention to the school garden in different education levels, from kindergarten to the university, there're many agricultural activities happened.

- **Ganztagsgrundschule**

This school is located in Hamburg Bernstorffstraße 147, including a primary school accompany with a nursery. It has a big campus with a school garden on the south side of the main building. The school consists of seven parcels, each of which is assigned to a class.

The reason for creating a school garden next to play and sports facilities is to bring the city kids to nature. A school garden provides the opportunity to see plants from seed to harvest for the students to design the ground, experience in the agriculture space and finally eat the vegetables and fruits of their own work. Not only for the spare time, there are also some relevant classes taking place in the garden, which contributes to health education as well as the social experience (Figure 6).

Figure 6. The garden and agricultural activities in Ganztagsgrundschule
*Source:* http://www.schule-bernstorffstrasse.hamburg.de/index.php/article/detail/1037

The Hamburger Bildungsserver accounts and shows some basic information of the school garden in Hamburg. To collect the information together can find the main characteristics of current school agriculture. Firstly, the gardens extend among all the school levels with the main functions of education and social experience. The types of farmland mainly include the public ground and roof gardens, and in some schools, the agriculture spaces also exist in the buildings like gym and lab. What's more, both inside and very nearby the school of the garden exist at the same time.

### C. Urban agriculture in city park

The parks work as attractive public greenery spaces in the city's green system. Traditionally, parks offer ecological environment and places for social communication, while in nowadays, urban agriculture has emerged in some city parks in Hamburg, creating more abundant greenery forms as well as functions of the park.

- **Hammer Park**

The Hammer Park was belonging to the family Sieveking in 1826 and less than a hundred years later, it transformed the originally landscape of English style garden as a public park in Hamburg. With at

least 16 hectares, it offers plenty of space for communication, play and fun.

Since 1982, there is a herb garden in the Hammer Park. The herbs can be cultivated as well as harvested by the citizens. The herb garden was formerly used well, but later became oblivion over some years that the variety of herbs decreased and the herb signs and information board turned empty. Trying to make the garden more attractive, the organizer has dealt with this issue to search for effective solutions. So far, several effects have been achieved, such as more herb diversity, better management with the support of certain club, regular events and herb festival, etc. (Glöckner, n.d.). In 2013, the garden has received the support of North German Foundation for Environment Development to offer a herbal workshop for seniors. With those efforts, now the agriculture activities in Hammer Park work well, making a creative agricultural space opening to all the citizens (Figure 7).

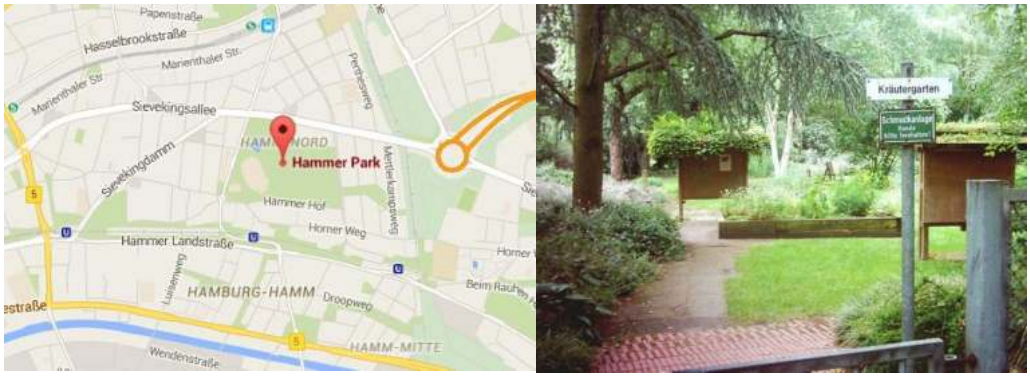

Figure 7. The location and image of Hammer Park

*Source:* http://www.google.com/maps & http://de.wikipedia.org/wiki/Hammer_Park

Compared with other urban community agriculture spaces, the advantage of city park is that it offers bigger green and public space to create agriculture production and activities. The common practice is to divide a certain area in the park as agriculture space, with unified management and unlimited participation. The integration models are mainly reservation and insertion, and the stationary land is the prior form for cultivation.

## D. Urban agriculture in commercial and business community

The commercial and business area is generally located in the central and sub-central parts of a city. In comparison with other areas, the commercial and business community seems with higher density, more complex context and less functional public spaces for agriculture. So trying to find more fallow land for urban agriculture is the key point.

- **Kallersche Gärten**

This project was aroused by Keller, a 79-year-old grandpa in 2003, on the traffic islands at Barcastraße/Ecke Ackermannstraße. It is located in the center of Hamburg old city as a typical example to make full use of fallow space in commercial and business area.

In the first few years, the garden was the responsibility of the old man dealing with the planting and reservation, but after his death in 2011, more and more citizens around this area even from other parts of the city joined in the urban agricultural activity, opening up more land on the traffic islands and the street green belt. The green plants and flowers not only beautify the environment, but also supply the green agricultural products for the citizens (Figure 8).

Figure 8. The location and image of Hammer Park

*Source:* http://www.google.com/maps & http://www.kallersche-gaerten.de/

### E. Summary of urban agriculture characteristics in different communities

After the analysis on typical cases of different community agriculture and some further related information from internet and literatures, the writer summarizes the characteristics of different communities in the aspects of integration model, spatial layout and main function (Table 2).

Table 2. The characteristics of different community agriculture

| Type | Integration model | Spatial layout | Main function |
|---|---|---|---|
| Residential community | Insertion / Substitution | Fixed / Mobile Ground / Roof | Improve the communication and locally food production |
| Enterprise organization | Insertion / Reservation | Fixed / Mobile Ground / Roof | Educational and social functions for specific groups |
| City park | Insertion / Substitution / Reservation | Fixed Ground | Visit and experience the agriculture landscape and activities |
| Commercial and business area | Insertion | Fixed / Mobile Ground / Roof | Full use of fallow space to create agriculture landscape |

### 2.3.4 Participants involved in agricultural activities

Relying on certain involving people, the community agriculture space has different target groups

according to the types, layouts and functions of it. In this paper, the urban community agriculture is defined in four different types: residential area, enterprise organization, city park and commercial-business area. The demographic structures of the participants, forms of participation and interaction modes vary based on the types of agricultural space.

### A. Demographic structures of participants

In the residential community, the agriculture garden is mainly focusing on the residents in this area as their target group because of the proper service radius and the functions of residential agriculture, offering a public space to improve the communication and integration among residents and create a locally production environment. All the ages are invited.

The enterprise organization like school is the specific area for fixed service groups. So the related participants are mainly the people in the organizations. For example, the agriculture space in school is for the students and teachers only on educational and social functions.
For the city park, the urban agriculture is more open to all the citizens in the city for visiting and experiencing, while the commercial-business area is relatively flexible in demographic structure of participants according to the agriculture forms.

### B. Forms of participation and interaction modes

Generally speaking, in spite that the enterprise organization is owned to specific groups, participation and interaction modes of other three types of community agriculture include two main forms, unlimited participation and membership participation. The membership form usually exists in the allotment garden, which mainly in the residential community and in some professional parks, while the unlimited participation distribute in all the three types. What's more, no matter of which types, the citizens can experience the entire process from sowing to harvest.

## 3. Conclusions

Firstly, the paper studied the research background, content and development process of urban agriculture, then defined the study range in the urban community level and selected German city of Hamburg as the research object. Based on the types of agriculture inner the city and the divided basic units of community agricultural types, the writer analyzed a few representative cases, focusing on the integration types, spatial layouts, functions and participants in different community agriculture types.

Conclusively, urban agriculture in Hamburg shows good momentum that urban agriculture works in all the types of residential communities, enterprise organizations, parks and commercial business district, both the forms of variety agriculture gardens in meso-level and small farms in micro-level attached to the buildings and sites.

Due to the low replacement rate of public lands, the integration model in commercial-business area is relatively simple, mainly the insertion; while the city park is most abundant, including the forms of reservation, insertion and substitution. Each community has a variety of agricultural space forms, including ground, roof, fixed and mobile, etc. The main functions of different types have own emphasis, but the core lies the social, environmental, economic integration, which pays more attention to the effectiveness of the social and environmental aspects.

Because of the target groups varying from different community types, the demographic structure, participation forms and interaction patterns are not the same. But all the communities offer participants personally involving in the whole process of production, which makes urban agriculture more practical significance through the communication and interaction with the participants.

# ROLE OF SCALE LEVELS, UNITS AND LAYERS OF BUILT ENVIRONMENT IN PLANNING PROCESS

Michal Kohout[1], Filip Tittl[2], Jan Karásek[2], Šárka Doležalová[2] and David Tichý[2]

[1] Department of Building Theory, Faculty of architecture, Czech Technical University in Prague, Prague, Czech Republic, kohout@unitarch.eu
[2]Department of Building Theory, Faculty of architecture, Czech Technical University in Prague, Prague, Czech Republic

Keywords: planning system, built environment, scale levels

*Abstract:*

*Gradual changes in social sphere, politics and economics (in context of Czech Republic accentuated in last twenty-five years of rapid growth following neo-liberal shift in planning policies and urban management) have serious impact on transformation of forces that are shaping our cities nowadays. Notable increase in range of project sizes (often including large portions of public space), varying typology and forms of development, shift in periodicity of changes in urban structure results not only in ambiguity in current notion of "public" and "private" both in spatial sense and division of responsibility, but as well in disconnection between planning tools and real processes in built environment, thus increasing instability and "fuzziness" in roles and responsibilities within the system.*

*In this context, the master planning system can hardly be derived only from institutional responsibility. The paper therefore explores alternative point of view on decision making process in urban planning and architecture, based purely on built environment and its parameters. The layers of urban environment (public spaces, built mass, infrastructural systems, programmatic pattern etc.) are examined and systemized using case studies of different urban setting and theoretical models. The research sets up a comprehensive framework of singular planning decisions that consequently form the urban structure by studying syntactic units of built environment and their role in different scale levels. In today's situation demanding flexibility in decision-making process, the results can serve as a ground for optimization of urban planning processes, standards and legislation.*

## 1. Introduction

Gradual changes in society and economics have significantly influenced the mechanisms that shape the form of contemporary cities. The significant enlargement of projects size diversity, the expansion of building typology range or the shift in the periodicity of changes in different layers of built environment have all led to a lower predictability of development, and greater demands placed on the tools of urban planning. Construction of public systems (including even such matters as public space) frequently comes under the control of the private sector. As a result, we find an increased ambiguity between public and private responsibilities, further accompanied by a loss of compatibility among urban-planning methods and other processes within the framework of urban development and the organisation of built environment in general.

The situation in the Czech context has, moreover, been accelerated by developments over the past 25 years, related to the sweeping political and economic changes in society since 1989. Radical shifts in property and particularly land ownership, along with significant urban growth, have been accompanied on the other side by a significant limitation of the role of the public administration in organising built environment, significantly below the level common in Western Europe.

For orientation within this context and the search for adequate strategies for the possible redistribution of responsibilities, it is essential to abstract from the current institutional framework of the system of urban planning and to examine the organisation of built space in terms of its physical essence and internal organisation. The theme of the presented work is henceforth the systematic description of the components of built environment and the issues connected with the organisation of its development and management within a hierarchy of proportional scales and units derived from the actual organisation of the environment. Specifically, the goal is to describe the relation of components of the built environment to their various scales, in other words how are the individual subjects of regulation related to scale levels and spatial units, how are they described within these units, how the methods of working with them have changed and on what scale they manifest themselves spatially. Equally the aim was to show the tie between the scale levels of the built environment and key decisions for the shaping and regulation of the city.

The paper describes the phenomena that are related to the given scale in general, i.e. without direct specification of the interface between public and private (responsibilities). This interface, it must be noted, varies dramatically with the amount of investment, method of construction, and needs for coordination in each specific locality. A great many of the themes described below could, therefore, be the subject of private decision-making, yet this does not mean that they can be omitted from the process of organising built space – only that the responsibility for them in a specific situation is entrusted to individual developers.

Presented in the text are partial results of a broader research assignment *The local plan in the system of urban planning in the Czech Republic* under preparation at the CTU Faculty of Architecture in Prague. The research is primarily oriented towards themes connected with larger cities, though nonetheless selected parts have been verified, in terms of the broader scope of description specifically with regard to urban and land-use planning systems, for smaller settlements. The work primarily concerns the common residential and mixed-use environment. At the same time, it also focuses on specific types of structures (large enclosed compounds, major industrial facilities etc.) and the expansion into the rural area and descriptions of themes related to the organisation of the landscape.

## 2. Units of the Built Environment

The presented text is based on the assumption that the built environment is structured into units that roughly correspond to the following descending classification:

- town
- district
- neighbourhood
- block
- plot / house
- flat
- room

These units are derived from common terminology used to describe parts of the built environment. Various methods are used to address them, from legislation regarding land use to a broad palette of theories of the built environment – from the Central place theory and it'shierarchies (Christaller, 1933) through the hierarchical structure of individual settlements (Doxiadis, 1966) up to the levels of the Open building system(Kendall, 2000).

In turn, these units (at least at the lower levels of the hierarchical system that the user commonly encounters immediately) are graspable by human senses (i.e. usually visible) and consciously distinguishable (i.e. usually commonly conceivable). In addition to being a physical whole, each

unit also reflects the social image and shared concept of a community (Kohout, 2010). At the same time, this scale of units is bounded by the parameter of the lifespan and periodicity of replacement of the individual elements (Kendall, 2000). Invariably, it holds that the lifespan of the elements on the lower hierarchical levels tends to be significantly lower than the lifespan of higher elements (typically the arrangement of space in a room changes on a scale of single-digit years, the arrangement of rooms within a dwelling changes on a scale of decades, the arrangement of urban blocks on a scale of centuries, etc.). The organisation of the environment on the level of neighbourhoods and blocks regularly implies decisions with a lifespan stretching across generations (Habraken, 1998).

No less important than the delineation of the units themselves is the question of their mutual hierarchical relations (Kohout, 2011). Each unit of a selected scale contains all units of a lower scale, as well as its own specific elements – tare (Berghauser Pont, 2010). In turn, these specific elements of each scale organise the units of lower scale (e.g. the communicative spaces in a building determine the position of living units; a standard street defines the organisation of its houses etc.). These specific elements are usually represented by a selected type of shared space (in the event of lower hierarchic stages) or of public space. And, in succession, these connecting elements then become the image (Lynch, 1960) of the units of the urban fabric – i.e., the space where these units can be "grasped", "lived" and "comprehended" (e.g. the organisation of a building can best be understood from the main communication area, typically the staircase; the overall setting of a district can be best understood from its central square or main boulevard).

*Units of Built Environment and Scale Levels*

Though in connection with the previously noted concepts we speak primarily about units – which may be ascribed certain attributes and in a certain sense may be treated individually as units – their mutual relations and capability to bind together the individual attributes of the components of the built environment in a comprehensible manner and in a hierarchical succession with precisely ensuing dependencies is – primarily on the higher stages of the scale, i.e. from the neighbourhood upwards – ambiguous (Alexander, 1965). The same principle holds true as well for the mechanism of organising the entire system into a hierarchical arrangement of mutually logically ensuing units. For this reason, the paper deals with these elements more in terms of their scale levels, i.e. stages in which there usually occurs a qualitative change in the method of approaching the components of the environment.

No less important is drawing attention to the relations of the scale level to the size of the unit. In this sense, the scale level is defined in the paper as the level of detail that corresponds to reasonable operation within the framework of the given unit. Hence, the size of the unit generally implicates the size of the smallest area with which it is logical to work on this given level. In common practice, though, this area can be (and often is) much larger. Typically, the scale level of the block represents the detailed work with attributes linked to individual plots. Logically, these could be effectively prepared for a single block, yet it is more common that these details are addressed in coordination for a territory over the size of several blocks.

For the requirements of the following text, which addresses the field of urban planning and construction coordination, specific focus is devoted to the units / scale levels between the district and the block, or if necessary the individual plot.

## 3. Components of the Built Environment

Components of the built environment represent the basic thematic lineage for the organisation of environment'sphysical elements. Bearing in mind their direct connection to the actual environment, it is not possible to view them as mutually equivalent independent layers of the plan, even though they do form a suitable analytical reference framework for investigating and practicing urban

planning. They can have a structural or infrastructural character, and their delimitation for the purposes of the present text is derived from the common, conventional descriptions of city organisation in relation to urban planning. In the city (i.e. a primarily built-up area), we can discern specifically:

- public spaces / street network (their delineation and arrangement of the parterre)
- built mass (as a spatial structure, including open spaces that contain both spatial and functional parameters)
- transportation and technical infrastructure
- civic and commercial infrastructure
- landscape infrastructure

From the nature of the system, it ensues that the individual components overlap, which means that systematic individual elements of the environment will repeat in differing contexts – e.g. a school represents both civic infrastructure as well as part of the built mass with spatial parameters.

*Methods of description / prescription*

From the standpoint of planning, the components of the environment and their individual elements become the subjects of regulation. The urban plan treats the differing subjects of regulation on various levels of scale in different ways. In this respect, the key factors are both the character of the subject of regulation as well as the level of abstraction and of detail with which the given subject and the given parameter are affected. Similar tools to those used for the regulation of elements of the environment and its parameters ("inscription") can be used as an analytical instrument for registering the qualities of the elements of the environment in the given site ('reading") – i.e., both in a descriptive as well as prescriptive sense.

Included in the determination of the elements is the definition (registering/setting) of their existence, their localisation within the given territory and the stating of their parameters (scope and qualities). In this respect, it is possible to divide the principles for the determination methods as follows:

- prescriptions that define the existence of a certain element of the environment but do not assign it a concrete spatial form; these can determine the position either in direct localisation/routing (e.g. stating the position of a height landmark or routing the axis of a transit route) or in relation to another element/surface (e.g.: prescribing the connection of a network of public spaces through urban blocks in specified points, but without setting a direct route, or prescribing the realisation of a park within a set part of the territory)
- delimitations that determine not only the positioning of elements in a specific place, but also their spatial extent; the delimitation could be determined as the precise boundary of a space by a solid element, or by setting a maximum boundary (e.g.: limiting the areas of the park or the built-up section of urban blocks)
- restrictions / regulations that organise space through the assignment of parameters, either through their qualities (e.g. determining the functional composition) or limits (e.g. regulating the share of paved areas)

The basic principles described above do, of course, overlap to a certain extent in various situations (e.g. selected parameters are often assigned to independently determined areas, while prescribing a concrete element it is also possible to limit the parameters of its size, etc.), yet nonetheless in their differentiation it is possible to note a basic division of the level of abstraction and the method of its determination.

### 3. Description of the Built Environment and Its Scale Levels

For expressing the relation between individual subjects of regulation and scale levels in the environment, as well as outlining the possible methods of their description, a verification study was performed within the research project in selected localities (fig. 01).

Fig. 01Selected localities for verification study: Prague, Dejvice / Prague, Novodvorská / Amsterdam, Ijburg / Štětí, Chcebuz; pictures showing three scale levels: district level / neighbourhood level and block level

Towards the aim of capturing a wider scale of elements of the environment and tools for their description, different areas were selected that represent varied types of urban patterns derived from the historic changes in the character as well as the size of the planned and administered units. The structure of a traditional city is represented by a section of the Prague neighbourhood of Dejvice; for confrontation of the examined tools with modernistic localities, the Prague housing estate of Novodvorská was selected and, bearing in mind the absence of a contemporary approach to planning to the necessary extent in Czech urban setting, the typology of a contemporary compact city is represented by the Amsterdam district of Ijburg. For verifying the selected principles on a different scale of settlements and in a landscape setting, these urban localities were matched

against one village – Chcebuz, located in the administrative authority of the town of Štětí in the Ústí nad Labem region in North Bohemia.

In the matrix grounded in this theoretical basis, the key connections between the components of the environment and the scale levels were identified. These connections were described in a system that assigned decisions concerning concrete elements of built environment to the scale range of district-neighbourhood-block (fig. 02). As has already been noted, the individual scale levels represent not only units of the environment with their definite attributes, but equally transitions between the qualitative transformation of components of the environment or their mutual relations. This change usually expresses not only the extent of greater precision of the given component through greater detail, but often represents an independently describable and unambiguously specifiable theme that directly corresponds to the given scale level.

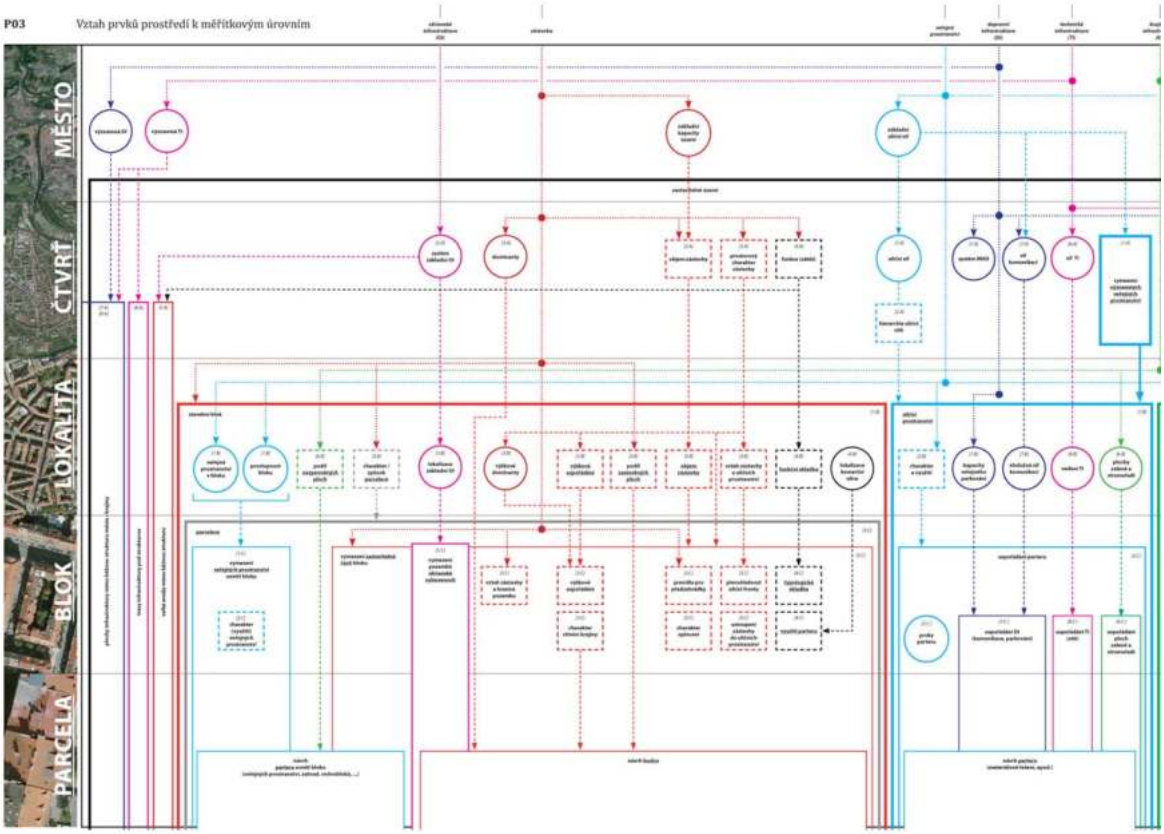

Fig. 02 Decision-making analysis through scale levels (system maquett)

The themes of the scale levels and changes in the description of each component of built environment can be described as follows:

*Scale level: district*

The scale level of the district is usually the last effective planning level for larger cities in planning these settlements as a whole. Typically, this is the level at which the more detailed relationships of city-wide systems are addressed (transportation, technical or landscape infrastructure) in relation to each other as well as to the basic organisation of the settlement on lower scale levels (i.e. the system of articulation into blocks, distribution of capacities and the ensuing possible basic typologies, organisation of transport on the lowest level etc.).

- Public spaces (fig. 03): The basic organisation of their network is formed (delimitation of places and axes of main public spaces, and directions or connections of secondary public spaces) and their connection to the superior systems of a city-wide character.

- Built mass (fig. 04): The basic capacities and land-use limits are distributed as well the basic spatial character including the composition of major landmarks is decided.

- Transport and technical infrastructure (fig. 05): On the scale level of the neighbourhood, what is usually addressed is the connection of local systems of transport and technical infrastructure to city-wide systems. At the same time, decisions are also made on the basic system of transport service in the area, the connection of separate transport systems (mass and individual transit) and cycle and pedestrian transport. On this level the detailed localisation of the main connection points of utility networks of city-wide systems of technical infrastructure is being distributed (transformation stations, sewage treatment plants, waterworks, etc.).

- Civic and commercial infrastructure (fig. 06): Elements of public facilities of medium size (primary and nursery schools, medical facilities or sports areas of local importance) are regularly assigned on this level – the capacities are known, but the concrete delimitations of the basic street network and built-up blocks are not. At the same time, also a basic organisation of the small scale services is decided, primarily by setting the place for their main concentration (main commercial boulevards).

*Scale level: neighbourhood*

In terms of planning, this level involves relatively concrete assignments and goals (usually the given capacity, the required spatial character of built mass etc.). Through the delimitation of the streets, the local character is to a significant extent stabilised, and a basic network of public spaces is formed. Thanks to the delineations of the streets, there occurs a basic distribution of capacities, outlining of urban blocks and localisation of main elements of civic facilities.

- Public spaces (fig. 03): Street space is delimitated by the street lines, i.e. the basic network of public spaces is stabilized (setting the street lines and basic characteristics of the street profiles, prescribing the permeability of individual blocks).

- Built mass (fig. 04): For built mass, this involves the final delimitation of urban blocks (setting the street lines). On this level, the character of built mass is generally regulated by specific parameters and to a large extent prescribed (simultaneously it is possible to guarantee it effectively from this scale level on). In addition from here onwards, it is possible to perform the effective setting of the basic elements of spatial regulation.

- Transport and technical infrastructure (fig. 05): Connected to the delimitation of the street pattern a more detailed specification of transport and technical infrastructure becomes possible.

- Civic and commercial infrastructure (fig. 06): Elements of civic facilities are delimited on this scale level in specific urban blocks. Likewise, there is also a more detailed organisation of the lowest level of commercial services (creation of a living ground level along public spaces etc.), which is related to the character of the street profile.

*Scale level: block*

On the scale level of the block projects of individual private and public builders are coordinated. In terms of the systematic organisation of the built environment, the block is also the basic compositional unit of the settlement. This statement holds true in spite of all heterogeneities of size and form of the block, as well as the fact that in certain types of construction (housing estates, large complexes etc.) its delimitation is somewhat difficult. At the same time, it is true that only very few other boundaries inside a settlement are usually so clear, and at the same time containing so many levels of meaning (private/public, accessible/inaccessible, formal/informal, mass/space etc.) as the boundaries of the blocks and streets. Nevertheless, it is important not to lose sight of how the block, as a scale level of settlement planning, contains in itself as well the adjoining street spaces, i.e. usually streets or squares.

- Public spaces (fig. 03): The network of street spaces is already delimited, and arrives at this scale level as the basic specification. On the level of the block (street), the organisation of the parterre of the public space is determined, largely through the setting of the street profile As a result, here it is possible to adjust in greater detail the basic relationship between public and private (primarily outdoor) space. A localisation of the permeability of urban blocks (walkways, arcades, covered passages etc.) takes place.

- Built mass (fig. 04): In terms of built mass, we encounter the delimitation of individual construction projects, usually through the form of parcelling of the land. There can also be a delimitation of the space inside the blocks, i.e. the organisation of the space as semi-private or as semi-public. Construction is formed by the already concretised volumes, thus usually occurring in the form of determining their positioning and height (delimitation of parcels, building alignments, heights of cornices and rooftops, number of floors, eventually with other concrete parameters ensuing from the nature of the location).

- Transport and technical infrastructure (fig. 05): On the scale level of the block, it is possible (keeping in mind the determination of the street profile) to set in more detail the organisation of transport service of the area (e.g. one-way or two-way traffic, ways of parking in public spaces etc.). Simultaneously, it is possible to effect a more detailed organisation of transport service for the block as a whole, primarily the system for parking.

- Civic and commercial infrastructure (fig. 06): Elements of civic facilities can be delimited here at the very lowest level of the public (nursery schools, children's playgrounds or sports fields occupying a semi-private inner-block area etc.).

## 4. Scale Levels of the Built Environment and the System of Urban Planning

As described previously in the introduction, the purpose of this analysis is primarily the description of the built environment on the basis of its implicit parameters and qualities, without regard to the distribution of responsibilities in a specific urban planning system. Nevertheless, for understanding the use of the results of this research and the adequate formulation of conclusions, it is necessary to give a suitable outline of the principal relationship between the described scale levels and the system of plans. The planning system is generally compiled from the scale of plans in varying degrees of detail, which form a more or less hierarchical system of planning levels. Here as well, scale is unquestionably a basic systematic parameter for articulation on the level of the plan. If we extend the systematics of planning levels to the basic framework of this text, in terms of scale the key question is in what detail (scale of detail) the plan operates, and at the same time to what units it is applied.

It is necessary to stress that the levels of the plan may well not cover the complete described scale range. The gamute will, out of principle, always be richer than the utilitarian quantity of planning levels. What is key here is the extent of detail in the description (organisation) of the space within which the relevant planning level operates. The consensus on organisation of built environment on a lower scale implicitly contains within itself the decisions that are necessary to implement on a higher scale. The hierarchy of these interrelations manifests itself in the process of preparation (creating, processing) of the plan, without it being necessary to formalise decisions in the higher scale level through an independent planning level. On the other hand, it is also true that various scales can function for a number of spatial areas on a single planning level – even with the use of descriptions and regulations with a varying amount of abstraction and detail corresponding to the differing scale levels.

Within the framework of the research, the relation of planning levels in individually investigated international planning systems towards the scale levels of the actual built environment was observed (fig. 07). The primary object for observation was the level of the local plan, and its relation to the higher level of urban-planning documentation. The majority of investigated systems have at their disposal planning levels corresponding in detail to the scale of the block, which aggregates within itself decisions on the scale level of the neighbourhood, possibly even the district. Supplementing this is the “city-wide” planning level, which ranges in its level of detail from the city to the district, in a few cases even to the neighbourhood. This planning level usually operates with greater flexibility in its level of detail.

## 5. Conclusions

On the basis of the performed analyses and verification studies, we can draw attention to selected essential findings concerning not only the importance of the components of the built environment in relation to scale levels, but also the changes in the method of their description.

The research verified that the components of the built environment and their individual elements permeate throughout all of the observed scale levels. The majority of elements find a relevant description on the scale of the district, neighbourhood and block. A change in the scale of the built environment causes not only a refinement of the description of the area, but also a change in the significance of the aspects of its individual elements. For instance, for determining public spaces the key on the scale of the district is the network relations of the system; on the scale of the neighbourhood the more important factors are its spatial dimensions and proportions. The use and character of the public space is, in turn, on the scale of the neigbourhood represented specifically by hierarchies of importance, yet on the level of the block through the organisation of the parterre.

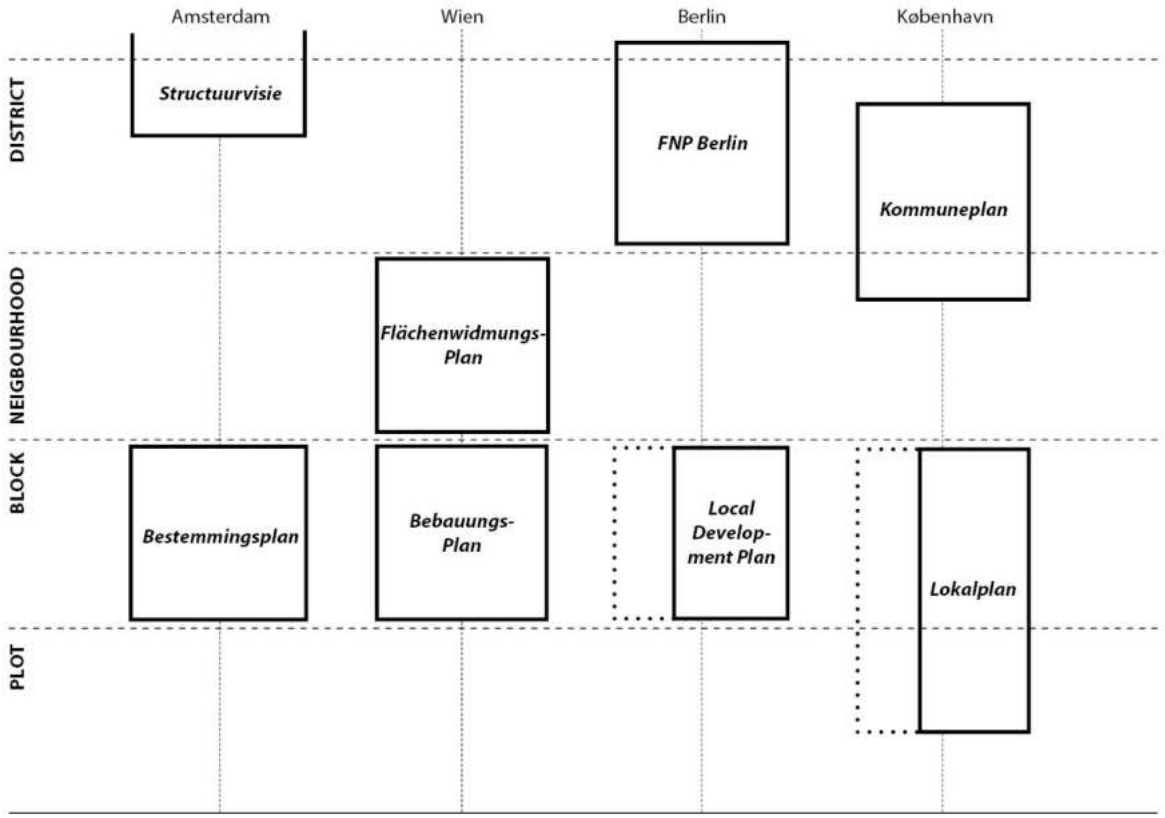

Fig. 07 The relation of planning levels to scale levels of built environment: Amsterdam, Vienna, Berlin, Copenhagen. The diagram likewise displays the amount of coverage of the area of the given urban-planning level (dotted lines represent partial coverage)

Nonetheless, it is also possible on the individual scale levels to identify key aspects of planning and its goals, or in other words to follow the gradual change in the sense of planning across the scale levels. Though each level understandably fulfils to a certain extent all of the aims of urban planning, it is possible to assign to each scale level a certain characteristic meaning:

- Scale level of the district – organisation (of public systems): The scale level of the district is usually utilised for operations on the boundary between city-wide and local systems. Here, the basic system of organisation is created, the city-wide public space is stabilised, as well as the infrastructural systems. The scale level of the neighbourhood thus represents primarily the record of public aims in space.

- Scale level of the neighbourhood – guarantee (of the character of the environment): On the scale level of the neighbourhood, we find the stabilisation of the basic physical attributes of the built environment. Here lies the determination of the street spaces and blocks as the key systematic delimitation within the framework of urban planning. The basic character of built mass is translated into parameters on this level. Hence, it is only at this scale level that there appears the possibility of its more precise definition in relation to the specific limitable space (block) and thus its effective assurance. The scale level of the neighbourhood, therefore, represents the basic framework for reaching agreement on the character of the built environment and the extend of its change.

- Scale level of the block – coordination (of individual intentions): The block is the scale level at which we find the main mutual coordination of the projects of individual builders

(private and public). The parameters of individual components of the built environment are translated into specific spatial arrangements, on the basis of which it becomes possible to speak of the determination of the planning typology of individual structures. The scale level of the block, therefore, primarily influences the quality and effectiveness of individual intentions in relation to their surroundings.

*Legibility of the Built Environment*

For all scale levels, it holds true that the system of public spaces can be regarded as the basic reference level for all other physical elements of the built environment. Without knowledge of their routing or (at lower scales) their delimitations, it becomes considerably difficult to prescribe the parameters for other elements of this environment. In essence, this principle holds true across all scales, though the surface delineation of street areas and blocks on the scale of the neighbourhood can, in this respect, be viewed as most essential.

As a result, it can be possible to refer back to the introductory analysis of the compositional and unitary sides of the built environment, in which an adequate hierarchy of units and 'connecting elements" leads to the legibility of the built environment. Legibility here does not refer solely to the comprehensibility of the urban structure for the ordinary user, but more significantly to the determination of the framework for its administration, management and the conditioning of the possibilities of its change across time, which frames both, top-down as well as bottom-up processes.

An open system of hierarchically ranked elements means that it is possible to a large extent to exchange individual elements of the whole – primarily those at lower levels – according to need, without in any way significantly harming the character or identity of elements at a higher stage in the hierarchy. Respect for basic relationships and ties, their gradual adaptation to the given circumstances of the place and the era, allows an urban structure its natural development while retaining its characteristic traits and basic identity.

# Urban transformation for resilient cities

# - Renaissance of comprehensive planning systems?

**Keywords:** *Resilient City – Climate Planning – Climate Governance*

**Abstract**

*In the last decades of neoliberal politics, urban planning had almost lost its requirement to deal with comprehensive development plans and regulated planning systems. In the face of climate change, mitigation and adaptation strategies are forcing the cities to deal with strategic climate concepts, which have a huge impact on the urban structure and urban planning policy. Meteorologists are acting as new "reformers", demanding for a new understanding of a regulated society to control the climate change. If climate concepts would be combined with strategic urban planning concepts, the comprehensive planning system could find a renaissance, together with new models of urban planning. Although a lot of mitigation strategies are already implemented, there is the need to deal especially with the consequences of climate change. Adaptation measures have a radical impact on the urban structure. This can change the understanding of a flexible planning system of the last decades. In Germany the federal building code ("Baugesetzbuch") gives a legal basis for a better integration of climate concepts into the regulated planning system. The "German Adaptation Strategy" focuses on comprehensive planning strategies, on integration of different stakeholders and on resilient urban structures to avoid conflicts between mitigation and adaptation. In the research project "Adaptation Strategies for Stuttgart Region" new adaptation plans and governance structures for two case studies will be developed, and how to implement them in planning instruments like land use plan and local development plan.*

## 1. Introduction

Climate change is accelerating, the change concerns every country worldwide. In Germany the average annual temperature has risen by 0,9°C between the years 1901 – 2006, this leads to more hot days with temperatures of more than 30 °C (Bundesregierung, 2008, pp. 9; Reuter u. Kapp, 2012, pp. 64; Henninger, 2011, pp. 176). Less rain in the summers and more rain in the late winters are expected. This affects more floods in spring and drought in the summers, in general there will be more extreme weather conditions (Umweltbundesamt, 2013, pp. 37-38; IPCC, 2007, pp. 32). Climate projections show that the changes will further continue (e.g. IPCC, 2007). Due to climate change, cities have to protect against the consequences and have to adapt to the climate changes, which are actually occurred. Cities need climate action plans to reduce their vulnerability and to be more resilient – as part of a comprehensive strategy and not only the result of project-oriented measures. However these new climate action plans are often without a comprehensible method and are seldom connected with other issues of urban development, which can have an indirect impact on climate policy. As Germany has a comprehensive planning system of Zoning Planning ("Bauleitplanung") for cities, the new climate action plans could be systematically and methodically connected with urban development strategies and a new urban governance, also as part of the general "Urban Development Policy" formulated in the Leipzig Charter of European Union 2007.

## 2. Regulative German planning system and governance

Although the "European Cities" have a similar tradition of urbanism and urban design, and a common context of European Union, the planning systems are very different. In West-Europe five different approaches can be differentiated (Duehr, S.; Colomb, C.; Nadin, V. 2010):

- „Urbanistic": Focus on urban design and building design regulations (South Europe like Italy).
- "Public-Private-Partnership": Negotiated masterplans for projects (Great Britain).
- "State planning": Centralistic planning, state infrastructure, controlled planning (France).
- "Social welfare": Social cohesion, state planning, balances of public interests (Scandinavia).
- "Zoning plans": Regulation through plans, controlled development (Germany).

In comparison to other European countries Germany has a high-regulated planning system, connected with strong planning governance in the municipalities – they have the authority to decide about almost all of their planning tasks. The Federal Building Code (Baugesetzbuch) gives a formal framework for zoning plans on the level of the city and the quarter (land use plan = Flaechennutzungsplan and local development plan = Bebauungsplan), so that in every city the same system and layout of plans have to be implemented. But also informal plans like urban development plans or framework plans have a strong impact on the order of the cities. Planning departments in the cities of Germany can regulate the zoning, the density and the design of all spatial and sectoral aspects of their city in their own responsibility. The German planning system has also aspects of negotiations and public-private partnerships, but all based on the strict regulated planning rules.

In the 1970s planning was seen as a comprehensive urban development approach, which covers all sectors and all spatial levels of a city, connected with strong governance in a cross-sectoral planning department. In the following decades this approach lost its power, because it was difficult to deal with too much complexity in such a planning demand. Also in the 1980s the interest in strategic planning decreased – neoliberal politics were supporting more project-oriented and investment-friendly urban planning. According to demands of sustainability and reurbanisation, development planning became more important again – as a strategic plan with a clear orientation on implementation and with participation (Albers, Wékel 1996). In the "Leipzig Charter" of European Union 2007 cities are requested to create strategic urban development plans – based on the experiences in Germany especially in cities like Berlin, Hamburg or Leipzig (European Union, 2007).

These different planning approaches are also reflected in the governance structure for planning. As in the 1970s the planning department was directly connected with the Lord Mayor or had a powerful, interdisciplinary department, it lost also its power in the 1980s and became a "normal" sectoral department like others. In the last decade again some new cross-sectorial departments for planning or sustainability had been established, as the case studies will show.

The question is, if challenges like climate change, but also demographical change and social cohesion will support a renaissance of urban development plans. Since the last decade, almost every city has launched a climate plan, mostly focused on mitigation and energy. These climate plans are not only a guideline to improve green energy. They also have to be implemented as objectives and measures into the zoning plans – the planning regulations had been expanded to climate aspects in the last years. As climate adaptation is a new approach, there are questions how to connect this with the existing planning system. Not only as task for landscape planning, but also as a general planning approach dealing with density and vulnerability. Anther question is, how to deal with target conflicts between adaptation and general objectives like Compact City

## 3. Integration of climate adaptation strategies into urban development

To reduce climate risks, a lot of mitigation concepts had been created and mitigation measures had been implemented. But climate change and its impacts will keep up, even if anthropogenic emissions of greenhouse gases are inhibited (IPCC, 2014, pp. 17). Adaptation strategies become increasingly important, they contain efforts to reduce the vulnerability to climate change impacts (Birkmann et al., 2012, pp. 1f). Adaptation is often seen as an antithesis of mitigation, but it must be more perceived as a dual strategy (Birkmann et al., 2012, pp. 1f; Stock, Walkenhorst, 2006), adaptation and mitigation are additional strategies (IPCC, 2014, pp. 17, BMVBS/BBSR, 2009b, pp. 7ff). For this reason the German federal government published the "German Adaptation Strategy" (Deutsche Anpassungsstrategie DAS), the main goal is to create a framework for dealing with the challenges of climate change. In this context risks and also the requirement for actions should be identified, goals for dealing with the climate change should be set and adaptation measures should be developed (Bundesregierung, 2008, pp. 4). The strategy also focuses on comprehensive planning strategies, on integration of different stakeholders and on resilient urban structures to avoid conflicts between mitigation and adaptation (Bundesregierung, 2008, pp. 7, 42).

It is important to combine mitigation and adaptation strategies, but also to realize the target conflicts. With mitigation we try to reduce the human effects on climate change. Without leaving this objective, adaptation is necessary to be prepared for expected changes. Both mitigation and adaptation strategies should be part of strategic climate concepts, which have a huge impact on the urban planning policy. But these strategies can be in conflict with each other: For example adaptation measures like flood protection, extending green belts or reducing urban density have a radical effect on the urban structure – on the other side most of the mitigation plans are following a city model of more density, functional mixture and small traffic according to the Leipzig Charta (BMVBS/BBSR, 2009a, pp. 32). Anyway also synergies between mitigation and adaptation should be defined (Barker et al., 2007, pp. 748 ff).

Most of German municipalities have a formulated planning model, which sets an overall urban development strategy. Existing planning models are "Compact City" or "Sustainable City" from Leipzig Charter. The question is, if the cities are already prepared for the challenges of climate change or if they need new models like "Resilient City", which can deal with uncertainties of consequences. Though the term "Resilience" is controversial because of varied definitions in different disciplines and fuzzy boundaries between them (Kaltenbrunner, 2013, pp. 290). Nevertheless some researches already examined different planning models regarding to climate change, founded on the concept of resilience. The term of resilience gives a basis for dealing with climate change at the city level (BMVBS/BBSR, 2009a, pp. 9ff; Knieling et al., 2012, pp. 14). The word describes resistance, robustness and adaptation capacity (Knieling et al., 2014, pp. 14). The existing planning models had been verified on their capability for climate adaptation with different criteria. The result was that no planning model was completely appropriate for climate change adaptation (BMVBS/BBSR, 2009a, pp. 17-18; Knieling et al., 2014, pp. 58ff) – but "Compact City" had the highest ranking before models like "Edge City", "In-between-city", "Decentralization"," New Urbanism" and "Net City".

Today municipalities mostly pursue the model "Compact City". This model has to deal with target conflicts concerning adaptation and mitigation. The main conflict is between density, which is positive for the energy efficiency and with creating wide green areas, which is positive for a comfortable climate. To find a balance between these target conflicts it is important to take in account specific initial situation (BMVBS/BBSR, 2009a, pp. 32). A planning model fixing a framework for climate-optimized development could be a first approach in a comprehensive climate strategy. If climate concepts would be combined with strategic urban planning concepts and also with the formal instruments, the comprehensive planning system could be strengthened, together with new models of urban planning.

In Germany the building code with its climate adaptation amendments of 2011 already gives a legal basis for a better integration of climate aspects into the regulated planning system (Umweltbundesamt, 2012, pp. 25ff). In particular, the amendments are forming a legal framework to the municipalities; there are new tools to support the preparation and implementation of climate change adaptation measures. Mitigation and adaptation are now planning guiding principles (§§1 para. 5 sentence 2, §1a para. 5). Thereby both mitigation as well as adaptation are getting more and more an important task of formal planning. Informal plans, also sectoral plans like climate concepts can be developed, which are then incorporated as outcome-related basis in the planning process. On this basis a city-wide strategy of "Climate Zoning Plans" can be achieved, which bundles all aspects of climate mitigation, adaptation and resilience. Climate reports (Fachgutachten), climate analysis and climate adaptation concepts can be implemented into different scale levels (Figure 1: HFT Stuttgart IAF).

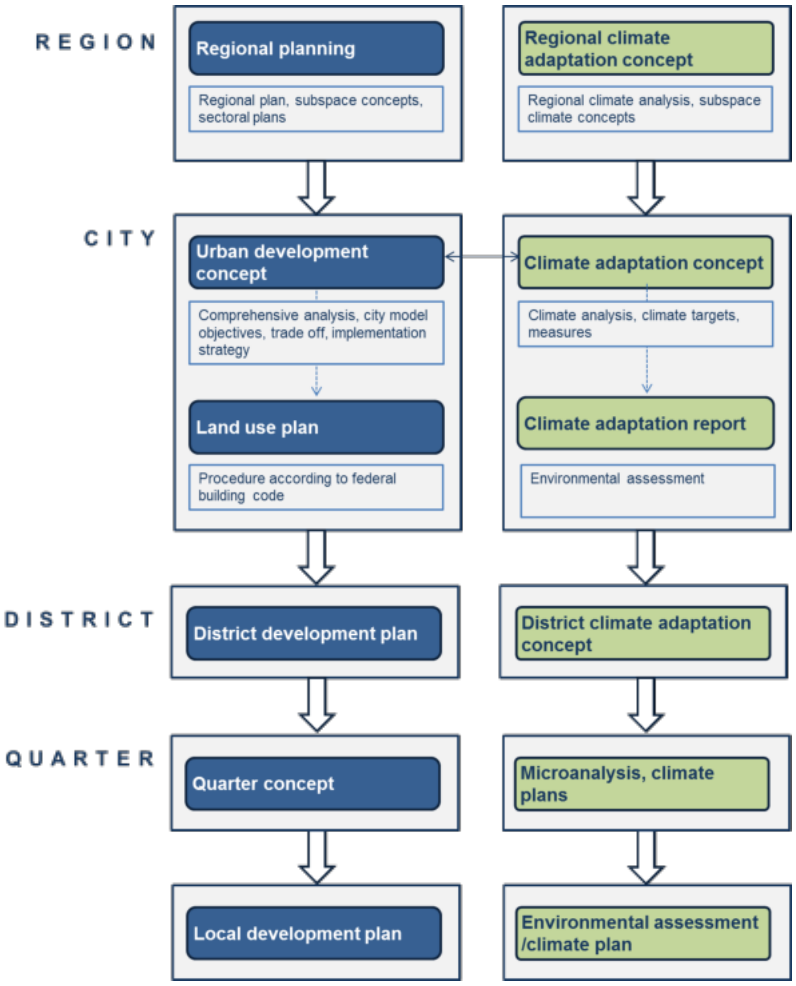

*Figure 1. Climate Zoning Plan*

## 4. Adaptation strategies of the cities of Esslingen and Ludwigsburg

The growing region of Stuttgart is located in the center of Baden-Wurttemberg. A valley and hillsides characterize the city structure. Because of this specific location, the climate and the building development the regular air exchange is restricted (Verband Region Stuttgart, 2008). In 2008 the Verband Region Stuttgart (VRS) has already launched a "Climate Atlas" for the whole region of Stuttgart (Regionaler Klimaatlas). Heat waves, floods, low water levels, drought, heavy storms and thunderstorms are expected impacts of the climate change in the region (Verband Region Stuttgart, 2008). These informations have already been incorporated into the regional plan; green belts and green corridors have been determined. The two case studies Ludwigsburg and Esslingen am Neckar are located next to Stuttgart, but both cities have different topographic situations. While Ludwigsburg is nearly flat, Esslingen has a valley and hillsides. The climate situation of the cities is described in the Climate Atlas. In 2011 as part of a research project a vulnerability analysis was created (Weis et al., 2011): One problem in both cities is the number of hot days, this has a high impact on the human health (Weis et al., 2011, pp. 87 ff; Verband Region Stuttgart, 2008, pp. 131ff). To encounter this problem, different measures are necessary. On this basis the two cities pursue model approaches in collaborative projects.

To face the climate change the joint project of the Verband Region Stuttgart, University of Applied Sciences Stuttgart, the cities Esslingen am Neckar and Ludwigsburg and the Energetikom - energy competence and ecodesign e.V. Ludwigsburg was initiated (Figure 2: HFT Stuttgart). The German Federal Ministry for Environment, Nature Conservation, Building and Nuclear Safety supports the research project, which has a focus on adapting to the impacts of climate change.

*Figure 2. Stakeholders and project structure*

The aim of the joint project "Climate Change Adaptation Region Stuttgart" (KARS) is to connect climate adaptation strategies with the urban and regional planning system, and to link them with energy concepts. In this framework, target conflicts between adaptation, mitigation and urban development will be examined. Also the existing city models will be analyzed if they are fitting to adaptation needs. In the next step a new suggested city model will be implemented on different planning levels and instruments, the climate zoning plan will be expanded with aspects of climate adaptation. Furthermore informal planning approaches such as inter-municipal cooperation, urban development concepts or climate concepts are examined and linked with the formal planning. As a result of the research project, a planning guideline is developed, which evaluates in the practice of urban and regional planning. We are also looking for new adaptation plans for the two case studies and how to implement them in planning instruments (BMUB, 2014). The approaches of the two case studies differ a lot in dealing with planning instruments.

**Case study Esslingen am Neckar**

The city of Esslingen goes the classical way based on the formal planning process. On the basis of a comprehensive urban development strategy and a participation process, the city is currently designing a new land use plan as a formal planning instrument. This process is part of the whole urban development strategy, which runs since 2007 combined with a comprehensive participation strategy for discussing about the future development of the city. Besides the elaboration of the new land use plan a new city model was discussed and will be implemented. The land use plan should be the instrument to fix the urban planning until 2030 (Esslingen am Neckar, 2014, pp. 4).

Esslingen has also a classical governance structure, with a strong urban planning section, which also includes climate topics. The planning section is responsible for both urban development plan and land use plan, and also for climate adaption and mitigation plans. The planners are responsible for the comprehensive approach, but they are only one section in a bigger department (Dezernat) (Figure 3: HFT Stuttgart).

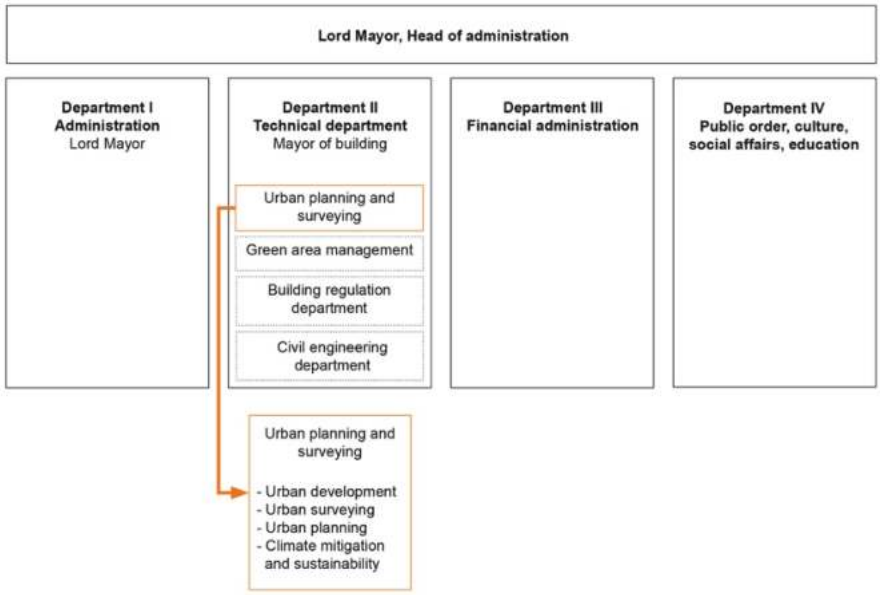

*Figure 3. Planning governance in city of Esslingen*

The city has already an integrated climate mitigation concept together with an energy use plan (Energienutzungsplan). These concepts are now going to be expanded on the integration of adaptation aspects. Esslingen am Neckar integrates measures to adapt to climate change at an early stage. The city council works on an innovative approach by extending the land use plan with climate aspects. Based on the planning regulation symbols (Planzeichenverordnung, PlanZV) the land use plan regulates different areas concerning the function. After a comprehensive analysis of the climate in Esslingen and suggestions from the residents, which came out of a wide participation process, more than 20 spatial structure plans were created. The plans deal with various sectoral topics, like industry, living, energy, use of energy, mobility, landscape, green areas, image and also climate (Figure 4: Esslingen am Neckar, 2012a). The most important content of the spatial structure plans for climate are fresh air corridors, which should be protected from the hillside into the valley (Esslingen am Neckar, 2012a).

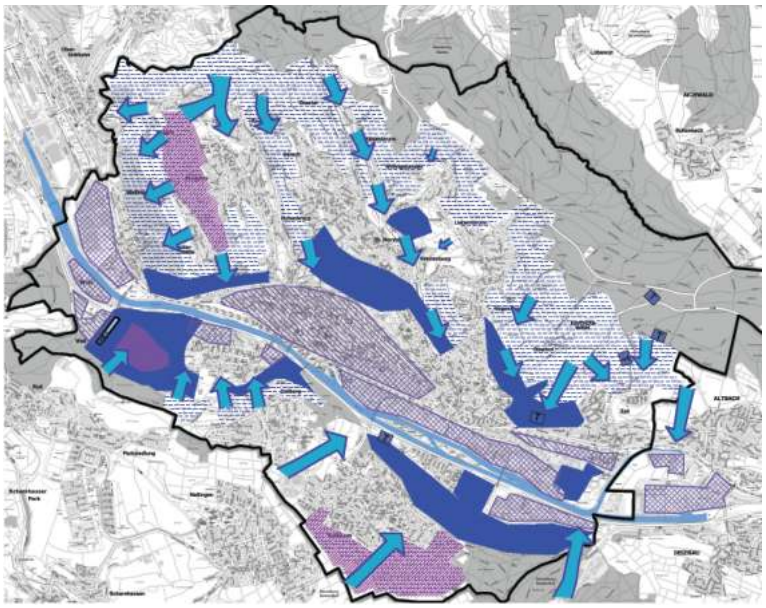

*Figure 4. Spatial structure plans for the climate in Esslingen (arrow symbolizes fresh air corridors)*

The main issues of the climate plan will be introduced to the land use plan with new planning regulation symbols (Planzeichen) (Figure 5: Esslingen am Neckar, 2012b). The symbols will show areas for protecting fresh air corridors and de-densification (Entdichtung), areas for expanding greenspaces especially in residential areas, areas where a densification is possible and areas where the inner development should be strengthened (Esslingen am Neckar, 2012b).

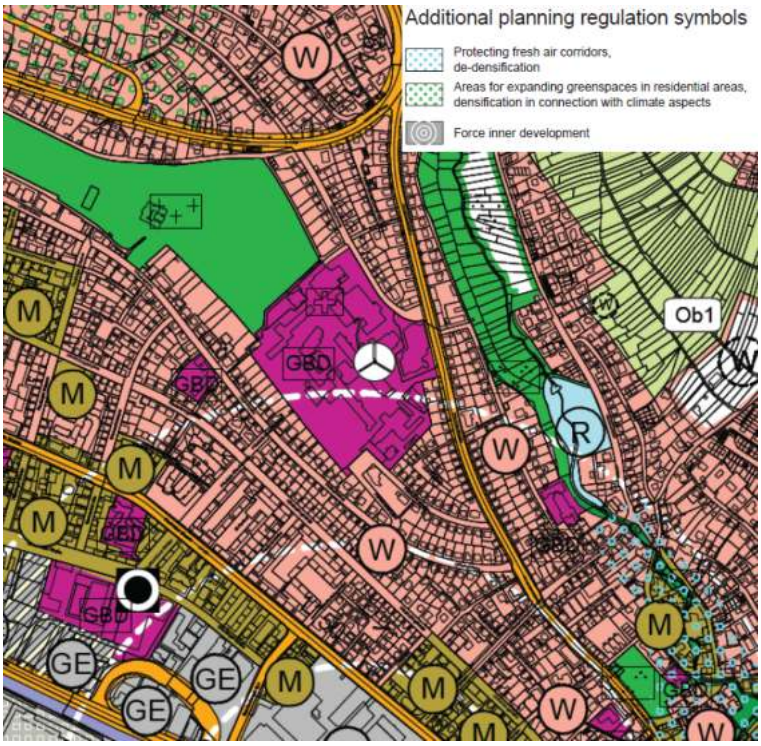

*Figure 5. Preliminary draft (Vorentwurf) of the land use plan, section of the plan Esslingen*

In the participation process it became clear that the questions of density and protecting fresh air corridors are crucial. Until now only a preliminary draft (Vorentwurf) exists for the land use plan, which has no legal binding yet. In 2015 an intense dialogue process has started for the future urban development, where all previous plans will be reconsidered (BMUB, 2014; Esslingen am Neckar, 2014).

**Case study Ludwigsburg**

The city of Ludwigsburg has a main focus on informal concepts. It operates since ten years a very intense urban development process with integrated sectoral concepts and a strong urban development department, but with less spatial concepts. However the formal land use plan is now about 30 years old. The whole urban development of the last years refers more to the informal urban development concept.

The urban development concept considers different sectoral plans, focusing various issues like cultural live, industry and employment, inner city, green in the city, mobility, energy, education, care etc. The concept also focuses district development concepts for the whole city. The whole process was accompanied by a participation strategy (Ludwigsburg, 2012). Every three years there is a big future conference (Zukunftskonferenz) open to the citizens, where the development strategy for the future is reviewed and further developed.

The governance structure of Ludwigsburg also changed following the comprehensive urban development strategy. In 2008 the new division of "Sustainable Development" (Referat Nachhaltige Stadtentwicklung) had been founded and is directly under control of the lord mayor. This division combines all cross-sectoral tasks like urban development, urban renewal, climate planning and economic promotion (Figure 6: HFT Stuttgart). As a consequence the comprehensive strategy is also part of the Governance structure, as all main measures of the city have to fit to the objectives of the urban development plan, monitored by the division. In difference to Esslingen the planning department is only responsible for the land use plan and the zoning plans, but not for the comprehensive urban development.

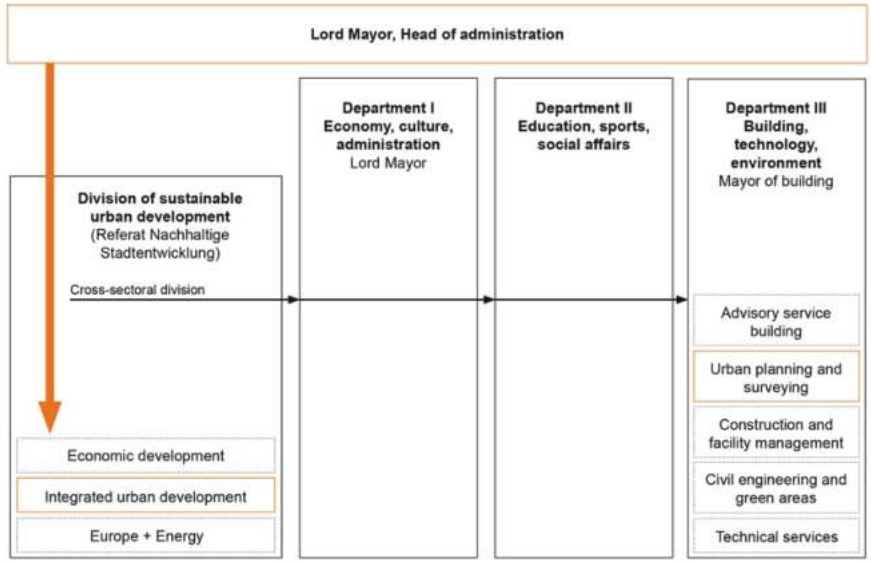

*Figure 6. Planning governance in city of Ludwigsburg*

In the research project Ludwigsburg is focusing on development and adapting plans at the district level for the Oststadt. A brownfield close to the stadium shall be transformed to a new housing area. On district conferences the residents had the chance to participate on the future targets. Also a design competition has been implemented in 2014 (Figure 7: Mess GbR, Urbane Gestalt, SHP Ingenieure).

*Figure 7. Result of the urban design competition in the development area East of Ludwigsburg*

As part of the competition a climate adaptation analysis was accomplished. Climate aspects - in form of a checklist - have already been mentioned in the examination (Vorpruefung) of the competition. To consider the climate more precise in the urban design and the height of the buildings, a microclimate analysis is implemented. At the end this should lead to a climate optimized plan for the future buildings. As an example a public space will be simulated and transformed into a climate-adapted space. Although plantings, floor covering, outdoor urban furniture and the whole design must be taken in account (BMUB, 2014).

## 5. Conclusions

Climate change forces the cities to develop comprehensive climate concepts for mitigation and adaptation. They have a huge impact on the city structure and the planning policy. Especially climate adaptation will get more important in the future. If climate concepts will be systematically integrated into the planning system like a climate zoning plan, the comprehensive planning approach will get a renaissance. Adaptation concepts also have to be also adjusted with mitigation strategies, because of synergies and target conflicts.

Adaptation as part of urban development also needs new governance structures, which are integrating experts of different disciplines like meteorology, urban climatology, urban planning, landscape planning and others. Departments responsible for climate planning should be close to the Lord Mayor and have a cross-sectorial approach.

Both cities are following different approaches in implementing adaptation strategies into the planning system and also in the governance structure in their councils (Figure 8: HFT Stuttgart). Both cities worked on comprehensive participation strategies, and they developed self-standing climate concepts. But Esslingen developed more formal planning instruments and integrated climate aspects (mitigation and adaptation) into the land use plan– connected with a strong planning section. In contrast Ludwigsburg worked with informal urban development plans, which are detailed in sectoral and district plans – they became powerful connected with a big division for sustainable development close to the Lord Mayor, which can implement and control main projects cross-sectorial.

The innovative approaches in dealing with climate adaptation could be a model for other cities. It is important to connect informal instruments with a formal planning strategy. If climate concepts stay informal like in Ludwigsburg, they cannot really be implemented if there are crucial conflicts on the level on a project or it can lead to a lot of approvals for exceptions. Esslingen is also starting with informal plans, but implementing them in the city land use plan, with new symbols and structural plans. This approach is more consistent, new objectives like air corridors will have a long-lasting effect.

Adaption strategies will be a main task for urban planning in the future. There are still a lot of open questions about the methods, the range and the effect on urban structure. But they will influence strongly our land use plans and our objectives of landscape planning and urban renewal. And it is still an open question, which city model considers best the climate change and strengthens the resilience, without loosing objectives of mitigation and sustainability.

# NEW LEGISLATION ABOUT ILLEGAL CONSTRUCTION IN GREECE. THE EFFECT OF ECONOMIC CRISIS.

Konstantinos Lalenis
Associate Professor, Department of Planning and Regional Development, University of Thessaly, klalenis@uth.gr

## Introduction

This presentation is the most recent one from a series of presentations and papers of this author, about illegal construction in Europe, and particularly in Greece. Every new piece of related work in the last 15 years dealt with new developments in relative legislation, policies, and implementations. This particular one is of special importance, since it deals with this issue but under exceptional circumstances –the severe economic crisis, which affected priorities and objectives of legislation.

Illegal construction seems to be an inherent element of Greek urban history. It has definitely affected the shape and function of Greek cities from the past to the present. Urban and rural areas throughout the country have been suffering by the old and widespread phenomenon of illegal constructions. This has been the main and most visible factor of leading to environmental degradation. Some 93,000 legal and 31,000 illegal houses and apartments were constructed each year in Greece between 1991 and 2001. Most of them were in Attica and along the coastline (Technical Chamber of Greece, 2004).

Since early 1980s, efforts have been made to face the problem of illegal construction, through the production of a series of laws and decrees. Usually, a much elaborated –but also complex and often rigid- legal framework had been synthesized, implemented, and replaced by a new one, and most of the times without any evaluation of the up to then implementation. In the meantime, research on the subject proved that the phenomenon of illegal construction continued exhibiting the same intensity, with periodic subsidence and peaks -after the inaction of a new law, and respectively, when the implementation of it faded because of bureaucratic procedures and political interventions.

Our hypothesis is that illegal construction cannot be tackled only by the production of continuously newer legislation, usually increasingly complex and with an alarmingly increasing pace of succession. Illegal construction will further increase if law enforcement is not subsequent and combined to policies. The proposed paper will describe the succession of related legislation in Greece, it will examine the structure of the various legal instruments currently in effect, and it will analyze the problems concerning their (in) effectiveness, accruing from their increasing complexity.

## Definitions

Illegal constructions are considered the ones:
without building permit or
with excess of the building permit or
with a building permit which was retracted or
in violation of the existing building regulations or
with change of its use without issuing a permit for it.
(L.1577/85 – L.2831/00: General Construction Code, art. 22)

## Historical Phases

First peak of illegal construction was in mid '20s, after the disaster of Asia Minor at 1922. It was mostly in the fringes of the cities, where 50% of the 1,5 million refugees resided.

The second wave was around 50s and 60s, as an effect of the internal migration from rural areas to the cities (mainly Athens, Thessaloniki). In 1951, 8% of constructions in the area of the capital were illegal, while in the period 1951 – 1961 there was a further 13,7% increase of the number of illegal buildings.

In the '80s and '90s the nature of illegal construction changed. It was not because of urgent needs for shelter any more, but for holiday houses. This was in accordance to the rise of living standards in Greek society. In order to realize the magnitude and endurance of the phenomenon, one has to consider that at the period 1985-1995, 20%-25% of constructions in Greece were partly or totally illegal, while at 1997, from a total of residence buildings of 4.643.379, 1.000.000 were partly or totally illegal. In this period, a network for exploiting rural land was developed, which lasts until today.

The process of exploiting rural land for creating illegal constructions, includes the following stages: 1. Illegal occupation of (usually) public and (seldom) private land. 2. Division of land in small parcels and sale of them. 3. Illegal constructions on parcels. 4. Political pressure for including the area in the expansions of city plans.

**Usual Causes for illegal construction**

The most frequently recorded reasons for illegal construction are: 1. Urgent housing needs, 2. Economic incentives and profiteering, 3. Lack of housing policies, lack of land cadaster, complex and controversial legislation, no regional planning*, 4. Political clientelism, gradual legitimization of areas of illegal houses due to political pressure, 5. Lack of effective system of detecting illegal constructions (no clearly defined city limits, uncontrolled urban sprawl, outdated technical methods of inspection). 6. Lack of cooperation among the involved departments, corruption. 7. The small size of the majority of properties in land.

* Currently only 3% of the housing production comes from organized housing programmes. Illegal housing was a solution for needs for cheap houses.

**Historic succession of laws related to illegal construction**

The first legislation concerning exclusively illegal construction was P.D. of 18/3/1926 "concerning illegal constructions and prosecution …". It was based on L.D. 17/7/1923, which was the basis of planning legislation for the 20th century Greece. According to it, illegal constructions were to be demolished by the police. There was minimal implementation of this law, and this signified the beginning of a tradition of impunity and indirect encouragement of informal building.

The two pieces of legislation which succeeded P.D. of 18/3/1926 were L. 410/68 "concerning illegal buildings" and R.D. 758/68 "estimation of fines...". The main difference which they introduced was that while illegal buildings before 1968 were exempted from demolition by paying a fine (3% or 10% of the value of the construction), according to them, owners of illegal buildings were to be prosecuted.

Despite the above, illegal construction was alarmingly increasing, so, in mid '70s there was another effort to restrict it by introducing a number of new legislative tools:

General Building Regulation (L.D. 8/73), L.D. 349/74 "concerning demolition of illegal constructions…", L. 651/77 "abolition of L. 410/68, regulations concerning illegal constructions…", etc. According to them, illegal buildings (new constructions) were to be demolished if they were violating significant planning regulations. Fines were imposed, equal to the value of the construction, which were multiplied by five in case of rebuilding the illegal

construction. Penalties also included imprisonment for the owners, as well as for the construction workers, the developers, and the engineers, and the machinery used, had to be confiscated. Illegal buildings were prohibited of being connected to networks of electricity, hydro etc. Complimentary measures were also introduced, such as prohibition of parcellation of rural land in pieces smaller than 4000 m2, etc. At the same time, though, another law, L. 720/77 "exemption from demolition of illegal constructions…", was working at the opposite direction from the above since, according to it, all illegal constructions are exempted from demolition, by the exception of the ones built in public spaces and protected areas, by paying a fine. This law was nullified three years later, after the reaction of the Council of State which characterized it as being unconstitutional (decisions 257, 1687/1980).

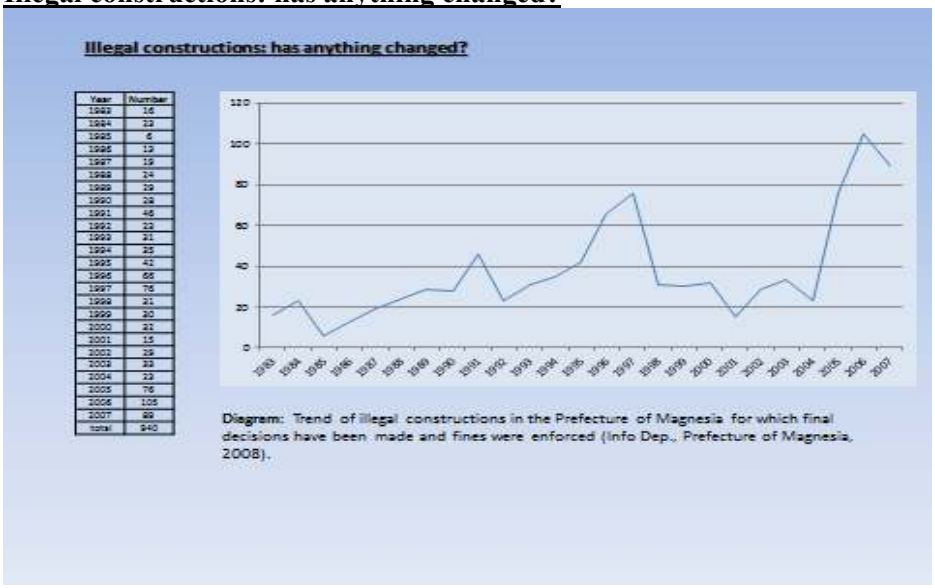
The basis for the various laws concerning illegal constructions was Law 1337/1983, which was also the basis for the contemporary urban planning legislation in Greece. It provided for a process of legalization of illegal constructions by paying fines. Constructions were exempted from being legalized when built in public and/or protected areas, if they were of low quality and dangerous, if their use or their aesthetics were not compatible to the surrounding environment. It also clearly stated that illegal structures made after 1983 should be demolished. This was also embodied to the 1985 revision of the Constitution. Since then, though, various related laws were introduced, setting stricter penalties, describing procedures for paying fines, but also describing various cases in which demolition would not take place. These were L. 1512/85 "modifications of planning regulations..", Ministerial Decision 23186/3626/15-31.4.85, L. 2052/92, L. 2242/94 "urban planning of areas of holiday residences…", P.D. 267/98 "procedure of characterization and demolition of illegal constructions…" and L. 3212/03 "Building license, and other planning regulations……."
.

Legal diversions from legal requirements at that period could also be considered:

- M.D. Γ.4//1983 Re-estimation of non-paid fines
- M.D. 31//1985 (ΥΑ 23186/3626 ΦΕΚ Β 172 1985): exemptions from demolition and connection to electricity and hydro networks for social reasons
- M.D. 231//1985 (ΥΑ 23188/3628 ΦΕΚ Β 172 1985): changing annual fines for exemption from demolition to once paid fines
- M.D. 381//1989: Connection of illegal constructions to electricity and hydro networks
- D. Circ.//1998: Special conditions of implementing legal acts (selling, inheriting etc.) for illegal constructions after the 31st.1.1983
- M.D. 110//1999: connection of illegal constructions to electricity networks
- L 2831/2000: exemptions from demolition
- M.D. 1208/2004: Procedure and documents for temporary connection of illegal constructions to hydro and electricity networks
- M.D. 109//2005 (ΥΑ 1090652/6799/Β0010 ΦΕΚ Β 1393 2005): special conditions of demolishing illegal construction on the coastline
- M.D. 2587/2005: Extension of the period of applications for purchasing illegally occupied land
- M.D. 348//2008 (ΥΑ 348849 ΦΕΚ Β 1 2008): Special conditions of exemptions of demolishing illegal constructions related to stock farming.

This ambivalent way of treating illegal construction did not only fail to discourage it, but proved to be an effective fertilizer for its growth and spreading all over the country.

**Illegal constructions: has anything changed?**



In 2009 pressure for legalization was mounting. Legalization seen as a source of fresh money in the National Treasury, as well as an "electoral weapon". The Ministry of Planning, Public Works and the Environment expressed intentions to prepare a bill for legalization, based on a drastic reduction of fines, which would encourage flat owners to declare the illegal closing of semi hypethral spaces, the illegal use of the basements as main residences etc.

Debates and heated reactions erupted among political parties, public bodies, NGOs, associations and unions, being for, or against such a prospect. Opposition to the bill was expressed by political parties from the centre and centre – left , the Technical Chamber of Greece, the Association of Notary Publics, unions of lawyers, environmental associations etc., on environmental, legal, and ethical grounds. Support for the planned bill was expressed by the Union of Developers and the Union of Owners of Immobile Property, who were claiming to express the desire of citizens for more residential space, and the desire of the government to gain more money.

With the change of government after national elections, the new Ministry of Planning and the environment suspended the "regularization" part of the implementation of Law 3375/2009, until May 2010. The rest of the measures concerning semi hypethral spaces remained. Furthermore, the Council of the State ruled that "regularization" is unconstitutional and all illegal constructions made after 1983 should have been demolished. L. 3375/2009 was replaced by L. 4014/2011.

The legislation which is in effect at the present in Greece, is Law 4178/2013. It is worth mentioning that L. 4178/2013 was introduced in haste, since in April 2013, the Council of the State ruled that the previous law (Law 4014/2011) was unconstitutional in specific articles and in its whole, and thus, it had to be replaced. L. 4014/2011 kept on using "regularization" in a way that many categories of illegal constructions could be allowed to be used as legal for the next 30 years, provided that a penalty was deposited for this purpose. In fact, the objectives of Law 4014/2011 –given the economic crisis in Greece- were directed towards fine collections, rather than dealing decisively with illegal construction. And this is also obvious to the objectives of the new legislation, although the very striking elements of the previous law were omitted.

According to its provisions, acts of law directly or indirectly granting property rights on immobile property containing or consisting of illegal constructions, are forbidden or –if

conducted- automatically nullified. The law also describes cases for which, there are exceptions to the above rule. Types of illegal constructions –characterized as "arbitrary"- excluded from the exceptions are the following:

- Illegal buildings or structures built on public property, and on open/public spaces.
- Illegal buildings or structures in preexisting adits/galleries.
- Illegal buildings that have been built on or too close to roads or streets and therefore pose a safety hazard to transport.
- Illegal buildings or structures on forestry land, seashores, beaches, or too close to coastlines, or riverbeds.
- Illegal buildings in other protected areas i.e. archaeological sites, historical sites, traditional UNESCO villages, NATURA areas, national parks etc.

Penalties and punishments are described, in the forms of fines, imprisonment, and expulsion from professional bodies, for the owner of the illegal structure but also for the engineers involved in their study and/or construction, the workers working in them, and the notary publics issuing legal acts granting property rights. Also, regarding the Environmental Authorization of works and activities, this Law proceeds in the formation of the Central Council of Environmental Terms and Conditions, aiming to consult on the outcome of Environmental Impact Assessments studies on specific cases.

**Concluding remarks**

Two main conclusions can be extracted from the above: a. illegal construction has been inherent to the development of Greek cities and villages. It is aimed to tackle it through a strict system of penalties, fines etc., the implementation of which, though, has been proved almost impossible. b. political initiatives up to now, were dealing with this phenomenon by having as main goal the maximization of economic and political profit, contrary to the principles of the wellbeing of citizens, the protection of the urban and rural environment, and sustainability in general.

Economic crisis made the above even more intense and the accruing contradictions even more obvious. New legislation seems to have as main objective the collection of money and not the discouragement of illegal construction. The indirect effects in fact, seem to let this phenomenon untouched and uninhibited, since it is a source of channeling more –badly needed- money to fill the government's dept. And the arising questions concern the sustainability principles put in gradually greater risk, and the fate of future generations being a matter of irresponsible gamble.

# Introduction of Land Readjustment in the Netherlands: reflections from Germany and Spain

**Dr. Demetrio Muñoz Gielen**
*Nijmegen School of Management, Department of Geography, Planning and the Environment, P.O. Box 9108, Nijmegen, 6500 HK; University of Amsterdam, Faculty of Social and Behavioural Sciences, Nieuwe Achtergracht 166, Amsterdam, 1018 WV; Municipality of Purmerend, the Netherlands; email: d.munozgielen@icloud.com.*

## Abstract

*Many say that Land Readjustment (LR) can potentially resolve the stagnation of development that accrues from scattered ownership and improve the financing of public infrastructure in private land development. Under this enthusiasm for LR lay the arguments that it avoids the need of expropriating land, empowers landowners to develop their land and provides the necessary public infrastructure at a lower or even no cost for the public budget. This enthusiasm has enticed the Dutch government, who asked an expert committee to submit a draft proposal for a LR-regulation and since the summer of 2014 is working towards a draft LR act. However, LR not always resolves the mentioned problems and in some countries it is even a 'dead word' in legislation. Unfortunately, no much literature analyse which aspects of LR-regulations might be critical in practice. Supporting on the experience with the German and Spanish LR this paper offers a framework of analysis to evaluate whether a Dutch LR-regulation might work or not in practice.*

**Key words:** land readjustment, financing public infrastructure, public value capture.

## 1. Introduction

Land Readjustment (LR) is experiencing a revival in academic literature (e.g. Hong & Needham, 2007; Van Der Krabben and Needham, 2012) and becoming popular among international development organizations like UN-HABITAT (e.g. 2012), the World Bank (e.g. 2014) and the Lincoln Institute of Land Policy (e.g. Hong and Brain, 2012). The instrument is advocated as being one important land management tool in developing countries, where a rapid urban growth is making thee need of large investments in public infrastructure more evident. It is also advocated that developed economies could profit from it too because it is as an alternative to the traditional two ways of assembling land: voluntary exchange or public expropriation[1]. E.g. Great Britain and the USA, where since the 2000's the use of public expropriation to transfer private property from one group of owners to another for private development is becoming more controversial and its enforcement more costly (Hong and Needham, 2007: xv-xix; Hong, 2007: 10-12). This enthusiasm is not new; it previously enticed at the end of the 1970's and in the 1980's many international organizations, scholars and practitioners (e.g. Doebele, 1982). They found LR, inspired by its successful application in the post-war reconstruction of Japan and South Korea, a useful tool to improve the quality of urbanization not only in developing countries but also in Western countries like the US. Land readjustment for large-scale urban development remained however largely untested outside Asia, Germany, Spain and Israel due apparently to the lack of an objective and trusted body of professionals in developing countries and due to the resistance of existing real estate interests (Doebele, 2007).

[1] *Expropriation* is equivalent to *eminent domain* and *compulsory purchase* or *acquisition*.

Similarly to those times also nowadays some voices are critical about the practical possibilities of LR. The instrument seems not always to be an effective and self-financing method of urban development, which is why it has sometimes been named a 'sleeping beauty', potentially interesting but rarely useful in practice (Alterman, 2012: 765). Unfortunately not much literature analyse with aspects of LR might be critical in practice. This paper thus seeks to contribute to literature aiming a more systematic analysis of the effectiveness of LR-regulations (e.g. Turk, 2008; Yilmaz et al, 2015). To do so it critically reflects on the recently announced plan of the Dutch government to introduce a LR-regulation in the Netherlands. The reflection supports on the experiences with two LR-regulations: the German *Umlegung* and the Spanish *Reparcelación*. Both regulations are being extensively applied for decades now, so cumulatively they contain many potential lessons from which other countries may learn. Based on this experience, this paper evaluates the current proposal for a LR-regulation in the Netherlands. As there is an almost dramatic lack of English spoken scholarly publications about the Spanish LR, this paper will also contribute to filling this gap in the international literature.

Germany introduced LR (*umlegung*) already in the 19th Century, and nowadays the regulation is applied with regularity, especially in small and medium sized urban green-field developments, but there are also cases of *Umlegung* in urban regeneration areas (interviews with Mueller-Joekel, 2014). Spain introduced LR (*reparcelación*) for the first time in 1956 and the regulation was modified in the 1970's and beginning of the 1990s. Until the 1980s the regulation was not applied properly. In the 1990's, following a reordering of competences in urban planning among the central and the regional public administrations, each of the 17 Spanish regions developed its own variant of LR. Of these variants this paper will focus on the one of the region of Valencia[2] because it introduced some novelties that extended to most other regions. After the 1980's the instrument has been extensively used in almost all urban development in the country. Since that time almost the entire urban development in Spain, except strategic developments (e.d. large industrial sites, some complexes of public facilities and social housing and other singular cases) and main infrastructure (highways, railways, airports, seaports, etc), has been developed through LR (Muñoz Gielen, 2010 and 2014). This paper will refer to the LR-regulation that was in force until the 1980's as 'traditional LR', the LR-regulation since then as 'Spanish LR' and the LR-regulation introduced in the 1990's in the region of Valencia as 'Valencian LR'.

Section 2 introduces the proposed new LR-regulation in the Netherlands. Sections 3 to 7, based on the experience with the German and Spanish LR, reflect on separate aspects of LR: section 3 analyses which party is empowered to implement LR, section 4 the enforceability of readjustment on opposing landowners, section 5 how much costs can be charged on landowners, section 6 whether LR guarantees the construction of public infrastructure and section 7 the transparency and accountability of the LR procedure. Finally, section 8 draws general conclusions.

## 2. The Dutch proposal of LR

The Netherlands already dispose since 1924 of a LR-regulation meant for reassembling agricultural land that has succeeded in reordering a large part of the total agricultural surface into more efficient plots. In 2013 the Dutch Ministry of Infrastructure and Environment assigned to a special committee (from now on: 'LR Committee') the task of drafting a draft proposal of LR-regulations meant for urban development. In previous years the problems with the stagnation of urban development created among professionals, academics and stakeholders (e.g. the Dutch Federation of Municipalities and the Dutch Federation of Urban Developers) support for a LR-regulation for urban areas. On the 1st of July of 2014 the Dutch

[2] 1994 *Ley de Regulación de la Actividad Urbanística de la Comunidad Valenciana*.

Parliament (second chamber) expressed its support to the introduction in the short term of a LR-regulation, and nine days later the LR Committee offered his conclusions to the Ministry (Commissie Stedelijke Herverkaveling, 2014). In its rapport, the LR Committee made a draft proposal of LR-regulation (from now on: 'Proposed LR'). The Ministry is at this moment organizing an open consultation among stakeholders and experts and working towards a draft law (from now on: 'Draft LR-act'), which will probably be published at the end of 2015. If finally approved, the act is supposed to become in force in 2018, together with a major revision of urban and environment legislation. This paper will thus reflect on the Proposed LR and, as far as some of its contents are known, on the Draft LR-act.

The Proposed LR regulates first the reallocation and realignment of all the rights in rem[3] regarding real estate (from now on: 'properties') within a development area (*blok* following the terminology of the LR Committee). Second, the Proposed LR regulates the construction of the necessary infrastructure. Within current civil Dutch legislation the owners of the rights in rem of real estate (from now on: 'owners') can agree land readjustment without any intervention of the public administration. However, in case there is a minority of owners opposing, the Proposed LR gives to the municipality, provided that a majority of owners supports it and the intended plan is economically feasible[4], the powers to force the readjustment of the properties of the minority. This compulsory readjustment is meant to be carefully regulated and foreseen with the necessary legal guarantees, the municipality remains responsible for all decision-making and an independent committee should supervise the procedure. Regarding these compulsory powers, the Ministry has recently announced that it will not include it in the Draft LR-act, leaving only the possibility of a voluntary readjustment that will require agreement among all the owners.

The procedure in the Proposed LR follows the following steps: after anybody undertakes the initiative, and provided that a majority of owners support it, the municipality makes a public notice of the draft Readjustment Plan (*Ruilplan*), which will be available to the public. A Readjustment Plan consists of two sets of documents: a List of Owners (*Lijst van Rechthebbenden*) and a Distribution Plan (*Plan van Toedeling*). These documents prescribe the physical transformation of the development area to the new uses and functions and the reassignment and reallocation of properties. In case these new uses and functions do not fit within the existing Land Use Plan, this plan will have to be modified[5].

Before the Land Use Plan is modified and before the draft Readjustment Plan is approved, municipalities must check whether all the necessary development costs are secured[6]. This means that the implementing party (the one who leads the process, see section 3) has to sign a development agreement (a private law contract) in which he commits to bear all the

[3] De most relevant 'rights in rem' regarding real estate are: property right (*eigendomsrecht*), building lease (*recht van opstal*), flat ownership or condominium (*appartementsrecht*), usufruct (*recht van vruchtgebruik*), leasehold or enphyteusis (*recht van erfpacht*), use right (*erfdienstbaarheid*) and mortgage (*hypotheek*).

[4] I.e. provided that the economic value of the land increases thanks to the transformation from the previous to the new uses.

[5] This paper focuses on LR-plans that involve such a modification of existing functions and uses that there is always need of modification of the Land Use Plan. With a modification of the Land Use Plan I mean any land-use regulation decision of any kind (rezoning, additional development rights, relaxation of existing land-use regulations, etc) that allow more economically profitable functions and uses.

[6] Costs are 'secured' when there is certainty that there is, or will be, financial means available to pay them. This certainty can be created in different ways: *i)* When there is a development agreement or any other form of private law contract that commits any party to pay; *ii)* When any public body commits itself to subsidy the costs; *iii)* When the municipality has the land and has calculated that the profits of selling the land will cover the costs (thus, in case of public active land policy, which is excluded from the situations described in this paper).

development costs (in kind or, in case that the municipality has to invest in the infrastructure, in money). The development costs that must be secured by the implementing party include the necessary infrastructure located inside the development area (the *blok*). See section 5 for a definition of infrastructure inside and outside the development area. In case the implementing party refuses to secure the development costs located inside the development area, the municipality has the power to refuse the approval of both the Readjustment Plan and the modification of the Land Use Plan. Regarding the costs of infrastructure outside the development area, the implementing party and the municipality can negotiate to include them in the development agreement too, but this is strictly voluntary. If the implementing party refuses, the municipality has not the statutory powers to refuse the approval of the Readjustment and Land Use plans. So in case there is no agreement about these costs, the municipality must try to recover them through section 6.4 of the 2008 Physical Planning Act (*Wet ruimtelijke ordening*). So one important feature of the Proposed LR is that it prescribes how to recover only part of the costs and partially supports on section 6.4 to recover the rest (see Frame 1). We will see later in section…. why this might be a problem.

**Frame 1: Section 6.4 of the 2008 Physical Planning Act**

Section 6.4 gives to municipalities the power to compulsorily charge infrastructure costs on landowners through a Development Contributions Plan (*Exploitatieplan*). When a land use plan has to be modified to allow a building plan, and municipalities do not manage to agree voluntarily with the landowner about his contributions for the infrastructure, they can approve this plan together with the modification of the land use plan. In the Development Contributions Plan municipalities calculate the costs that landowners will have to contribute. Once the municipality approves this plan together with the new land use plan, she can make granting the building permit conditional on this contribution. If the landowner does not secure this contribution the building permit becomes nullified. In this sense, municipalities can compulsorily charge these costs on landowners: if landowners do not pay, they cannot build.

There are many drawbacks of this way of charging landowners through the Development Contributions Plan. First, the 2008 Act and the 2008 Physical Planning Decree (*Besluit ruimtelijke ordening*) regulate in detail the costs that can be included in a Development Contributions Plan and charged to the landowners: mostly local, site-specific, on-site public infrastructure. Large public infrastructure, especially that one located off-site, largely cannot (partially or totally) be charged to the landowners. There have been examples of municipalities charging these costs to landowners through a Development Contributions Plan, but judicial scrutiny is limiting this practice (Buitelaar et al., 2012: 63-65). Second, specially in urban regeneration areas, the evaluation methods of land prescribed in the 2008 Act and Decree often diminish further the amount of costs that be charged to landowners. Third, the approval of this plan involves an active and direct involvement of municipalities, who bear responsibility on the implementation of the infrastructure and might suffer losses if finally the costs are higher than initially calculated.

Due to these drawbacks municipalities do preferably agree a development agreement with the landowner in which he commits to bear the costs, instead of approving a Development Contributions Plan. Indeed, Development Contributions Plans are not used frequently: up to July 2010 municipalities used it in only 3% of the building plans (Buitelaar et al., 2012: 62). However, municipalities are not free to force a development agreement and landowners must agree voluntarily. The lawmaker presupposes that in case there is not agreement, municipalities are able to recover the costs through a Development Contributions Plan, so following jurisprudence municipalities cannot easily refuse the plan. Recent jurisprudence is punishing those municipalities who refuse plans just with the argument that the landowners did not agree a development agreement (Fokkema, 2014; BVH Ruimte i.s.m. Vreman Advies, 2014: 19-20). Municipalities must prove that with a Development Contributions Plan the municipality will finally end up subsidizing the costs. Only then municipalities can refuse the

initiative without the risk of loosing the case at the Courts. This implies that municipalities have to do a draft Development Contributions Plan beforehand to prove the need of subsidization, which implies a direct organizational input that not all municipalities can afford.

Together with the draft Readjustment Plan, the municipality also makes a public notice of a draft List of Pecuniary Regulations (*Lijst van Geldelijke Regelingen*), which will also be available to at least the owners. A List of Pecuniary Regulations transposes the Readjustment Plan into its financial consequences: it includes a land exploitation calculation[7], the 'initial value' of all properties included in the development (*inbrengwaarde*) and the 'end value' of the resulting serviced building plots (*uitneemwaarde*)[8], a calculation of the balance for each owner, a calculation of the compensation for those owners that cannot receive a serviced building plot[9] and of other costs as for example compensation for the removal of existing buildings or users.

After the public consultation, and after the implementing party signs a development agreement in which he secures at least the development costs located inside the development area, the Municipality approves the Readjustment Plan (but not yet the List of Pecuniary Regulations). Previously or after this, the municipality modifies the Land Use Plan[10]. Once the Readjustment Plan is irrevocable[11] the Property Register (*Kadaster*) reassigns and reallocates the properties, i.e. issues new titles to returning property owners. Now the financial processing starts: the implementing party works out the List of Pecuniary Regulations, the municipality approves it, the implementing party constructs the infrastructure or pays the municipality for doing so and finally the serviced building plots are delivered to the owners and the public infrastructure to the Municipality.

## 3. Who is the implementing party?

One important feature of a successful LR might be whether it offers or not the possibility to different parties of becoming the implementing party[12]. The implementing party is the one who:

a) Prepares the necessary documents (the Land Use Plan, the Readjustment Plan and the List of Pecuniary Regulations in the Proposed LR for the Netherlands), creates enough

[7] A 'land exploitation calculation' includes a calculation of all costs and incomes made in the development of the land, i.e. the process that starts with the initial physical situation and ends with the delivery of serviced building parcels ready for building. The costs and incomes are translated to their present or future value and incremented or diminished with the expected indexes.

[8] The 'initial value' is the market value of the properties under the presumption that the Land Use Plan is not going to be modified, the properties are not going to be readjusted and the area is not going to be developed. It excludes thus the expectations of future value increase due to the development of the area. The 'end value' is the market value of the resulting serviced building plots, i.e. after the modification of the Land Use Plan, the readjustment of the properties and the construction of the infrastructure.

[9] Because for example their initial property was too small to account for a full serviced building plot.

[10] Provided such modification is needed. As said, this paper focuses on those cases that involve such a modification of existing functions and uses that there is always need of modification of the Land Use Plan.

[11] A Readjustment Plan is irrevocable after the legal possibilities of challenging it at the Courts have passed, or in case of appeals, after the Courts confirm the municipal approval.

[12] The 'implementing party' receives different names in literature, e.g. a 'self-governing agency for redevelopment' or 'land assembler' (Hong and Needham, 2007: xv-xix), a 'land readjustment agency' (Hong, 2007: 20), ….

political and social support for the plans and submits them to the public administration in charge (the Municipality in the Dutch case);
b) Actually provides the public infrastructure and delivers serviced building plots (and in case he has to advance investments, the one who also bear financial risks, see later).

It is relevant whether not only public bodies, but for example also property developers and associations and cooperatives of owners have the possibility of becoming the implementing party. This is relevant because public bodies are not always powerful enough (organizationally and financially) to lead LR. For example public bodies might lack the necessary technical and managerial skills, and if other parties can also lead the readjustment the chances are larger for an effective implementation of LR (Yilmaz, 2015: 159, 162).

*Who is the implementing party in Germany and Spain?*
In both Germany and Spain, the same as in the Dutch Proposed LR, it is the Municipality who keeps all the competences of approving the plans and of organizing all necessary administrative procedures, included all public consultation. But the implementing party does most of the work (a and b). Who is the implementing party in Germany and Spain?

- In Germany the implementing party is a public development company, most of the times belonging to the Municipality;
- In Spain there are different possibilities, the Municipality (or sometimes another public body) can point out as implementing party:
    - In both the Spanish and the Valencian LR: a public development company;
    - In the traditional LR: besides a public development company, municipalities can also point out the landowners of at least 60% of the surface of the development area as the implementing party;
    - In the Valencian LR: besides a public development company, municipalities can point out in a public selection not only the landowners, but also any other party (not necessarily owning land, although most of the times it is a property developer who owns part of the land). So there is not anymore the threshold of 60%.

*Who is the implementing party in the Proposed LR for the Netherlands?*
In the Proposed LR the implementing party is the majority of owners and, if the Draft LR-act finally excludes compulsory readjustment, a 100% majority. It is possible for the owners to agree with for example commercial developers to implement LR together, but the support of the majority is *conditio sine qua non*. So, the same as the German LR, the Proposed LR in the Netherlands reduces the universe of parties that can implement LR: in Germany only a public municipal development company can implement LR, in the Netherlands only the majority of owners or those parties that have an agreement with the majority of owners. Leading LR in Germany relies thus on strong municipalities, and in the Netherlands on an agreement with a majority of owners.

In the traditional Spanish LR, where both a majority of landowners and a public development company could implement LR, there were often many landowners opposing the plans. In theory municipalities could overcome resistance through compulsory LR or through expropriation: In Spain, besides the compulsory land readjustment, there is also the possibility, rarely used, of expropriating the land. However, municipalities were not strong enough, and/or they did lack the necessary political will or financial resources to intervene, so opposition of landowners often delayed LR and/or forced municipalities to lower the amount of public infrastructure and other requirements. This lead in the 1960s, 1970s and 1980s to badly provided developed areas. In the 1990s the region of Valencia gave to municipalities the statutory powers to point out private parties not necessarily owning land as implementing parties, and gave them the powers to enforce readjustment. This was already introduced in the 1970s in the traditional Spanish LR, but the Valencian LR gave to the selected parties enough certainty about their risks so that they actually dared to assume the responsibilities of

becoming implementing party (section 6 reflects further on these certainties and risks). This novelty reduced the need for commercial developers to acquire land beforehand and thus reduced their financial risks, this leading to a sharp increase of private implementation of LR, which coexisted alongside those LR-plans implemented by public bodies. The Valencian LR contributed in this way to increase the effectiveness of LR in terms of a sharp increase of areas developed with LR and a clear improvement of the quality and quantity of the public infrastructure in the developed areas. This novelty extended to almost all Spanish regions (Muñoz Gielen & Kortals Altes, 2007). Whether LR in the Netherlands could benefit with such a measure is difficult to answer, but it seems that at least the requirement of supporting on a majority of owners will exclude many areas to become developed with LR.

## 4. Voluntary or compulsory LR?

*Voluntary and compulsory LR in Germany and Spain*
In both Germany and Spain there is the possibility of both a voluntary and a compulsory LR. In the voluntary LR the implementing party agrees with all the owners the terms of the readjustment, i.e. the detailed infrastructure provision projects (quality, quantity, costs), when will he provide the infrastructure, how much and when will the owners pay their share of the costs, which serviced building plot will receive each owner, etc. Voluntary LR can only be done if all owners agree to the terms of the readjustment. That's why voluntary LR is also called 'private' LR. With an increasing number of owners the chance to get this agreement from all participants decreases, so the experience in both countries show that there is need of a compulsory LR.

In the compulsory LR the implementing party can impose the readjustment terms upon the owners (usually just a minority of them opposing the development) and force the readjustment. This means that the implementing party, after the public administration approves the LR-plan, inscribes in the property registers the new property boundaries (new serviced building parcels for the owners and the public infrastructure for the municipality). All owners, whether they agreed or not with the LR-plan, receive a new serviced building parcel, so there is no expropriation, i.e. the property of owners who do not agree just becomes readjusted without the need to expropriate it. This serviced building parcel uses to have different dimensions than the former property (smaller, as there was some land needed for the public infrastructure), and might be located in a different place, but it is more worth in economic terms than the former property. Compulsory LR is not always applied in Germany and Spain, but the mere possibility of it has been central in the effectiveness of the regulation. This conclusion for Germany and Spain is also said to apply for any LR-regulation that wants to become effective (e.g. Hong, 2007: 17-21).

*Voluntary or compulsory LR in the Netherlands*
The LR Committee proposed to the Ministry the possibility of forcing LR on a minority of owners provided that a majority supported it. In the Proposed LR it is the local council (local legislative body) the one who should decide whether there is sufficient support among owners, and the LR Committee suggested a minimum percentage of 80% of the total surface of the plan area, of the number of owners or of the market value of the land. Here the Proposed Dutch LR is more conservative than the German or the Spanish LR, where no minimum support among owners is needed. Based on the experience in Germany and Spain this can lead to delay and stagnation of LR in the Netherlands. As recently the Dutch government announced to introduce only a voluntary LR, this shortcoming will be worst, and LR might become a 'dead letter' in legislation. As far many stakeholders manifested their disconformity with this decision and there seems to be also resistance in the Parliament, so this will be one important discussion in the next months.

## 5. How much do owners pay?

LR is often priced as being a self-funding way of paying all the externalities of urban development. In theory, the economic value increase that accrues from the development should pay for all necessary development costs. The value of land increases thanks to (1) modifying the land use plan towards more profitable uses, (2) readjusting the properties to adapt to the new uses and (3) providing the infrastructure[13]. The development costs to be paid with the value increase potentially include the construction of public infrastructure directly needed for the development and also those external negative impacts in the wider physical or social realm (off-side infrastructure, 'soft' social infrastructure, affordable and social housing, sustainable measures, etc). There are for owners two possible ways to contribute: ceding land for free or very cheap (meant for public infrastructure or as payment in kind for the costs of constructing the public infrastructure) and paying monetary contributions (*cfr.* Yilmaz, 2015: 160). A distinction should be made between costs that can be compulsorily charged to the landowners, and additional contributions that can be agreed voluntarily.

*How much do the German owners pay?*
In Germany landowners can be compulsorily charged through LR with the following costs:

- The area designated for local public infrastructure in the legally binding land use plan (the 'hard' local infrastructure like roads, sewerage, etc, which occupies from about 20% to 40% of the total development area[14]) must be ceded for free provided that the value increase due to LR (the second value increase step of the three mentioned above) is large enough to compensate owners for this, see under. This means that in areas with high land values municipalities usually can obtain this land for free, but in areas with low land values municipalities will have to compensate landowners or just designate less land for local public uses;
- German municipalities can also, after providing the local public infrastructure, charge a Recoupment Charge on landowners (*Beitragsbescheid*) to pay at most 90% of the costs of constructing this infrastructure[15]. This contribution (formally not a tax) is based on the *Erschließungsbeitragsrecht* of the Federal Building Code (Hobma et al., 2014: 33-39).

So in principle German municipalities will not recover all the costs made. Regarding the costs of constructing the local infrastructure, the Recoupment Charges covers a maximum of 90% of these costs. Regarding the land needed for this local infrastructure, municipalities have to support on a second charge, the 'Readjustment Charge'. After the readjustment of the properties municipalities can charge landowners the economic value increase of their land that accrues from the readjustment (i.e. the fulfilment of the LR-procedure and the reshaping of property boundaries in the property registers, this is the second value increase step of the three mentioned above). The economic value increase that accrues from the modification of the land use plan (first value increase step) belongs in Germany to the landowners and cannot be charged. Landowners usually pay by ceding for free the land that is needed for the local public infrastructure (the mentioned 20 to about 40% of the total development area). In case this land is not enough to pay the value increase due to readjustment, landowners have to pay an additional amount in money, or they can also pay with extra land. These extra payments in money or land can be enough to pay all the costs (land and construction costs) of the local infrastructure, and sometimes also to cover part of the costs of supra-local public

[13] For example a former deteriorated industrial area or an agricultural area has to be rezoned to residential before land readjustment can proceed. Only the fact that the administration rezones the land does automatically increases the market prices of the land. After the land has been readjusted, the price of land also increases again, and once the infrastructure has been constructed, the price might increase too.

[14] The local public infrastructure that can be compulsorily charged excludes 'soft' social facilities usually serving wider areas, e.g. schools.

[15] This regards only the costs of constructing the local infrastructure, and excludes the needed land and of course the costs of 'soft' social facilities.

infrastructure (contributions for infrastructure that serves a wider area and are located in, near by or far away from the development area) and of 'soft' infrastructure (like schools, sport facilities, health-related buildings, retirement homes for the elderly, affordable/social housing).

Summarizing, both the Recoupment and the Readjustment charges together sometimes cover all the costs of the local public infrastructure, and sometimes less, depending on the land values and market circumstances in the specific area. If taking into account the supra-local public infrastructure and other 'soft' infrastructure, neither the Readjustment and the Recoupment charges are usually enough to pay all the costs, so there is a need of public subsidization[16].

This might be the reason that many German municipalities try to avoid the formal compulsory procedure and prefer to agree LR voluntarily with the owners. In case of voluntarily land readjustment, municipalities can negotiate with landowners to contribute more. They do so sealing a development contract, referred to as 'administrative contract' because it is regulated in public law (Section 11 of Federal Building Code –BauGB). Any party and the Municipality can seal different sorts of administrative contracts: *Erschließungsvertrag* and *Folgekostenvertrag* (Hobma et al., 2014: 28-30, 32). It is also possible to seal a 'private' law contract (ruled in Civil Law). These contracts can include additional contributions for supra-local and soft infrastructure (Hobma et al, 2014: 35). For example in Stuttgart these contracts are used to provide up to 50% of the land for public infrastructure or to provide free/cheap land for affordable/social housing; in Munich they are used to charge part of the economic value increase that accrues from modifying the land use plan. However, both landowners and Municipalities must agree voluntarily on this. If there is no agreement the Municipality cannot charge more than the above-mentioned Recoupment and Readjustment charges.

*How much do the Spanish owners pay?*
In the Spanish LR landowners are compulsorily charged with the following costs:

- Landowners must cede for free all the land designated for local, supra-local and soft public infrastructure in the land use plan. This is an average between 60% and 80% of the development area. Depending on the regional LR-variant, this might include important amount of land ceded for free or for a cheap price meant for affordable and social housing[17];
- Important contributions in land for supra-local public infrastructure located outside the development area;
- All the costs of constructing the local public infrastructure (but not the supra-local and soft infrastructure);

[16] For example, in good areas (Frankfurt) the value of agricultural land can be about € 8/m2, once rezoned about € 200/m2 and once readjusted about € 400/m2 (this latter value is an estimation of the value of the final building plots, provided with local public infrastructure, minus the cost of constructing this local public infrastructure). In this example the landowners have to cede for free up to 50% of the total surface of their original parcels (they receive 50% of their former property as serviced building plots, which is as worth as the value of 100% of their property before readjustment). If there is need of less local public infrastructure, landowners will have to pay the remaining in money or with land.

[17] For example, in the Bask country regional legislation prescribes that 20-40% of the development area in regeneration sites (20% from 1994 to 2006, and 40% onwards), and 65-75% in green-field sites (65% from 1994 and 75% from 2006) must be ceded partly for free and partly offered for a cheap price (between € 100 and € 200/m2 of building area). This land is to be used for social and affordable housing. In the Bask city of Vitoria-Gasteiz this led to a share of 70% of affordable and social housing in all new residential areas during the period 1994-2005 (Burón Cuadrado, 2006 and 2012).

The same as in Germany, landowners must finally receive serviced building plots that are economically speaking more worth than the initial value of their land. The difference with Germany however is that landowners in Spain can be charged up to almost the full value increase of land (the value increase that accrues from all three steps mentioned before). Landowners have by law the right to keep part of the value increase, which means that the resulting readjusted serviced building plots are more worth than the initial value plus the costs of public infrastructure that they have to pay, this allowing a reasonable profit. But still Spanish municipalities generally force land landowners to cede more land and pay more contributions than in Germany. In addition, the same as in Germany, Spanish municipalities can negotiate additional voluntary charges, for example the building of public buildings or monetary contributions towards it, the building of social/affordable housing, or money payments to the general municipal budget. An important difference with Germany however is that in Spain LR is the obligatory, statutory land development tool, and municipalities cannot refuse to proceed if, for example, implementing parties do not agree voluntarily on additional contributions. Agreed additional contributions are frequent in Spain, but not omnipresent.

*How much must the Dutch landowners pay following the Proposed LR?*
The Proposed LR is not very clear in this. It differentiates between infrastructure located inside and outside the development area (*blok* in the LR Committee's terminology). It seems that the LR Commission means that costs inside the development area are those that can be compulsorily charged to landowners through section 6.4 of the 2008 Physical Planning Act (see frame 1 above).

The Draft LR-act will need to clarify the link that the Proposed LR establishes with section 6.4: for example following section 6.4 infrastructure located inside the development area that serves areas outside it cannot be fully charged to the landowners, while the Proposed LR seems to suggest that these costs can be fully charged. The ambiguity is due partly to semantic ambiguity[18] that should be clarified. But this in not the only aspect where the link with Section 6.4 will create problems.

The Proposed LR prescribes that the implementing party must secure in a development agreement the costs and the needed land of the infrastructure located inside the development area or *blok*. If not, the municipality can refuse to approve the Readjustment Plan and modify the Land Use Plan. So this development agreement is partly voluntary (the implementing party is not obliged to sign it) and partly compulsory (if he doesn't development goes not further). It is possible also to negotiate contributions for infrastructure outside the *blok*, but this is voluntary, i.e. the municipality is not allowed to refuse to approve the Readjustment Plan or modify the Land Use Plan in case the implementing party does not agree. Legislation and jurisprudence presuppose that municipalities can recover the costs via a Development Contributions Plan. This has two main problems:

- If there is a minority of landowners that do not agree to secure any costs (of infrastructure inside and outside the *blok*) in the development agreement, the municipality has statutory powers to refuse the initiative. If the implementing party wants to go further he will need to sign the development agreement and advance the share of the minority. It is unclear whether he will be able to recover this share from the minority, see in frame 1 the limits of cost recovery through the Development Contributions Plan. This problem can be resolved if, similar to the Spanish LR, the implementing party receive or sell part of the serviced building plots of the opposing minority to pay the contribution they refuse to pay. Another way of resolving it could be, at least partially, the German Recoupment and Readjustment charges, to be levied on the landowners after delivery of the serviced

[18] The Commission LR uses the term *noodzakelijk* (necessary) as something different from the legal term *toerekenbaar* (attributable), while they mean (as far as it is used to remark which costs can or cannot be compulsorily charged to landowners) the same.

building plots. If the value of land increases enough due to the readjustment, these charges can recover most or all the costs of the local public infrastructure.

- Anyway, if landowners refuse to secure the costs outside the *blok*, the municipality can formally speaking not refuse the initiative and will have to advance these costs and try to recover them through Section 6.4 (so most probably will end up having to subsidize). This problem can be resolved if, similar to the Spanish LR, the municipality is allowed to refuse the approval of the Readjustment Plan and the modification of the Land Use Plan in case the implementing party refuses to secure in the development agreement the costs outside the *blok*. With other words, the Proposed LR should not support on Section 6.4 and prescribe it's own way of charging all the costs through the development agreement.

The same as in Germany and Spain, the Proposed Dutch LR includes the provision that the economic value of the resulting serviced building plots must be higher than the value of the former properties. This guarantees that landowners will profit economically from LR. The Proposed Dutch LR is more similar to the Spanish LR because landowners can be charged up to almost the full value increase of land due to all three value increase steps mentioned above (modification of Land Use Plan, readjustment of properties and infrastructure provision), which bears the potentiality of recovering all costs of infrastructure located inside the development area. However, while in Spain also the costs of infrastructure outside the development area can be charged compulsorily, in the Dutch Proposed LR these costs can mostly no be compulsorily charged because here the Proposed LR supports on Section 6.4 and this regulation does not guarantee a full cost recovery.

## 6. LR should guarantee the construction of the infrastructure

One important feature of LR is whether it succeeds or not in providing the necessary public infrastructure and facilities and avoids the situation that land has been readjusted but the infrastructure never is constructed, or too late, e.g. because there are not sufficient means for paying it (Yilmaz e.a., 2015: 158). Here LR needs to create two sorts of certainty.

*Certainty that the implementing party will construct the public infrastructure*
LR is effective if it creates certainty that the implementing party will construct the necessary infrastructure. How this certainty is created differs in the Spanish and German LR. In the Spanish *Reparcelación* the certainty is created in a developer agreement between the municipality and the implementing party in which this party commits to construct the infrastructure or to pay to the municipality for it. Generally speaking market parties are reluctant to commit because they have to deal with many uncertainties about the feasibility and the profitability of the project. During several decades the traditional Spanish LR did not include the obligation of sealing a development agreement, which resulted in delays and badly provided development areas. In the 1990's the Valencian LR (and later on this novelty became extended to almost all other regions) prescribed an obligatory development agreement: after an implementing party submits a readjustment plan municipalities organize the public decision making process (which includes a public selection among this and other possibly submitted readjustment plans) and modify provisionally the land use plan. However, this land use plan is approved definitively only after the development agreement has been signed. So in the Spanish LR implementing parties must sign a development agreement in which they guarantee the construction of the infrastructure. If they don't the land use plan does not become ratified, building permits cannot be issued and landowners can thus not profit from the new building possibilities. With other words, profiting from enhanced development possibilities is conditioned to a contractual commitment to bear all related costs.

In the German LR, formally speaking, municipalities are not allowed to condition the modification of the land use plan to any party signing any contract. However, the system

creates certainty because municipalities are the implementing party and commit to construct the infrastructure, if necessary subsidizing part of it.

*Certainty that the implementing party will obtain enough financial resources to construct the infrastructure*
In order to commit the implementing party to the construction of the infrastructure, both the Spanish and in the German LR they need on their turn certainty about how they will obtain the necessary financial resources. In Spain these resources fully come from the landowners, and in Germany there is often, besides the landowners' contributions, a public contribution too. In Spain the implementing party (a public company, a developer or the landowners) has certainty about the contributions of landowners because he has certainty that the municipality will use her statutory powers to force the readjustment of the properties and, in case landowners refuse to pay their share of the costs, also to charge part of their serviced building plots as paymend in kind. In Germany the implementing party (a municipal development company) has certainty about the contributions of landowners because the Municipality can charge both a Recoupment and a Readjustment charge. However, in case these do not cover all the costs, municipalities have to issue a subsidy.

Besides whether landowners cover all the costs or not, it is also relevant when do they contribute. In Spain landowners pay in instalments, just before the implementing party constructs the public infrastructure. And, as mentioned before, landowners pay all the costs. This implies that most of the times the implementing party only has to advance a minimal part of the investments (the costs of preparing the necessary documents previous to the selection as implementing party), and thus does not need to advance almost any investment. In Germany landowners pay afterwards, once the Municipality has readjusted the properties and provided the public infrastructure. This implies that the municipal development company has to advance the investments and the possible subsidy. It is however possible to charge part of the costs of infrastructure while completing part of the public infrastructure, which diminishes the need of previous investments.

Concluding, in Spain the implementing party has certainty about the legal possibilities of recouping all the costs, so he can commit in a development agreement to provide the infrastructure, which is a legal obligation. In Germany the municipality has also certainty about the legal possibilities of recouping an important part of the costs, so if she disposes of supplementary subsidies there is certainty that the public infrastructure will finally be constructed.

*Certainties in the Proposed Dutch LR*
In the Proposed LR Dutch municipalities, the same as in Spain, can condition the approval of the Readjustment Pland and the modification of the Land Use Plan to the majority of landowners signing a development agreement in which they secure the costs of the public infrastructure located inside the development area. Thanks to the flexibility of development agreements, municipalities can also require the landowner to pay before the infrastructure construction, or to pay in instalments, which reduces the need for municipalities of previous investments.

There are however two aspects in which the Proposed Dutch LR could learn from the German and Spanish experience. Regarding the local infrastructure, in both countries there are legal possibilities of compulsorily charging the costs to all landowners, also to an opposing minority. In the Netherlands however the only statutory way of compulsorily charging costs to a minority of opposing landowners is applying Section 6.4, which implies the possibility of not recovering all these costs, or recovering them with delay. This means that implementing parties have to advance the share of the minority of landowners and do not have certainty about recovering this investment, and when. Regarding the supra-local, off-site and 'soft' infrastructure, in the Proposed Dutch LR municipalities cannot require from the implementing

party to commit contractually to pay these costs, so municipalities can only try to obtain them through Section 6.4, which implies most probably having to end up subsidizing them.

The perspective of not being able to recover all the costs will discourage Dutch municipalities to undertake formal steps in the LR procedure before obtaining certainty from the implementing party. Dutch municipalities, the same as they already do with normal building initiatives on private land, will encourage also in LR informal ways of negotiation and condition any formal step (i.e. organizing a public decision making process about the Readjustment and the Land Use plans) to the implementing party previously agreeing in a development agreement to pay all the costs. This increases the uncertainties for the implementing party: while municipalities ask him to sign a development agreement there is no certainty about the future building possibilities and thus about the potential profits. The formal public decision making about the Readjustment and Land Use plans will start only after the signing of the contract, so before there is for the implementing party no certainty about whether the Local Council will finally agree, and under which circumstances and requirements. This uncertainty can also undermine the agreement between the implementin party and the landowners, as one of the basic parameters for their business case (how much will increase the value of their land) is uncertain. Specially not professional, somehow reluctant landowners will not be seduced to join a project with uncertain profits and will prefer free-riders strategies as for example forcing the Municipality to rely on Section 6.4, which implies lower costs for the landowners. Clear estimations of the expected profits are central in any LR-regulation (Hong, 2007: 16).

In short, the Proposed LR creates too much uncertainties for implementing parties, who will be reluctant to secure the costs of public infrastructure in a development agreement. As a reaction, municipalities will not be willing to undertake any formal step, this leading to a vicious circle: municipalities do not dare to give the certainty that the implementing party needs because they are afraid of ending up having to support on Section 6.4 and thus having to subsidize part of the costs. On their turn, implementing parties cannot afford giving certainty about the construction of public infrastructure.

**7. Transparancy and accountability**

This negotiation strategy does not constribute to an open, transparent and accountable decision making. Negotiations will namely be secret and decisions be made before the Local Council and the public will be consulted. The risk is also that the secrecy of negotiations will favour the best positioned stakeholers and harm an equitable distribution of costs and profits among all owners, which in general is one important prerrequisite of an effective LR (Yilmaz et al, 2015: 161). LR is presented in literature as a transparent alternative to other land development tools, one that allows more support among landowners and other stakeholders, but the Proposed LR for the Netherlands might end up not fulfilling this expectation.

At this point the Spanish LR offers an interesting experience. Spanish municipalities do not hesitate to approve the new land use plan and a draft of the readjustment plan before the signing of the development agreeing because they have the statutory powers to reverse these plans if finally the implementing party does not secure the costs in a development agreement. This gives to implementing parties enough certainty about the future building possibilities. It is important however to remark that this certainty is not only created through the provisional approval of the plans. Also, there is certainty about the costs of infrastructure thanks to three other ways: 1) municipalities also prescribe together with the provisional approval of the plans which infrastructure is required; 2) specific regional legislation prescribes minimal urban standards and percentages of minimum required social and affordable housing[19]. The negotiations, which must end in a development agreement, take thus place after a first open

[19] For example the previously mentioned Bask regional legislation on minimum percentages of social and affordable housing.

and public decision making proces and on the basis of openly prescribed requirements. The final results of the negotiations must be reverted back to the local council, who must ratify the plans. If there is no agreement, the provisionally approved modification of the land use plan is not enforceable (building permits cannot be issuded). A similar negotiation process takes place in England when local administrations negotiate planning gains and obligations ex Section 106 (Muñoz & Tasan-Kok, 2010).

## 7. Conclusions

The Dutch Proposed LR includes the possibility of charging compulsorily almost the full value increase of land due all three possible value increase steps (modification of Land Use Plan, readjustment of properties and infrastructure provision) to recover the costs of infrastructure located inside the development area. In this the Dutch proposal improves the German LR, where only the value increase due to the readjustment of the properties and the construction of infrastructure can be charged, this excluding the value increase that accrues from modifying the land use plan and often leading to the need of public subsidies. So the Dutch LR might be able to a full recovery of the costs of infrastructure located inside the development area. However, in order to recover the costs of a minority of landowners opposing to the plans, and in order to recover the costs of infrastructure located outside the development area and of 'soft' infrastructure, the Proposed LR supports on Section 6.4 of the 2008 Physical Planning Act, which in practice does not help much. The relation of LR with other land management tools (specially cost recovery and land acquisition tools) is mentioned as important for any effective regulation (Yilmaz, 2015: 159). The upcoming Dutch Draft LR-act should better fit within the existing Dutch legislation and avoid actors circumventing LR through Section 6.4.

As a consequence of this mismatch, municipalities have not the certainy a full cost recovery of all necessary public infrastructure. The perspective of ending up having to subsidize will discourage Dutch municipalities to undertake formal steps (i.e. modify the Land Use Plan and approve the Readjustment Plan) in the LR procedure before the implementing party securing all the costs in a development agreement. Implementing parties will be required to sing an agreeement without certainty about the building possibilities and about whether they will be able to recover the costs from the minority of opposing landowners, so they will be reluctant to secure the costs. This vicious circle will delay the process and rise the costs, for example financial costs (higher risks lead to banks asking higher loan interests and shareholders requiring higher profit margins for their investment) and other transaction costs related to making the plans, consultations, negotiations, etc. These costs are already very high in the Netherlands in 'normal' urban development on private land, i.e. with just one or few professional landowners-developers (Muñoz Gielen, 2014: 73-75). LR, that is supposed to deal with a multitude of not always professional landowners, might therefore suffer from high transaction costs.

The Proposed LR will subsequently revert into informal and untransparent negotiations, leading to a lack of accountability and the risk of a not equitable distribution of costs and profits. A transparent and equal distribution of costs and profits is one important prerrequisite of any effective LR (Yilmaz et al, 2015: 161).

Finally, the Proposed LR limits the amount of parties that can implement LR to those having the support of a majority of landowners, and excludes thus other agencies and parties. If the Draft LR-act finally prescribes the requirement of a 100% support among owners, as recently announ ced by the Dutch government, the regulation will encounter difficulties to be tested in practice.

Keywords: urban open space, sustainable development, open spaces characteristics

## Abstract

*Urban open spaces have been gaining in significance in an unprecedented fashion in recent years. Their character, quality, state, and variability directly affect the development or, conversely, the decline of the urban environment, thereby directly impacting quality of life and the willingness of urban populations to identify with their surroundings. Open spaces also play an essential role in the sustainable development of cities.*

*Following the condition of open spaces and continuing to support their development in areas which are found to be stagnating are imperative. These areas of potential worth and unique merit can be characterized and quantified. In the process, it becomes possible to continuously monitor the influence and effectiveness of planning measures on the quality of real spaces inside cities from the standpoint of sustainable development.*

*Using a wide selection of sites, we will establish locally and universally applicable characteristics of urban open spaces, related to their historical, economic, ecological, and social potential. We will also attempt to demonstrate their immediate effect on sustainable urban development and quality of life. The results will contribute to the development of the theory of sustainable urban development and urban open spaces.*

## 1. Introduction

The protracted worldwide financial crisis, which began with the stock market plunges, bank bailouts, and high unemployment of 2007 – 2009, has had a significant impact on the importance and development of urban open spaces. In any number of European and American cities, socioeconomic and environmental changes have become the driving force behind a series of visionary projects aimed at regenerating and improving the surroundings of urban inhabitants with the goal of reversing the negative impact of an unfavorable economic climate. Urban planners, architects, economists, sociologists and ecologists are working together to capture the imagination of urban dwellers and encourage them to invest their energies and capabilities in establishing healthy, society-friendly, and environmentally friendly urban development.

## 2. Research background

Urban open spaces form an urban ecosystem, which is open to a wide array of users and is held together by an intricate web of social and economic relationships. At the same time, these spaces represent important centers of sustainable urban development. When examined from this vantage

point, the character, quality, and condition of open spaces have a direct impact on the development (or, conversely, the degradation) of the urban environment and on whether communities tend toward homogenization or diversification. These factors, in turn, directly affect the well-being of the local residents and their willingness to become active participants in the transformation and development of their surroundings. Open spaces, therefore, play an irreplaceable role in the sustainable development of cities.

Yet another role which open spaces play in the urban environment is that of nodes in the network of urban greenery. The results of research conducted in the year 2006 on a sampling of fifty-five cities in the United States (Nowak, Crane, & Stevens, 2006) have proven the efficacy of urban greenery in removing pollutants from the air. Urban open spaces with 100 percent greening are responsible for a two percent improvement in air quality during the course of the day (when the trees are in leaf) as they remove airborne particles such as ozone and sulfur dioxide from the air. Retention of rainwater, reduction of noise pollution, and regulation of air temperature are other functions of urban greenery which improve quality of life in the area.

Research conducted over the last fifteen years in Belgium (Van Herzele & Wiedemann, 2003) has shown that when quality open spaces are lacking, as was the case with the city of Leuven and its dearth of playgrounds and parks, families (especially those with young children) prefer to move to quiet, natural locations on the outskirts of cities to build their homes, thus contributing to higher levels of suburbanization.

In terms of social sustainability, other research (Wolch, Byrne, & Newell, 2014) shows the need to ensure free access to open spaces across the widest possible spectrum of the population. Access is crucial not only during the periods of recovery and implementation but for the long term as well.

Post-industrial spaces have also benefitted from the use of greening as a tool for renewal. Greening is currently being employed in the urban planning strategy of New York City, for example. A developmental plan called VISION 2020: New York City Comprehensive Waterfront Plan (Bloomberg, 2011) was created in response to a lack of open spaces. The goal of the plan is that the majority of New Yorkers will live within ten minutes of an accessible waterfront recreation area. Strategies for achieving this goal include renewal of parks, open areas, and plazas, greening of streets, planting of trees by volunteers, and renewal of the waterfront. In the year 2014 alone, forty-four hectares of new park lands came into being through the renewal of wetlands and river banks.

Another example of renewal in a post-industrial area in Brooklyn demonstrates a consciously creative approach to the development of sustainable urban open space. Middle-class inhabitants of the Greenpoint neighborhood formed the Newton Creek Alliance, named after one of the most polluted industrial sites in the US. Their goal was to improve the quality of open spaces without destroying the industrial spirit of the neighborhood. Using a “just green enough” strategy, the Alliance was able to make a stand against developers and prevent another case of environmental gentrification (Curran & Hamilton, 2012).

Yet another example in which significant investment in greening has played a major role in the gradual renewal of a post-industrial open space is that of the New York High Line. A campaign initiated by two local men, J. David and R. Hammond, successfully blocked the intended demolition of the defunct railway construction and led to the creation of a dynamic public park with a decidedly industrial flavor. However, in this case developers took over, and with the

construction of luxury high-rise buildings in the immediate vicinity, middle- and lower-income residents have been steadily pushed out of the area.

## 3. Hypotheses

Our research derives from the hypothesis that urban open spaces can be perceived as areas of potential capital and unique worth. As such, these spaces can be characterized, and their influence on sustainable urban development can be quantified by means of various indicators. By analyzing trends and observed values, we will be able to create models of development, which can be used to positively impact the quality of real spaces in cities from the standpoint of sustainable development. We likewise expect the results of our research to contribute to the development of workable theories of sustainable development of cities and their open spaces.

## 4. Methodology

Our research is based on a diverse sampling of locations for which we will determine locally and universally applicable characteristics, related to their historical, economic, ecological and social potential. We also aim to demonstrate the immediate effect of these characteristics on sustainable urban development and quality of life. The transformative projects, both at home and abroad, which will become the focus of our study, will provide us with an inspirational image of the metamorphosis of urban areas while allowing us to draw conclusions generally applicable to other cities facing similar challenges.

This paper opens with a description of the focus of our research as it pertains to open spaces with the aim of identifying the significant characteristics that influence quality of life as well as sustainable urban development. The foundational step of our research has been to define the very concept of open space. In the next chapter we describe the general characteristics of open space, defined with respect to the three pillars of sustainable development. Selected characteristics are then applied to case studies in housing estates in Brno, Czech Republic. Subsequently, we outline the next phase of our research and present a selection of case studies in the cities of Graz, Austria, and New York City, USA. In the final section, we provide a working list of anticipated indicators, the specifications and interrelations of which we will explore in subsequent years, along with the evaluation of their impact on urban development.

## 5. Urban Open Space

For the purposes of our research, we have broadly defined Open Space as outdoor areas, originally of natural character, which are located between or among buildings due to subsequent urbanization of the area. As part of the urban landscape, such spaces have a significant impact on the quality of life of urban inhabitants.

We have further narrowed the scope of our research to those spaces which occur in residential areas of large Central European cities, including cities in the Czech Republic. Our research also includes selected examples of open spaces situated in the center of metropolitan New York, the most densely populated urban agglomeration in the world. This is where demands on quality of life are the highest, directly touching the greatest number of inhabitants.

Concerning the emergence of open spaces, our research focuses on residential areas that have come into existence in the last twenty-five years. The research methodology we have defined within the scope of this project will also be used (for comparative purposes) on older housing estates,

specifically prefab high-rise apartment complexes, constructed between the years 1962 and 1989, in the city of Brno, Czech Republic.

For the purposes of our research, we have also defined Open Space as occurring within a built-up urban area, situated among primarily residential buildings or in their immediate vicinity, with a maximum built-up area of ten percent within the boundaries of the space itself. A meadow, a park, or similar green spaces may also constitute an Open Space. Our definition also includes areas in the transitional zone between residential buildings and the area in their immediate vicinity (the so-called soft boundary line) made up of small front lawns, gardens, and courtyards, as well as green areas utilized for informal markets, recreational activities, and night life (Alexander et al., 1977; Gehl, 2013). The flexibility of such spaces allows them to function as urban catalysts (Oswalt, Overmeyer, & Misselwitz, 2013). They are places of innovative cultural production, tempting to the eye, with a wealth of detail. At the same time, open spaces can be public, semi-private, or private in character, both from the perspective of ownership and that of accessibility.

With the exception of Palavske Square (Brno – Vinohrady, Site 1) spaces which are primarily associated with transportation (streets, squares, and parking lots) have been excluded from our research.

## 6. Characteristics which impact quality of life and sustainable development

For the purposes of our research, we have distinguished between three sizes of cities: large cities with more than one million inhabitants (New York 8,491,079 and Prague 1,243,201), mid-sized cities with between one hundred thousand and one million inhabitants (Graz 269,997, Bratislava 491,061, and Brno 385,913) and small cities with fewer than one hundred thousand inhabitants.
Each open space in the study is then assigned a territorial index to which observed characteristics and measured or detected indicators and their values refer.

Territorial indices:
A – area of the assessed open space
B – a block or open area, including neighboring buildings
C – locality, neighboring area with comparable characteristics
D – neighborhood, district, town

In order to locate the assessed space within the city structure we distinguish between: city center, city proper and periphery. Individual characteristics of the open spaces are then applied to the social, economic, and environmental pillars of sustainable development.

### *6.1 Characteristics of Open Space in terms of social sustainability*

In its broadest sense, social sustainability can be explained in relation to the number of visitors to a particular place whether from different demographic groups or the predominant population. Where visitors are lacking, decline is inevitable. In a narrower sense, social sustainability can be more diverse as it includes gender, age, income, and ethnicity. With increasing diversity, however, comes the potential for conflict. Conflict leads to security issues making personal security another important indicator of sustainability. Additional characteristics relating an area A to neighboring buildings (areas B and C) are ownership, spaciousness, and condition of facilities. These factors especially influence how public spaces are used by providing space for activities for which the surrounding dwellings are not suitably equipped.

### *6.2 Characteristics of Open Space in terms of economic sustainability*

Case studies in New York City (specifically the High Line and Bryant Park) will provide the foundation for studying the various manifestations of economic sustainability, especially as it relates to a rise in property values, which is often connected with the recovery of public spaces. Also of interest is the question of funds for the continued maintenance of regenerated areas.

Economic sustainability is basically a matter of achieving balance. It involves using available resources in a way that allows a system to continue to operate effectively over a period of time. The vast majority of renewal projects begin with the idea of improving an existing area for the benefit of the people who live there. Occasionally a particular project, for its uniqueness or innovative approach to a problem, attracts the attention and capital of "outsiders" (developers and investors, for example). At first this may seem like a positive development; however, the weight of the outside investment gradually changes the economic balance of the area, eventually leading to gentrification sometimes called ecological gentrification. In such cases, the regeneration process has not led to economic sustainability of the original community.

Economic sustainability is relevant not only in the initial stages of regeneration but also in relation to maintenance or upkeep of the regenerated area. An interesting example is Bryant Park. Much of the park's history has comprised cycles of decline and subsequent regeneration. For this reason the current management (Bryant Part Corporation, a non profit private management company) has chosen to find ways to generate revenue for continued upkeep from the park's cultural offerings in an effort to maintain economic sustainability.

### *6.3 Characteristics of Open Space in terms of ecological sustainability*

Urban open spaces provide adequate green areas for physical activity and so contribute to the health of the urban population. As part of the urban ecosystem, they also make a significant contribution to safeguarding biodiversity. A number of cities are initiating programs to support the creation of parks with the aim of rejuvenating neighborhoods burdened by brownfields and unused transportation infrastructure. When greening leads to gentrification, as we mentioned earlier, the very people who were meant to benefit are instead forced out of the area. It is therefore imperative that urban planners, architects, and ecologists continue to search for new strategies which will establish a balance between ecological and social sustainability (Wolch et al., 2014).

Cities are actively seeking balance and harmony between the natural and the urban areas of which they are made. A number of locations have had positive experiences with grassroots movements, which seek to improve public spaces using strategies such as community gardens and volunteer tree planting. Where community support is missing, public spaces often fall into neglect.

### *6.4 Internal and external characteristics of Open Space*

Individual characteristics can be grouped into two sets of parameters: external, in relation to area B (respectively C or D as well), and internal, in relation to area A.

The following are included in the set of external parameters: location (with respect to population, with respect to residence), description of the city (urban structure, average building height, architectural quality, condition of buildings), and functional context (interactions, precedence of personal vehicles, public transportation connections).

Internal parameters include: space (size, boundaries, shape, and condition) and facilities (proportion of vegetation, number of trees, area covered by water, proportion of parking spaces, services for personal vehicles, play areas, public facilities, lighting, small buildings and artwork, advertising).

Internal parameters influence factors such as appearance of the surroundings and the environmental quality, ease of orientation, visibility, security, and social controls. They also influence the utilization of open spaces and their subsequent maintenance.

## 7. Case studies, Brno, Czech Republic, Vinohrady and Lesna

Work on the case studies outlined in the following text will commence in September 2015 and will be completed in June 2016. The following are examples of mid-rise, prefab apartment complexes, located on the outskirts of the city of Brno in the Czech Republic. Of the five sites, four are located in Brno – Vinohrady and one in Brno – Lesna.

The housing estate Brno – Vinohrady (authors: J. Dolezal, M. Dufek, A. Janecek and P. Plsek, project leader: J. Dolezal, chief project engineer: V. Vanek) was built between 1981 and 1989, commercial facilities were in place by 1992 (Doležal, 1980). Vinohrady was one of the last housing estates to be built in Brno and is distinguished by its purely rational orthogonal urban structure with regularly recurring types of buildings. This area also has the highest population density in Brno.

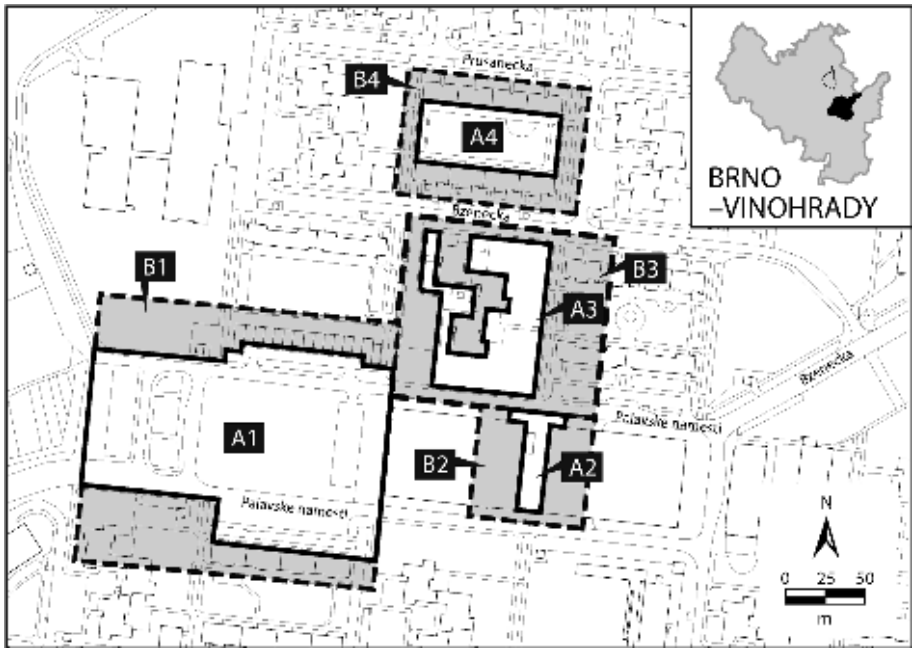

Figure 1. Location of case study areas in Brno–Vinohrady. Source: cartography and GIS by authors, based on MMB cadastral map.

Brno – Lesna (authors: F. Zounek, V. Rudis, M. Dufek and L. Volak) built between 1962 and 1970, was the first major housing estate in Brno. At the time of its inception, the settlement was subject to both criticism and admiration. Along with the Brno Exhibition Grounds, it was the largest and most radical structural intervention since the demolition of the city walls in the mid-19th

century. It is considered one of the most successful implementations of the concept of the garden city (free modernistic buildings surrounded by greenery) in the Czech Republic. The center of Lesna is broken by a large wooded area, crisscrossed with walking trails, called Certova Valley, and there are large parks between individual buildings. The arrangement of prefabricated apartment houses is based on the morphology of the terrain and does not form a regular grid. The main road circles the perimeter of the neighborhood with short branch roads providing access to the surrounding buildings. The majority of the buildings and services are located within the traffic circle.

## 8. Case studies, Graz, Austria, Mariatrost, Tannhof I and II

The following are examples of residential complexes, located on the outskirts of the city of Graz in Austria. The two sites, Tannhof I and Tannhof II (author: German architect Hubert Ries), were built in the Mariatrost neighborhood between 1989 and 1990 (Szyszkowitz & Ilsinger, 2003).

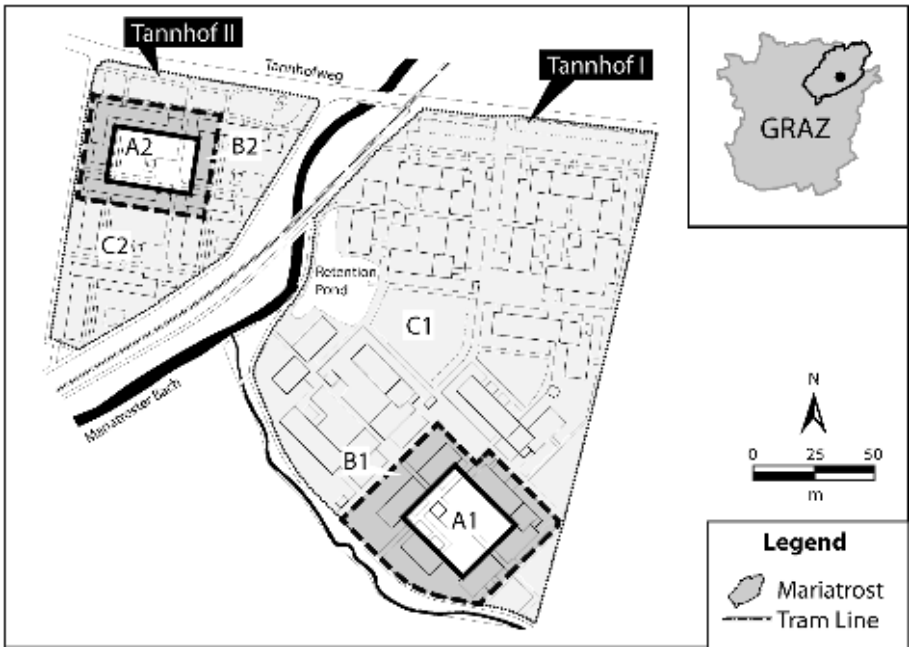

Figure 5. Location of case study areas in Graz–Mariatrost. Source: author's presentation based on OpenStreetMap.

Tannhof I consists of five residential blocks, which are symmetrically arranged around a large meadow with a playground and a retention pond. Each of the five blocks has a small, central

clubhouse, containing, among other things, mailboxes for all of the apartments. Each block consists of one to three-story apartment houses. Apartments on the higher floors are accessible by the characteristic external covered staircases. There are between eighteen and twenty-two apartments in each of the block, totaling one hundred units in the entire complex.

Apartments on the ground floor feature front gardens which are bordered by a hedge on both sides of the houses. These gardens connect to a common area in the center of the apartment block on one side as well as to open space on the outside of the apartment block on the other side. The outside area is accessible only to residents of the complex.

Figure 6. Graz–Tannhof I, 2005. Photo: L. Frantisak.

A tram stop, located right next to a pond, can be found between the two residential complexes. The tram lines, as well as a path for pedestrians and cyclists, follow the path of a creek as it leads toward the city. Tannhofweg Street provides motor vehicles access to the complex. There are parking spaces both under pergolas and in an underground parking garage, including spaces for motorcycles and bicycles. Each apartment also has a small wooden shelter for bicycles and garden tools.

Located on the right bank of the creek is Tannhof II, two years younger than its sister complex. Tannhof II also consists of five residential blocks composing an L-shape; however the newer complex is more spatially efficient. It combines two- and three-story row houses and apartment houses, five blocks in total, which share three community centers, clubhouses with bicycle booths, and children's playgrounds. The community also shares an underground parking garage, central heating, and an area for recycling and disposing of garden waste. Common and private space is delineated by hedges, while at the same time the areas of the complex are connected by sidewalks. Access staircases for apartments on the second and third floors are supported by concrete columns. Motor vehicle access as well as access to the tramline and bike path are the same as for Tannhof I.

## 9. Case studies, New York City, USA, Manhattan, the High Line and Bryant Park

The following are examples of city parks that emerged from the regeneration of previously neglected areas. The High Line and Bryant Park are both located in the Midtown Manhattan neighborhood of New York City, USA.

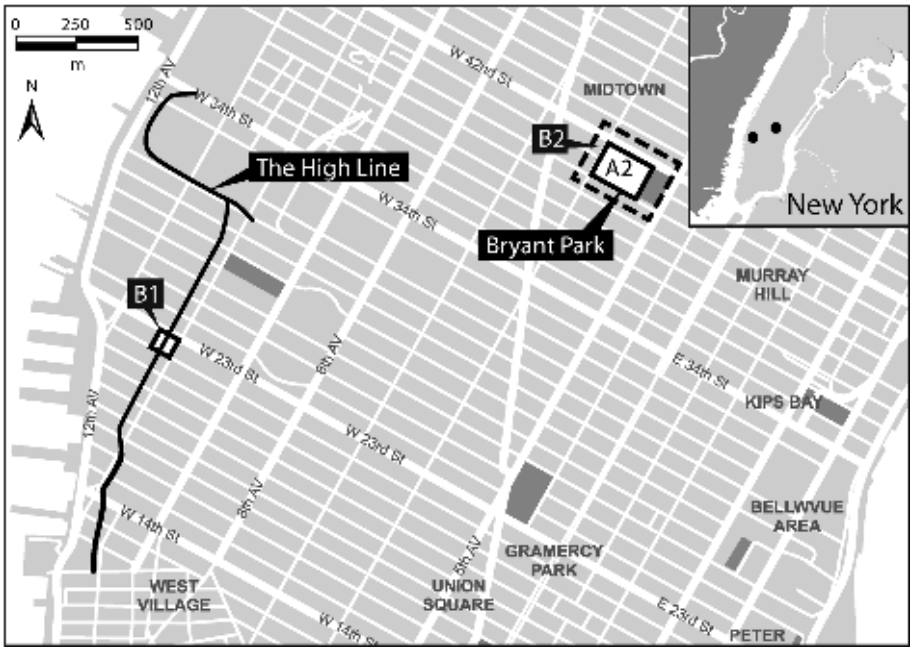

Figure 8. Location of case study areas in New York City, Midtown Manhattan. Source: author's presentation based on New York Map by dikobraziy/Shutterstock.

### *9.1 The High Line*

The High Line is a former elevated freight railway from 1934 that supplied the industrial area of Manhattan's West Side. The closing of the structure in 1980 marked the start of a period of decline and plans for its removal. It was saved from demolition by an ambitious economic plan on the part of local residents J. David and R. Hammond (founders of the non-profit organization Friends of the High Line). The plan proposed that the defunct railway be transformed into a new open public space in the form of a linear park. Reconstruction of the 2.4 km structure was carried out in three stages, from 2006 to 2014, according to the winning design proposal, submitted by James Corner Field Operations (project lead), E. Diller, R. Scofidio, Ch. Renfro (designers) and P. Oudolf (planting designer). The realization of the project was overseen by the New York City Economic Development Corporation, in cooperation with the NYC Dept. of Parks and Recreation, the NYC Dept. of City Planning, the Office of the Mayor, and Friends of the High Line (David & Hammond, n.d.). The organization Friends of the High Line annually raises funds which support more than seventy percent of the park's operating costs.

Figure 9. The High Line, W19th St. view of Hell's Kitchen, June 2011. Photo: J. Palacky.

Today the High Line is an attractive park/promenade, providing spaces for spontaneous theater presentations, secluded meeting places, exhibits, and social activities year round. Like the Charles Bridge in Prague, it entices visitors from all over the world to enjoy its unique atmosphere again and again. Owing to the preservation of the original railway construction and costly investments in its renewal, the High Line has also attracted intense attention from investors, who have entrusted the realization of cultural institutes, luxury high-rise hotels and apartment houses into the hands of prestigious architects. The latest example is the New Whitney Museum of American Art (between 10th Ave and the High Line) by Renzo Piano. It will open in May of 2015. Some of the luxury apartment buildings in close proximity to the High Line erected in the course of the last few years include The Standard High Line Hotel (Meatpacking District), the High Line 23 by Neil-Denari (Chelsea Arts District), the 505 West 19$^{th}$ Street by Juul-Hansen, the 520 West 28th Street by Zaha

Hadid, the 551 West 21st Street by Norman Foster, and the 515 Soori High Line by Soo Chan (Budin, 2014).

This rapid development has wrought changes in the quality of the space itself, which had been characterized as providing pedestrians with peaceful, bird's-eye views of Manhattan and the Hudson River. As property values and population have risen, the image, character, and social structure of the area are gradually changing and a new, distinctive identity is evolving. All this has led to gradual, inevitable environmental gentrification (Patrick & Kowalski, 2011).

It is not only the magic of the High Line but also the innovative and community-driven approach that has inspired a growing number of similar projects in other areas of the United States. These derivative projects have also managed to successfully implement the public-private financing partnerships, but what is more, they have re-created the strong involvement of community supporters. Among the most interesting are the Bloomingdale Trail in Chicago (recently renamed The 606), a former 4.5 km regenerated railway; the Atlanta Beltline, a 35 km regenerated railway which circles the downtown area (McMillan, n.d.); and the Jersey Embankment, a 1 km public park overlooking the Hudson River waterfront, situated on a historic structure that was once part of the Pennsylvania Railroad Freight Way.

Figure 10. Bryant Park, June 2011. Photo: Andrew F. Kazmierski / Shutterstock.com.

### *9.2 Bryant Park*

Bryant Park, named in memory of poet William Cullen Bryant, was built in 1842 on Reservoir Square near the western wall of the former water reservoir, which is now the New York Public Library. The New York Crystal Palace was installed there in the years 1853-1858 to house the World Industrial Exhibition.

The park was partly closed as a result of construction of the subway line at 42$^{nd}$ Street and fell into decline during the 1920s due to negligence. A park regeneration competition in 1934 led to the park's being rejuvenated, grassed, fenced off and equipped with a fountain. In this state it was occasionally used as an open-air reading room for the adjacent library until the advent of the Second World War when the park again went into decline. In the 1960s and 70s it was a favorite gathering place for New York City's drug dealers. In 1980, the Rockefeller brothers initiated another restoration by founding the Bryant Park Restoration Corporation (BPRC).

D. Biederman, innovator and president of the Bryan Park Management Corporation (BPMC), initiated an experiment with the aim of bringing visitors back to the park and generating revenue for continued park management. The park was closed for renovation from 1998 to 1992. When it re-opened, it had become a beautiful and vibrant public space which could offer visitors a variety of activities year round. In 1996, the park was awarded the Urban Land Institute Excellence Award for Public Projects (Biederman, n.d.). Bryant Park now boasts a public outdoor cinema, a venue for concerts, concession kiosks, and restaurants, and in winter an ice rink and a winter village. The park is equipped with moveable chairs that allow visitors a sense of control over their recreational experience. Even the open-air reading room has been resurrected. All this has led to a 92% reduction in crime, and the number of visitors per year has doubled.

This successful implementation of the arrangement of the park and the creation of an open urban public space was met with an overwhelmingly positive response from the local community. As in other areas it has brought about ever- increasing property values (Morris, 2015).

## 10. List of characteristics to be monitored and expected indicators with impact on sustainable development

The list of sites examined in the case studies:

1 Brno – Vinohrady, Palavske Square
2 Brno – Vinohrady, area in front of commercial facilities
3 Brno – Vinohrady, open area between high-rise buildings
4 Brno – Vinohrady, open area – inner courtyard
5 Brno – Lesna, open space between two prefab high-rise apartment houses
6 Graz, Tannhof I
7 Graz, Tannhof II
8 New York, residential segment of the High Line
9 New York, Bryant Park

Urban open space is significantly affected by its functional context. For prefab housing estates, the dominant urban function is residential. Localities 1 and 2 in Brno – Vinohrady are a minor exception. Palavske Square (Locality 1) attempts to fulfill the function of a public space – act as a meeting place, a place for recreation and various other activities. While localized services and supplementary commercial facilities do exist, detailed examination is not necessary to determine that the square has failed to fill its primary function. Aside from the problematic appearance of the space itself, there is also the negative influence of an unfortunate transportation solution. The entire square functions as a traffic circle. This both complicates access and makes the square an uncomfortable place to linger. Locality 2, though smaller, does a better job of acting as a public space. It is situated at the crossroads of important pedestrian traffic routes (connecting the public transportation stops with the housing estate) and near the entrance to commercial facilities, which are used by the entire housing estate (a grocery store, a drug store, a flower shop and a bank). This area hosts a number of activities throughout the year, various kinds of open-air markets, wine festivals, and so on.

Localities 3–5 are purely residential in character. The parterre of the apartment buildings is practically cut off from public spaces and serves merely as a point of entry to individual buildings. This basic, common characteristic is labeled “interaction,” and in this case it is possible to define it as “small.”

Localities 6 through 9 will be examined in detail in the period from September 2015 to June 2016.

After a complete list of sustainability indicators has been formulated, we will be able to evaluate their respective impact for each of the cases studied. This influence will then be analyzed and confirmed by means of observations of open spaces within a specific period of time. Next, data measurements taken from the open spaces under consideration will be reviewed and relevant comparisons of data will be made. Finally, influence will be evaluated through questionnaires to be completed by residents/users of the adjacent buildings. Using the results that have been obtained, it will then be possible to identify those characteristics of open space that affect sustainability indicators and thereby enhance or degrade the potential for sustainable urban development.

Examples of expected indicators and additional parameters are listed below (Table 1).

Table 1. Expected indicators of sustainable development of open spaces

| Framework indicators and additional parameters | Lead variables |
|---|---|
| **Social Indicators**<br>To be obtained by observation and from statistical data | Intensity of attendance, predominant use of space, demographic diversity, problems,<br>In the Czech and Slovak Republics, data from census of houses and apartments, abroad data obtained from registers |
| **Economic Indicators**<br>To be obtained from statistical data | Obtained from the cadastre, by findings and observations, average price of property, average rental rates, type of ownership, operation costs |
| **Environmental Indicators**<br>To be obtained from passports, aerial photographs, measurements, and observations | Ecological value (increase of ecological stability, occurrence of problematic plants, increased retention of rainwater), well-being of citizens (reduction in summer temperature peaks, increased air humidity, reduced sunstroke in summer, limited insolation apart from summer, wind reduction, control of dust and chemical pollutants, natural fragrance, limited noise pollution, pleasant natural sounds, optical isolation from street activity, attractiveness, security risks), bodies of water |

## 11. Conclusion

Both identical characteristics and differences are already apparent from the analysis of the urban characteristics of the two prefab housing estates and their sub-sites in Brno. One of the crucial differences would seem to be the unique urban concept of the site Brno – Lesna, which is assumed to provide considerable potential for the development of the environmental pillar of sustainable development. The support for the other two pillars will evidently be similarly unbalanced and questionable, as in the case of the site Brno – Vinohrady. These are all assumptions, however, which will have to be confirmed by further research. Relevant conclusions will be drawn after a

thorough analysis of data gathered at target sites (during the period from September 2015 to June 2016) has been completed.

## 12. Acknowledgments

This research endeavor is supported by funds from the Czech Science Foundation (GACR) 15-05237S: The Importance of Open Space for Sustainable Urban Development Project. We thank T. Ctibor, M. Culek, M. Kafkova, G. Kopacik, I. Kyselka, and A. Vaishar, for assistance with the description and definition of characteristics and indicators of urban open spaces for the purpose of this research.

## Abstract

The Conservative led coalition government in the UK identified regulation management as a key priority and intended to simplify and address the complexity in the system. From the perspective of Development Management a paradox has emerged however; the more the Government attempts to simplify the decision making system and facilitate development, the more complex the system has become. This can be clearly seen in the manner in which the Permitted Development rights planning permission arrangements have been revised and the application of decision making mechanisms extended.

This paper will explore how new Permitted Development rights have been created, existing rights extended (some permanently some temporarily), the prior approval process has increased in prominence and usage, and the use of Local Development Orders extended. The paper will present the impact of these changes, including the unintended consequences and potential to undermine the effective management of the built and natural environment,

Issues of regulation density and complexity will be highlighted, together with how some of these changes are potentially disrupting the fundamental principle of proportionality and justified local planning authority intervention in the public interest.

## 1. Introduction

The idea of regulatory control of the built and natural environment is not a new one. Although planning legislation requiring the creation of plans to guide development in a given area is relatively new, the use of legal controls to manage the built and natural environment can trace its origins in the UK back to medieval times. Although evidence suggests even earlier controls existed in London, an Assize of Nuisance in 1275 can certainly be highlighted as one of the earliest forms of control over buildings. This introduced various controls that are akin to basic building regulations and arguably all modern systems of control over the built environment, from planning through building regulations to environmental health legislation can trace its history back to this point (Booth, P. 2002).

From the Assize of Nuisance we can see the evolution of control, with further mechanisms introduced to regulate construction standards, layouts, fire prevention, public health and neighbour nuisance. This was not just a case of strengthening control though, some important changes took place to which planning today owes much. For example, Elizabeth I introduced systems to manage the growth of London, while James I and Charles I both created controls that influenced design and appearance. To the origins we can perhaps draw parallels to modern planning and policies to prevent over development and encourage high quality design (Booth, P. 2002).

The greatest change, however, took place in the early 1900s. From this point forward, various public health acts were passed in response to the challenges associated by the massive growth and change seen during the industrial revolution and soon legislation required the preparation and approval of plans for new housing growth, and strict standards in construction, design and layout. The

culmination of this period of development effectively occurred immediately after the Second World War (Booth, P. 2002).

During World War Two, even while the bombs were still falling on London, research was being undertaken into how the UK would emerge from the war. Evidence highlighted the need for large scale reconstruction, but also a change in the way spaces and places were managed to respond to the social and economic changes occurring across the country. In 1947 a Town and Country Planning Act was published and the system we have today still works in the same basic way. From this point forward control of land was nationalised (not ownership), plans were required to manage town and country, and permission was required to undertake new development.

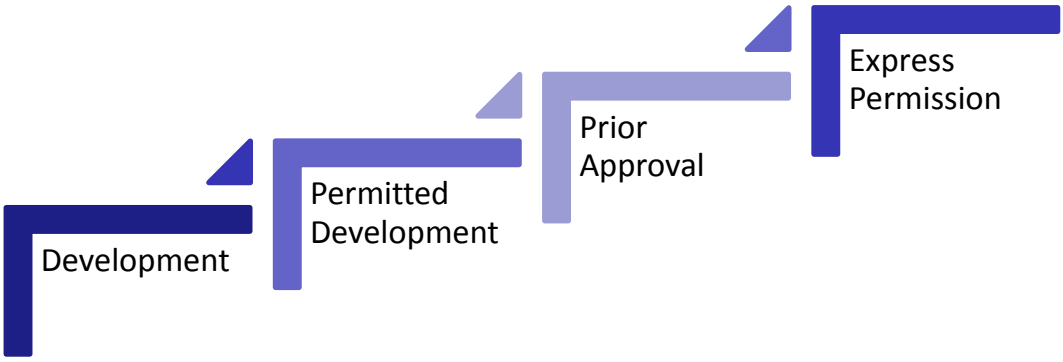
A planning system represents, from a first principles perspective, state intervention into a market. The story presented above is underpinned by a key phenomenon; necessity. The evolution of state intervention, and the broad acceptance of the justification for state intervention, was driven by the necessity of responding to events and circumstances that required address and that private arrangements either could not, or would not, respond to adequately alone (Gilg, A. 2005). From the earliest legislation concerning the prevention of fire, the state has intervened in the public interest and with some degree of a social justice motivation. Ultimately, as a result of the rapid development witnessed during the industrial revolution and the failure of previous health and planning legislation, land *rights* were nationalised and the modern planning system of the United Kingdom was born. As noted by Cullingworth, B and Nadin, V et al (2015), the urban growth witnessed during the later 19$^{th}$ and early 20$^{th}$ Century and the associated environmental, health and social challenges that resulted ultimately led to an appreciation and wide acceptance of the necessity of the state interfering into the market and private property rights in the public interest and with regard to social justice.

## 2. The proportionality hierarchy

Across the European Union, two key principles exist; subsidiarity and proportionality. These principles also underpin in some respects the recent liberal conservative government in the United Kingdom; from the perspective of planning the Government proceeded with a presented parallel objective of a more proportionate approach to intervention by reducing state control and procedural burdens, and 'Localism', which theoretically involved the further application of the subsidiary agenda through the development of the neighbourhood scale of planning (DCLG, 2011). It is beyond the scope of this paper to consider the reality of the Localism agenda as realised.

Returning to first principles, the manner in which proportionality is realised in the United Kingdom from the perspective of control over development is via a hierarchy modeled on the basis of increased state involvement set against the likelihood of impact/harm. This is delivered in the context of a discretionary, as opposed to codified, model of decision making and development management.

Figure 1: The proportionality hierarchy



(Sheppard, A. 2015)

Figure 1 above demonstrates the basic steps of intervention. In the first instance the question must be asked as to whether the activity occurring. As stated in Section 57 of the Town and Country Planning Act 1990:

> '…planning permission is required for the carrying out of any development of land. '

The definition of development is therefore an important first question. Development is defined as the carrying out of building, engineering, mining, or other operations in, on, over or under the land, or the making of any material change in the use of any building or other land (S.55, T&CPA 1990). A 'building' in this context is any structure or erection, the ultimate decision being based upon professional judgement informed by case law; matters such as size, permanence, physical attachment to the land have all be held as key in this respect. By defining 'development' a basic parameter is created with the identification of matters which fall under the control of the planning system, and those that do not. On the bottom step of the hierarchy we have effectively established a legitimacy in potential intervention, but it is the impact based approach of the hierarchy which gives the system its sophistication.

Permitted Development, with which Prior Approval is also based, resents the key tool of proportionality within the UK planning system. Permitted Development Rights are effectively identified forms of development that can be undertaken without the requirement for an express application to the Local Planning Authority for permission; effectively, they are forms of development that national government has pre-granted planning permission for, subject to adherence to the conditions prescribed. The Permitted Development system utilises a tool called a Development Order; this is the mechanism employed by national government to effectively grant permission for prescribed works on a national level. Currently it is under the Town and Country Planning Act (General Permitted Development) Order 2015 that national Permitted Development rights are prescribed. Local Development Orders (LDO) can also be used at the local level by Local Planning Authorities (LPA) to vary Permitted Development rights within an identified geographical space. The counter-tool against both LDOs and the nationally set Permitted Development rights are Article 4 Directions (under the Town and Country Planning Act (General Permitted Development) Order 2015).

Prior Approval is effective a 'catch' on certain Permitted Development rights; usually more significant forms of minor development. The Permitted Development rights exist within the Prior Approval model, but intention to undertake development requires a Prior Approval notification to the LPA. The LPA are then able to review the proposal against specified and limited criteria and determine whether to approve the scheme or refuse it. The Prior Approval scheme is therefore something of a middle ground between Permitted Development rights, where the LPA have no ability to influence subject to adherence to the requirements and condition, and express permission, where LPA effectively have full discretion over the decision against a formal planning application.

The planning system in the UK is a discretionary model, meaning that where express permission is required from the local planning authority the decision is made in accordance with the provisions of the legally recognised Development Plan, unless 'other material considerations' indicate that another outcome is merited. Interestingly there, Permitted Development rights effectively represent a codified model of decision making embedded within a discretionary one.

## 3. Proportionality in context

The hierarchy presented above is modelled firmly on the basis of proportionality; where impact upon amenities may occur state intervention is justified in the public interest. The transition from recognition of 'development' through Permitted Development and prior approval up to the full express planning permission process is the realisation of this proportionate response in practice.

The system in place is not solely based around the amenity driver, there is also the parallel need to ensure that the system is able to operate effectively and efficiently; ensuring that the system is response, manageable, and does not represent an administrative burden is therefore also highlighted.

The above two drivers can be seen to be operating in conflict to one another in some respects; the state intervenes in the public interest but in doing so impacts upon the functioning of the market, in doing so implementation and delivery of change are influenced. The presentation of planning as a 'barrier' to implementation and delivery and as a 'burden' has become particularly commonplace since the 2010 General Election; from the earliest days of the new government it was made clear that planning would be a key focus of reform in an attempt to deliver economic growth. In the 'Plan for Growth' it was stated that:

'One of the most significant burdens highlighted consistently during the Growth Review has been the UK's overly slow and bureaucratic planning system'
(HM Treasury, 2011, pg. 21)

## 4. Barriers and implementation

"We're determined to cut through the bureaucracy that holds us back. That starts with getting the planners off our backs, getting behind the businesses that have the ambition to expand and meeting the aspirations of families that want to buy or improve a home." (Rt Hon. David Cameron MP, 2012)

The reliance upon the private sector for delivery is greater now than ever before with the retraction of the state as an actor since the latter part of the twentieth century. In the immediate post-war period, the state was a more active actor.

Gilg (2005) discusses the role of the state in the immediate post-war period and notes how a key feature of the newly emerged system system was a presumption that the local authorities would be the developers, building a majority of the residences, employment opportunities and social infrastructure.

The move to a model of development almost completely reliant upon the private sector arguably makes question of delivery more pressing from the perspective of the market dynamics and the importance of the state facilitating an effective regulative and legislative implementation environment.

Barriers of implementation concerning delivery of policy objectives are discussed from a theoretical perspective by Peter Dorey (2005). Dorey builds upon the work of Hood (1976) to present a series of barriers to 'perfect' implementation. Dorey recognised the impossibility of creating a perfect implementation scenario but the barriers are presented to enable understanding and an ability to minimise impact. The theory also draws upon the work of Pressman and Wildavsky (1973) in relation to the concept of 'street level bureaucrats'; those who administer and apply public policy. Public sector planning professionals are an example of such 'street level bureaucrats'. The barriers to implementation as presented by Dorey are summarised below:

Table 1: The barriers to Implementation

| | |
|---|---|
| 1 | External agencies or events impose major constraints – policies / remit of other organisations get in the way, or events, such as the performance of the economy. |
| 2 | There are too many dependency relationships – to administer the policy as intended requires the agreement or cooperation of others. This can lead to communication problems or different organisations / individuals pursuing their own particular goals. |
| 3 | There are too many decision points – once a policy is adopted there are too many stages in the delivery chain. The policy can change at each stage due to the involvement of street level bureaucrats at each stage of the process |
| 4 | Resources are inadequate:<br>• There is insufficient time – to achieve the aims / objectives of the policy.<br>• There are inadequate human resources – lack of staff or lack of suitably qualified personnel.<br>• There are inadequate financial resources – lack of finance or funding. |
| 5 | The policy is based on an invalid theory of cause and effect – most policy is a response to a problem / situation, but are the policy makers' assumptions about the underlying causes of a particular problem correct? |
| 6 | The objectives are unclear, incoherent and inconsistent – if there are too many objectives, inconsistencies will become apparent at the implementation stage, or unforeseen or unintended consequences can arise. |
| 7 | The objectives are not understood or accepted by street level bureaucrats – those who implement the policy may not fully understand the intent of the policy makers, or they may have different |

| | |
|---|---|
| | values or organisational goals. |
| 8 | Those to whom a policy is applied or targeted do not respond in the anticipated manner – will the majority of people accept the measures concerned and act accordingly? |

(Dorey, P. 2005)

The planning system, and indeed planners (as 'street level bureaucrats'), can be related to the barriers presented by Dorey, including from the perspective of the planning decision making process. The express planning permission routeway is challenged in relation to the dependency relationships, the number of decision points, the resource demands, and the behaviour of 'street level bureaucrats' for example.

Given the challenges facing any form of state intervention into a market it is to be expected that issues will exist with the effectiveness of any created 'system'. It is therefore unsurprising that the government moved to address the presented planning barriers; the Plan for Growth (2011, pg. 23) stated an intention 'To reform the planning system radically and fundamentally…' including an intention to 'bring forward proposals to extend Permitted Development rights…' (ibid).

## 5. A flawed justification and approach?

The extension of Permitted Development rights is presented as solution to planning as a barrier because it is a way to remove some developments from requiring an express planning permission, instead allowing them to proceed subject to adherence to the stated conditions and parameters. This intention presumes that the extant balance of necessity of state intervention is incorrect and inappropriate.

In 2011, in response to the pressure facing the planning system, the Royal Town Planning Institute presented a paper entitled 'The Top Five Planning Myths' which considered in part the planning application process that reforms have sought to address as a suggested barrier to implementation and economic growth. The contents of this paper are summarised below:

Table 2: The Top Five Planning Myths

| **'Myth'** | **Response** |
|---|---|
| The Default Response to a Planning Application is "No" | Over 80% of planning applications have been granted – higher (around 90%) for major commercial applications.<br><br>Communities need the power to say 'no' to prevent harmful development and drive up built environment quality.<br><br>Businesses want councils to say 'no' to inappropriate development that would harm their investments. |

| | |
|---|---|
| Planning is Slow | Councils as a whole meet or exceed the 8 or 13 week targets set for them.<br>Only 0.7% of planning applications take longer than 12 months to reach a decision.<br><br>The development industry often conflates planning with other consent regimes, such as licensing or environmental permits.<br><br>The overall development process in England is among the quickest in western Europe |
| Planning is Costly | Planning creates wealth by promoting regeneration, securing funding for infrastructure and mitigating the negative effects of development. |
| Planning is a Drag on Economic Growth | "Planning is core to achieving a wide range of objectives for business and society, and for achieving sustainable development." (CBI)<br><br>In 2003, the then ODPM Select Committee Inquiry into Planning and Competitiveness, said "Claims that planning damages the nation's competitiveness seem to have been made without evidence. The evidence that we have received suggests that businesses generally support the planning system and seek a number of changes in implementation, which do not necessarily require legislation." |
| Planning Forces House Prices Up | House price inflation is not solely the result of a lack of housebuilding: the Barker Review found that the effect was marginal taking into account the other determinants of supply and price, i.e. the availability of finance and demand.<br>The private sector has only ever been able to contribute around 150-200,000 new homes a year across Great Britain. Until the government ended mass council housing in the 1980s, the public sector helped to almost double this. If public sector housing had continued there might be at least 2 million more homes now.<br><br>The current slump in housebuilding is the result of a lack of finance, both for homebuyers and housebuilders, prevalent since the "credit crunch". The slow-down in planning permissions is the result of a lack of planning applications.<br><br>There is not a lack of homes, premises to convert or sites to build on. In England, there are around |

| | |
|---|---|
| | 750,000 empty homes, nearly half of which have been empty for over 6 months, and developers have permission for around 300,000 homes they are not building. |

(RTPI (2011) 'Top Five Planning Myths')

In the first instance we must therefore consider the possibility that the very basis for the steps taken to increase the use and scope of Permitted Development are based upon a flawed assumption that it is the necessary and appropriate step for many of the reasons presented by government.

A fundamental issue exists here; the suggested driver for change pertained in part to the presented concerns associated with the planning application process and the implications of these upon the ability of the planning system to support implementation and delivery. The system was seen as a barrier to the delivery of economic growth. The response was not to consider further possible adjustments to the planning application system; rather it was to remove developments altogether from the requirement for express planning permission. Permitted Development rights were the focus of attention, with this mechanism seen as a way to provide an easy route through the planning 'maze', enabling a barrier free system to support implementation and delivery.

In accordance with the previously presented hierarchy, the behavior of the state was modeled on the basis of increased state involvement for justifiable public interest and social justice reasoning set against the likelihood of impact/harm, historic revisions to Permitted Development rights were undertaken based upon the desirability of removing unnecessary burdens associated with the planning system whilst preserving protections for amenities etc. This was the case with the revisions pursued in 2008 relating to householder extensions where is was made clear that the intention was to remove some forms of development from requiring express planning permission, but only in circumstances in which amenities are preserved (CLG. 2008). Revisions post 2010 have, it is suggested here, been approached differently, with economic growth the driver and scant consideration given to the wider implications.

## 6. Permitted Disorder

Within the contested space, change did occur. Change did not take place in a single measured step, instead a series of amendments were introduced in 2010, 2011, 2012, 2013, 2014 and 2015. It is beyond the scope of this paper to detail all of these revisions, but in each case the revisions each had the effect of extending the Permitted Development allowances in some way.

Through the attempts to extend Permitted Development rights and remove developments from the requirement for express planning permission it is suggested that a paradox has emerged however; the more the Government attempts to simplify the decision making system and facilitate development, the more complex and flawed the system has become (Sheppard, A. 2014).

The changes introduced have led to new Permitted Development rights being created, existing rights extended (some permanently some temporarily), the prior approval process becoming increasingly prominent and used, and Local Development Orders have been presented as a potential solution to the planning 'barriers' associated with everything from minor work to comprehensive brownfield land redevelopment. The nature and intentions of the changes are not in themselves necessarily all problematic, but the continuous and piecemeal manner in which these changes are being introduced is making for a very cumbersome, complex and confusing system which, conceptually, needs to be none of these things. As a result, it is suggested that we now find ourselves in an environment where regulation density and complexity is a real issue to the extent that the system is becoming

dysfunctional. It is also argued that in some cases the changes have failed to consider the important question of the necessity of state intervention and the system emerging does not necessarily represent a proportionate model based upon impact and controls existing where justified on the basis of social justice and the public interest. Some recent adjustments concerning, for example, changes of use, limit the potential for state intervention to manage impact and spatial planning where this is potentially very important (Sheppard, A. 2014).

## 7. Case Study: Office to Residential change of use

*Introduction*

On the 30th May 2013 the Town and Country Planning (General Permitted Development) (Amendment) (England) Order 2013 came into force. Included in this amendment was the right for a period of three years to change the use of a building from an office use to dwellings. This effectively allowed existing office buildings to be converted into dwellings without the requirement for express planning permission. This was a new step; previously such a change would have required the express permission of the Local Planning Authority. The intended effect of these amendments was to support an increase in housing supply, encourage regeneration of offices and bring empty properties into productive use.

Local Planning Authorities were given the opportunity to exempt themselves from this new arrangement where concern existed that such rights would lead to either the loss of a nationally significant area of economic activity or substantial adverse economic consequences at the local authority level not offset by the positive benefits the new right would bring. It was also a requirement that the office building was vacant prior to the point of the new amendment being introduced to ensure that buildings with a viable use were not inappropriately lost. The amendment also does not apply to protected heritage assets (Listed Buildings and Scheduled Monuments).

Although the amendment removes a change of use from office to residential from requiring an express planning permission, it was not completely without oversight. The system employs the 'Prior Approval' model whereby it is necessary apply to the local planning authority for a determination as to whether the prior approval of the authority will be required in relation to the acceptability of the proposal upon:

(a) transport and highways impacts
(b) contamination risks on the site;
(c) flooding risks on the site.

The requirements associated with the prior approval process are not extensive though; applications only need to be accompanied by a written description of the proposed development; a plan indicating the site and showing the proposed development; contact details and any fee payable. Consultation with the necessary bodies is also required where significant traffic impacts are involved and/or when the development is within an area at risk of flooding.

*Delivering change*

The intention of the changes introduced were to increase housing supply and in parallel address weaknesses in the office supply market concerning both the amount of space available and its quality.

Research undertaken by planning consultancy GVA suggests that nationally over 11m sq ft of office space has left the market for alternative use (Morris, M. 2015). In 2014 some 6.8m sq ft of office space left the market and it is suggested that 17,500 homes could ultimately be provided through the policy (ibid). These changes can be seen as positive in some respects; surplus office space supply does exist in some areas, a surplus of lower grade office space does exist in some areas, and there is a national housing shortage. A report from planning consultancy Nathaniel Lichfield and Partners

(NLP) in May 2015 noted that the change had led to some positive effects in some areas, noting in particular that some poor quality office space has been removed and replaced with much needed residential accommodation and also that removing office space from the market has driven up rental values to the extent that new office development that was otherwise stalled where becoming viable again (NLP, 2015).

*The cost of change*

The introduction of the allowances for office to residential conversions has seen a mixed response however, and it has been controversial in some respects due to the impacts that appear to be resulting.

In some cases the arrangements are placing undesirable pressure on the office market. In London, Westminster City Council is seeking to protect its declining office supply because they have estimated 1.8million sq ft of space has been lost driving undersupply and higher rents (Estates Gazette, 2015). The NLP report highlights that the conversion of offices to homes since the right was introduced has caused problems in areas with a housing shortage because this is placing significant pressure upon vacant office space to the extent that the fasted decline in the availability of office space was being witnessed since 1998 and that this could lead to a potential supply crunch and unsustainable rising rental levels (NLP, 2015).

Conversions of office buildings to residential use that utilise the Permitted Development arrangements are not normally required to make planning gain contributions. Whereas a conversion pursued through the traditional planning application process could be required to make financial contributions towards infrastructure delivery and provide affordable housing, this is not the case through Permitted Development rights. The provision of affordable housing in the UK is dependent upon planning gain to a significant extent.

In addition to the affordable housing issue, the absence of planning gain means important resources are not provided to the local planning authority to support physical and social infrastructure provisions. Thus, not only is the change of use less open to scrutiny in the first instance from the perspective of the fundamentally suitability of the location for the introduction of new residential accommodation, it also lacks planning gain resources to mitigate against the resulting impacts. Changes of use can therefore take place in less desirable locations from a social infrastructure perspective and further contribute to the challenges being faced in the area. This issue becomes magnified when development is possible in areas where social and physical infrastructure is inadequate to accommodate further residential development; a scenario entirely possible through the current arrangements. It is essentially only through arguments relating to transport and highways issues that less desirable locations can be resisted in the context of the sustainability of a given location; a more limited basis that would be the case where full permission was required.

Research undertaken in Bristol suggests that schemes that are coming forward in this City are broadly occurring in locations with good access to adequate infrastructure (Frost, A. 2015), but it remains the case that the legislative mechanism now in play does not provide an opportunity to prevent change from taking place with this not the case except in respect of a few very specific situations, the market is once more effectively the determinant of where these forms of changes of use occur, a situation which is suggested as being a regression to the pre-1947 Act environment of inadequate controls and where it must be remembered intervention became necessary because of the failure of the market to always deliver acceptable change (Gilg, A. 2005).

Finally, the resource question must be considered. The planning fee for a Prior Approval application £80. In contrast, the fee for a change of use full planning application can be significant:

Table 3: Planning Fees Extract

| **Change of Use** of a building to use as one or more separate dwellinghouses, or other cases | | |
|---|---|---|
| Number of dwellings | Not more than 50 dwellings | £385 for each |
| Number of dwellings | More than 50 dwellings | £19,049 + £115 for each in excess of 50 up to a maximum of £250,000 |
| **Other Changes of Use** of a building or land | | £385 |

(The Town and Country Planning (Fees for Applications, Deemed Applications, Requests and Site Visits) (England) Regulations 2012 – correct at April 2015)

A Prior Approval application has resource implications; the application still requires administration, consideration and investigation by the local planning authority team. The income is associated with an application is insignificant however, meaning a significant cost is borne by financially stretched local planning authorities.

Most significantly perhaps, the Permitted Development allowances remove the ability of the local planning authority to strategically manage office and residential supply, nor can they influence the spatial distribution of new developments.

*Summary*

The office to residential allowances provided through the 2013 Permitted Development rights amendments were essentially introduced to increase housing supply and on the basis that some buildings that were previously in use as offices are now residential there is some success to be recognised. However, the cost of this is suggested as being significant; strategic management of office supply has been lost in areas without protection in place and importantly the Permitted Development regime does not allow local authorities to prevent/influence inappropriate development taking place in less appropriate locations without appropriate access to services and amenities except in more limited circumstances.

In parallel, planning gain is not supported, further undermining the ability of the local planning authority to act effectively in the management of the built and natural environment and their ability to support the delivery of required physical and social infrastructure. The fee model approach further impacts upon resources, making the system flawed from the local planning authority perspective in relation to process/system viability.

## 8. Conclusions

As noted at the beginning of this paper, the evolution of state intervention, and the broad acceptance of the justification for state intervention, was driven by the necessity of responding to events and circumstances that required address and that private arrangements either could not, or would not, respond to adequately alone. The hierarchy of intervention, employing the development, Permitted Development, prior approval and express permission steps supports proportionality conceptually, and historically change was predicated on an impact based approach with balanced consideration of costs and benefits (CLG, 2008).

The recent changes to Permitted Development rights in England, including the office to residential example provided, arguably renege on these principles. The economic growth motivation has primacy and inadequate consideration has been given to the implications of the changes pursued from the

perspective of the ability of local planning authorities to strategically and spatial manage change in the built and natural environment. It is suggested that the emerging system is flawed and potentially dangerous; in the case of the example presented local planning authorities lose effective control of strategic office floorspace management and residential dwelling distribution. In parallel, planning gain is absent and fee income is minimal making local planning authorities resource changed and potentially unable to effectively mitigate impact and provide adequate social and physical and social infrastructure.

Effective proportionate control is at risk and although the system is only emerging, evidence is presenting itself already to suggest that effective planning is being lost in the drive to facilitate economic growth.

# INFORMAL SETTLEMENT'S ACT: WHAT WENT RIGHT IN THE PORTUGUESE CASE?

Paulo Silva

University of Aveiro, Department of Social, Political and Territorial Sciences, paulosilva@ua.pt

Keywords: informal settlements, law making, Lisbon Metropolitan Area

***Abstract:***
*Informal settlements rose in the developed world for some decades, affecting, in the European context, mainly the southern countries. Many have been the models to react to this dynamic, namely through legal action. In todays' world this is still affecting a significant part of the population, according to main world institutions (UN Habitat, OECD, World Bank). It is estimated that in Europe there are still around 50 million people live under these conditions.*
*In the past, Portugal was one of the countries most affected by informal settlements. In the 1980's over one tenth of Lisbon's population was living in slums and in illegal urban areas. What started by being a critical issue in territorial terms is today almost an inexistent problem. This paper will focus on the way planning institutions were able to design a responsive legal framework, addressing informal settlements and creating a setting favourable to regenerate those areas.*
*The paper will discuss the role of planning institutions, as well as the role of informal settlement in the law making process and in the law improvement process, a process that started in 1995 and lasts until nowadays. Beyond the formal procedures there were some key factors which warranted the success of this tools: several decades of experimentation, short links and a constant interaction between agents will be presented.*

## 1. Introduction

Informal settlements is a broader expression that is used to describe a wide range of illegal urban occupations. They are in general (1) associated with a mismatch with planning and architectural rules and (2) are in some cases the result of the occupation of land not belonging to the settler (OECD, 1998). They rose in the developed world for some decades, affecting in the European context mainly the southern countries. Many have been the models to react to this dynamic, namely through legal action. In todays' world this is still affecting a significant part of the population, according to main world institutions (UN-Habitat, 2003, OECD, 1997). It is estimated that in Europe there are still around 50 million people live under these conditions (UNECE, 2010), namely in the eastern region.

This wave of informal settlements is not new. It affected central European countries like France in the decades of recovery after the Second World War – adopting mainly the shape of slums formed by precarious constructions in someone else's land - and in southern Europe countries like Italy. Later during the 1970's and 1980's the three then young democracies of southern Europe – Portugal, Spain and Greece – were also affected. Due to the effort put on some of these experiences and to the need of models to intervene in new cases – still emerging in the Balkans, institutions as UN consider that lessons should be extracted from well succeeded cases. The need of new models is perceived as crucial in terms of governance, of bottom up solutions and on legislation (UNECE, 2010).

In this paper, the Portuguese experience in dealing with informal settlements will be focused. When 48 years of dictatorship ended in 1974 the housing situation in the country was dramatic. Underneath a peaceful middle class atmosphere created by the previous corporative state, there was an explosive housing situation involving derelict buildings in city centres on one hand; shacks build in empty spaces close to the inner city (in public but also in private land) on other hand; and

the occupation of rural areas in the peripheries. They corresponded to different groups in the Portuguese society. The ones living closer to the city centre, either in old building or in slums had less resources – the places didn't belong to them, they had less income and they were older – while the third group had different characteristics – they owned the land, were younger and possessed a stable job and an income. While the state tried to mitigate the two first situations by institutionalized solutions such as the construction of social housing, the third type of precarious housing continued to grow (Silva, Farrall, 2014). This was the result of the consolidation of a new middle class, of the return of financial revenues of Portuguese emigrated mainly in central European countries and the needs of housing from civil servants returned from the African ex-colonies.

The focus of this paper in on the way planning institutions dealt with informal settlements in the peripheries of main Portuguese cities, based on an informal market of rural land, illegally divided in order to stimulate urban sprawl at low prices. They started to be known as *"bairros clandestinos"*, in the bureaucratic jargon of the 1970's, the same way they were called *"marginales"* (sp.) or *"abusivi"* (it.) in other idioms. The line was drawn: even if not much was made to deal with them, they were placed beyond legality. When a more responsive law was launched in Portugal in 1995 they adopted a new name, AUGI. The acronym meant that they were urban areas of illegal origin. This was the beginning of a process which will be addressed in this paper.

The reason for this is the fact that were these kind of informal settlements which had a stronger impact in the Portuguese urban system. This occurred to such an extent that planning institutions were under pressure to find legal alternatives to deal with informal settlements.

In the past, Portugal was one of the countries most affected by informal settlements. In the 1980's over one tenth of Lisbon's population was living in slums and in illegal urban areas. What started by being a critical issue in territorial terms is today almost an inexistent problem. This paper will focus on the way planning institutions were able to design a responsive legal framework, addressing informal settlements and creating a setting favourable to regenerate those areas.

The paper will discuss the role of planning institutions, as well as the role of informal settlements both in the law making and in the law improvement processes, which started in 1974 and lasts until nowadays. Beyond the formal procedures there were some key factors which warranted the success of these tools: several decades of experimentation, short links and a constant interaction between agents will be presented.

Much has been researched in terms of informal settlements in Portugal. In the early years after 1974 a relevant number of publications were produced in order to discuss the causes and effects of informal settlements. Main authors were practitioners who reflected on their professional practice in planning meetings (most of them promoted by local authorities) and in academic research (Portas, 1988). As the territorial impact was stabilized – this started to happen in the 1990's – this wave of research slowed down significantly. A decade later, when the results of the application of the AUGI act started to have some physical impact in the urban system a set of new works started to be produced, focusing on the impact of ex-informal settlements in the urban system (Silva, 1996, 2010).

One of the main conclusions of some of these post-AUGI act researches relate with the special status that informal settlements acquired in the Portuguese planning system. Less has been said about the lessons that can be extracted from the making, implementing and monitoring of the management model behind the legal frame. Considering the AUGI act more than legal action to deal with informal settlements, it is possible to find a rich process in terms of testing, of sharing knowledge, of networking, of brokerage, on monitoring and feed backing, which can be useful to informal settlements in other contexts and to the regular urban management models in general.

It is the aim of this paper to shed light on the process behind the AUGI act, identifying their main actors, the problems related with informal settlements at different levels – governance of the process itself, financial resources and bureaucratic procedures – and the main answers to respond to them. This has as final goal he replicative role of this legal frame in regard to other urban management contexts.

## 2. Legal, illegal and legitimate: what shapes legal frames for informal settlements?

### *2.1 Legal, illegal and legitimate*

Informal settlements are the expression of a conflict between two parts. On one hand, the landowners, who bought rural pieces of land without any planning permit to urbanize or build and transformed these places in very precarious urban settlements – where infrastructures, collective facilities, accessibilities were missing. On the other hand, there are planning institutions, defining rules to that informal settlements don't match as urban settlements. They were not planned to exist in the urban system, therefore they lack all the basic conditions needed for an urban settlement – infrastructures, collective facilities and accessibilities, among others.

Legal frameworks play a crucial role in this set and in the way each side perceives its own rights. They establish what is legal. Urban formality and informality are addressed in regard to legal frames. It is in regard to a set of rules established by law that property rights are recognized. But laws are itself interpreted in a systemic way. In abstract, and according to the law, occupation might be considered illegal due to the mismatch with legal frames. But in concrete if the same occupation is related with the fulfilment of a housing need, although it continues to be illegal, that same occupation might be considered legitimate, as for instance housing is considered a social right. Under this context, legality and legitimacy play an important role when it comes to discuss informal settlements.

At the same time law draws the line between legal and illegal. On one hand, in the case of informal settlements a legal tool designed to control them, is perceived as a limitation of a property right, when seen from the landowners' point of view. On the other hand, when a legal tool is not just controlling but it is contributing to a balanced solution in order to allow some planned occupation this is seen by planning institutions as a concession to informal settlements.

### *2.2 Portuguese informal settlements milestones*

The emergence of informal settlements is well documented, to start with, by the fact that was a territorial dynamics which affected mostly – in terms of surface, but also in terms of number of residents – the Lisbon Metropolitan Area, shaping the suburbia of the capital. It is a process which consistently started 50 years ago, when the Portuguese capital experienced some prosperity as the result of the opening of the economy to the exterior. Informal settlements' emergence reflect this starting point and evolved according to some main key dates: 1960´s - the decade of a strong migratory movement towards Lisbon, from all the country regions (Fonseca …); housing shortages occur, leading to the development of an informal division of rural land, later occupied by illegal constructions; 1966 - the year of the construction of the first bridge in Lisbon over the Tagus river which opens the door to the speculation with rural land in the south bank of the river; 1968 – water floods in Lisbon's region put in evidence housing conditions; hundreds of people died most of them due to the precarious conditions of informal settlements in the north bank; 1974 – the revolution stands for the establishment of a democratic regime with a new constitution (approved in 1976) in which housing and association are recognized as constitutional rights; first attempts to plan informal settlements produce the first urban layouts soon after the revolution; 1976 - central and local governments are elected; the cooperation between municipalities and informal settlements is established; 1986 – The entrance of Portugal to the European Union adds a new meaning to the problem of informal settlements; they are not anymore only a matter of housing scarcity, due to the scale that in the meantime they achieved, they became an environmental and

planning problem; 1995 – After two decades of "try and fail" (in fact not much progress was apparently done in this period) in order to deal with informal settlements the AUGI act is approved by the Portuguese parliament after a surprisingly short period of months of discussion.

In order to understand this process, two milestones associated with trigger events have two be underlined. The first one is the revolution of 1974 which will change politically, ideologically and socially the country. The second one was the entrance to the European union, which had less impact in the short term, but which transformed the country in the long-term in terms of environmental and planning standards (and of the financial means to achieve them). It is in this sequence of these trigger events that the AUGI act, not without before other attempts being made.

*2.3 How Portuguese planning institutions tried to deal with informal settlements for almost 30 years*

Until the 1960's, urbanization in Portugal was an activity exclusively carried on by the central public administration. However after the first years of that decade, it became impossible to planning institutions to ignore the rise of informal settlements around the city of Lisbon, even where they were just starting, like in the south bank of the metropolitan area (Silva, 1996). Therefore, the first legal initiative to control informal settlements was to open to the private initiative the possibility to urbanize. The expected results from this legal initiative was to increase the offer of urbanized soil and by that way to reduce the attractiveness of informal settlements in the real estate market. However, this did not happen: the needs of housing were so large by then that private entrepreneurs explored the high density market while at the same time other sector of society continued to invest in informal settlements. Acknowledging the failure of this policy and not wanting to openly recognize that informal settlements were emerging out of the control of the authoritarian regime, it was only in the early 1970's that some legal initiatives were carried out, with very limited effects. The attempt to control the existent informal settlements was not doing any harm to the emergence of new ones. Data from the 1970's showed how this was a flourishing industry in Portugal, answering to housing needs (Ferreira, 1984).

With the 1974 revolution informal settlements assumed a political and ideological meaning. On one hand informal settlements were seen as an answer to housing needs; on the other hand, not all the informal settlements were related with housing scarcity. In some cases landowners were buying several plots of land, due to their low price; others were buy plots of land in coastal areas in order to build secondary houses. Different actors' agendas generated a new perception of informal settlements: there were the "good" ones, corresponding to a legitimate aim to a home and there were the "bad" ones related with speculation and with less legitimate aims – like, at the time, to have a secondary house. From 1974 on legal documents will reflect this ideological setting with an institutional discourse emphasizing that there was not only one but two kinds of informal settlements.

Some other factors were: (1) different political parties with opposite agendas involved in plan-making at the central government, at the local government and at the landowners associations' levels; (2) the use of similar legal procedures for informal settlements and for legal settlements, despite of the fact that they had very different characteristics; (3) diversity of informal settlements, from small but heavily occupied to very large but weekly occupied areas; (4) different impact at national level, with informal settlements mostly concentrated in the Lisbon metropolitan area and in the coastal areas of Algarve, in the south; (5) different spatial planning approaches and tools with different characteristics, scales and levels of detail; (6) The need to cater to spatial planning indicators and to make a correspondence of those indicators and an uneven distribution of land by landowners.

These factors on one hand, turned the process of dealing with informal settlements more complicated; but on the other hand it allowed to explore most of the sides of the problem, which turned out to be two decades of experimentation. Some of these experiences had similar protagonists: politicians re-elected for different terms (in Portugal until recently there was no limit

of terms for local elections); practitioners who specialized in dealing with informal settlements; and landowners who embraced the legalization of the informal settlements almost as a full time job. Also as time passed landowners settled in and became residents, gaining political weight. This set of conditions played a key role on the way the AUGI act was produced and approved in 1995.

*2.4 The AUGI act*

Law-making are usually long, are based on the intervention of many actors, are highly hierarchical processes and tend to become very static bodies. We find this pattern in most of the spatial planning laws produced in Portugal. The AUGI act process, before and after its approval contradicts this pattern in many ways. As opposed to other legal frames, the AUGI act was discussed by a parliamentary commission and approved by the national parliament in few months. During the process a much reduced number of entities was consulted, but those who intervened were highly representative of main parts – municipalities, which were in charge of spatial planning; and informal settlements' landowners associations. As opposed to other cases the production of the AUGI act missed the intermediate levels of the hierarchical planning institutions pyramid; instead the main actors on the production of the law were the parliament, on the top of the hierarchy and representatives of the municipalities on the opposite side. And finally, this legal body became highly dynamic, with several revisions in the last twenty years.

The process of law-making showed a great consensus among the four largest political parties in Portugal. The extension of the problem of informal settlements became so large in the 1980's and early 1990's that all the political parties realized that had more gains than losses in dealing with informal settlements. The left wing parties had a traditional linkage with informal settlements at the local level and the centre-right wing parties had a significant part of their electorate living in informal settlements, namely in Lisbon suburbia; in addition, they aimed to dispute also left wing parties' local influence. For these reasons, when the law was produced and about to be approved they all wanted to be part of solution and not of the problem.

Among all the technical details included in the AUGI act, the priority was to solve those aspects that in the past affected planning institutions responsiveness. The first of this was the fact that prevalent rules obliged the total amount of landowners to agree on decision-making. This became an almost impossible task, regarding the fact that in many cases informal settlements had hundreds or even thousands of landowners. To even reach them was sometimes very difficult; in addition any decision had to be taken with the agreement of all. Due to this, an equivalent body to the old landowners' associations was established – and called management commissions. According to the AUGI act, the majority of their members are entitled to decide in general assemblies by the whole of the landowners. This possibility became very important to allow processes to move on medium and large size informal settlements. But on the other hand, it could imply a heavy burden for small informal settlements. Aware of that, the AUGI act introduced a rule in which small informal settlements could be exempted of management commissions, if they wanted.

Law-making was influenced by the fact that the majority of informal settlements were concentrated in Lisbon metropolitan area. Over 10 % of the population was living in informal settlements by the 1980's. The major practical contributions to the law came from those municipalities most affected. On the north bank, one municipality's territory (Loures) was particularly occupied by informal settlements, mainly of small size but highly occupied by housing and small activities as well. On the south bank, another municipality (Seixal) had its territory largely occupied by large scale informal scales, although still with a comparatively small population by then.

Diversity of planning tools used in the past was one of the exploratory qualities of previous experiences. Aware of that diversity, the AUGI act not just accept it but also promoted it, leaving the option to the management commissions and to the municipalities, according to each case. From then on, they were free to choose which kind of tool to use in order to legalize the settlement, either an urban or a detailed plan or, for simpler cases, only a parcelling out project.

Finally, the ability to match planning needs in terms of collective spaces was another critical issue addressed by the AUGI act. In order to meet this need different mechanisms were established: municipalities together with management commissions could decide to include extra areas to the future settlement in order to meet the urban needs; they could establish a balanced distribution among the different landowners; or even decide to compensate financially the municipality when it was impossible to find spaces in connection with the informal settlement.

**3. Analysis and discussion of results / findings;**

Flexibility was apparently the secret to meet under the same set of rules such diversity of circumstances involving informal settlements. In less experimental contexts what could have happen instead? Probably a highly hierarchical planning institutional structure would establish a legal frame which, as it happened before, (1) would have been contested; or (2) ignored. Apparently the AUGI act was published too late for an informal settlement's process started in the early 1960's. However this "delay" seems to have been crucial to explain some of this legal tool's characteristics.

*3.1 Pressures to legislation and planning innovation*

Experimentation went through various phases and although it is clear that 1974 revolution was a milestone in this process. It is however necessary to admit that all the initiatives taken before and after the revolution were part of a learning process which culminated in the AUGI act. From this perspective, all the previous legislation initiatives, although bad-succeeded were part of a learning process – the public administration machine and a large set of practitioners guaranteed the continuity between dictator and democratic regimes. Legislation actions taken before and after 1974 were ineffective due to the fact that it was an exhausted state - politically talking, before the revolution and financially talking after that – who knew that very few alternatives to informal settlements could be offered. Also the state as a unified entity is something that disappears after the revolution, since municipalities started to be democratically elected. Their closeness to residents in informal settlements and to the rest of landowners very soon created conditions stretch ties, proved soon after to be stronger in some cases than institutional solidarity.

In terms of planning instruments that shift between central and local governments before and after the revolution was even more evident. While planning instruments before the revolution ignored the emergence of informal settlements and municipalities had not a say in terms of planning, after the revolution both levels of government engage into planning in order to deal with the explosive situation of informal settlements. In general, centralized planning initiatives were less accepted by landowners while local planning initiatives turn to be the beginning of an experimental phase of twenty years. The length of the processes and the perception of the landowners – of losing construction and property rights, although they never had them according to the law – was one of the main reasons for the failure of these processes. In addition to the growing pressure to legalize and the lack of responsiveness of plans, a growing environmental awareness regarding urban sprawl entered into the Portuguese scene with the entrance of the country to the European Union in 1986.

Also in 1986, an exception is open in order to deal with the largest informal settlement in Portugal, covering an area of over 400 hectares (Quinta do Conde). In order to register the plot of land under the name of the new landowners an exceptional authorization was established by the central government in articulation with the municipality (Sesimbra) – since it showed to be a successful mechanism, nine years later that exception was included in the AUGI act as a rule. And the experimentation effect continued. Since it worked successfully to the informal settlements the application of the rule was later extended to every other urban developments in order to ease the land registration process.

*3.2 Governance concerns*

In many aspects the AUGI act met governance goals considering the kind of rules created. But this was not something achieved at once. In the initial version of the act, all the mechanisms are set mainly around two structures – the municipalities and the management commissions. A remarkable flexibility of the law allowed that for each case there were three open options – legalization managed (1) only by landowners (through management commissions), (2) only by the municipality; or (3) by both entities. Again, this was a way to create the options to cater the needs of each specific informal settlement. In some cases their pro-activity would allow them to move on their own; in other cases, due to short resources or lack of technical expertise they could make the management together with municipalities; and eventually if they would not accept o move on at all, municipalities could take the lead on their own.

In many situations along the AUGI act making a pattern was set: experimentation was an opportunity to acknowledge the diversity of situations to be addressed; the setting of rules translated that diversity. That was not only an initial pre-disposition; along the years of implementation, from 1995 until today efforts have been put in terms of keeping a constant improvement. Reflecting this, the first major revision of the AUGI act was made in 1999. Among several changes, we underline two of them.

The first one is concentrated on redistributing the power in relation with the decision-making process. According to the 1995 version, the management commissions were the only entity representing the landowners. In 1999 the act is changed in order to allow individuals to be more vocal in the decision-making. Parliamentary reports refer the fact that this was the result of the disappointment of some landowners in regard to the management commissions. The same reports refer that this information was send to the parliament through the Ombudsman. In fact in the 1998 Ombudsman yearly report we found references to landowners' complaints about the lack of responsiveness of management commissions.

The second one refers to the role of the original landowner – the one that illegally divided the land and sold the parcels to others, but most of the times was still owing part of it. The initial version of the AUGI act, excluded them from any kind of decision-making process. In a way, this was a "moral" statement, to move away any decision from the sphere of action of the agent responsible for the process. However, when management commissions and municipalities started to apply the law, they realized that in some cases most of the needed spaces for collective facilities and public spaces for instance. In one of the law's revision, this was one of the changes introduced. Despite of the "moral" statement behind the initial version of the law, a more pragmatic perspective realized the need to include the original landowner also in the process.

This work of monitoring and improving the law has been based on a set of long-term relations between agents, and on "institutional by-passes", or short chains, between the parliament (who is responsible by operating the changes), the municipalities most affected by informal settlements (who deals with the planning process) and the management commissions (who tests on the field the rules). Some protagonists – landowners' representatives, law-makers, parliamentary commission's members – are in the process for decades, carrying information, sometimes staying in the same job and other times moving from one context to another. Some parliamentary deputies have been councillors in municipalities where informal settlements took place; in some cases, a landowner started by being a management commission member, then became elected for the local parliament and later was hired as municipality's advisor for informal settlements, being one of the representatives in parliamentary auditions; law-makers started by working to residents' associations, carried that experience for the law-making process of the AUGI act, continued to work in the successive law-changes and eventually that accumulated experience to adapt other spatial planning legal frames.

This context established a dilemma in Portuguese planning institutions. On one hand, there was the awareness of the need to prevent urban sprawl; on the other hand, there was a public recognition of housing needs and a more discrete assumption that informal settlements would be in part the answer to those housing needs. Both sides of this dilemma were part of the experimentation phase which shaped the 20 years before the AUGI act was approved. The failed appliance of punitive decree-laws showed that that was not the way at the legal level. But the initiatives to frame informal settlements through planning seemed to be also unfruitful. Plan-processes were too long and their approval was too difficult. Traditional ways of planning, implying a full agreement between all the landowners, were in many cases very difficult or almost impossible to achieve.

**4. Final ideas: the outcomes of a law-making process**

We started this paper by enhancing the impact of informal settlements in the developed world in the past as well as in the developing world in the present. However, looking closer to the Europe this is a not so irrelevant issue, when considering still southern and eastern parts of it. The need for solution in many various contexts is necessary and yet the lessons to be taken should be put in perspective in order to be effective to other contexts. From many models tested, legal aspects are always present, since solutions for informal settlements have necessarily a legal impact on property rights, which can be seen from different angles. From those who are landowners, the process of legalizing informal settlements can be seen as putting in risk, if not legal, at least legitimate property rights. For those who are on the other side – public administration, planners, politicians – to legalize informal settlements tends to be seen as the achievements of those rights that for landowners were already acquired.

In face of this evident conflict of different informal settlements' perceptions, the following lines will conclude about the way a legal frame, in a country heavily fustigated by informal settlements processes during several decades, managed to establish a consensual set of rules for both parts. In this section, as opposed to previous attempts to control informal settlements, the process based on experimentation, the key-issues addressed, he dynamics of the law itself and the impact on other legal frameworks will be underlined.

What made this law to have such an effect on dealing with informal settlements and later with other kinds of urban settlements? As referred previously, if there is a lesson to be extracted from the AUGI act process of law-making is the one of the importance of experimentation, long-term relations and short chains. Experimentation was useful to test traditional models – using pre-established planning procedures – to the limit in which planning institutions recognize their failure. Testing and failing brought out the search for new solutions. And if they were not in plans nor in planners, than they should be "above" them, in the legal frameworks. The trial and fail process, long of two decades brought with it another outcome – the establishment of long-term relations. These long-term relations between politicians, planners and landowners were crucial to create trust among them, one of the key-conditions for governance settings. Actors involved in the law-making and in the law-evaluation processes interacted at different levels sometimes already for three decades. But in order to permit a fluid flux of information, on the top of long-term relations, short chains were required. The brokerage role of some actors was crucial to establish links between informal settlements and the planning institutions responsible by the law-making, in this case the national parliament.

In this paper it has been discussed a rather successful case of establishing a legal frame in order to deal with informal settlements. The impact of this process can be multiple. On one hand, the way experimentation was present is very evident. Twenty years (1974-1995) of dealing with informal settlements was the process that lead to the establishment of a new legal frame. What seems obvious today, only happened due to a learning process of two decades. Much work can be done in further researches in order to understand his shift happened only after such long period. Maybe one of the reasons is related with the fact that for many years and even after the revolution, informal settlements were seen like something to be punished and repressed at the legal level while at the plan level some attempts were made in order to legalize with strict urban criteria those who had conditions to be integrated in the urban system.

What the AUGI act also reveals is an awareness that informal settlements were not only a matter of city planning, neither of property rights, but also a matter of governance. Much of the changes imposed by this act are related with the quality of the decision – based on the majority of the elements of the management commissions but also with its effectiveness. Decisions are based on consensus-building but they are as well associated with the need to move on. This act shows a clear concern with exempting the decision making process from "grey zones", in which the planning process could get stuck. Due to the complicatedness of the traditional administrative land registration process, new rules are set in order to allow individuals to register their plots of land without depending from the other co-owners. For a conservative public administration based on the same rules for decades something of this kind would have unthinkable some decades before.

Another relevant conclusion of this paper in regard on the AUGI act is related with its dynamics. This law, approved 20 years ago was subjected to a significant number of changes until our days. The stunning and unusual pace of changes might lead to a first suspicion of a badly done law. But analysing the number and the content of those changes it is possible to observe the consistency and the coherence of the adaptation of this law to the contexts in which it was applied. It reveals a close evaluation of the impacts of the law in the contexts in which it was applied – a diversity of informal settlements in terms of size, number of agents and uses.

And finally, the replicative effect of this law must be underlined. This legal tool was effective to deal with a specific dynamics, the one of informal settlements. But from this experience lessons were extracted to other spatial planning legal tools. The assumption that property rights were associate with property obligations, was firstly set within the context of informal settlements. Only later this was assumed for every type of urban settlements, being legal or illegal. The experimental context had to be "accepted" by planning institutions in order to deal with an exceptional problem. This exception was later adopted as a rule in order to deal with urban settlements in general.

# Resolving Urban Land Disputes: Lessons from the Portland, Oregon Region

Edward J. Sullivan[1] ©

Keywords
Regional planning, Planning Law, Growth Management

## Abstract

*The Portland Metro area is the largest urban area in Oregon. The Metro planning agency makes binding planning decisions for the region, including establishing an urban growth boundary (UGB) to provide sufficient urban lands for 20 years. After successful challenges to additions to urban lands, the Oregon legislature established new rules for "urban reserves" for 20-50 years. Urban reserves are presumptively the next additions to the UGB. To maximize discretion, the legislature authorized Metro to balance certain unweighted "factors" (instead of fixed criteria) in designating urban reserves.*

*The paper recounts the controversy that revolved around the attempt by Washington County to add substantial farmland to urban reserves to accommodate employment growth. Resource land preservation is a high value in Oregon's planning system. Opponents suggested that adding a large amount of resource lands could not be justified by the findings purportedly "balancing" these factors. The urban reserves process failed when the Oregon Court of Appeals held that the use of the factors did not obviate justification of addition of resource lands to urban reserves. The legislature intervened, setting the urban growth boundary and most reserve areas by statute.*

*The paper provides an assessment of this regional urban reserve process – factors in lieu of criteria, temptation to solve UGB problems at the legislature, the need for more predictable "safe harbors" for future urban designations, and accountability through uniform and transparent growth projections. While deference may be given regional planning decisions, those decisions must be coherent and justified by an adequate factual basis.*

## I. Introduction

Over time, coordinated planning for urban areas has been recognized and encouraged. The federal government has required such planning with regard to transportation and housing funding,[2] and the once-dominant model that planning and land use regulation may be done by public bodies independent of each other[3] has been superseded by a model in which regional impacts must be considered and resolved.[4] Conflict resolution is necessary because of the diverse and strongly held views of citizens, interest groups and public agencies. The resolution of conflicts, given these diverse views over the pace, direction and extent of urban growth, are the subject of this article, which focuses on the recent controversy over urban growth in the Portland, Oregon metropolitan region. It is highly likely that similar conflicts will also arise in other regions; thus this article will deal with the lessons learned from that controversy.

To put the matter into context, a brief description of the legal aspects of the Oregon planning system will be presented, followed by a description of the urban growth management law that applies specifically to the Portland region. The article will then provide a brief history of previous urban growth conflicts between 1979 and 2005 and the legislative response to these conflicts in the enactment of new rules to

deal with perceived shortcomings in the process. Those new rules, as applied to the current controversy (2010-14), will then be examined, followed by a discussion of lessons learned and applicable to similar resolutions of conflicts over urban growth.

## A. The Oregon Planning System and Urban Growth Boundaries

Space limitations prohibit a fuller description of the Oregon planning system;[5] however, for purposes of this article, a synopsis, as relevant, will be given. In 1973, the Oregon legislature enacted SB 100, which provided for a new state agency, the Land Conservation and Development Commission (LCDC) to adopt binding standards ("goals") for local plans (which in turn would be binding on local land use regulations and actions).[6] Eventually, there were 19 statewide planning goals addressing a number of planning issues and falling into five categories: Process (Goals 1 and 2), resource lands protection (Goals 3-5), human interaction with the environment (Goals 6-8 and 13), public facilities and urbanization (Goals 9-12 and 14) and specific areas of state interest (Goals 15-19).[7] Local governments were obliged to have their plans formally certified or "acknowledged" by LCDC as complying with the goals by incorporating the goals in their plans, so that state policy, as embodied in the goals, was implemented.

The most familiar component of the Oregon planning system is the urban growth boundary (UGB) that separates "rural" from "urban" land, so as to assure that almost all urban development occurs on urban lands. Whether land is located on one side of the boundary or the other is significant.

In the same session that enacted SB 100, the legislature also recognized the need for regional planning for the Portland metropolitan area that presently includes portions of three counties, 25 cities, and services approximately 1.5 million people. As a result, the legislature delegated to a predecessor agency the powers to:

* Coordinate all planning activities of member cities and counties, special districts and state agencies.
* Review all comprehensive plans to determine conformity with statewide planning goals.
* Adopt regional goals and objectives.
* Prepare a plan for the region in accordance with statewide and regional planning goals.
* Designate areas and activities having significant impact on the region and establish rules and regulations for them.
* Review plans adopted by its member governments and recommend or require changes to assure the plans conform to the regional goals and objectives.[8]

The current structure of regional government evolved from a legislative determination to reassign regional planning duties and provide for a different regional planning agency (Metro). Following enactment of a state constitutional amendment,[9] an elected regional government with powers to deal with matters of regional concern evolved.[10] Among the powers Metro possessed was that of enacting and amending a regional UGB.[11] For purposes of this article, many of the other powers granted Metro, including those of regional coordination,[12] adopting a Regional Framework Plan[13] and requiring local governments to "substantially comply" with that plan[14] are generally not discussed further; rather, this article focuses on Metro's UGB amendment process.

Under this legislative delegation, Metro establishes and maintains the UGB for the 25 cities and the urban portions of three counties in the region.[15] Thus, unlike most other areas of the state, those cities and counties in the Metro region do not establish their own UGBs; rather, the regional government, which has its own procedures and obligations in addition to those applicable to other local governments, undertakes that task.

The task of establishing, and changing, the UGB is both controversial and complicated. Because plans are dispositive as to how land may be used in Oregon, it makes a great difference to the use, and thus the value, of land. Some farmers desire to continue agricultural operations on good soils on flat lands near the boundary subject to preferential tax rates, while some businesses and industries, as well as cities, view the development potential of that same land in a different way. Conflicts over future urban growth are inevitable. The complicated aspect of the establishment and change of UGBs lie in the multiple factors and criteria involved.

The factors involved in the establishment or change of a UGB are twofold – one set of factors deals with the need for urban land, while the other set deals with the location of the boundary, given that need. Currently, the need factors require showings of:

> (1) Demonstrated need to accommodate long range urban population, consistent with a 20-year population forecast coordinated with affected local governments; and
>
> (2) Demonstrated need for housing, employment opportunities, livability or uses such as public facilities, streets and roads, schools, parks or open space, or any combination of the need categories in this subsection (2).[16]

Significantly however, the need factors must also promote the efficient use of land:

> Prior to expanding an urban growth boundary, local governments shall demonstrate that needs cannot reasonably be accommodated on land already inside the urban growth boundary.

Assuming that the need for the UGB change can be shown, there are additional "locational" factors that apply, namely:

> (1) Efficient accommodation of identified land needs;
>
> (2) Orderly and economic provision of public facilities and services;
>
> (3) Comparative environmental, energy, economic and social consequences; and
>
> (4) Compatibility of the proposed urban uses with nearby agricultural and forest activities occurring on farm and forest land outside the UGB.[17]

In addition to these more flexible factors contained in Goal 14, there are also statutory criteria that apply to the location of a UGB under OR. REV. STAT. sec. 197.298(1), which provides in relevant part:

> In addition to any requirements established by rule addressing urbanization, land may not be included within an urban growth boundary except under the following priorities:
>
> (a) First priority is land that is designated urban reserve land under ORS 195.145, rule or metropolitan service district action plan.
>
> (b) If land under paragraph (a) of this subsection is inadequate to accommodate the amount of land needed, second priority is land adjacent to an urban growth boundary that is identified in an acknowledged comprehensive plan as an exception area or nonresource land. Second priority may include resource land that is completely surrounded by exception areas unless such resource land is high-value farmland as described in ORS 215.710.
>
> (c) If land under paragraphs (a) and (b) of this subsection is inadequate to accommodate the amount of land needed, third priority is land designated as marginal land pursuant to ORS 197.247 (1991 Edition).
>
> (d) If land under paragraphs (a) to (c) of this subsection is inadequate to accommodate the amount of land needed, fourth priority is land designated in an acknowledged comprehensive plan for agriculture or forestry, or both.

These statutory priorities require some explanation. The first priority is given to "urban reserve land," which is land the city or region desires to be first in line for an expanded UGB and has been vetted through the urban reserve process, described below. The second priority relates to lands which are usually committed to urban development, or which have urban uses on them[18] or are lands that have soils with less agricultural or forestry resource value.[19] The third priority also focuses upon soils of lesser resource value within an overall agricultural land use designation.[20] The final category relates to lands that have resource value, but (with some exceptions) are to be included in the UGB if and only if lands of higher priority for inclusion are not available.[21]

Both the Goal 14 factors and statutory priorities for establishment and change of UGBs require a local government to bear the burden of proof to show the need for any additional urban land, and that the location of additional urban lands is done in such a manner so as to promote urban efficiency and avoid unnecessary impacts on resource lands. While flat lands with good soils for farm and forest production may be included within the UGB, the factors and criteria discussed above tend to discourage their consideration. The always-controversial inclusion of those lands in the Portland region now also utilizes an urban reserve process enacted by the 2007 Oregon legislature[22], discussed in more detail below.

## B. Portland Regional Planning Obligations and Urban and Rural Reserves

Metro has certain obligations that directly relate to its UGB management duties, as it is obligated to undertake a "legislative review" of its current UGB at least every six years to demonstrate that its regional plan "provides sufficient buildable lands" within the UGB "to accommodate estimated housing needs for the next 20 years."[23] The legislature provides extensive direction over the nature and scope of this review[24] and sets out the consequences of a determination that there is insufficient capacity to meet housing needs for that 20-year period.[25] One of the alternatives to meet a lack of capacity is to expand the

UGB.[26] Metro is also under a specific obligation to accommodate one-half of a buildable lands shortfall within a year of completing its analysis and must either amend its UGB within one year or increase densities within the existing UGB not later than two years after such completion.[27] Finally, Metro is subject to a reporting obligation to LCDC regarding performance measures including housing, conversion of vacant to improved land, and job creation.[28] If Metro determines it does not have a sufficient buildable land supply or housing densities to meet is 20-year housing needs, it is then obligated to adopt and implement a "corrective plan" to assure those ends are met.[29]

Metro is thus under a rigorous regime of reporting and responding to housing needs, and the two-year turnaround on housing capacity analysis results in the amendment of the regional UGB being a continuing point of controversy within the region.

The priority of urban reserve lands as the first resort for meeting residential land needs results in increased attention to the inventory of those lands and their sufficiency in responding to urban land shortfalls. Since 2007, the Oregon legislature has required Metro to adopt urban reserves as well as "rural reserves" simultaneously. Lands lawfully classified as urban reserve jump to the head of the queue and avoid other statutory priority considerations for UGB amendments, so that prime agricultural or forest lands within an urban reserve may more easily come within a UGB, once need is established.[30] "Rural reserves" on the other hand place certain resource lands off-limits for inclusion in the Metro UGB for up to 50 years.[31] This political tradeoff was designed to satisfy both development and conservation communities.

Urban reserve lands are defined lands outside an urban growth boundary that will provide for:

(a) Future expansion over a long-term period; and

(b) The cost-effective provision of public facilities and services within the area when the lands are included within the urban growth boundary."[32]

Under the statutory scheme applicable to the Portland region, Metro was required to enter into an intergovernmental agreement with any or all of the three counties in the region that had land use authority over candidate lands for urban reserves,[33] so that both Metro and local approval of specific urban reserves were required.

Designating urban reserves is governed by certain "factors," including whether those lands:

(a) Can be developed at urban densities in a way that makes efficient use of existing and future public infrastructure investments;

(b) Includes sufficient development capacity to support a healthy urban economy;

(c) Can be served by public schools and other urban-level public facilities and services efficiently and cost-effectively by appropriate and financially capable service providers;

(d) Can be designed to be walkable and served by a well-connected system of streets by appropriate service providers;

(e) Can be designed to preserve and enhance natural ecological systems; and

(f) Includes sufficient land suitable for a range of housing types.[34]

The factors are unweighted and appear to give wide discretion to Metro and the three urban counties to designate urban reserves so that certain lands may be included within the regional UGB relatively easily, so long as the needs for inclusion were established and the individual county agreed. Given the flexibility of the factors, participants in the urban reserve process turned to the persuasion of local governments and Metro to lobby their own causes. It appeared to onlookers that sufficient findings in the application of the urban reserve factors to justify particular outcomes could easily be attained.

## II. Urban Reserves Before 2010

The original UGB for the Portland region was acknowledged in 1986.[35] Since then, Metro has amended that UGB on many occasions.[36] Those amendment actions are outside the scope of this article. It was not until 1999 when under a previous statutory scheme Metro undertook a significant effort to designate 18,579 acres as urban reserves, an effort that was struck down in *D. S. Parklane, Dev., Inc. v. Metro*.[37] While Metro's determination of land need was upheld, Metro's use of decisional criteria outside those contained in applicable state statutes and administrative rules resulted in remand of that decision.[38] That decision led to legislative changes in 2007, resulting in the current reserves scheme, described above.

There were no further cases over reserve decisions until the *Barkers Five* case discussed below. In *D. S. Parklane*, as well as in the UGB amendment cases, the judicial focus was largely over the justification of the decision to amend the UGB in terms of findings. *Barkers Five* would be no different.

## III. The *Barkers Five* Urban Reserve Decision

Using the 2007 revisions to the reserves enabling legislation, Metro, along with Clackamas, Washington, and Multnomah Counties concurrently adopted urban and rural reserves in 2010-11, designating respectively lands available for future UGB expansion and lands to be retained as farm and forest land at least until 2060.[39] The result was designation of 28,256 acres of urban reserve lands and 266,628 acres of rural reserves.[40] Under the 2007 legislation establishing the Metro reserves process, the concurrent decisions of these four governmental agencies were submitted to LCDC for acknowledgment.[41] LCDC duly acknowledged the urban reserves jointly submitted in August 2012 and various participants sought review in the Oregon Court of Appeals[42] in *Barkers Five, LLC v. LCDC*.[43]

In an opinion that spanned more than 100 pages and took more than a year to decide, the Court of Appeals remanded LCDC's acknowledgment order on several grounds. The Court upheld LCDC's overall approach to the acknowledgment, as well as deferring to the Commission's interpretation of the urban reserve statutes and rules.[44] Deferral could be justified on both separation of powers and practical political considerations.[45]

However, the Court remanded the acknowledgment, finding some lands in each of the three counties incorrectly justified:

- A 62 acre area designated as "rural reserve" by Multnomah County.[46]
- 
- A 7,300 acre area designated "urban reserve" in Clackamas County to which a challenge was made to findings that transportation facilities were adequate.[47]
- 
- A 171,000 acre area designated "urban reserve" by Washington County by using additional factors not provided by law.[48]

The impact of the court's decision was immediate and electrifying. The prospect was that the reserves decision would take many more years and be made by elected officials with different views and priorities than those officials who passed on the original designations. Landowners and local governments were concerned over not being able to plan sufficiently for the future and Metro worried over the credibility of its planning process. Enter the Oregon Legislature.

## IV. Planning by Fiat

The decision in *Barkers Five* was handed down in January 2014, while the Oregon Legislature was in session. To alleviate the concerns of multiple parties to the litigation, the Legislature adopted a "Grand Bargain," that resolved only the Washington County disputes, leaving the issues in the remaining counties (along with those of the parties who articulated these and other concerns) to an LCDC remand to Metro and the two other counties for resolution.[49]

The Washington County urban reserves were adjusted so that much of the land that had been designated urban reserve and contested went instead to a rural reserve and, at the same time, the urban growth boundary was enlarged to take in other urban reserve designated lands.[50]

This agreement may have settled the Portland metro urban growth disputes but it emboldened other local governments to seek legislative intervention. The legislative session following the one that adopted the "Grand Bargain" for the Portland region was asked to act on a bill to validate the Woodburn UGB[51] that had been remanded twice from the courts.[52] Other 2015 bills sought to include a portion of Clackamas County as an acknowledged urban reserve,[53] another corrected the 2014 legislative designations,[54] while a third demanded a report on the status of the Bend UGB, possibly with a view of intimidating LCDC.[55]

The point is that having the legislature plan by fiat instead of providing a deliberative, though sometimes wrong, planning process is intoxicating to legislators and interest groups wishing to forgo the pleasure of lengthy hearings and appeals. The precedent that such "quick-fix" efforts generate threatens to undermine the planning process instead of addressing the planning issues in a thoughtful manner.

## V. Lessons Learned from the Portland Metro Urban Reserves Process

In addition to the dangers of quick-fix solutions, other lessons may be gleaned from the experience of the recent controversy over the nature and extent of the Portland regional UGB.

- There is a downside to centralization of planning administration. A sufficiently motivated interest group need only to bring influence to bear on that authority to achieve an objective, thus avoiding the need to convince numerous regional or local planning officers and agencies.

In any case, it is easier to do "one stop shopping" by lobbying through a centralized process.

- Similarly, it is easier to influence the regional planning process if the bigger or more motivated players in that process are won over, or worn down, sometimes to the detriment of the smaller players and the process itself. For example, there was some concern by Clackamas County that the region deferred too much to Washington County and that county's focus on expanding the "silicon forest," which had promised (and delivered) a significant boost to the region's employment gains over the previous 20 years. Whether wisely or not, the Oregon statutes relating to urban reserves require an agreement among Metro and each of the three counties in which Metro has urban planning authority.[56] The need for an agreement gives each of those counties an opportunity to exert significant influence over the process.

- In addition to the intoxication of power, the opportunities for grandstanding and the appearance of the legislature "riding to the rescue" to save certain areas, because of their size or economic contributions, also has a detrimental effect on planning by truncating the process and giving non-planning factors a larger influence.

- The necessarily complex decision-making involved in considering multiple factors creates a priestly class of planners, lawyers, and administrators to deal with decisions that appear to be made in a "black box," thus reducing the legitimacy of the regional planning process.

- A further consequence of this complex decision-making is the need for detailed findings, which runs the risk of failing at one or more points or failing to evaluate the multiple factors involved in a complex decision and raising the value of the priestly class over planning issues. While it is true that the Oregon legislature has striven mightily to reduce complexity, the presence of multiple and often competing criteria make this job complex.

- Just how much deference should be given to the regional authority is also a troubling question. The question of how much land is needed can be dealt with by the use of a consistent and established methodology. However, much of the recent litigation over UGB changes has to do with where to expand the UGB, rather than by how much. The urban reserves legislation implicitly recognizes the political nature of UGB changes by its use of "factors," as well as criteria in that process. However, the Oregon courts also note that those factors must be weighed and balanced and the findings must set forth the reasons for the location of the boundary, especially when there are competing sites. It is arguable that the use of factors has made the process more, rather than less, difficult by requiring articulation of the reasons why one site was chosen over another.

Oregon plans for urban growth. Other regions may find it necessary to devise a similar process to accommodate urban growth, a process that must have political legitimacy and provide for the consideration of the needs of citizens at all levels of government in the region. It is also likely that many of the same difficulties seen in the Portland Regional Urban Reserves process will be experienced in other regions and may be helpful in the construction of a regional planning process elsewhere.

In addition, there are other federal programs that have advanced regionalism as a planning tool:

- The US Department of HUD has made recent efforts to focus housing planning at the regional level (See HUD Sustainable Communities Regional Planning Grant web page: http://portal.hud.gov/hudportal/HUD?src=/program_offices/economic_resilience/sustainable_communities_regional_planning_grants).

However, Congressional opposition has left those programs without new funding since FY 2011.

- HUD has also encouraged regional fair housing planning from grant recipients in their Affirmatively Furthering Fair Housing planning process; that effort includes a website tracking the implementation of related administrative rules and assessment tools: http://www.huduser.org/portal/affht_pt.html

- HUD has also pioneered with the U.S. Department of Transportation to develop a combination housing and transportation cost estimator [Location Affordability Portal] that provides both highly local and regional housing and transportation cost estimates. http://www.locationaffordability.info/

[26] OR. REV. STAT. § 197.296(6)(a) (2003). The other alternatives are increasing density within the existing UGB or a combination of a UGB amendment and increasing density. OR. REV. STAT. § 197.296(6)(a)–(c) (2003). Despite Metro's legal powers to increase density among its constituent jurisdictions, there are political limitations on that power.
[27] OR. REV. STAT. § 197.299(2) (2014).
[28] OR. REV. STAT. § 197.301 (1997).
[29] OR. REV. STAT. § 197.302 (2001).
[30] The current version of the urban and rural reserves system was established in 2007 through 2007 Or. Laws ch. 723 and implementing administrative rules adopted by LCDC in 2008. OR. ADMIN. R. 660, Div. 27 (2008). These efforts responded to earlier, unsuccessful attempts at implementing an urban reserves system struck down in *D. S. Parklane, Dev., Inc. v. Metro*, described below. The current system was designed to allow a more simplified process for the designation of reserves.
[31] OR. REV. STAT. 195.143 (2007). These reserves are designed for the long-term protection of valued farmland and Metro is required to consider, among other factors, whether the land:

> (a) Is situated in an area that is otherwise potentially subject to urbanization during the period described in subsection (2)(b) of this section [i.e., 30-50 years], as indicated by proximity to the urban growth boundary and to properties with fair market values that significantly exceed agricultural values;
>
> (b) Is capable of sustaining long-term agricultural operations;
>
> (c) Has suitable soils and available water where needed to sustain long-term agricultural operations; and
>
> (d) Is suitable to sustain long-term agricultural operations, taking into account:
>
> (A) The existence of a large block of agricultural or other resource land with a concentration or cluster of farms;
>
> (B) The adjacent land use pattern, including its location in relation to adjacent nonfarm uses and the existence of buffers between agricultural operations and nonfarm uses;

(C) The agricultural land use pattern, including parcelization, tenure and ownership patterns; and

(D) The sufficiency of agricultural infrastructure in the area.

Under OR. REV. STAT. § 195.141(4), LCDC was instructed to adopt administrative rules for rural reserve designation, upon consultation with the Oregon Department of Agriculture. There is no further discussion here of the application of the rural reserves, which would have excluded natural resource lands from consideration of inclusion in the regional UGB.

# PLANNING LAW AND SUSTAINABILITY IN AUSTRALIA: ACHIEVEMENTS AND CHALLENGES

Peter Williams[1]and Angelique Williams[2]

[1]Faculty of the Built Environment, University of New South Wales, email: p.williams@unsw.edu.au

Keywords: sustainability, ecologically sustainable development, legislation

## Abstract

*In 1992 the Australian Government published its National Strategy for Ecologically Sustainable Development, a policy document representing Australia's response to the World Commission on Environment and Development 1987 report Our Common Future (the Brundtland Report). Through the auspices of Australia's federal system of government, it was envisaged that the sustainability principles in this national policy document would progressively be implemented, through both policy and law, at the national, state and local levels of government. Beginning with a description of the Australian concept of 'ecologically sustainable development' (ESD), this paper first examines the implementation of ESD through both policy and legislation at the Commonwealth level. The State of New South Wales (NSW) is then selected for more detailed assessment, with, examples of key State government legislation and court decisions considered. Equal emphasis is placed on both the achievements in ESD policy development and implementation through legislation, statutory planning procedures and litigation, as well as the challenges that have confronted the pursuit of ESD in NSW. Noteworthy amongst these challenges has been a failed recent attempt by the NSW Government to introduce new planning legislation which sought to replace ESD with the arguably weaker concept of 'sustainable development' as one of its objectives. Apparent from this episode is strong community and institutional support for robust sustainability provisions within the State's statutory planning system.*

## 1. Introduction

In 1992 the Australian Government published its *National Strategy for Ecologically Sustainable Development* (Commonwealth of Australia, 1992), a policy document representing Australia's response to the Brundtland Report, *Our Common Future* (United Nations World Commission on Environment and Development, 1987). Arguably Australia has pursued a fundamentally different model for the interpretation and implementation of sustainable development which involved a modification of that used in the Brundtland Report. The divergence stems from the adoption of *ecologically* sustainable development, and the changes in conceptual focus which consequently emerged from this model.

In accordance with Australia's federal system of government, it was envisaged that the concept of 'ecologically sustainable development' (ESD), would progressively be implemented, through both policy and law, at the national, state and local levels of government. This paper first examines the implementation of the 'principles and programs' of ESD through both policy and legislation at the national (Commonwealth) level. Second it traces the adoption of ESD at state level, using the State of New South Wales (NSW) as a case study. Third, it considers an attempt to retreat from ESD as part of recent statutory planning system reform in NSW, which culminated in the formulation of a Planning Bill in 2013 to replace existing planning legislation.

Replacing the uniquely Australian statutory and policy formulation of ESD, the Planning Bill 2013 adopted the broader concept of sustainable development. With the entrenched institutionalisation of ESD and its active implementation in NSW forming a contextual backdrop, this paper examines the potential implications of the Planning Bill's proposed conceptual change from ESD to sustainable

development. The paper thus examines how ESD has been implemented and interpreted in NSW, and what changes may occur under a new Planning Act.

## 2. Conceptual framework, hypothesis and methodology

From a conceptual perspective, this paper examines the statutory expression of sustainable development in the NSW Planning Bill, and argues that it represents a significant departure from the 'traditional' the Australian ESD framework for environmental policy. Broadly, this change of focus can be attributed to a general neoliberal reform process confronting planning systems (including NSW). In particular, it is contended that the proposed planning legislation alters – indeed removes – ESD to ensure that any express reference to an integrated approach for the purpose of achieving sustainable development is deleted. As such, this new conceptual framework ignores the necessary integration of economic, environmental and social considerations in decision-making so as to facilitate development that is sustainable.

Pertinently, considerable criticism was directed in stakeholder submissions on the planning reforms toward the significant change in emphasis or approach by the NSW government in its adoption of sustainable development. Specifically, the problem statement examined here is the argument that, as a consequence of this envisaged change, the depth of environmental analysis of the impact of planning proposals and projects in NSW will be diminished and economic considerations enhanced, under the proposed new planning legislation. To this end, the methodology adopted here is to: first examine the Australian concept of ESD; second consider its application and interpretation in NSW through legislation and case law; and then to analyse the proposed change of approach to sustainable development through a consideration of relevant provisions of the Planning Bill 2013 and submissions made by interest groups as part of the planning reform consultation process.

In considering ESD at both national and NSW levels, particular emphasis is placed on the precautionary principle, as arguably this has been perceived as the most problematic aspect of ESD. Concern over the operation of the precautionary principle appears to have been a major 'cause' of the move to replace ESD with sustainable development.

## 3. The Australian concept of sustainability – ecologically sustainable development

Perhaps somewhat harshly, it has been argued that sustainable development contains little merit as a framework for contemporary environmental policy-making, and should be replaced by a more 'workable paradigm' (Owens and Cowell, 2011, p.43). In the Australian context, the word 'ecologically' has been added as a prefix to 'sustainable development' to form the title to the current ESD process. The interpretation of ESD appears broadly synonymous with the Brundtland concept, but emphasises our particular concern with the ecology and the protection of the ecology including the protection of biodiversity in Australia. To elaborate, the Australian Government states that the prefix 'ecologically' was added to the normal international usage of sustainable development 'in recognition of the very great importance of protecting ecosystems in the context of a continent in which many unique ecosystems were under threat' (Commonwealth of Australia, 2002, p.5).

Significantly therefore, at the domestic level of Australian environmental policy-making, the interpretation of sustainable development has assumed the unique form of ecologically sustainable development. Both government and academics have recognised that the insertion of the adjective 'ecologically' into the formula of sustainable development introduced a qualifying term that imports a peculiar emphasis on the integration of the environment into development discourse (see for example, Commonwealth of Australia, 2002; Harding, 2006; Bates, 2010; and Farrier and Stein 2011). Farrier and Stein for example state that ESD gives 'the concept of sustainable development greater precision and … make it a more useful tool in legal contexts (2011, p. 8). Further, they content that ESD requires the integration of economic, environmental, social and equitable considerations, over both the short and long term (Farrier and Stein, 2011).

The sustainability process in Australia began in June 1990 with the release of a Commonwealth government Discussion Paper on ESD (Commonwealth of Australia, 1990). Here the term ESD was broadly interpreted as:

> Ecologically sustainable development means using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained, and the total quality of life, now and in the future, can be increased.
>
> (Commonwealth of Australia, 1990, p.3)

In 1992, the Commonwealth government finalised a *National Strategy for Ecologically Sustainable Development* (NSESD) (Commonwealth of Australia, 1992), which was endorsed by the Council of Australian Governments (that is, the Commonwealth, state and territory governments) on 7 December of that year. While the NSESD stated that there was no universally accepted definition of ESD, the strategy had as its goal:

> Development that improves the quality of life both now and in the future, in a way that maintains the ecological processes on which life depends.
>
> (Department of the Parliamentary Library, 1994, pp.3-4).

Harding (2006) convincingly argues the status of ESD as a uniquely Australian concept which differs in emphasis from the concept of sustainable development at the international policy level, due to the added importance placed by the former on ecological integrity. Harding writes that ESD,

> … is a peculiarly Australian term and arose in the early stages of a government initiated discussion of sustainable development in Australia in 1990. It seems that the environmental groups, concerned that the sustainable development discussion process would be hijacked by business and industry and interpreted as just *economically* sustainable development, successfully fought for the inclusion of ecologically in the 'official' terminology. This is the term that has been used since then in Australia including in legislation and policy.
>
> (Harding, 2002, p.233).

Harding's analysis draws a clear distinction between the perception of economic prioritisation that could be engendered by the concept of sustainable development (i.e. *sustained* development), and the relevance of the deliberate insertion of the adjective 'ecologically' in the Australian formula of sustainable development.

The significance of ESD in Australia is demonstrated by Bates, who states:

> ESD has become the most important legislated criteria for environmental management, not just as an object of legislation, but as a mandated consideration for environmental decision-making. Statutory requirements to 'have regard to' ESD when making decisions appear not just in environmental legislation, but perhaps more importantly in legislation conferring discretionary powers on a wide range of government agencies to take or approve activities that might impact adversely on the environment and natural resources.
>
> (Bates, 2011, p.208).

Although legal definitions of the concept of ESD differ between Commonwealth and state legislation, most are fundamentally based on the definition of ESD agreed to by Commonwealth, state and local governments and expressed in the NSESD and the *Inter-Governmental Agreement on the Environment,* signed by Commonwealth, state and territory governments and the Australian Local Government Association in May1992 (Bates, 2011). In summary, the term ESD embodied in these documents imports the principles of: a) the precautionary principle; b) inter-generational equity; c) conservation of biological diversity and ecological integrity; and d) improved valuation and pricing of environmental resources.

A significant element of the uniquely Australian emphasis on the ecological aspect of sustainable development is the parallel importance of the precautionary principle as a core principle of ESD. Recognition of scientific uncertainty in relation to the environmental impacts of development has represented an important shift in approaches towards environmental management. In particular, this approach holds that a more anticipatory attitude in relation to the environmental harm created by human activities must operate as a necessary pre-requisite for progress towards sustainability.

Controversy and debate has existed in relation to two different perspectives on the application of the precautionary principle. On the one hand an absolutist interpretation and operationalisation of the precautionary principle has sought a 'zero-risk' outcome, while on the other perceptions of the variable and open-ended articulations of the principle have resulted in a lack of consistency in its application (Harding and Fisher, 1999).

In the context of the debate surrounding the efficacy of the precautionary principle, several national and state policy and legislative documents make specific reference to the relevance of a 'risk-weighted' approach in applying the principle. The insertion of this operative provision in the definition of ESD in s 6(2) of the *Protection of the Environment Administration Act 1991* (NSW), for example, came as a consequence of judicial interpretation of the proper means of applying the precautionary principle. Specifically, in *Greenpeace Australia Ltd v Redbank Power Company Ltd and Singleton Council* (1994) 86 LGERA 146, Chief Justice Pearlman of the Land and Environment Court stated (at p. 154) that 'the application of the precautionary principle dictates that a cautious approach should be adopted in evaluating the various relevant factors in determining whether or not to grant consent; it does not require that the greenhouse issue should outweigh all other issues.' The precautionary approach thus requires the gravity of potential environmental harm to be combined with an assessment of the balance provided by other salient social and economic factors when making a decision in relation to a particular proposal or activity. Through application of this approach, fears of an absolutist implementation of the precautionary principle, were somewhat allayed.

Indeed, in assessing the suggestion that the precautionary principle operates as an absolutist dictum, Nollkaemper concludes that the 'status of the precautionary principle as a principle allows for a balanced approach to risks. It serves the interest of risk-aversion; yet it means that the precautionary principle is not a trump-card that a priori overrides other considerations' (Nollkaemper, 1996, p.73). Harding has likewise identified that from the Australian perspective, 'opposition to the principle will grow unless its application … occurs within the context of application of the full suite of ESD principles' (Harding, 2006, p. 18). However, when applied to the structures of sustainable development in Australia and NSW in particular, the broad policy expression of the precautionary principle contains an in-built mechanism against the absolutist status of precaution through explicitly requiring 'an assessment of the risk-weighted consequences of various options' (Harding, 2006, p.6). To this extent, Harding has correctly identified that absolutist interpretations represent 'an extreme interpretation of the precautionary principle' (2006, p.6) and that a 'risk-weighted' interpretation has been statutorily adopted in Australia.

Thus it is suggested that Australia has pursued a fundamentally different model for the interpretation of sustainable development from that which is utilised in the Brundtland Report. This divergence stems from the adoption of the concept of ESD, and the changes in conceptual focus which consequently emerge from this model. In particular, attention is drawn to the relevance of the precautionary principle as a leading principle of the Australian model of ESD, and its proper application through a risk-weighted approach in environmental decision-making.

## 4. ESD in New South Wales

Two Australian states that adopted ESD as part of their planning laws have recently attempted to retreat from this position. The states of Queensland and New South Wales have, as part of a neoliberal statutory planning reform agenda, sought to displace ESD as an object and purpose of their planning acts, by the broader – and arguably weaker – concept of 'sustainable development'.

Queensland's current planning law, the *Sustainable Planning Act 2009* (Qld), incorporates ESD as the specific purpose of the Act by seeking to achieve 'ecological sustainability', including the application of the precautionary principle and provision for intergenerational equity. However, draft Planning Bills currently being considered in Queensland propose to introduce a new Panning and Development Act which removes entirely the principles of ESD (EDO Qld, 2014), to be replaced with the object of facilitating 'prosperity, including through ecologically sustainable development that balances economic growth, environmental protection and community wellbeing'. Although there was a change in State government in Queensland in January 2015, the new government remains committed to continuing this planning reform process in that state (Department of Infrastructure, Local Government and Planning, 2015).

Nonetheless, NSW has been selected for closer scrutiny as it has incorporated ESD in a range of environmental laws, including the main land use planning law, the *Environmental Planning and Assessment Act 1979*, as well as having, in comparison to other planning jurisdictions in Australia, a body of established case law in this field, due in part to the presence of a specialist tribunal, the NSW Land and Environment Court. Also, as Bates (2010) point out, NSW has quite consciously adhered to the NSESD definition of ESD.

*4.1 ESD in legislation*

The first statutory manifestation of ESD policy in NSW occurred in 1991 when ESD, and its attendant principles, were incorporated into s 6(2) of the *Protection of the Environment Administration Act 1991* ('POEA Act'). The 'principles and programs' of ESD contained in s 6(2) of the POEA Act are:

(a) The precautionary principle – namely, that if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In the application of the precautionary principle, public and private decisions should be guided by:
    (i) Careful evaluation to avoid, wherever practicable, serious or irreversible damage to the environment, and
    (ii) An assessment of the risk-weighted consequences of various options,

(b) Inter-generational equity – namely, that the present generation should ensure that the health, diversity and productivity of the environment are maintained or enhanced for the benefit of future generations,

(c) Conservation of biological diversity and ecological integrity – namely, that conservation of biological diversity and ecological integrity should be a fundamental consideration,

(d) Improved valuation, pricing and incentive mechanisms – namely, that environmental factors should be included in the valuation of assets and services, such as:
    (i) polluter pays – that is, those who generate pollution and waste should bear the cost of containment, avoidance or abatement,
    (ii) the users of goods and services should pay prices based on the full life cycle of costs of providing goods and services, including the use of natural resources and assets and the ultimate disposal of any waste,
    (iii) environmental goals, having been established, should be pursued in the most cost effective way, by establishing incentive structures, including market mechanisms, that enable those best placed to maximise benefits or minimise costs to develop their own solutions and responses to environmental problems.

Environmental protection has figured as a key object of the *Environmental Planning and Assessment Act 1979* (EP&A Act) having an expression in three of the ten objects of the Act (s 5(a)(i), (vi) and (vii)). ESD inserted as an object of the EP&A Act in 1997. The definition of ESD adopted by the Act

is the same as that found in s 6 of the POEA Act, which in turn accords with national policy framework of ESD. The principles and programs of ESD found in the NSESD have been incorporated into the objects of several other pieces of NSW legislation, including the *Mining Act1992*, *Coastal Protection Act 1979*, *Local Government Act 1993*, *Water Management Act 2000* and *Native Vegetation Act 2003*, and is adopted as the standard terminology used in over 60 NSW statutes. Notably, the *Environmental Planning and Assessment Regulation 2000*, requires that these principles be incorporated into environmental impact assessment under the EP&A Act.

As a signatory to the *Inter-Governmental Agreement on the Environment* in May 1992, the Australian Local Government Association committed itself to the promotion of the agenda of ESD. Further, s 8 of the *Local Government Act 1993* (NSW) explicitly declares ESD as a constituent element of the Charter for Local Government, which includes the following '… to properly manage, develop, protect, restore, enhance and conserve the environment of the area for which it is responsible, in a manner that is consistent with and promotes the principles of ecologically sustainable development.'

*4.2 ESD in case law*

The statutory requirement of ESD has further been augmented by a significant body of case law developed in the NSW Land and Environment Court, which has assisted practitioners in the application of ESD to planning and development matters in NSW. In its jurisprudence on questions of law concerning the application of ESD principles to the development assessment process, the Court has recognised that, whilst environmental degradation may be outweighed by the overall benefits of a proposed development project, it is nonetheless crucial that decision-makers take care in considering the existence of appropriate and adequate measures to control and mitigate likely environmental harm (*Leatch v National Parks and Wildlife Service and Shoalhaven City Council* (1993) 81 LGRA 270 at 282).

With regards to the interpretation of ESD and the nature of its proper application in the context of the development assessment process provided for in the EP&A Act (specifically Part 4 – 'Development Assessment'), the Court has adopted an approach safeguarding a strong form of sustainability. Despite the omission of 'ESD' from the mandatory requirements that a consent authority must take into consideration in determining a development application under s 79C of the EP&A Act, the Court has consistently read the requirement of ESD into the 'public interest' factor of that section.[1] As a consequence of this interpretation of s 79C, the Court has acknowledged the NSW Parliament's intention of introducing ESD as an additional object of the Act, and has subsequently explicitly elevated ESD to the status of a legal requirement in the development assessment process.

In the context of interpreting the principle of ESD which endorses conservation of biological diversity and ecological integrity, several judgments of the Land and Environment Court have recognised the check that ESD places on the ostensible 'certainty' of zoning. In particular, in *BGP Properties Pty Ltd v Lake Macquarie City Council* [2004] NSWLEC 399, McClellan CJ took cognisance of the legal relevance of ESD in the EP&A Act to find that a decision-maker should refuse development consent where the proposed project will cause environmental harm, irrespective of the land in question being zoned for development purposes. Thus the Court held that ESD considerations may override the zoning provisions of planning instruments: that is, ESD considerations may render a site undevelopable, displacing the presumption or expectation of gaining approval for a 'suitably' designed proposal, despite it being zoned for development. Implicit also in the judgment was the proposition that development consent, and not zoning, operates as the source of the conferral of the right to develop. In *BGP Properties* ESD was recognised as a relevant legal condition that burdens other,

[1] See for example, *Carstens v Pittwater Council* [1999] NSWLEC 249 at [74]; *BGP Properties Ltd v Lake Macquarie Council* [2004] NSWLEC 399 at [113]; *Telstra Corporation Ltd v Hornsby Shire Council* [2006] NSWLEC 133 at [123]-[124]; *Minister for Planning v Walker* [2008] NSWCA 224 at [43]; *Port Stephens Pearls Pty Ltd v Minister for Infrastructure and Planning* [2005] NSWLEC 426; *Gales Holdings Pty Ltd v Tweed Shire Council* [2006] NSWLEC 85.

legally-created zoning criterion, which would have otherwise facilitated unsustainable and environmentally harmful development. Further, the authoritative nature of this statement as a settled point of law is evident in the status of *BGP Properties* as a precedent that has been applied and followed in numerous succeeding NSW cases.[2]

The case of *Telstra Corporation Ltd v Hornsby Shire Council* [2006] NSWLEC 133, a merits appeal against the respondent local council's decision to refuse an application made by Telstra for the installation of mobile phone towers, involved a comprehensive engagement with ESD principles by Chief Justice Preston. The precautionary principle provided the context of the major issue in the litigation: namely, whether there was a need to apply the precautionary principle in the development assessment process, so as to address the potential public health impacts caused by radiofrequency electromagnetic energy (RF EME) emissions from the proposed facility. A court-appointed expert reiterated the consensus scientific view that the risks caused by RF EME from the proposed towers 'could not conceivably cause any adverse biological or health effect' (at 78-89). The Court accepted the expert's opinion that 'a high standard of environmental and health protection would be maintained if this station is allowed to be constructed as specified in the proposal from Telstra' (at 89). Furthermore, it was estimated that the emissions from the proposed towers would be less than one fortieth of those permitted under the relevant Australian Standard.

In interpreting the precautionary principle, Preston CJ identified its operation as but one component of the package of principles of ESD. Thus, rather than viewing the precautionary principle in isolation, it was reaffirmed that precautionary measures must not only be appropriate having regard to the precautionary principle itself, but also in respect to the other principles of ESD. On the facts of the case before him, Preston CJ held that there was no basis to invoke the precautionary principle, given that the proposal for the mobile phone towers already incorporated measures to ensure the compliance of the level of RF EME emissions with the relevant (precautionary) Australian Standard. As a consequence, 'any harm to the health and safety of people or the environment caused by exposure to such extremely low levels was negligible' (at 184). Importantly, the judgment clarified (at 186) that:

> This conclusion did not mean that there had been an avoidance of a precautionary approach. On the contrary, the conclusion was a direct consequence of the fact that a precautionary approach had already been adopted in the standard setting process, the terms of the relevant Australian standard, the design and location of the proposed base station, the equipment to be provided, the operation of the equipment, the application of the Australian Standard to the RF EME generated from the base station, and the likelihood of actual RF EME being significantly less than predicted.

The authority of *Telstra* in relation to the point of law that deals with the interpretation and application of the precautionary principle has remained undisturbed. Indeed, the absence of a judicial review case in the years since *Telstra* has been supported by the parallel development whereby *Telstra* has been periodically applied in merits review cases heard by commissioners of the Land and Environment Court. This consistent interpretive approach by the Court has made a clear contribution to understanding the weight to be given to the precautionary principle in such areas of practice as development assessment. Also revealed is the preference of the Court for adopting a standard of sustainability that is predicated upon appropriate invocation of precaution.

---

[2]See for example, *Chappelow v Sutherland Shire Council* [2005] NSWLEC 56; *BT Goldsmith Planning Services Pty Ltd v Blacktown City Council* [2005] NSWLEC 210; *Joye v Valuer-General* [2006] NSWLEC 341; *Wei v Holroyd City Council* [2007] NSWLEC 163; *Martin & Sporke Pty Ltd v Wingecarribee Shire Council* [2007] NSWLEC 598; *Telstra Corp Ltd v Blacktown City Council* [2008] NSWLEC 1261; *Addenbrooke Pty Ltd v Woollahra Municipal Council* [2008] NSWLEC 190; *Wygiren Pty Ltd v Kiama Municipal Council* [2008] NSWLEC 1233; *Motorplex v Port Stephens Council (No 3)* [2008] NSWLEC 1280; *Drazdon Pty Ltd v Ku-ring-gai Council* [2009] NSWLEC 1147; *Qur'anic Society 'Dar Tahfez El-Quran' Inc v Camden Council* [2009] NSWLEC 1171*; Homemaker Hub Pty Ltd v Strathfield Council* [2009] NSWLEC 1265; *Southern Cross Community Housing Ltd v Shoalhaven City Council* [2010] NSWLEC 1306; *Urban Link Pty Ltd v Lane Cove Council* [2011] NSWLEC 1279; *Landmark Group Pty Ltd v Lane Cove Council* [2011] NSWLEC 1303.

The matter of *Walker v Minister for Planning* [2007] NSWLEC 741, concerned a concept plan approval by the respondent under (the now repealed) Part 3A of the EP&A Act, for a proposed residential subdivision and retirement development on a flood constrained coastal plain near Wollongong, south of Sydney. In a lengthy judgment which navigated the policy and legislative history and context of ESD, as well as the body of jurisprudence that has developed around it, Justice Biscoe of the Land and Environment Court found in favour of the applicant, invalidating the approval of the concept plan on the ground of the respondent's failure to take into account principles of ESD as a mandatory relevant consideration. ESD considerations were held to be relevant to the concept plan assessment process as a consequence of the increased flood risk which was identified as a major constraint to development, and the added fact that this impact was enlarged due to the compounding effect of climate change.

A notable feature of the judgment in *Walker* by Biscoe J was his Honour's comprehensive analysis of the international, national and NSW policy frameworks for ESD, as well as a survey of the Court's body of case law concerning ESD, so as to reinforce the relevance of the extensive incorporation of the principles of ESD in both Commonwealth and NSW environmental legislation. Biscoe J maintained that a crucial consequence of the widespread adoption of ESD in law and policy was its intended operation as a requirement with sufficient legal weight to ensure that it was taken seriously by decision-makers when executing environmental management functions such as determining development proposals. The judgment by Biscoe J was subsequently appealed by the NSW Minister for Planning and, in a decision which at face value might appear to undermine the case of 'strong' sustainability, was overturned by the NSW Court of Appeal (*Minister for Planning v Walker* [2008] NSWCA 224). The NSW Court of Appeal held that as a matter of statutory construction of Part 3A of the EP&A Act, it was not mandatory to have regard to one or more of the principles of ESD due to the extremely broad discretion available to the Minister under that part of the Act. The Court of Appeal emphasised however, that it *was* mandatory to have regard to ESD under other parts of the Act. Significantly, the deeply unpopular Part 3A of the EP&A Act was repealed in 2011, leaving ESD as a mandatory relevant consideration in the current project assessment provisions in the EP&A Act.

The more recent judgment of the Land and Environment Court in *Bulga Milbrodale Progress Association Inc v Minister for Planning and Infrastructure and Warkworth Mining Ltd* [2013] NSWLEC 48 has reaffirmed the application of ESD principles in the NSW planning system. Here the Court upheld a third party appeal for merit review of a decision in 2010 by the Minister for Planning to approve an extension of an open cut mine under Part 3A of the EP&A Act. While significant for several reasons (for example it provided an exhaustive review and assessment of the merit issues of the case), the decision was particularly illuminating because reference was made to the relevant principles of ESD throughout the judgment to assist the Court in its merits review task. The judgment can be distinguished from that by the Court of Appeal in *Walker* because, although both related to development approvals under Part 3A of the Act, *Walker* considered whether ESD was a mandatory consideration as a discrete planning issue, whereas in *Bulga* the Land and Environment Court considered a variety of relevant planning impacts through the context of ESD. Significantly, the Land and Environment Court's judgment in *Bulga* was subsequently upheld on appeal by the NSW Court of Appeal (*Warkworth Mining Limited v Bulga Milbrodale Progress Association Inc* [2014] NSWCA 105).

In *Bulga*, Warkworth's project application was refused by the Land and Environment Court due to, *inter alia*, it's likely significant adverse impacts on biological diversity, including on four types of endangered ecological communities listed under the *Threatened Species Conservation Act 1995*. Specifically, the Court held that the project would have unacceptable impacts on biological diversity which, despite proposed biodiversity offsets and other compensatory measures, were not able to be adequately avoided, mitigated or compensated. In the course of considering this case, the Chief Justice's deliberations were infused with acknowledgment of ESD principles. It is sobering to note that, with the abandonment of ESD as proposed by the Planning Bill 2013, it is unlikely that the grounds and reasons relied on in *Bulga* would be available in future litigation in the Court.

## 5. The move to sustainable development in NSW

Broadly, planning systems (including in Australia) have been impacted upon by governments' neo-liberal requirements as to the fast-tracking of the planning process, the privatization of many public industries and services, and the reduction in public spending. The neo-liberal paradigm has been harnessed to explain much of the rationale of planning system reform in recent years (Blowers, 2000; Gleeson and Low, 2000a; 2000b). In NSW planning reform had become a major policy concern and, following its electoral success in March 2011, the incoming State government announced a review of the existing EP&A Act with the intention of replacing it with a new Planning Act.

A period of extensive consultation commenced in July 2011 with the establishment of an independent panel to review the planning system which published two issues papers in December 2011 and May 2012 (NSW Government 2011; 2012a). This was followed by the release of a Green Paper (NSW Government 2012b), and finally a White Paper and Exposure Draft Planning Bill 2013 (NSW Government 2013a). While the report of the independent panel recommended the retention of ESD as an object of a new Planning Act, both the 2013 White Paper *A New Planning System for NSW*, and the subsequent Planning Bill 2013, omitted any reference to ESD. In its place, the term 'sustainable development' was adopted. While the NSW government justified this change on the basis of the adoption of the term utilised in the Brundtland Report, this omission of ESD was crucial as the highly significant principles and programs of ESD found in the EP&A Act would be displaced.

To examine some of the substantive implications of the operationalisation of sustainable development in the Planning Bill, this section considers its legislative definitions and objects. It is submitted that sustainable development contains a clear comprehension which reflects the NSW government's preference for economic growth as the overriding philosophical core of the regulatory planning system created by the Planning Bill. Specifically, this argument maintains that the adoption of sustainable development is not merely a minor issue of semantics, but rather a calculated removal of the integrated approach to decision-making provided through the framework of ESD, which includes the joint consideration of economic, social, equitable and environmental factors.

In analysing the relevance of the proposed change from ESD to sustainable development, it is important to acknowledge the deliberate position taken by the NSW government in the debate concerning the relative weight to be assigned to economic, social and environmental factors in planning decision-making. When read in concert, the nine objectives of the Planning Bill reinforce a strong growth focus. For example, the eighth objective promotes 'efficient and timely development assessment proportionate to the likely impacts of the proposed development.' Some submissions in relation to the Exposure Planning Bill identified a fundamental philosophical shift in the objects of the current and proposed Acts; namely, from one which focused on the outcomes of planning decision-making to another which 'is directed more at the process of plan-making and development assessment' (Local Government NSW, 2013, p.14). As a consequence of this interpretation, the Property Council of Australia has succinctly surmised in its submissions that the Planning Bill would be the 'primary land use and economic growth legislation for NSW' (Property Council of Australia, 2013). One may accordingly observe that the by-product of the process-oriented focus of the Planning Bill was a clear encouragement of expediency in the development assessment process – a focus which significantly alters the outcome-driven emphasis of ESD, and lends support to an interpretation of growth on the basis of sustained development.

Of the nine equally-weighted objects of the Planning Bill, the first-stated object is that of 'economic growth and environmental and social well-being through sustainable development.' The Planning Bill purports that 'sustainable development is achieved by the integration of economic, environmental and social considerations, having regard to present and future needs, in decision-making about planning and development.' The proposed change to the object of ESD, and its replacement with the new object of sustainable development creates an immediate, fundamental conceptual and definitional divergence. Of great significance for the removal of ESD is the nullification of the principles which

attached to its statutory definition. In particular, the definition of sustainable development is silent on three of the principles and programs of ESD – the precautionary principle; conservation of biological diversity and ecological integrity; and improved valuation, pricing, and incentive mechanisms, including the polluter pays principle. Furthermore, the definition only contains an abridged version of the more detailed principle of inter-generational equity. The result of removing such principles of ESD is the potential for reduced depth of environmental analysis undertaken in the development assessment process.

In the face of this omission of ESD, and legislating to replace it with sustainable development involving a choice between economic growth and environment-social values, it would appear that NSW courts may be jurisdictionally impotent to revive an application of ESD in the operative sections of the Planning Bill. In the context of statutory interpretation, the objects of any regulatory system are the clearest litmus test for the intended manner of its operation (Pearce and Geddes, 2011), and the philosophical foundation of an economic imperative in the Planning Bill's objectives accordingly creates a clear directive for the courts in the determination of conflicting values.

A misconception of ESD as a policy that unduly prioritises environmental factors possibly accounts for the NSW government's decision to abandon ESD in favour of sustainable development. Indeed, this decision is particularly significant when one considers that the retention of ESD was an explicit recommendation made by the Independent Planning Review (NSW Government, 2012a). Further, advocates of the retention of ESD would agree with the broader recommendation of the Independent Planning Review that ESD should be included in the planning reforms as the overarching object.

With regards to the argument of policy misconception, the following observation by the Nature Conservation Council of NSW and the Total Environment Centre clarifies the relevant legal application of ESD:

> It is important to recognise that ecologically sustainable development does not seek to raise environmental matters above other matters. Ecologically sustainable development seeks to integrate environmental, economic and social considerations in decision making.
>
> Properly applied, ESD recognises that ecological integrity and environmental sustainability are fundamental to social and economic wellbeing, particularly when considering the needs of both present and future generations. Despite the challenges presented by the concept of ESD, experts have recognised that there is no other credible candidate for an integrative policy framework.
>
> (Nature Conservation Council of NSW, 2013, p.12).

Recognising the consequences of removing ESD principles and the attendant economic, environmental and social factors to be considered in their application, Local Government NSW, in a submission on behalf of NSW local councils, noted the earlier recommendations to retain ESD. In particular, the submission emphasised the concern of councils 'that the removal of these principles may limit their ability to protect important natural assets which underpin future economic and social viability' (Local Government NSW, 2013, p.14).

The Law Society of NSW supported this argument by expressing concern that 'in the absence of a focus on ecologically sustainable development in the objects, this is likely to have the consequence that inter-generational equity, the precautionary principle and other environmental benefits will be outweighed by perceived public benefit in economic and social terms' (Law Society of NSW, 2013, p.9).

## 6. Conclusions

This paper contends that the NSW government's adoption of sustainable development on the apparent basis of reconciling NSW planning laws with international environmental standards involves the

misconception that sustainable development can only operate in practise through the prioritisation of either economic or environmental concerns. As a consequence of this approach, the legal safeguards that exist when an integrated approach to decision-making is adopted through the 'triple bottom line' focus of ESD on economic, social and environmental factors, are removed.

The argument for the retention of ESD as an object of planning laws has been presented through: its consistent application in national policy documents and inter-governmental agreements; its operationalisation through an exhaustive definition in the POEA Act which captures the national policy framework for ESD and which was also incorporated in the EP&A Act; its adoption as the standard terminology used in over 60 NSW statutes, including the *Mining Act*, *Coastal Protection Act*, *Local Government Act*, *Water Management Act*, and *Native Vegetation Act*; and its well-established basis in planning law jurisprudence, with a body of case law concerning its interpretation and application.

The paper claims that sustainable development represents a somewhat different paradigm which reflects the NSW government's preference for facilitating economic growth as the overriding purpose of a reformed planning system. Specifically, the adoption of sustainable development is not merely a minor issue of semantics. Rather, it suggests that the abandoning of ESD is symptomatic of the NSW government's calculated prioritisation of economic growth values in planning decision-making processes. This contention is supported by an examination of the definition and operationalisation of sustainable development in the Planning Bill, and subsequent assessment of the limited extent to which this concept is competent in achieving the integrated approach to decision-making, as provided through the framework of ESD.

In particular, it is suggested that the envisaged concept of sustainable development fails to achieve the integrated approach of ESD, which includes the joint consideration of the three 'bottom lines' economic, social and environmental factors. Alternatively, insofar as the Planning Bill links the future economic growth of NSW with an active development industry, it erroneously represents the decision-making framework of planning law as requiring a 'false choice' between economic growth on the one hand, and social, equity and environmental values on the other. A crucial corollary of this growth focus of the Planning Bill is the simultaneous erosion of the imperative for environmental protection. This has the consequence of signalling the NSW government's readiness to promote a weak form of sustainability through the reduction of environmental safeguards which place a check on individuals' expectations to development.

Analysis in this paper of the consequences of the definitional divergences which arise from the replacement of ESD with the broader concept of sustainable development, suggests the ascendancy of a pro-developer cause at the expense of guarantees for environmental protection in land use planning and management. Through removing the well-established principles of ESD from key operation areas of the proposed planning system – namely, the legislative objectives, but also strategic planning and development assessment – the NSW government has endorsed a statutory planning system that seeks to produce expedited and short term economic gains at the expense of sustainable outcomes which have influenced environmental management in Australia for over 25 years.

# TRACK 06

# Urban Design Quality and its Social Dimension

## Track description

Co-chairs: **Ali Madanipour**, **Marion Roberts**

Urban design strongly reflects the values of contemporary society. On the one hand, the desire for social cohesion demands urban spaces that are accessible, open and democratic. On the other hand, society has been stratified and fragmented along the lines of income, age, gender, ethnicity and culture; and spatial and technological barriers have been raised to consolidate these gaps and differences. What should the role of urban design be? Can it rise to the challenge of creating democratic spaces? Can it help make spaces and places safer and overcome issues such as sexual harassment? How differences between are day and night produced and experienced? In what ways can urban design overcome the fragmentary social pressures such as privatisation, withdrawal from public space, and the emergence of virtual and gated spaces, without becoming an instrument of consumerism?

Keywords: Public space, society of strangers, urban violenc

**Abstract**

*Joel Migdal argues that the concept of public space has been idealized by various socio-political philosophers who claim that public space is a space of meeting points that form the basic condition for the creation of 'the public'. Contrarily, Migdal suggests a perception of public space as a space of conflict between forces of inclusion and exclusion in unequal societies. Following Migdal, this article portrays ethnography of struggle in public space in Musrara, a Jerusalem seam line neighborhood. The research is based within the contexts of the neighborhood's history and the concentration of crime events and urban violence along that seam line. The research conducted analyzed the negotiations between the architects who were invited by the Jerusalem Municipality to plan and design the seam line between East and West Jerusalem and Musrara neighborhood residents regarding public space. Two oppositional views were apparent: the architects' perception that public space is a meeting point and therefore encouraged density as a tool of personal security versus the residents' wish to block the neighborhood's wall gates for the creation of defined urban territory. This study offers an understanding of the real-urbanism of Jerusalem's public space as a battlefield between connectivity and separation, exclusion and inclusion.*

## Introduction:

*'I remember the conversation in which I was asked to come and plan the border seam line. ...we wanted to turn it into a connecting area, connecting both parts of the city– our intention was that the institutions will serve the Arab population in the area. But the institutions were only for the Jewish population, places that do not create meeting and sharing.'*

(Interview with the architect who planned Jerusalem's seam line)

*'You see an Arab near your house. You ask him what he's doing here and he says that he's looking for a job. He is lying. He came here to steal. On Elisha St. they steal women's purses. You can't contain these Arabs – they come to you.'*

(Musrara neighborhood resident)

The above two quotes mark and symbolize in a nutshell the two forces at work in Jerusalem's seam line public space. The first is the professional stand of the architect who wishes to enhance strangers encounter in public space thereby enabling Jerusalem's Arab population's access to institutional services, which, in turn, deepens their involvement and participation and strengthens their perception as citizens. The second stand is that of the residents who experience the presence of Arabs in their neighborhood as a tangible threat and wish to create a distinct border that will enable them to impose their game rules in a given territory. This article claims that Jerusalem's public space is not the space that the architect envisioned nor a district of total separation as wished for by the residents. By use of the theoretical concept of real-urbanism, this study portrays public space as an arena determined by the struggle between these two forces. This concept affords focusing research perception on representational space, as termed by Lefebvre[1] or space in use.

The theoretical basis of this study was inspired by Joel Migdal's claims regarding public space and public sphere presented in his article 'The creation of public space: between separation and merge'.[2] Migdal argues that public space dynamics spring from the tension between being simultaneously an inclusive and exclusive space. This tension is not permanent but rather comes as a result of constant struggle. This claim offers an effective toolbox for the analysis of Jerusalem's seam line public space, where the conflict between trends of inclusion and exclusion are both present in differing forms and intensity.

This study documents the conflict between the architects who wished to plan public space as an inclusive space versus the Jewish seam line neighborhood who wished to exclude Arabs from public space in contexts of crime and personal security. Article Structure; Inspired by Migdal's work, the first section of this article presents a critical stand regarding the theory of public sphere and public space followed by a suggestion of an alternative approach to research and analysis of public space. The second section presents a historical-urban review of Musrara seam line neighborhood with significant emphasis on data related to personal security in the seam line area as a whole and Musrara in particular. The central section of the article portrays the ethnography that explains the residents' persistent wish to fence the neighborhood and focuses on the manners by which this perception affected the dialogue with the architects who were summoned to plan Jerusalem's seam line. The summary discussion offers a synthesis of Migdal's suggestion and the central ethnographical insights of this study leading to a new analysis from a real-urbanism perspective.

## Public space as an arena of tension between forces of exclusion and inclusion

Migdal's basic assumption is that the public space is the place in which public *sphere* manifests itself.[3,4,5,6] Migdal argues that the notion of public sphere has been idealized by socio-political philosophers such as Habermas[7] who suggested this concept in 1962. Public sphere is best imagined as

the suite of institutions and activities that mediate the relations between society and the state.[8] What stands at the core of public sphere is interaction and communication between strangers. Public place is perceived as a place where 'public opinion' originates. Charles Taylor sees face-to-face encounter as highly significant[9] an encounter where people are able to create a 'common opinion of themselves'.

Was there any point in history or in space, that this ideal was actualized? In his Constitutive work, Mitchell[10] argues that the presented perceptions of public sphere and public space are norms and ideologies:

'The ideal of a public sphere is normative, Habermas[11] theorizes, because it is in this sphere that all manner of social formations *should* find access to the structures of power within a society'.[12]

Habermas' main critics argue that his theory of public sphere ignores the importance of class differences[13] and his study of public space was solely focused on the bourgeois, without referring to comparative public spaces. [14]

Mitchell too argues that public spaces, from the Greek Agora to the American park, are places of exclusion,[15] yet in his belief 'Public space occupies an important *ideological* position in democratic societies'.[16]

Mitchell illuminates one of the most influential social theories of the 20th century that serves as a Language of ideology: 'This is a normative ideal for public space, more than an empirical description of the ways that public spaces have functioned in 'actuality existing democracies'.[17, 18]

Mitchell adopts this ideology as a theoretical frame for his work. He argues that this ideological construction 'implies a notion of inclusiveness that becomes a rallying point for successive waves of political activities'[19] hence his aspiration for an inclusion-based theory enables him to formulate his famous notion of 'Right to the city'. He suggests an understanding of the ideal as a point of political struggle:

'By calling on the rhetoric of inclusion and interaction that the public sphere and public space are meant to represent, excluded groups have been able to argue for their rights as part of the active public'.[20] Mitchel concludes his work saying that public space is increasingly privatized or otherwise brought under greater control.

This ideology and the understanding derived from its logic became a *professional truth* for planners and architects. In various blogs, websites and conferences many professionals share their common belief that a 'good' public space is one that encourages connectivity between strangers.[21]

This research adheres to an empirical description of the ways in which public spaces function in 'actuality existing democracies' and investigates a study-case where this ideology represented by architects manifested itself in the complex reality of Jerusalem.

Migdal (2008) claims that tension in public spaces results from the continuous conflict between inclusion and exclusion of unequal groups in society and not, as Habermas claims, from tension between the state and society,[22] nor tension between corporations and society, as Mithcell (1993) and others argue. In the case of Jerusalem, the aspiration for order or control not only forms the interest of corporations and the state but also serves as the basis of different groups' claim for their 'right to the city'.

Based on Elias' (1994) work, Migdal argues that what enables the existence of public space are shared codes of daily behavior: where and how does one blow his nose, go to the toilet, enter or exit a cinema – a long list of do/not do rules that endow physical spaces with a sense of security and a means for social identification for groups of middle-high social class, notifying them that they have reached a

civilized, cultured, familiar hence secure space. Yet many times in these spaces, claims Migdal, there are imposing regimes of separation, suppression and deference.

Migdal further argues that by means of daily activity in what consequently becomes an established public space people come to appreciate the joint *manner* by which things are being conducted: emphasis is placed on joint activity which stabilizes the principles of public spirit. Migdal states that there are institutional barriers that prevent containment and sharing yet they can become flexible. It is important for him to suggest a dynamic theory. Thus, claims Migdal, public space in the U.S.A and Israel results from 'the laws of encounters between people' that not only lead to encounters and the creation of a 'public' but also simultaneously unify and **separate**.

Migdal's theoretical suggestion greatly contributes to the discussion within contexts of crime for it enables theoretical space for the concept of class. Although in the case of Jerusalem the cardinality of ethno-national categories and the dramatic manner in which they constitute space is highly apparent,[23] Migdal places great significance on the category of class and the ways in which it affects the formulation of common social codes in public space.

## Musrara –Jerusalem's seam line neighborhood

Musrara was established in 1889 by wealthy Arab Christians of Jerusalem's Palestinian community.[24,25] During the 1948 War, the Palestinian residents were forced to flee and Musrara was subsequently divided between Israel and Jordan. The neighborhood's area that remained in Israel encompassed 163 acres and included 80 abandoned houses. Following the war, approximately 60 families moved into the Israeli part of the neighborhood, most of them Mizrahi Jews who emigrated from Middle Eastern and North African countries.[26]

The living conditions in the Arab houses were dire.[27] Already in a state of decay, the accommodation was divided into 340 housing units[28] and four to eight families shared each house. Only 63% of the apartments had direct access to a shower or bathroom, 28% had neither, and 8% lacked a basic toilet facility. The structure's high ceiling made the heating during the cold Jerusalem winter a considerably difficult task. Another problem was constant dampness that existed in approximately 200 apartments, causing serious health problems for the young and elderly.[29]

In addition to problematic living conditions, Musrara residents also suffered from the fact that a significant part of the neighborhood was in close proximity to the Jordanian border and was a no-man's-land exposed to Jordanian soldiers' sniper fire, resulting in numerous casualties. This situation changed following the 1967 War when Jerusalem was unified under Israeli rule and Musrara ceased to function as a frontier settlement.

Musrara residents' feelings of anger intensified as they witnessed how Israeli society enjoyed improved quality of life while they remained in their moribund condition. In the early 1970's, the neighborhood's unemployment rate was considerably high: approximately 180 men aged over 20 (which made up more than 30% of the families) did not work, and 75% of those that did work were employed in low wage labor.[30]

Only 56% of the children aged 14-17 were in educational frameworks, of which 16% were still in elementary school. Out of 838 adults, 431 lacked a minimal 8 years education and not one person from the neighborhood was registered in any higher education institution.[31]

Numerous scholars and policy makers blamed the residents' ethnic origin as one of the reasons for the neighborhood's harsh socio-economic condition, arguing that they were unaccustomed to modern and Western way of life.[32] However, recent studies depict that because they were Mizrahi Jews the population of Musrara was marginalized and disenfranchised by the misallocation of resources.[33,34]

Nevertheless, the shared ethnic identity of the inhabitants became a solid basis for socialization among the residents themselves,[35] and a fertile ground for political activism. In January 1971, a small group of Musrara's youth who regularly met at one of the neighborhood's youth clubs established a social movement called 'The Black Panthers', directly inspired by the American Black Panther Party.[36]

Musrara's Panthers focused most of their efforts on organizing public demonstrations and publishing a series of pamphlets where they presented their arguments regarding inherent inequalities embedded in Israeli society, linking between their ethnic identity as Mizrahi Jews and their socio-economic status.[37,38] They encountered fierce resistance from the authorities yet attracted wide scope attention from the Israeli public.[39,40]

In 1978, the continuous crisis let to the inclusion of Musrara into the official governmental scheme entitled Project Renewal.[41] This project was designed to provide a multifaceted answer to different problems the neighborhood faced.[42] Beyond the expansion of physical space, the project ostensibly aimed to address the social and educational issues that required serious amendment for the improvement of Musrara's residents' wellbeing.[43]

However, several local residents objected to Project Renewal and were concerned that Musrara will be gentrified and its population will be removed in favor of wealthier occupants.[44,45] Resistance acts included violent demonstrations as well as squatting into renovated apartments.[46] This confrontation and the fact that Musrara's residents were already politically organized prevented the area from undergoing considerable demographic change, and the number of wealthy outsiders who purchased property in the neighborhood was thus limited.[47,48]

By the end of the 1990's, three distinct social groups were evident in the neighborhood. The first were families of Mizrahi Jews who moved into the neighborhood in the 1950's and 1960's. The second were the 'new comers' who managed to buy property in the neighborhood during or prior to Project Renewal. The third group was ultraorthodox Jewish families who relocated into Musrara in considerable numbers from adjacent overcrowded neighborhoods. This recent development was resented by the two aforementioned groups and created a new political reality in the neighborhood.[49]

In order to comprehend the events that occurred in the neighborhood within the context of crime events, the following presents cardinal data related to spatialized crime along the border seam line in general and Musrara in particular. The receipt of this data necessitated the establishment of official relations with Jerusalem Municipality, the Israeli Police and the Emergency & Rescue Services. Following the receipt of necessary permits (which took approx. 2 years), the Police Research & Statistics Dept. provided the necessary data related to reported crime events in Jerusalem.

## Figure 1: A spatialization of crime events in Jerusalem in relation to city boundaries

The research point of departure was the centralization of crime and terror events in Jerusalem along the historical border seam line on a neighborhood scale, using Musrara as a case study. The formulation of the neighborhood's crime map was conducted by use of data files dealing with major and minor violence offenses that provided information regarding the sociological profiles of the offenders. A total of 447 reported violence events occurred in Musrara neighborhood during the years 2003, 2005 and 2010. Interviews with the residents revealed that their central concern regarding the issue of crime was the question of the criminals' ethno-religious origin. The police data files depicted whether the offender was: (1) Jewish (senior Jew or Russian immigrant), (2) Muslim (a resident of the Occupied Territories or an Israeli citizen), (3) 'foreigners' (offenders not included in the first two categories).

## Figure 2: Violence events in Musrara according to religion/origin

The analysis results were normalized and represent the percentage of population responsible for the events that occurred in the neighborhood: the dominant group was Palestinian Israeli citizens (39%), followed by Jews (31% all senior) and Territories residents (25%), i.e., approximately two-thirds of the events were operated by Muslims and a third by Jews.[50]

The data files contained original and primary information as to where architecturally and urbanely the offense took place: in the street/store/elevator/car? Categories were coded as follows: open public space (streets, squares), closed public space (public institutions, stadium), liminal space (parking lots, stairways, elevators), private space (residencies, workshops), private space open to the public (restaurants/shops, motels, hotels).

Most of the offenses occurred in open public space and only 23% occurred in private residencies, an insight that will play a crucial role in the analysis of the findings of the field investigation conducted in the neighborhood.

A correlation between religious-origin and the location of the violence events was found: 39% of the crimes that Jews committed took place in public space vs. 70% of the events committed by Palestinian Israeli citizens and 80% of the events committed by West Bank Palestinian residents. These findings mark the marginality of the two Palestinian groups in the neighborhood: they do not reside there and their actions had no other space to be performed other than the street. These findings also shed light on their exhibitionist activity in space. While Jews committed crimes mostly in the victim's or offender's house and far away from public eye and opinion, Palestinian Israeli citizens as well as West Bank residents committed violence crimes publically.

## Ethnography of struggle on public space:

## Violence at Jerusalem's seam line

The research question that guided the fieldwork conducted in the neighborhood was how do the residents interpret and act, within their complex reality of conflict between different neighborhood groups, with regards to the possibility of closing the neighborhood and their perceptions of the 'other'. Henceforth, the research documented the conflict from the viewpoint of different agents operating in the neighborhood arena, placing special emphasis on the spatial implications of the actions each group performed. Additional information was received from the architects who planned the border seam line and provided the original plans within the context of two extensive interviews where they relayed their professional truth.

The first interview conducted in the neighborhood was held with S., a 50 yr. old man who works at an antiques store. He told us that the historical border line exists not only in the minds of the offenders but also in that of the neighborhood residents. Upon seeing the map which centralized the findings in Jerusalem he nodded his head in approval, came out of the store and pointed with his finger:

*'Here is where the border ran and for me it is still a border, to this day. Up to here it is 'us', from there it is 'them'… here was a defense wall 8 meters high…the war ended, they dismantled the wall and now it's open. When I look at it I see it as it was…as a child I was here a lot. Now it's the 21st century but it's still a border.'*

S. describes how the most effective spatial borders are group borders; the border is where 'they' end and 'we' begin. Even though the international border was dismantled in 1967, the urban border still exists as a sociological apparatus. Moreover, it clearly affects the residents' conduct:

*'I am 58 and unashamed to say that I am afraid to go to the Old City like I used to as a kid with my father… Since the Intifada you don't feel safe that you can go freely and, in fact, you are in*

*danger…that all kinds of extreme people will see someone like me, who wears a skullcap, and want to stab me. So I – the God Almighty says to stay away from any place which is dangerous.'*

Further conversations and interviews confirmed that the international border still exists in the collective consciousness and that in contexts of crime it is forms a nostalgic reminiscence:

*'When there was a border there were no thefts. I used to live with Arabs in the past. There was friendship. They were different people. Now it's all over. Everything is hatred. But you can't blame them. They grew up in nearly 40 years of hatred. In the past we used to live poorly but peacefully. They don't need a bomb. The bomb is walking around here outside, along the seam line. An [international] border is better. To give them everything under the condition that we won't see even one Arab. This whole country is lawless.'* (Community Center employee)

Other interviews with residents were surprising in their attitude towards the separation that existed up to 1967. Even though it was a 'hot' border line lined with mines and subjected to sniper gun shots and thrown stones, still many of the residents expressed a sense of security living next to a border – *'we lived in poverty and serenity'*, said one of the residents. Such sayings reconfirm a phenomenon well-known to Anthropology – a territory identified as 'home' is experienced as more safe for its residents even if it is subjected to violence such as Jordanian snipers' gun shots. One of the senior residents who left the neighborhood following the entry of Orthodox Jews yet remained active there, said*:*

*'After 1967 the border was opened and there was a plague of drugs. I remember. It was very difficult. Even those who weren't into it were forced to. Children.'*

S. reconfirmed the above:

*'Before the war there were no 'Jews' and 'Arabs': there were only [Jewish] residents of the neighborhood that didn't harm one another because everyone was in a difficult state.'*

The above clearly relays that even when 'home' is poor and subject to gun-fire it is perceived as safe because it is separated from neighboring East Jerusalem Arabs. Paradoxically, the dismantlement of the urban line, which was perceived as victory on the national level, turned into a point of insecurity for Musrara neighborhood residents. This issue is fascinating in light of the fact that Musrara was one of the most complex slums in Israel. The fact that in the 60s-70s, some of its Jewish residents participated in criminal activity makes their position towards others –Arab and criminal – quite intriguing.

## Unwilling criminal: the cousins, the criminals and I

Crime is no stranger to the neighborhood: it was forced upon them. Many of the interviewees did not express a distanced attitude towards the criminal as a social type but rather one of understanding and affinity:

*'There was severe hardship here and I'm lucky I didn't go in the ways of crime. But my friends were big criminals, some are still doing time in prison. And you can understand them. They had no choice, it was like a survival movie'* (S. antiques shop salesman).

*'At the time'*, said another resident, *'there were Black Panthers and there was poverty, it was necessary to steal and commit crime'.*

The above quotes suggest that the public attitude of neighborhood residents regarding their past is that of being 'unwilling criminals'. Furthermore, Musrara's struggle against the establishment built mental barricades that caused senior residents to claim *'the establishment abandoned everyone, Arabs and Jews and criminals.'*

The analysis of violence events that occurred in the neighborhood depicts that one third of the criminals was Jewish, coming mostly from the neighborhood or bordering neighborhoods. The public opinion in Musrara relates crime to Arabs alone, and in the event that Jews are also taken into consideration there is little awareness of the fact that they come from within the neighborhood. A careful study of the crimes committed in the neighborhood during the above mention years depicted that Jews who committed crimes in the neighborhood performed them in private houses, restaurants, motels and the street vs. Palestinians who committed most of their crimes in the street. Since Palestinian crimes were more publically visible, it is highly possible that this data explains their perception as a criminal group and the public belief that they form the major crime group that hazards their streets.

The dominant perception in the neighborhood was that the residents significantly improved their status since the 80's due to two processes: their entry into the primary organized labor market which endows social rights (e.g Jerusalem Municipality), and the purchase of the abandoned houses that were owned by governmental housing companies – real estate which doubled and even tripled its value in a short time period. In light of this data, the neighborhood residents concluded that Jews have no reason to commit crimes. To support their claim, the residents described the types of offenses:

*'Today, most of the crime is committed by our 'cousins' [i.e. Muslims]. Be it a car that disappears from the parking lot, anything, pipes, air conditioner dismantled from a house. No Jew would do that. In order to receive 100 Shekels he will go and dismantle an air conditioner and cause a damage of 7-8 thousand? But the 'cousins' are willing to do anything. Even for less.'*

The above quote suggests that residents perceive East Jerusalem Arabs as 'unwilling criminals' also.

The most talked about offense in residents interviews was laundry theft. It was very common in the neighborhood and perceived as a poor man's offense, serving as proof of the offender's identity and the reason for his actions. *'They get up in the morning and steal everything. For instance laundry. For instance a wheelchair. So they came and caught him and the policeman told me that they will release him because he won't come to court.'* (Community Center employee)

According to neighborhood residents, the Separation Wall that separates East Jerusalem from the West Bank is to blame for the social and economic problems in East Jerusalem:

*'Since the Separation Wall, the situation got worse because everything originates from the residents of East Jerusalem. They left them in a state of unemployment, no employment no money… I grew up in such a neighborhood. When the parents of all of the residents here did not have jobs and income, so what choice did their children have, that they can't bring home bread and milk, they stole because they had no choice. Families with 12 children.'*

It is important to note that like in other mixed cities in Israel[51] everyday law obligates conducting discussions without involving politics. Any discussion on positions regarding the Israeli-Palestinian conflict is forbidden in the neighborhood's area, markets or any place where there is a mixture of Jews and Arabs or Jews from diverse social and political groups. One of the central expressions of 'no politics' was the abstention from using the word Arab, an intimidating adjective when used in their space. Most of the interlocutors used the term cousins, smiled or sighed and said, 'You know who I'm talking about.' The choice of such a familial term – cousins – is fascinating and deserves separate cultural-linguistic research.

The neighborhood scale discussion revolved around power relations. From their perspective, they are the victims:

*'The problem moved there but it reaches us because we are their nearest neighbors.'*

This suggests that even though the residents understand and empathize with Muslim offenders, knowing that their conduct springs from a state of poverty and lack, they nonetheless distance and protect themselves from them. The neighborhood residents believe that they have no influence on wider circles such as the Municipality's policy regarding East Jerusalem, arrests and permit policies and certainly not future agreements and arrangements. Hence, their solution is to hide behind walls and separate themselves from them.

## The struggle for the reconstruction of the Wall: open public space is dangerous

It is clear that under the above mentioned conditions, open public space forms a threat.

*'You see an Arab near your house. You ask him what he's doing here and he says that he's looking for a job. He is lying. He came here to steal. On Elisha St. they steal women's purses. You can't contain these Arabs – they come to you'* (Community Center employee).

Under such conditions of ethno-national and social status inequality, border zones become points of contact and friction and not of separation.[52,53] The wider the gaps become, so too the attraction of the weaker side becomes more fierce and demanding (*'you can't contain these Arabs – they come to you'*). This friction occurs in public spaces:

*'They [the Arabs] hang around more in our space than in theirs. **A person gets accustomed to this.** It's been 40 years. You get them used to something so this is what they become. You [as a Jew] can't walk around there. The wheels have turned.'* (Resident)

*'Today, an Arab is allowed to sit in the public garden. The Municipality built benches for the residents. So he comes and sits. You can't say anything to him. I didn't have a problem with this until the number of thefts and robberies became too much. They leave nothing, take everything, they even dismantle copper lines they can sell'* (Antiques shop salesman).

The construction of the Wall is not perceived by Musrara residents as a move of a strong party but rather a solution they are dragged into for two reasons: the first is their incompetence in municipal or geopolitical regional issues – *'what can you do to them? Transfer – you can't. The Supreme Court protects them and you can't act against it. So what else can you do? Build a Wall.'*

*'The Wall is located on the Separation Wall. It's something psychological. If there is a neighborhood they will ask him right away what he is doing in the neighborhood. **You defend yourself so you don't have to be aggressive**. This affects people psychologically. They know that this is the framework, like in America where everything is in a framework.'*

The second reason is even more fascinating:

*'I was here at the time of the Black Panthers. I was 17. I operated terror. We were together. We were family. We struggled because we were in distress. (But) when we had children we were fearful for them and brought them up to be good kids. In our time, an Arab didn't dare to pass here.'*

These resident statements convey a fascinating reversed relation between the condition of the people and that of the neighborhood. The time period when the residents' condition improved and the next generation turned into 'good children' became the last days of the neighborhood, as one of the active residents said:

*'I did a Program in university and wrote an essay about it. The neighborhood will be gone. I predicted it. The children have no power to deal with it.'*

It appears that once the neighborhood rebelled and residents left the neighborhood, those who remained felt abandoned and were in need for a protective wall.

*'I was the Chairman of the [Community] Administration at the time of Teddy Kollek [former mythological Mayor of Jerusalem]. He wanted to construct Road no. 1. The architects presented a 9-meter wall, with a porch facing Nablus Gate, a bridge and a waterfall. They presented it beautifully to Teddy Kollek. They talked about a train, and everything was very beautiful. They wanted to construct gates in every neighborhood to enable crossing. I requested to close the neighborhood and the porch. Teddy Kollek said to do what he [I] said, but to leave the waterfall. Two months later they closed it down because Arabs began to swim there. They wanted it to be beautiful and all they got was a mess. We still have a border because we built the Wall. That's the border. We requested the Wall. 25 years ago, before the 6-Day-War there was a fence. They constructed the Wall on the exact same spot.'* (Former Chairman of the Community Administration)

**Figure 3: The aqua duct in its glorious days**

**Figure 4: The aqua duct today**

The current Chairman of the Community Administration:

*'At the time of Road no. 1's construction, the Wall was two-times higher. They wanted to construct a promenade and a tunnel and there was a conflict regarding the route. They wanted to construct a tunnel to the other side but we were concerned that it would attract junkies and harm. We fought for lowering the Wall – we were sealed off. They wanted [by use of the Wall] to decrease noise pollution. They wanted to construct a passage in the middle of the Wall and we objected, we didn't want people to cross straight into the houses, robbing elders, burglaries etc., and stabbing. They finished the project in the early 90's. The City Engineer said that when they will build the gate they will call it the Gate of Peace. I told him that when there will be peace we will open the gate'.*

**Figure 5: Border seam line area – built environment**

In his interview, the architect who planned the Wall and the entire seam line space relayed his version:

*'I remember the conversation in which I was asked to come and plan the border seam line. I told them that I wanted to study the subject…we wanted to turn it into a connecting area, connecting both parts of the city (we added 3 latitude axes) – our intention was that the institutions will serve the Arab population in the area. But the institutions were only for the Jewish population, places that do not create meeting and sharing. The Triangle was supposed to be the end point of this event'.*

The architect's purpose was to plan and design the border seam line in a new formation: Road no. 1 and both its sides. The architect office's investigation focused on the axis itself. In other words, the first gap between the neighborhood residents and the architect was the angle of perception: while the residents experience their neighborhood as a center from which they observe the seam line as a border which is imprinted in the collective consciousness, the architect's central view point is the axis and the neighborhood as a side-effect of this axis. From the architectural point of view, the neighborhood was the back yard of the road vs. the residents who perceived the road as the back yard of the neighborhood. Moreover, it's location along the historical border line emphasized its role as a tool of separation.

The planning team divided the road into five segments, each of them planned within different infrastructure and landscape contexts. They recommended the pavement of six latitude axes that will connect the Muslim East and the Jewish West, thus enabling a merge of both sides. The architectural agenda was a perception of urbanism that encourages urban intensity and wishes to connect parts of the

city. However, the geopolitical consequences were many and diverse, bearing dramatic significance on the city's unification.

**Figure 6: The plan outline emphasizing the latitude roads that connect the parts of the city, of which only two were constructed.**

Being a main axis of transportation (two lanes on each side of the road) and a significant train route, the architects were certain of the need to construct acoustic walls that will protect the neighborhood from noise pollution. The wall was also supposed to function as a pedestrian promenade. It was designed as a double wall where one wall is high and the other – the one closer to the road – is lower thus enabling pedestrians a view of the Old City. Once again, the architects' point of view considered the road users and the tourists. They, in turn, requested that the wall will be lowered so they could enjoy the view of the Old City and they were acquiesced. The architects planned gates along the wall to enable pedestrian crossings and added a pedestrian bridge that linked the eastern and western parts of the city at the core of the neighborhood.

**Figure 7: Right: the neighborhood wall composed of a double wall and a promenade. Opposite: the bridge. Both were not constructed. From: Border Seam Line Plan: 2007.**

**Figure 8: Nablus Gate area: the Triangle, Road No. 1 and neighborhood outskirts. From: Border Seam Line Plan: 2007.**

The Triangle, which used to be a no-man's-land, was planned as an urban square with an underground parking lot and was destined to function as a meeting point, enabling trade peddling in assembled structures. The eastern side of the Triangle was meant to function as an active commercial front that enlivens the square.

During his interview it was apparent that the architect was trying to anchor his plan and design approach so as not to appear like a naïve architect denying the tough reality of Jerusalem.

*'It is a fact that Nablus Gate was a beautiful place – an open space with watermelon- stands and everything. An appropriate political and social climate is necessary. Personally, we used to go down there and drink Arak, eat watermelons. Those were good times. There were tourists. It ended with the First Intifada.'*

As is frequently the case, there was a huge gap between plans and reality:

*'In reality, the wall was built with a watchtower. This watchtower was meant to mark the start of the promenade – that wasn't built. The entrances in the wall were blocked and the wall runs sequentially. Thus Musrara turned into a closed neighborhood. The pedestrian bridge that was designed to connect to the southern wall of the Triangle was not constructed.'*

**Figure 9: The blocked entrances, a view from within the neighborhood. Photography: Author A**

*'The panoramic promenade along the wall was constructed, but the market that was designed for Hanevi'im St. was transferred to a promenade shaded by a long pergola, eventually becoming a drug station which the Police later decided to evacuate. The market was neglected. As for the Triangle: the train was transferred to the Western Wall and together with the tunnel caused complete separation between Musrara and East Jerusalem that were supposed to become connected at the Triangle. The Triangle became a large parking lot where its eastern side serves as a parking lot for trucks – the whole area became 'transportation biased' instead of one of meeting and activity. It's a sad story.'*

Transportation can be a meeting or separating point. In this case, the transportation routes, double-lane separation walls and parking lots had indeed created a separating transportation biased zone. In a research on the spatial implications of Road no. 1, the authors[54] claim that it plays a major role in the division of Jerusalem and the recreation of the ethno-national order.

Considering the gap between the architect's intentions and reality, he was asked if he felt angry:

*'Of course,' he replied, 'we invested 45 thousand office work hours. That is 10 years of hard work.'*

At the end of the interview he was presented with the findings of this study related to crime events in the area and the residents' struggle to keep the neighborhood closed and clear of meeting points with their neighboring Muslims. His response was: *'It could have been different. It used to be different. When you don't allow encounters in public space, then begins desolation and negligence. It could have been a turning point. But I guess the conditions weren't ripe.'*

His remarks left an open question: does the existence of open space indeed create encounters between Jews and Muslims in Jerusalem? Can a bridge bring peace or only under peace can a bridge be constructed?

In succeeding interviews with two Neighborhood Committee members, the architect's vision and the fact that even during complex times in the past there were encounters and good neighboring relations were mentioned:

A.: *'There were encounters of Jews and Arabs but without constraints. It was open. There were watermelon stands on the road. We used to go down to the Triangle and have a good time – it was a no-man's land. And all along the avenue there were stands. We used to come – see movies together – it wasn't constrained. [The plan] forces us to go back to those days. Constraint doesn't work.'*

M.: *'When you do something of your own free will it's much better and more natural. Things have changed. In the times of the watermelon stands the political awareness of the Palestinians was low. They wanted to make a living. There was no violence. Today there is political awareness and all they do is to fight us.'*

The above quotes once again re-establish the neighborhood residents' position regarding the inter-generation gap among the Palestinian Israeli residents.[55] The neighborhood residents relate to political events (*'Everyone has a cousin or brother which we killed, so we live in hatered,'* said one of the interviewees) and to political-national awareness but, they believe, what's done is done.

## Discussion

The controversy between the Residents Committee and the architect touches core issues: how is it possible to maintain urban intensity between different ethno-national groups under conditions of sharp political and economic inequality? This question sheds new light on the notion of 'public space'.

The architect represents the approach that perceives urban planning and design as a tool for turning the border seam line into a public space. Relying, in different levels of awareness, on the theory of public sphere the architect represents an approach that perceives public place as a place where 'public' formulates.

Migdal's (2008) criticism of such public space perception explicates the residents' position by bringing back the concept of *class* into academic discussion. Migdal claims that in order to study public space it is necessary to study separation regimes that enable participation of a very particular public. His suggestion provides an effective toolbox for understanding the position of people who mocked the decision to construct aqua ducts, a waterfall and a pool at the base of the Triangle near Damascus Gate.

Hence, when the residents said that *'the Arabs will go and swim there and create havoc*,*'* they implied that it is impossible to create common public space under extreme relations of inequality - a pool is not a landscape resource but rather a place of recreation for children to be offered to and regularly available for most of Jerusalem's Jewish population.

It appears that in different contexts, separation is what enables daily existence between conflicting groups in a dense space. This study suggests that from the perception of Real-Urbanism, separation means an organization of space that enables different groups to live in high density. The construction of walls is not a municipal conspiracy but rather the residents' defeated reaction to violence they experience. They are aware that crime is a reaction to state institutional violence and, to a certain degree, also identify with the hardships of living and have no patronizing stand because *'many of my friends are in prison and it's a wonder that I'm not there also*,*'* as one of the residents said. Nevertheless, they feel that they, as simple citizens, are unable to influence or design the state's attitude towards the Palestinian issue in general and East Jerusalem Arabs in particular. Hence, they wish to separate and define a frame for themselves and by doing so they anchor and protect their nativity and legitimate existence in this space. This explanation does not endow legitimacy to the residents' actions but rather serves as a report on the events occurring and offers a new-old principle for understanding the urban situation in these cities – separation. As a research community, our ability to discuss urban dynamics of separation outside the normative language of 'good' and 'bad' depends on our ability to shift from ideological **interpretation** of 'public space' to real-urbanism, thus studying cities and their public spaces without prejudice or judgment.

[50] The number of **Palestinians in the West Bank** is approximately 2,264,000 and approximately 250,000 more in East Jerusalem (according to the Palestinian Central Bureau of Statistics, as of end of 2007). In Israel, there are approximately 8,107,000 residents, of which approximately 75% are Jewish (approximately 6,040,000 residents) and approximately 21% are Arabs (approximately 1,656,000 residents) (according to the Israeli Central Bureau of Statistics, 2013). This means that Muslims in general, those from the West Bank and Israeli citizens, are excessively represented. There is a significant gap between the two populations: Palestinian Israeli citizens are in excessive representation also in relation to West Bank residents. This explanation relates to a fascinating discussion: currently, most of the West Bank is surrounded by a Wall and under severe permit regime, making entry to Israel extremely difficult.

# VITALITY AND SOCIAL VALUE OF PUBLIC SPACES: A SOCIO-SPATIAL ANALYSIS IN TWO URBAN SQUARES IN LONDON

Abdulaziz Alzahrani[1], Katharina Borsi[2]

[1]Ph.D. Candidate (Department of Architecture and Built Environment, University of Nottingham), ezxaa3@nottingham.ac.uk

[2]Assistant Professor (Department of Architecture and Built Environment, University of Nottingham), lazkb@exmail.nottingham.ac.uk

Keywords: Public Space; Social Value; Vitality

**Abstract**

This paper aims to investigate the impact of vitality on the social values attached to two public squares in London. Based on an extensive review of the literature and empirical work, this paper will explore the similarities and differences between these two squares in order to deliver a better understanding of the reasons behind urban design vitality and quality in generating social values attached to physical spaces. These two squares are comparable in size, physical setting and geographical and social context providing unique contexts for socio-spatial analysis. This study follows a case study approach with a qualitative method. For both case studies, there are 100 surveys and 33 semi-structured interviews in total conducted with participants at the squares. In addition, many site observations for this study have been taken, in both cases, at different times of the day to track human movement, activities, spatial qualities, social interactions and spatial interrelations. This study demonstrates the complex nature of the generation of vitality in urban spaces.

## 1. Introduction

In densely populated urban areas, urban public spaces work as important physical sets, fulfilling the needs of urban residents by providing social interactions and a considerable part of a city's transaction base (Space, 2003). The life of public space occurs in open public spaces in a complex set of functions and forms(Gemzøe and Gehl, 2006). The attribute of these spaces usually is capable of containing diverse behaviour, activities and use such as walking through, shopping, conversation, using the facilities, relax, people watching or even just passing the time as a daily activities (Ibid, 2006). One of the key aspects that determine the failure or the success of urban space is vitality (Montgomery, 1998, Engwicht, 1999, Carmona et al., 2001). However, the lack of the use of vitality as a tool that can distinguish successful urban spaces from others occurs in many contexts. Urban designers whose task appeared to be aiming toward the healed public spaces among sociologists, geographers and politicians show more interest in the subject of public space. However, focus has been on the requirements of vehicles in the modernist planning rather than pedestrians and their needs and expectations which leads according to Oktay (1996) to negatively affected the quality of everyday life in cities. Consequently, the attention toward social value has been increased as a result of the need for investment in good urban design (Carmona et al., 2001, CABE, 2002, Carmona et al., 2002a, Carmona et al., 2002b, McIndoe et al., 2005, Macmillan, 2006a).

This paper aims to investigate the impact of vitality on the social values attached to two public squares in London. Based on an extensive review of the literature and empirical work, this paper will explore the similarities and differences between these two squares in order to deliver a better understanding of

the reasons behind urban design vitality and quality in generating social values attached to physical spaces. These two squares are comparable in size, physical setting and geographical and social context providing unique contexts for socio-spatial analysis.

## 2. Understanding vitality and social value of public spaces

Lynch (1984) recognizes vitality as one of the performance elements of urban design and defines it as the degree to which the setting of the space support the functions, biological requirements and capabilities of human beings. Sherman et al. (1988) consider vitality as one of the indicators of successful urban places. Vitality can distinguish socially beneficial places from the others. According to Montgomery's definition (1998) vitality 'refers to the numbers of people in and around the street (pedestrian flows) across different times of the day and night, the uptake of facilities, the number of cultural events and celebrations over the year, the presence of an active street life, and generally the extent to which a place feels alive or lively'(p.97). Many of contemporary research findings indicate that vitality is a product of visual quality and the variety of the supported activities to these environments. (Space, 2003, Townshend and Madanipour, 2008, Gehl and Matan, 2009, Nemeth, 2009).

It is recognizable that the good design contributes to human needs and satisfactions. It is essential to meet people's needs and adapt their activities in order to have a proper public space. Maslow (1999) identified a five stages hierarchy of basic human needs starting from physiological needs such as food, warmth and survival toward more complex needs such as social needs that includes safety and belonging needs. Similar to these, the most important social elements in a public space could be accessibility, equity and safety. The viable place has the capability of providing more choices for social activities to take a place in urban public space as well as being the arena for cultural exchanges(Gehl, 2010). These spaces are successful due to the result of the active engagement that peephole seek out (Carr et al., 1992) and due to the process that had been taken when place making for people (Carmona, 2010).

According to Macmillan (2006b) social value has coloration with the encouragement provided to residents by places and buildings to interact in ways that lead to trust, shared understanding, shared values and supportive behaviours. Walmsley (1988) claimed that there is a relationship between the environmental perception of a place with its social behaviours. He also claimed that human behaviours are not only developed by inter-relations within the environment but also urban environment can be the foundation of this development. Social value emerges when people have common interests that can join them with others. (Macmillan, 2006b). Social value usually measured by indicators to identify areas where enhancements are desired. Many attempts have been done to identify the possible indicators that used to measure the social value of urban design (Table 1).

Table 1: Assessing and measuring the social value

| Research | Possible indicators |
|---|---|
| The Value of Urban Design<br>(Carmona et al., 2001) | • Identity/civic pride.<br>• Place vitality<br>• Inclusiveness<br>• Connectivity<br>• Safety<br>• Facilities and amenities |
| The Value of Urban Design<br>(McIndoe et al., 2005) | • The percentage of peoble who are involve in community and cultural activities.<br>• Increased use of public Space. |

| | |
|---|---|
| | • Gives greater sense of personal safety.<br>• Attracts social engagement, pride and commitment to further achievements.<br>• Public art contributes to greater community engagement with public space. |
| The value handbook<br>(Macmillan, 2006b) | • The strong sense of a community.<br>• Being proud of the neighbourhood.<br>• Feeling safe when out at night.<br>• The decrease in the number of people suffering from mental health problems.<br>• The number of people taking regular exercise. |
| Urban Design Toolkit<br>(Environment, 2009) | • The way people live, work, play and interact with each other on a daily basis.<br>• Culture.<br>• Community services and facilities, community character.<br>• Ability to participate in decision-making.<br>• Personal and property rights.<br>• Perceptions about safety or future aspirations for the community. |

The importance of the role of the public realm and associated semi-public spaces is emphasized by Montgomery (1998) which is providing the territory for social interactions and a substantial part of a city's transaction base such as the market square, the shop frontage, the street vendor and the sidewalk café. It is advisable to be linked and connected to the community. Emphasizing relationships and social significance of the site can reflect the physical qualities of it(Carr et al., 1992).

Accessibility is the most fundamental level of the social elements in public space. It has two forms that are visual and physical accessibility. Visual accessibility allows people to see open public spaces and be informed about the activities there while the physical accessibility offers an entry to that space and allow people to use its functions (Carmona, 2014). Open public spaces should stimulate and invite people to come inside and use its amenities. At the same line with the concern of urban design with the formation of physical setting of open public spaces, urban design is concerned with the creation of equitable, open public space as well (Gehl, 2010). One feature of these spaces is democratic spaces due to its availability to all users to use them. They also might be categorized as spaces that increase choice. Thus, they are responsive places. The result of considering equity in the design of the public realm is getting more blended, democratic environment which is accessible for all. Equity provides safe and vibrant public spaces in which different groups of the society from across the social structure can socially interact with each other without conflict (PPS, 2013) .

## 3. Case study approach

A case study approach was chosen as viable tools for gathering qualitative and quantitative data. Moreover, selecting the case studies are an important part of this research. The case studies were selected after an in-depth review of many mixed- use development in central London. The cases adopted for this study meet the following indicators: 1) they are both mainly contain residential blocks in order to seek the impact on the development residents and the local community within the development. 2) The volume of the mixed- use development are large enough to produce a practical impact on the level of the neighbourhood with surrounding community. 3) Both mixed-use developments include a public open space that available for its residents and the surrounding community. 4) Both selected cases reflect the importance of urban design policy and plan after the

Urban Task force's report in 1999. 5) The selected cases have different approaches in term of developing the scheme to enable a meaningful comparative assessment between both cases(Table 2). Even though it is not an easy mission to identify the suitable pair, Empire Square and Bermondsey Square pair were selected to make this study (Figure 1). They are located in London Borough of Southwark (Figure 3).

*3.1 Brief background of the Borough of Southwark*

Southwark is one of the inner London boroughs that face the river Thames. It is home to a wide range of commerce, business and leisure. The Bankside area contains many tourist attractions, such as the Tate Modern and Shakespeare's Globe Theatre; these are located beside large regeneration developments such as the Elephant & Castle, one of the largest redevelopment schemes by borough in London, and the Aylesbury Estate. Southwark gets the benefit of many attractions at its fringes, which offer substantial tourist traffic that is associated with providing many job opportunities (southwarkheads, 2009). In this paper, both case studies will be delivered from the borough council and developers vision to the concept of providing public spaces.

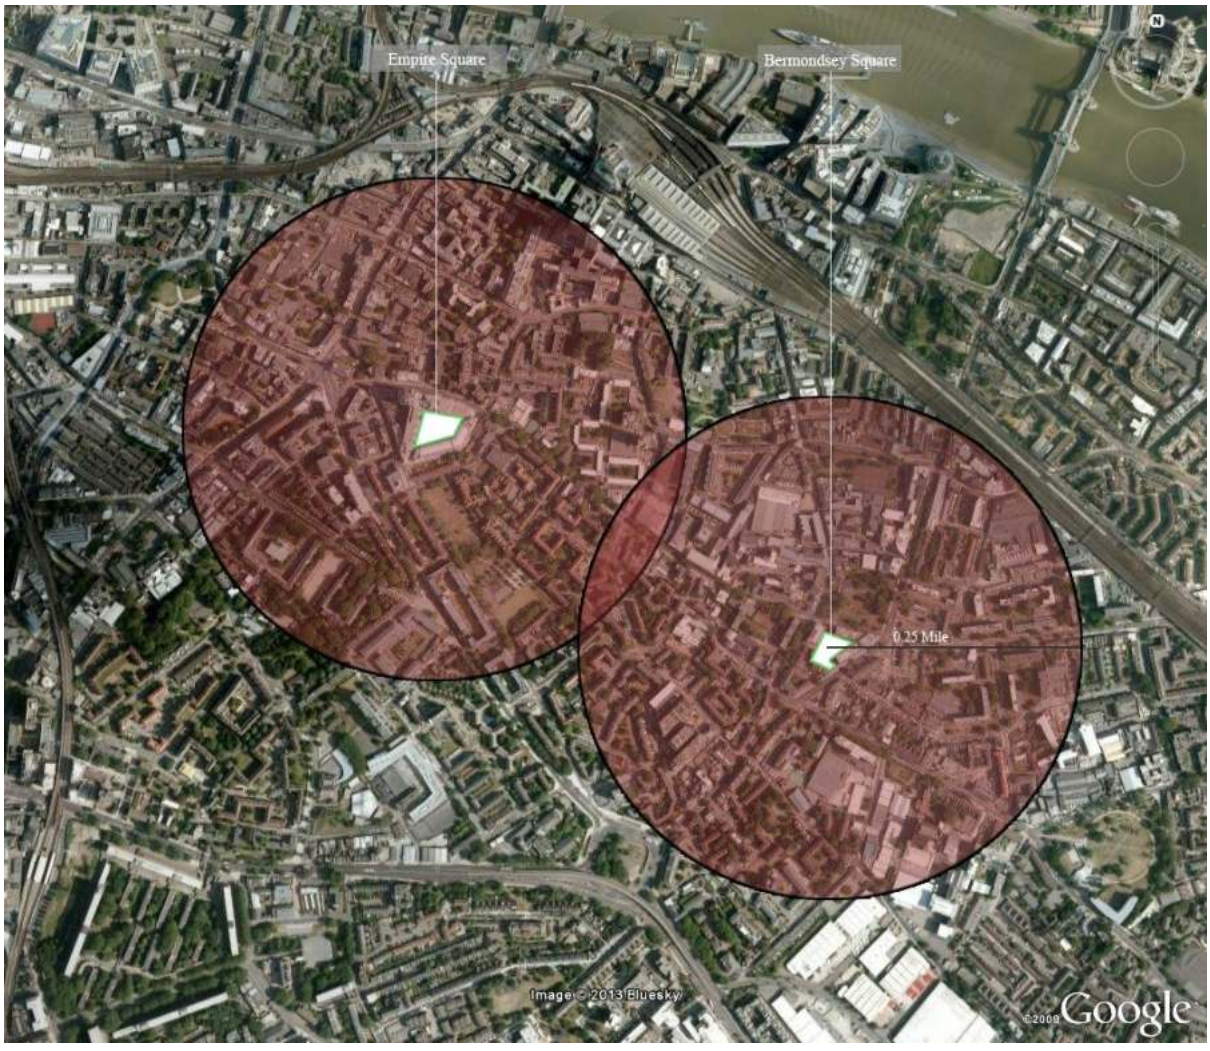

Figure 1. The location of Empire Square and Bermondsey Square (Obtained from Google map)

Figure 2. Bermondsey Square (top), Antique market is taken place on Friday the 24th of April 2015. (Image: the author). Empire Square (bottom), Even though it is sunny noon on Friday the 24th of April 2015, the square appears empty. (Image: the author).

Table 2. The characteristics of the selected case studies

| | Empire Square | Bermondsey Square |
|---|---|---|
| Location | London Borough of Southwark | London Borough of Southwark |
| Usage | Offices, health club, retail units and residential. | Offices, retail units, residential, hotel, bar, restaurant, cinema and café. |
| Developer | Berkeley Homes | Igloo Regeneration |
| Design | Rolf Judd | Munkenbeck + Partners Architects |
| Size | 572 units & commercial retail space | 76 units, a 79-bed boutique hotel & commercial retail space |
| Occupiers | Gym, retails, nursery, NHS facility, grocery store and office uses | Hotel, restaurants, café, bar, cinema, grocery store and office uses |
| Completed | 2007 | 2008 |
| Site Plan | Obtained from www.rolfe-judd.co.uk |  Obtained from Igloo, 2013 |

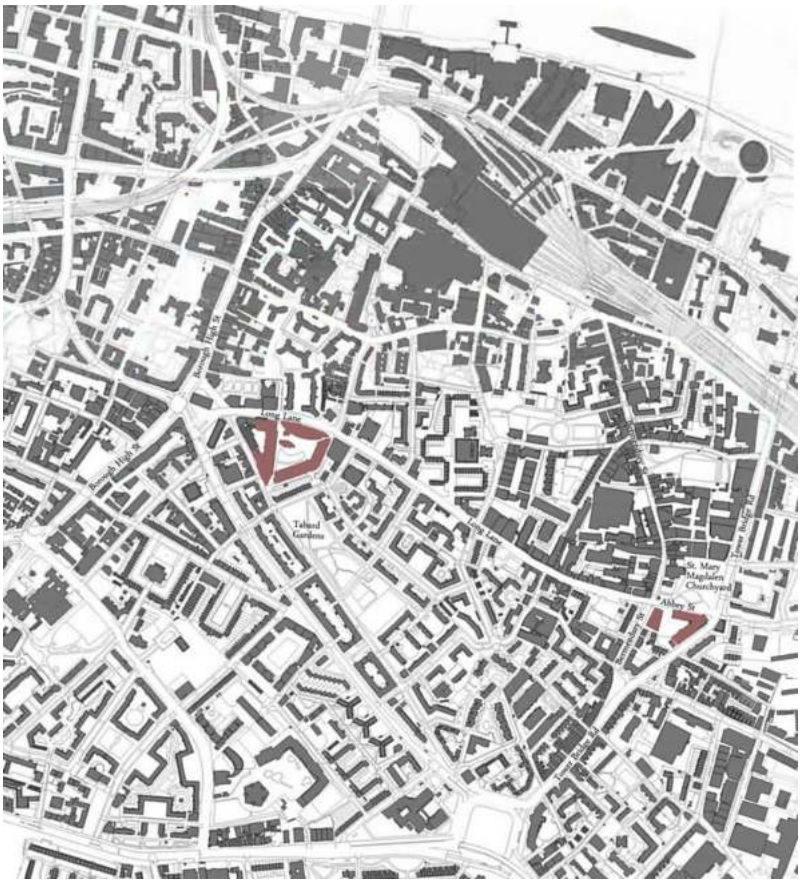

Figure 3. Empire Square & Bermondsey Square - Urban structure and built form. (Obtained from 2012 OS Mastermap)

*3.2 Case 1: Empire Square*

Empire Square is a residentially led development in the historic district of Southwark, located at the end of Borough High Street. The site was used industrially, including as a good's depot, until the London Borough of Southwark saw possibilities for its development. They emphasised high quality, to be addressed in this project. Initial approval was granted for 270 residential units of a gated community development with no public access. However, Berkeley Homes, the developer, sought to increase the density to 576 mixed-tenure units. Thus, they saw the potential of a new public square and affordable units by giving around 33% of the site to public use. The new public square was a price worth paying for the additional units they got (Carmona and Wunderlich, 2012).The project was completed in 2007 and won the Housing Design Awards and CABE Gold award (Keddie, 2010).

*3.3 Case 2: Bermondsey Square*

The Southwark Council and Igloo Regeneration Partnership worked together to redevelop Bermondsey Square as part of an economic, social, environmental and physical intervention. The vision of Bermondsey is set around a new square that hosts the Bermondsey Antique Market. A farmer's market, exhibition, and community-related outdoor events are being scheduled and held at Bermondsey Square to help increase social interaction and enliven the space. The development is at the end of Bermondsey Street and intersects with the less-gentrified Tower Bridge Road, the outer limit of the city centre. The square is intended by the developer and council to be the heart of Bermondsey (Stewart, 2009).

## 4. Methodology

The methodology of this study is employed to demonstrate and evaluate the study outcomes. Moreover, the study will need to undertake the analysis of social-spatial behaviours in relation to the social value of urban design as a mean. There is several different research methods have been developed and used in this study as one comprehensive methodology. Therefore, the knowledge claim for both case studies from all the methods will provide qualitative and quantitative data as well. There are two different trips have been undertaken in order to obtain data for this study. For both case studies, there are 100 surveys and 33 semi-structured interviews in total conducted with participants at the squares. The participants are occupiers, managing agents, residents and everyday users. All 100 participants have been asked to answer face to face survey takes about five to eight minutes to complete, and 33 participants have been asked to spend 10 minutes of face to face interviews. At the first trip, the data gathered from questionnaires in both sites. It has developed supporting knowledge for the social analysis of the study. The findings of each case are demonstrated in various charts and tables to express a valuable range of knowledge to promote the understanding of the outcomes of the observational and socio-spatial analysis work.

The 33 semi-structured interviews are taking place to eliminate the limitation of some data that occur from the questionnaire in the first trip. The way semi-structure interviews are constructed for this second trip of conducting data is to cope with the lack of understanding regards with the complexity of vitality among some participants in the first trip of data collection. Therefore, the questions of the second trip are set the aim of the study, in a way that can encourage the participants to reveal their opinion directly. At the same time, the primary goal of this interview is not to measure the perception of users but rather recognize the social, spatial value and vitality in a relationship to the urban design.

In addition, many site observations for this study have been taken, in both cases, at different times of the day. The unobtrusive observational approach was used to track human movement, activities, spatial qualities, social interactions and spatial interrelations. The pedestrian traffic movement and static activities such as gathering and meeting are recorded on the basis where individuals sit, meet and move. The outcomes of the site observations will give a comprehensive vision of the movement and the use of each square during different times of the day and reflect the vitality and viability of each square.

This research will be analysed in the comparative analysis approach that aims to minimize the deficiency of research work. It also can generate findings that support and benefit the overall outcome of the research. Therefore, a comparative study is considered to be the ideal approach for such a study due to its understanding of the socio-spatial interrelation and social values (Ragin, 1989). The comparative analysis approach will allow the researcher to assess and evaluate the theories and test the outcomes of the study as well. According to CABE and DETR (2001), place vitality is among the possible indicators, which are identity and civic pride, place vitality, inclusiveness, connectivity, safety and security and amenities and facilities, for assessing the success of the social value that added by urban design through the open public spaces within a new mixed-use development to be spread all over the neighbourhood.

## 5. Empire Square analysis and evaluation

The square connects Long Ln. North with Sterry St. south creating a walking path for local people who are going to their work or reaching their homes. People come mostly to Empire Square individually from 6:00 to 22:00. The majority of people in Empire Square, according to the questionnaire, live either within the development or within ¼ mile from it (Figure 4). Many people stated that they use the square because of its proximity to their home. People who live more than two miles away from the square stated that they visit mainly because they study or work nearby.

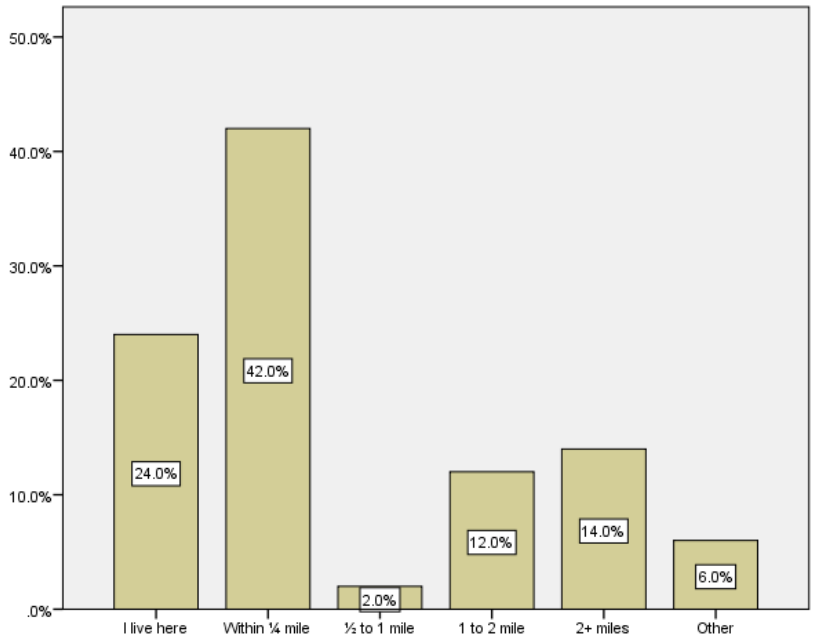

Figure 4. Home Distance from the Square

The majority (46%) of interviewees stated that they were using the Square as a through-route to their destination, while the second most popular purpose was to use the gym (Figure 5). In the winter, people did not come to the square to spend time with friends or relax in the sun; but results indicate that they instead use the square's indoor facilities.

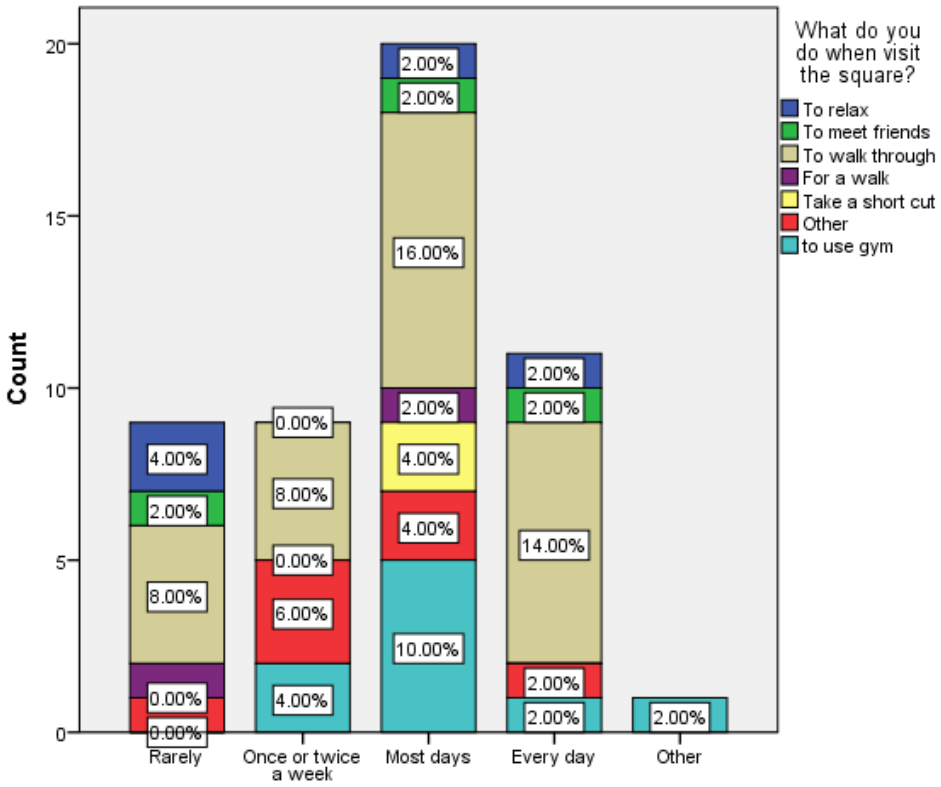

Figure 5. The purpose of visiting the square and how many times

The development itself contains a variety of facilities, including NHS Guy's and St Thomas' Borough Kidney Treatment Centre, CPC Connect Company in the pavilion building in the middle of the square, a small Tesco convenience store, a gym, a nursery, and small commercial offices. With most of these commercial spaces facing onto Long Lane, there are no connections to the square to enliven it. Moreover, the pavilion was originally planned to hold a restaurant, but instead has become an office space (Figure 6). In other words, most of the active use of the development has no relationship with the square.

According to the manager, 'The Square was designed with no public access which was the original intent. However, the council did say I have to have limited public access between the hours of 6:00 to 22:00 and the public can come in and use the area as long as they do it within the confines and rules and regulations of being here.' Most of the interviewees supported this: 'The management of this development try to provide as much privacy as they can, so the square is quiet and empty.'

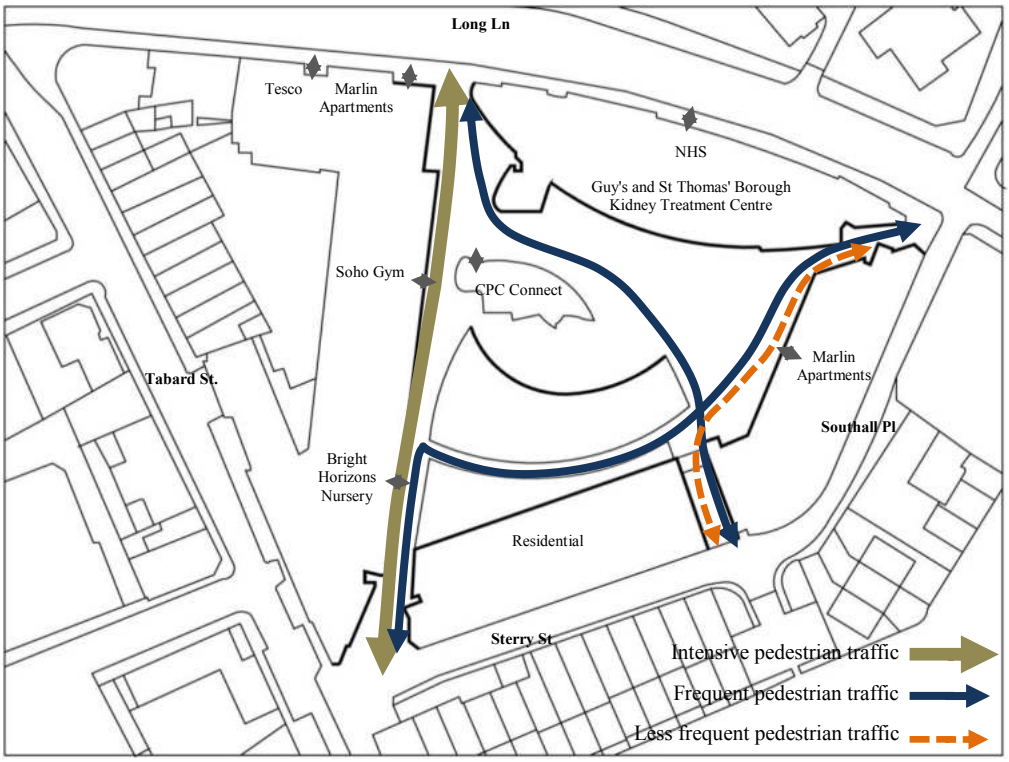

Figure 6. The pedestrian movement of Empire Square

Most of the interviewees pointed to the role of the management in keeping the square quiet for the desire of its inhabitants. A resident stated that 'the management of this development try to provide as much privacy as they can, so the square is quiet and empty'.

Some interviewees commented on the lack of sunlight and high degree of enclosure, while others suggested that the profusion of signs, CCTV, and gates increase safety and security but at the same time limit access by some social groups: 'Seeing sings and CCTV around makes it unwelcome for us [residents]. I think it needs more attractive point for people to come around and stay longer time.' Even though the majority of the development scheme is residential, residents do not constitute a large proportion of square users. This is due to the car park underneath the square and the lack of a playground for children.

There are two aspects of the control of this public space. First, the management needs to keep Empire Square as safe and quiet for residents as possible. The manager of the Marlin Apartment, who is in charge of running this development, said, 'It is a quiet area that non-residents and residents can use. As I said, if we start using any form of noise in there, it is like a gladiator arena. It easily gets noisy, and I start getting complaints. There is no way to expand the grass area.' He also explained, 'the rules are simple rules: no loud noises, no cycling, no litter, and no ball games. It does not say no drinking but if we end up getting large parties sitting on the grass and start getting loud we [as management] would ask them to kindly calm that down because they cannot turn it to loud.' From this point of view, then, limitations prevent local use of Empire Square and reduce its vitality, even though it is clean, well maintained, well lit, safe, accessible, and comfortable to use. According to Nemeth (2009), developers of privately owned, publicly accessible spaces are often financially driven, and this leads to limitations on political, social, and democratic functions of the spaces. In addition, such spaces can directly impact visions of citizenship and representation, which implicates them as new models for urban space provision and management.

The second aspect of control is the for activities from the perspective of a visitor to the square. One participant commented, 'It is a dead area. There is nothing to do here. I do not use this space. It is just a waste of land for us [residents] but for them [developers] it is important to make the development looks fancy.' Empire Square has a substantial basis toward inactive space. As one visitor said, 'The gates seem to be the big issue of this development even for its residents—when they come late at night they have to walk all the way around to get inside.' Therfore, lack of facilities is a main reason people do not visit Empire Square (Figure 7). Although a noisy street runs along one side of the development, the square appears from the outside to be a quiet and isolated place, making people reluctant to visit. People are attracted spontaneously to activities and other people (Gehl, 2010).

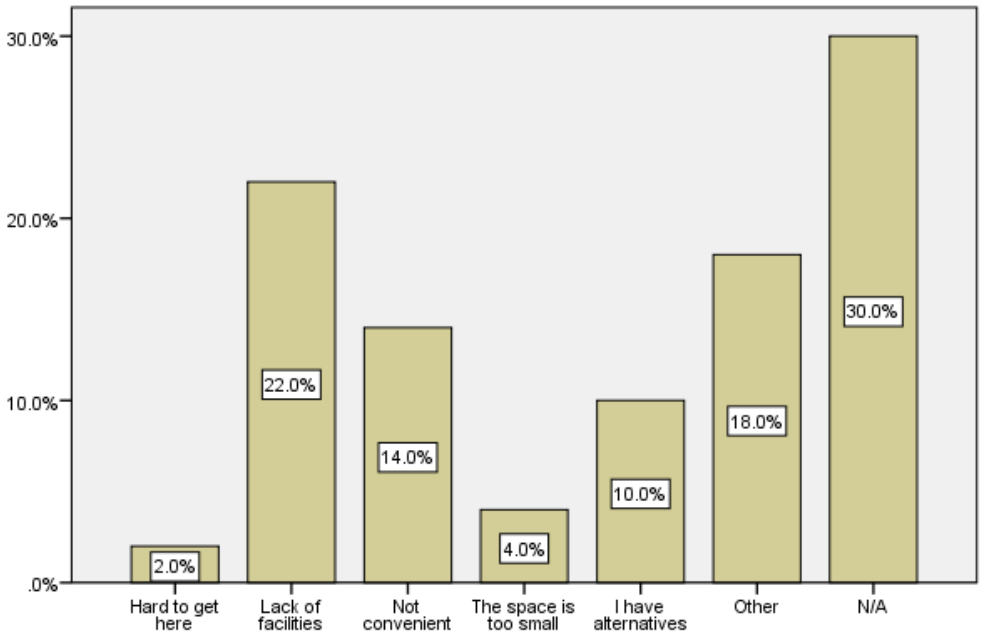

Figure 7. Reasons why people do not visit Empire Square

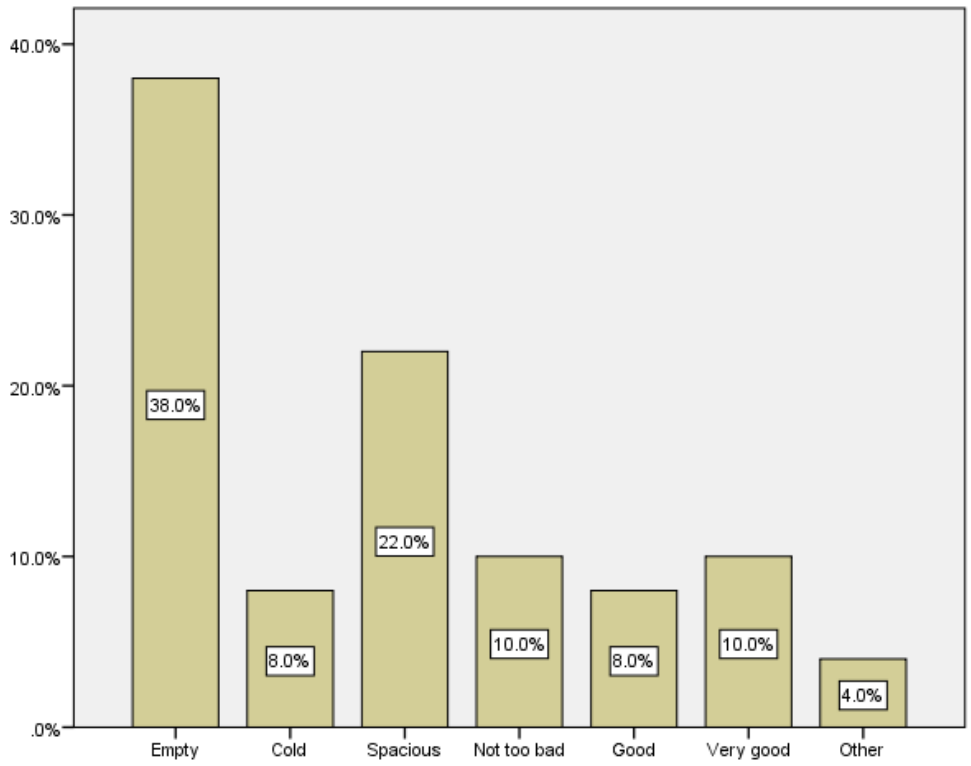

Figure 8. Users' impressions of Empire Square

The predominant impression of Empire Square was that it is empty and spacious (Figure 8). Aside from perhaps a small group of students having lunch or a few workers taking a smoking break, few people linger or walk through. No residents come and go because their flats are accessible from the street or the car park underneath. Attracting people to linger and is not easy; but a lack of activities can make public places seem empty. The square is also underused because its inside edges fail to attract people from the surrounding streets; people tend to be more motivated to walk by a row of shops than a blank wall(PPS, 2013). The land-use of Empire Square therefore has a direct influence on the failure to achieve the desired vision. However, some residents hold the opinion that the square's emptiness is not a bad thing, as it makes for a quieter living area.

## 6. Bermondsey Square analysis and evaluation

Bermondsey Square, the second case study subject, is open to the public both day and night, with major activities taking place during the weekend, such as the Bermondsey Antique Market and a farmer's market. The majority of interviewees live more than 2 miles away from the square (Figure 9), and the most frequent visitors use the square as a throughway to where they work or study .If designed well, however, small urban spaces can be energetic and encourage people to use them (Whyte, 1980).

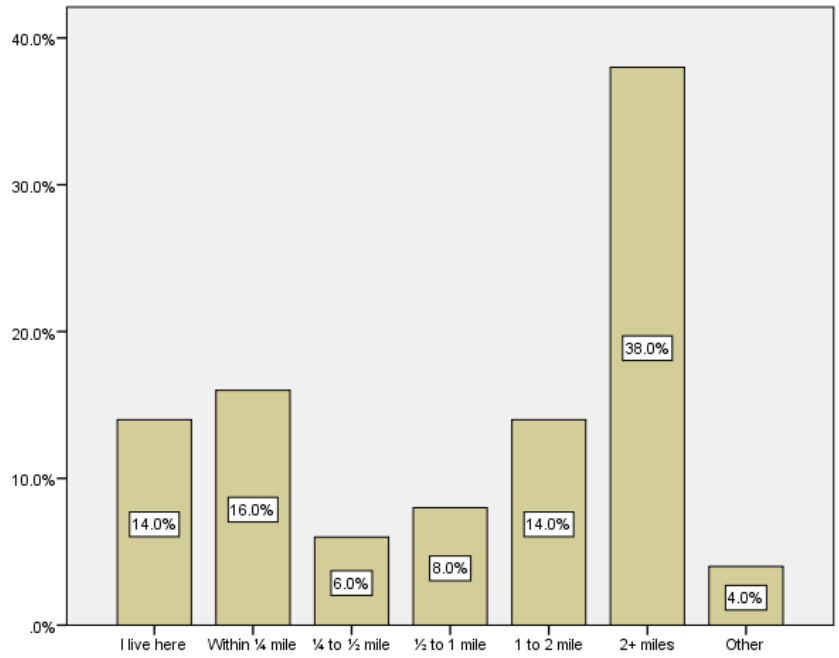

Figure 9. Home distance from Bermondsey Square

The development contains a variety of functions, including a hotel, restaurants, bars, a café, a cinema, markets, and a grocery store. The restaurants and bars attract tourists, while workers prefer the recreational facilities. The restaurant and café add vitality to the square during the week, as their seating areas are often fully occupied in good weather. Most interviewees also pointed to the market and seasonal activities as creating a vibrant atmosphere. According to a seller at the antique market, local patronage is strong: 'I can tell you that 90% of the market costumers are local people. I have worked here in the market for two years, and most of our customers are from these areas around here.' The lack of tourists is possibly due to a large number of nearby attractions that draw them away, such as the Saint Mary Magdalene Churchyard, Tower Bridge, and the Shard. Moreover, many locals see the square's activities as directed toward residents. As one user said, 'The Square with all its amenities serves the residents but local people use it for walking through.' Despite this, the range of offerings was appreciated: 'I think Bermondsey Square is an active place with all the activities and the different atmospheres during the year.' Bermondsey Square has a high degree of openness to the streets, and this can work as a hook to attract people into the square.

From the questionnaire, there are three types of activities that occur in Bermondsey Square. First, there are necessary activities such as walking through and taking short cut using a square for transit that occur mostly on daily basis. Second, there are optional or leisure activities that can take place in the square such as relaxing, going to a restaurant or the cinema. Third, the social activities take place when people meet their friends and interact with each other. The result of these questionnaires indicates that necessary activities do not dominate the use of Bermondsey Square on daily basis. However, leisure activities are the most popular reasons for visiting the square this is especially true at weekends when the antique and farmer's markets occur.

This case study consisted of five elements that structured towards social and perceptual dimensions. These elements are the dominant user type, dominant social group, dominant activities, time of activities and the most vital time of the square during a day. As Bermondsey Square is open to public and is mainly used for relaxation and seating purposes, there are some other activities occur there during a particular time of the year. However, the majority of the space is open to public for the purpose of seating, gathering, and relaxing. The analysis works are undertaken during February,

March and September 2014. From the interviews that had been conducted, many people consider Bermondsey Square to be dependent on activities that occur there and the good weather condition. The availability of seating around the square seems to add significant value to the attachment of the place.

In a very general approach, the sense of vitality of Bermondsey Square depends on the amenities that the square provides for local users as well as the markets that take place during the weekend. One said, 'The Square becomes the centre for the area, and it could be improved but it is definitely the focus of the area. It was being used for various events. In the summer, they have Bermondsey street festival and the Christmas and another time of the year they have evening events.' From the data collected, most interviewees build their understanding of the vitality of the place depending on their previous experiences with activities that happened at the square. The place vitality to most interviewees is related to some conditions that must occur in order to reach the optimum capacity of the space. The dependence of Bermondsey Square on the markets during the weekend increases the vitality of the space and creates an atmosphere that expressed with social values. Not only have the markets at Bermondsey Square emerge as the most significant elements but also it reaches the level of the surrounding context being the core of activities in Bermondsey area. It mentally became the central theme of the image of the place.

The accessibility of Bermondsey Square has an essential basis of vital spaces exists in this place. The degree of openness in Bermondsey Square was designed to provide sight interaction directly with the activities that are taking place in the square itself. This degree of openness to the streets works as a hook that can drag people into the square. Moreover, 86% of interviewees agree that Bermondsey Square is freely accessible, due to its connections to surrounding streets (Figure 10). Bermondsey Square was planned toward increasing social interactions and enlivens the space by providing events and activities for the community in order for the square to be the heart of Bermondsey. A majority (61%) of interviewees thought that the design of the square impacts its vitality

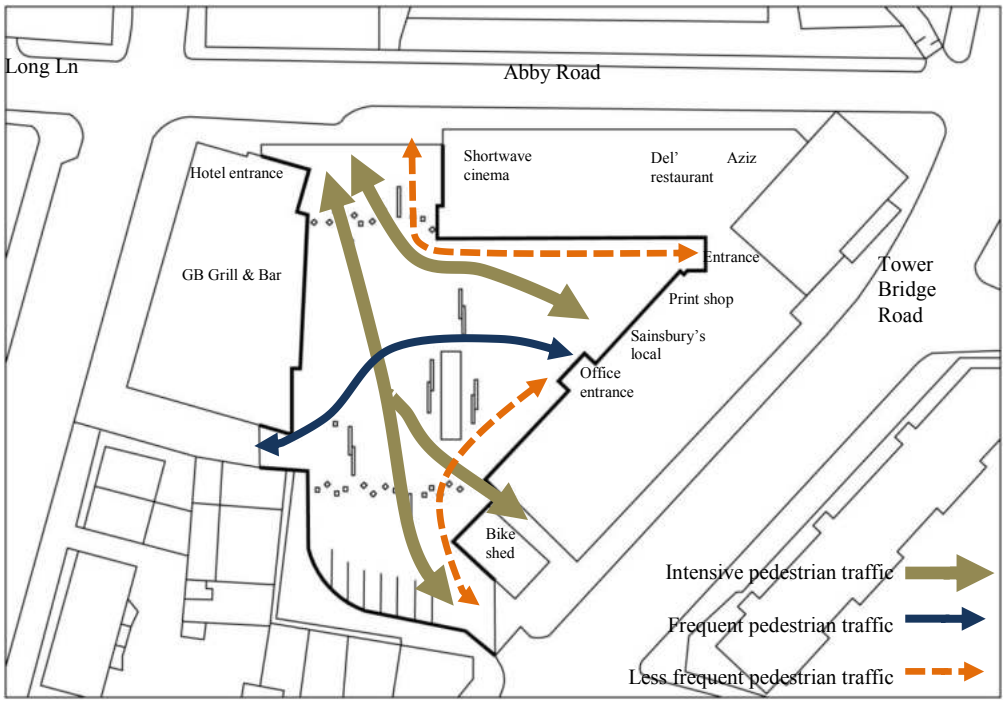

Figure 10. Pedestrian movement study of Bermondsey Square

The amenity as a significant basis of vibrant spaces remains as a key indicator of vitality in this open space. Due to the developer trend and vision of Bermondsey Square, the general quality of space is

sufficient. Moreover, 80% of users agreed that the square improves the supply and quality of amenities in the local context, a key indicator of vitality.

## 7. Discussion

The new creation of space at Bermondsey Square and Empire Square has indicated vitality as a common attribute of both places in particular ways. However, the central question to be asked here is whether they are similarity animated in term of feeling and essence. The comparison of these two sites explains how they work according to the effect of management of both public spaces while considering the current policy directions. The Selection of the two cases is regard to their similarity in term of the region, size, population, climatic and culture context. There is a complex set of elements works towards producing social components in these two spaces. Besides the physical form and environment of Empire Square and Bermondsey Square, there are some other social concerns. The comparison of both Squares was carried out while aiming at the following factors: user types, social groups, activities and social interactions, and the time of activities in the open space.

The most significant difference is the vitality in Empire Square is brought by residents from the surrounding area to the mixed-use development. Meanwhile in the case of Bermondsey Square, residents, office workers and tourists' presence is the main reason of the vitality in this site. The dominant user groups in the case of Empire Square are local people from the surrounding area whereas diverse users include families, and friends groups are noticeable in Bermondsey Square. Users in Empire Square tend not to engage with others in the space daily since they are mostly just walking through to their destinations. In Bermondsey Square, the ordinary way of use and regular engagement of users play a useful role in making the social atmosphere friendly. It is distinguished that users' attention in Bermondsey Square is more towards socialising rather than exploring the surrounding environment. The social interactions are entirely different from that in Empire Square.

The short cut between Steery St. and Long Ln at Empire Square works like a magnet that attracts local users to walk along this path that considered being the main activities in this case. The image of activities in Bermondsey Square mixed with the image of users who are using the seating areas outside the café and restaurants. Sitting at the café and restaurants is more noticeable than shopping from the Sainsbury's store in Bermondsey Square. The time and duration of users' presence and activities are not similar between the two squares. Empire Square is active from early morning about 6:00 in the morning when the gates are open until 20:00 when the gates are closed. The most vital time is from late morning until evening time when most users come to Soho Gym and walk back home coming from work. In Bermondsey Square, the place is alive from early morning especially when the market is taking place at the square until about 23:00 while the bars, restaurants and Sainsbury's store are still open. The most vital times at Bermondsey Square is early morning and evening.

Table 3. The similarities and differences between the two places

| The Factor of comparison | Empire Square | Bermondsey Square |
|---|---|---|
| Dominant user type | Residents | Residents, office workers & tourists |
| Dominant social group | Friends groups | Friends groups & families |
| Dominant activities | Walking through & using the gym | Walking through & shopping |
| Time of activities | From early morning to evening | From early morning to late night |
| The most vital time of the square during a day | Late morning & evening | Early morning & evening |

The social value of urban public spaces is a key factor in the cities due to its close relation to people needs from the very basic level to the complex. Since public spaces can affect people's quality of life, one role of the public spaces is that affording activities. If public spaces fail to provide these activities, parts of the society will be moved out of the public realm. The attention toward social value has been increased as a result of the adverse effects of the visual–artistic trends in urban design and a focus on the requirements of vehicles rather than pedestrians. In this context, a comprehensive review of different tactics and aspects in urban public space was found important to uncover that social value has a deep connection with the encouragement provided to residents. Encouragements are provided by places and buildings to interact in ways that lead to trust, shared understanding, shared values and supportive behaviours among society. Social value emerges when people have common interests that can join them with others. The social value of public space depends on the input that can be provided to people in term of increasing people's attachment to their local life, interacting face to face with others and people's memories of sites. Streets and markets that reflected hard spaces are extremely beneficial to many people as green spaces such as parks(Cattell et al., 2006). Therefore, Social value can be a part the urban identity where these social behaviours are controlled by the design of these public spaces or developed along with it.

The analysis of Empire Square and Bermondsey Square in London indicate how they socially work. Empire Square is vital at certain times due to the presence of local users when using the square as a path to their destination early morning and when coming back from their work, while local users, office workers and tourists are the primary users that make Bermondsey Square dynamic place. Therefore, Bermondsey Square is better than Empire square according to the data gathered due to activities and opportunities that the square provide to its users. People stay and spend much time in Bermondsey Square more than Empire Square. Bermondsey Square provides more opportunities for groups to hold their activities there. Also, it seems more open, and the degree of openness is higher than Empire Square that seems isolated from residential buildings. The greater degree of openness and accessibility in Bermondsey Square is representing more interaction with busy streets around with creating a dynamic space. Bermondsey Square wins the multiple uses of space while Empire Square considered as an attractive design for much of participants in this study. It is important to work toward the use value more than the aesthetic value in order to increase the enjoyment of occupiers and attract more people to a place in order to create a vital place. Most of the participants agree that Bermondsey Square is active and livable place comparing to Empire Square. The design plays a useful role in Bermondsey Square to increase the vitality of it.

## 8. Conclusion

In conclusion, vital spaces do not have the exact reasons or work in similar procedures. Therefore, some public spaces considered to be neat, clean and empty while some other can be vital as a result of different basis that produce different feeling in the space. It is notable that vitality is an essential component for healthier and safer spaces where people tend to interact socially with each other and spend a long period in public. However, empty urban public spaces indicate that something is not right with its design, its management or perhaps both. People attract other people but still planners, and architects seem to find that mysterious. It is easy to realise that busy streets have both users and crowd watchers (Jacobs, 1961). Yet, the presence of people should not be only for the commercialized functions but must be supported by well-designed spaces and facilities that enable them to sit and spend more time in public without necessary purchasing food or drink to have a reason for their presence. The outcomes of this research suggested that vitality add value by increasing the vitality of space and delivering social benefits. The findings of this paper are leading toward future researchs such as exploring the reasons for the mixed- use development residents' absence and the lack of users from the local area in Empire Square. It would help having balanced public space for all different groups of their society. Moreover, this future research should focus on assessment of urban public

spaces in view of both the social and physical dimensions. According to the most recent trend in urban design that is place making, the research can provide responses to the current condition of these spaces as a result of this sequence.

# TOWARDS GUIDELINES FOR SOUNDSCAPE DESIGN

Östen Axelsson

Department of Psychology (Stockholm University), oan@psychology.su.se

*Architects and urban planners request guidelines with regards to soundscape design. In 2013 staff and students at the University of Sheffield, UK, were invited to take part in an electronic survey to investigate what kinds of urban open spaces that they prefer, and how these spaces should be designed with regards to soundscape. Respondents were asked to freely name their favourite outdoor place in Sheffield, and to what extent they found a list of 45 social and recreational activities, as well as a list of 40 sound sources appropriate for this place. A total of 935 individuals completed the questionnaire. A hierarchical cluster analysis of the 45 social and recreational activities revealed three main categories of favourite outdoor places: 'Urban Park', 'City Centre', and 'My Space'. For 'Urban Park' natural sounds were appropriate when clearly audible, sounds of individuals when moderately audible, sounds of crowds when slightly audible, and technological sounds when inaudible. For 'City Centre' sounds of individuals were appropriate when moderately audible, whereas natural sounds, and sounds of crowds were appropriate when slightly audible. Technological sounds were appropriate when inaudible. For 'My Space' natural sounds and sounds of individuals were appropriate when moderately audible, whereas sounds of crowds and technological sounds were appropriate when inaudible. This kinds of profiles may serve as design guidelines for urban outdoor spaces with regards to soundscape, based on their social and recreational purposes.*

Keywords: soundscape, urban design, guidelines

## 1. Introduction

In 2010 I organised the international conference *Designing Soundscape for Sustainable Urban Development* in Stockholm, Sweden (Axelsson, 2011). The purpose was to introduce soundscape to architects and urban planners, and to discuss how soundscape may be implemented in these creative disciplines. A number of internationally renowned architects and planners were invited to present their thoughts on soundscape. Still, in the final panel discussion and in the evaluation of the conference, participants requested further information on how to approach soundscape in practice. To bring this work forward, I organised a special session on soundscape at the annual conference of the Association of European Schools of Planning (AESOP) in Ankara, Turkey, 2012. Also here, participants in the session requested further practical guidance on how to approach soundscape. A specific request concerned soundscape design guidelines. The present paper is an attempt to meet this need.

The environmental planner Lex Brown, Griffith University, Brisbane, Australia, has argued that soundscape quality is a matter of the match between the soundscape and a place, and particularly whether the soundscape enables desired activities (e.g., Brown & Muhar, 2004). This notion was one of my inspirations when I, in collaboration with the Noise Abatement Society, tried to map the soundscape of urban outdoor areas in Brighton & Hove, UK, in 2011, in order to develop an applied soundscape strategy for the city (Lavia, Axelsson & Dixon, 2012). Another source of inspiration was the Sociotope Mapping that the City of Stockholm developed in the early 2000s in order to better understand the human scale of urban outdoor space (Ståhle, 2002, 2003, 2006). Sociotope Mapping involves investigating what social and recreational values the citizens associate with specific places. This knowledge is used to avoid goal conflicts in the planning process.

In order to map the soundscape of urban outdoor areas in Brighton & Hove, I and the Noise Abatement Society developed an on-line questionnaire. It was circulated to local interest groups with support from the Brighton & Hove City Council. Among other things the questionnaire asked the respondents to name their favourite outdoor place in Brighton & Hove, and to assess to what extent a list of 27 social and recreational activities would be appropriate for this place. The respondents were also asked to assess to what extent a list of 29 sound sources would be appropriate in their favourite place (Lavia, Axelsson & Dixon, 2012). This is a similar approach as used when Sociotope Mapping was introduced in Stockholm.

In total, 354 individuals, 15 years or older, completed the soundscape questionnaire in Brighton & Hove. Using hierarchical cluster analysis, 5 categories of favourite outdoor places, as well as 5 categories of soundscapes, were identified. A Chi Square analysis showed that there was a statistically significant and meaningful relationship between the 5 categories of favourite outdoor places and the 5 categories of soundscapes.

A similar approach as used in Brighton & Hove would be useful for creating soundscape design guidelines, by focusing on categories of favourite outdoor places and what sounds would be appropriate there. In the present paper I present a study conducted in Sheffield, UK, in 2013, in which I used an improved version of the questionnaire used in Brighton & Hove.

## 2. Method

### *2.1 Participants*

Staff and students at the University of Sheffield were invited to take part in the study through the established email lists for staff and student volunteers. A total of 1,437 persons began the questionnaire, while 935 (65 %) completed it. Among the 935 persons who completed the questionnaire 598 were females and 337 were males; 529 were aged 15–34 yrs, 389 aged 35–64 yrs, and the remaining 17 were 65 yrs or older. With regards to occupation, 530 were employed or self-employed, 379 were students, the remaining 26 were retired, unemployed, long-term sick, or on leave. Although the participants virtually lived all across Sheffield, areas close to the University of Sheffield were clearly over represented.

### *2.2 Questionnaire*

The online questionnaire was an improved version of the questionnaire used in Brighton & Hove in 2011. It consisted of four sections. Section 1 concerned demographic data, such as the postcode of the area where the respondents lived, gender, age, as well as occupation. To allow respondents the opportunity to register complaints about noise, Section 2 concerned noise annoyance. It was based on the ISO/TS 15666 question with verbal rating scale (ISO, 2003), with the amendment that the response category ‘Not at all’ was divided into the two response categories ‘Not at all (don’t hear it)’ and ‘Not at all (hear it but not bothered by it)’. Section 2 also included a few questions on sensitivity to sound. In Section 3 the respondents were asked to name their favourite outdoor place in Sheffield, and to indicate to what degree a list of 45 social and recreational activities would be suitable in this place (5-point category scale: ‘Not at all/not applicable’, ‘Slightly’, ‘Moderately’, ‘Very’, ‘Perfectly’). In Section 4 the respondents were asked to indicate to what degree a list of 40 sound sources would be appropriate in the favourite place (5-point category scale: ‘Not audible’, ‘Slightly audible’, ‘Moderately audible’, ‘Clearly audible’, ‘Completely dominant’). The two lists of social and recreational activities, and sound sources were extended based on open-ended responses obtained in Brighton & Hove in 2011.

## 3. Results

*3.1 Favourite outdoor places*

The 45 variables of social and recreational activities were subjected to a hierarchical cluster analysis, using Squared Euclidean Distances and the Furthest Neighbour (Complete Linkage) algorithm (SPSS 22 for Windows). The improvement of the agglomeration coefficients suggested that it would be reasonable to select 3, 5 or 7 clusters of favourite outdoor places in Sheffield. Cross Tabulation of the three different cluster solutions against the name of the favourite outdoor places showed that the 3-clusters solution provided enough detailed information.

Cluster 1 was named 'Urban Park'. This is the sort of place where people go to enjoy the surroundings, to hang out with friends and family, go for a walk, let the children play, or to play informal games, like Frisbee or Rounders, or to have a picnic or a barbeque.

Cluster 2 was named 'City Centre'. This is where people go to enjoy active street-life together with their friend. The 5 and 7-clusters solutions suggested that Cluster 2 in the 3-clusters solution could be split into two sub-clusters: one representing areas for outdoor dining, like a sitting out area of a restaurant or a pub, and one representing enjoying active street life and shopping. However, these two potential sub-clusters were only a matter of the degree to which certain city centre activities were given priority. In the first of the two potential sub-clusters, people gave priority to having something to eat or drink together with their friends, whereas in the other people gave priority to experiencing active street life. Thus, Cluster 2 in the 3-clusters solution represents a combination of these two potential sub-clusters.

Table 1. The five sound-source variables most strongly associated with each of the four variamax rotated components.

| **Technological Sounds** | **Natural Sounds** | **Sounds of Individuals** | **Sounds of Crowds** |
|---|---|---|---|
| Construction | Rustling leaves | People talking | Buskers |
| Industry | Insects | People enjoying themselves | Outdoor events |
| Waste collection | Birdsong | People calling out | Non amplified music |
| Sirens/alarms | Wind | Children at paly | Amplified music/ announcements |
| Ventilation | Wildlife | People walking | Sporting events |

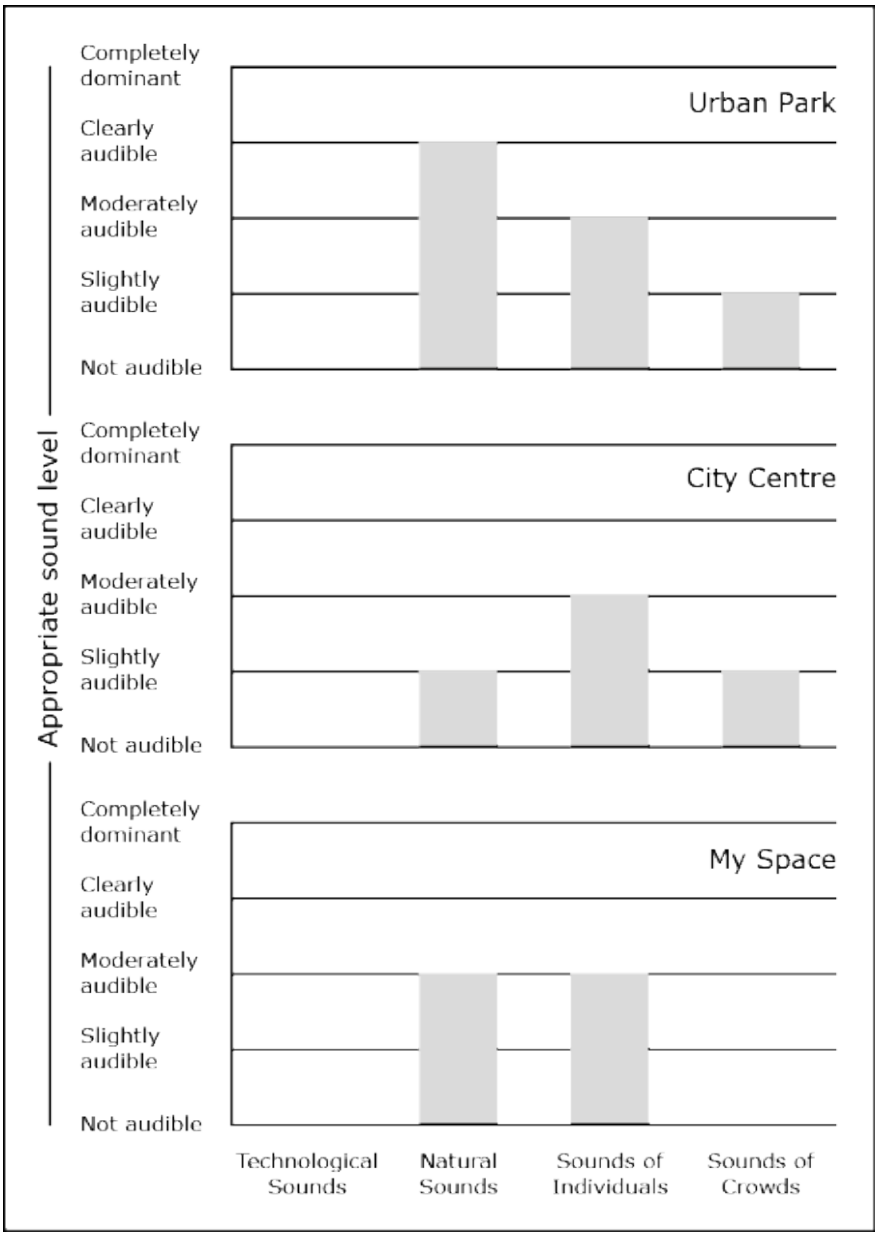

Figure 1. Soundscape profiles of 'Urban Park, 'City Centre' and 'My Space'.

Cluster 3 was named 'My Space'. This is where people go to withdraw from crowded areas and to escape the city stress. A typical place in this category was 'My own garden' or 'My allotment'. In Sheffield 'My Space' could also be found in one of the city's many parks or green areas, or the Peak District National Park.

*3.2 Sound source components*

Because it was impractical to work with 40 variables of sound sources, it was decided to reduce them by the aid of a Principal Components Analysis. Using the matrix of Pearson correlation coefficients, and Eigenvalues larger than 1.0 as criteria, it turned out that there was a small number of deviant

sound-source variables in the set of data, creating a rather indistinct set of principal components. After removing five such sound-source variables, the analysis resulted in four clear varimax rotated components. They explained 26.4, 17.2, 6.2 and 4.1 % of the variance (53.9 % in total). The four varimax rotated component were named 'Technological Sounds', 'Natural Sounds', 'Sounds of Individuals', and 'Sounds of Crowds' (see Table 1).

*3.3 Soundscape profiles*

Soundscape profiles were created for each of the 3 clusters of favourite outdoor places. For the four varimax rotated components of sound sources, the five sound-source variables with the strongest association with each component were selected to form indices, based on their median values. Table 1 presents these five sound-source variables for each of the four variamax rotated components. Figure 1 presents the soundscape profiles for each of the three clusters of favourite outdoor places. The values on the Y-axes are median values calculated across the five sound-source variables for each of the four variamax rotated components, representing appropriate sound levels.

Figure 1 shows that the appropriateness of natural sounds varied with the type of place. For 'Urban Park' natural sounds were appropriate when clearly audible, whereas for 'My Space' they were appropriate when moderately audible, and for 'City Centre' when slightly audible. The sounds of individuals were appropriate at a moderate level in all three sorts of places, while the sounds of crowds were appropriate when slightly audible, except for 'My Space' where the sounds of crowds were unacceptable. Technological sounds were unwelcome in all of the three types of places, also in the city centre of Sheffield.

## 4. Discussion

Architects and urban planners are requesting guidelines to soundscape design. In the present paper I propose an approach involving defining a place based on its social and recreational values, and identifying what sounds are appropriate in the place and to what extent. In the present case I conducted an electronic survey among staff and students at University of Sheffield in the UK, asking them to name their favourite outdoor place in Sheffield. They were also asked to assess to what extent a list of 45 social and recreational activities, as well as a list of 40 sound sources would be appropriate in their favourite place. Through a cluster analysis of the list of 45 social and recreational activities, I identified three types of places, named 'Urban Park', 'City Centre', and 'My Space'. For each of the three types of places I created soundscape profiles based on the list of 40 sound sources.

The three soundscape profiles presented in Figure 1 may serve as soundscape design criteria for these sort of places in Sheffield. For example, the top panel in Figure 1 suggests that if the City of Sheffield would like to create a new urban park, it should aim to create a lush, green space that promotes the sound of nature, including wind in vegetation and singing birds. The park should be located at a safe distance from surrounding roads and industrial areas to avoid technological sounds. The park must allow individual human activities, like walking, jogging, informal games, picnic and barbeque, without forming large crowds of people.

A potential limitation in the present approach to soundscape design is that it is based on human memory and imagination. An alternative would be to invite people to a laboratory where the soundscapes can be reproduced or simulated. The participants could then either assess reproduced soundscapes or create their own ideal soundscapes. Soundscape design guidelines based on such experiments might be more detailed.

In the present study the participants expressed that technological sounds are unacceptable in any place, but what does this actually mean. Would there be a sound level at which, for example, road traffic is acceptable although it may be heard in the background?

In a study in Stockholm it was found that 80 % of the visitors in parks and green areas rated the soundscape as 'Good' or 'Very good' when the sound levels from road traffic was at or below 50 dB(A) (Nilsson, 2007). Probably such a sound level cannot be considered as equal to 'Not audible', but to correspond to 'Slightly audible'. So, perhaps, in reality, people would accept another sound level than what they would imagine. Possibly the appropriate sound levels could be identified more accurately in a laboratory study. On the other hand, it would be laborious and impractical to survey a whole city with this method.

Another potential limitation in the present approach is that it relates to a general and overall scale, giving the impression that all areas under 'Urban Park' should be the same throughout. This is probably not the case. It is more likely that a large urban open space should provide a diversity of social and recreational activities, and corresponding soundscapes. For example, among the 149 participants who mention the Sheffield Botanical Gardens as their favourite place, 76 responses fell in the category 'My Space', 60 in 'Urban Park' and the remaining 13 in 'City Centre'. Thus, the present approach to soundscape design provides us with rules of thumb, not detailed roadmaps to every destination.

A specific limitation with the present study is that it only concerns Sheffield in the UK, and mainly involved staff and students at the University of Sheffield. The results must not be generalised to any other city, not even within the UK. More studies of this kind are needed to learn how this approach to soundscape design may be implemented in practice. In particular it would be interesting to conduct a survey with a representative sample of the population in a city.

## 4. Acknowledgments

This research was conducted while the author was a Newton International Fellow at the School of Architecture, University of Sheffield, in the UK. The fellowship was sponsored jointly by The Royal Society and British Academy. Professor Jian Kang was the host of the fellowship in Sheffield. The author also acknowledges the Marianne and Marcus Wallenberg Foundation.

# CAUGHT BETWEEN FAUST AND FAUX: DEVELOPMENT AND CITY DESIGN [*]

Tridib Banerjee

Los Angeles, CA, USA

Abstract

This paper considers the challenges of contemporary urban design in the developing world -- China in particular, but "Asia" more generally – in the face of rapid economic growth and explosive urbanization. This extraordinary growth led by the deliberate state policy in collusion with local and global capital has provoked many scholarly ruminations. Editors of a recent book celebrate "the urban dreams, projects, and practices" as a "worlding" phenomenon that eludes the conventional frames of political economy or postcolonialism. But the urban outcome and "dreams" of this rapid development -- "Faustian" in scope -- is neither authentic nor sustainable. The absence of authenticity and sustainability is reflected in what one critic describes as the "original copies" in discussing the rise of simulacrum and simulacrascape in China. This paper argues however that mimesis, not unique to China, is inevitable, in the absence of genuine endogenous response as the exigencies of global capital leaves little time for reflection and deliberation. The paper concludes by making a case for an urban design manifesto for China, and the global south more generally based on considerations of cultural continuity, livability, social justice, and sustainability.

I write this essay from an outsider's perspective on the breathtaking urban growth and transformation that are currently underway in China, and what I consider are the concomitant challenges for urban design.[1] I will begin by discussing what I consider the two major challenges for urban design in China: (1) the momentum of growth and development, which I call the Faustian imperatives for urban transformation; and (2) emergence of the faux, or "Original Copies: Architectural Mimicry in Contemporary China" – as the title of a recent book by Bianca Bosker suggests.[2] I will conclude by suggesting how the Chinese urban designers might address these challenges, and thus making a case for an "urban design manifesto" for China.

[*]AUTHORS' NOTE: An earlier version of this paper was published in Chines. See . Tridib Banerjee "From Faust to Faux: Concomitant Challenges for Urban Design In China" (translated in Chinese by Wan Li and Yang Yuzhen) ***New Architecture.*** 06:126-130.

(1). The Faustian Imperative of Development:

Currently the media is full of stories about China's stunning economic growth –7.8 percent in the third quarter of 2013, and a projected 7.5 percent by the end of the We read stories about China's rise as a "global factory," its voracious appetite for energy, its dominant contribution to global warming, economic impacts of its export on domestic markets and jobs in other countries, its "colonization" of primary resource producing countries in Asia and Africa, its domestic income inequality and rural poverty, a steadily growing consumer economy, the growth of its cities and corresponding investment in infrastructure and architecture, and so on.

While occasionally these stories are critical, more often than not they are adulatory, or at best one of deference and awe both in the media and professional circles. In publications on finance, technology, engineering, architecture and real estate such obsequious stories abound. In architecture trade magazines and glossy coffee table publications homage is paid regularly to China's modern structures and infrastructure, the emerging skylines of its cities, and its growing collection of "signature architecture" produced by world-renowned architects and firms. Today not just China, but also other "emerging markets" – as the recently prospering developing countries are fondly referred to in international finance and business circles – have created a new sandbox for Western architects to play out their aspirations, fantasies, and imaginations under the indulgent auspices of an authoritarian state and global capital. It will be recalled that in the immediate post-colonial years when the craze for new capital and new town development provided opportunities for the frustrated visionaries whose ideas were never fully accepted, indeed ridiculed in the West, to see their megalomaniac fantasies take shape in the desperate and helpless terrains of the decolonized world. The new global economy and the powerful authoritarian states have again created opportunities for such architectural fantasies to be built in the deserts of Saudi Arabia and the Emirates, or in the coastal plains of China. These projects have become the driving images of development today.

In a recent article critiquing contemporary urban development of China, Daniel Abramson aptly invokes the legacies of Hausmann and Corbusier as the defining characteristics of the transformation of the Chinese cities.[3] But the names of neither Hausmann nor Corbusier necessarily symbolize the driving force behind these changes rather it is the Chinese, or earlier, the Saudi state that drives this change. To define the role of an authoritarian state in urban transformation and development in the contemporary project of modernization, it is apropos to consider the work of Marshall Berman. [4]

Although Berman's work predated the fantastic changes in the developing world we are observing today and was mainly retrospective of the nineteenth and twentieth century urbanism of the Western world, his treatise on "the experience of modernity" is still relevant today. In his treatise on the experience of modernity that combines a Marxist vision of modernism with a more humanistic interpretation of modernity drawn from Baudelaire and contemporary literary writings – the Faustian metaphor, especially that of

Goethe's "Faust as a Developer" – is of immediate interest to us. This metaphor remains an important trope in the way Berman subsequently describes the modern transformation of cities and the human consequences of the passage from tradition to modernity.

Of the many versions of the story of Faust told over some 400 years, Berman found Goethe's rendition of Faust most appealing because of the imperative of development intrinsic to this Faust' desire for change. "The vital force that animates Goethe's *Faust,*" writes Berman, "...is an impulse that I will call the desire for *development*." (p. 39) What appeals to Berman about Goethe's interpretation is the "affinity between the cultural ideal of self-development and the real social movement toward *economic* development."(p. 40) In other words the transition to modernity can be achieved only through the parallel development of the individual and the larger society, a very republican idea that is embedded in many of the contemporary development theories.

According to Berman, Faust emerges as "the Developer" with his own imperative for rearranging the world by dismantling the traditional order and creating the modern world. During this phase Faust transforms the impetus for self-development to the development of the entire society and the physical environment. His visions are no longer in the realm of dreams and fantasies, but that of concrete projects and plans. Faust is not just a developer but also a planner. In Berman's (1982) words:

> "He outlines great reclamation projects to harness the sea for human purposes: man-made harbors and canals that can move ships full of goods and men; dams for large-scale irrigation; green fields and forests, pastures and gardens, a vast and intensive agriculture; waterpower to attract and support emerging industries; thriving settlements, new towns and cities to come – and all this to be created out of a barren wasteland where human beings have never dared to live." (p. 62)

But development requires -- in modern terms -- capital, labor, and power. But where and how would Faust obtain such resources? Berman thought that this is an area that necessarily involves politics if not political economic explanation, which Goethe muddled through because of his uneasiness with the unavoidable political implications.

If Goethe's Faust is a developer, and development is an intrinsic experience of modernity, who then is Faust and who is Mephistopheles in the contemporary development experience? The answer may not be immediately obvious. Berman places the "desire for *development*" (p. 39) squarely in the imperatives of capitalism that requires growth, innovation, and change. But there is also an implicit notion of agency here, which Berman defines further when he expresses his own despair and disbelief in the way large scale public works projects – the Cross-Bronx expressway to be specific -- under the leadership of Robert Moses demolished the core of the Borough of Bronx where he grew up. The tableaux of New York in the middle of the last century, according to Berman, have been "an image of modern ruin and devastation" (p.290). Berman does not invoke Faust here, nor does he suggest Robert Moses as the twentieth century proxy for Faust, just as it would have been inappropriate to think of Hausmann as the Faust of the late nineteenth century Paris. Yet the Faustian imperative of change and growth that is manifested in the routine clearance and renewal of urban spaces, it can be argued, is

deeply embedded in the experience of modernity. The principal agencies of change lie in the authority of the state and in the capitalist economies, and some would argue, are intrinsic to the capitalist mode of production. Indeed contemporary theories of the political economy of urban growth have variously characterized the nexus between the state and capital as the "growth machine," [5](Molotch, 1976), the "state apparatus"[6] (Clark and Dear, 1984), and the "urbanization of capital" (Harvey, 1985).[7]

Some of the recent writings on the urban outcomes of globalization are beginning to capture the dynamics of development.[8] Particularly worth noting is William Site's account of the contemporary changes in New York, a sequel to Berman's account some fifty years later.[9] Rather aptly Sites describes the dynamics of redevelopment in midtown and lower Manhattan during the last two decades as "primitive globalization" which he defines as the process where "certain states, neither circumvented by globalization nor resistant to it, instead, actively facilitate globalization through the use of state power in highly destructive or "disintegrative' ways" (p. 2). The concept of "primitive globalization" captures the essence of what I have called the Faustian imperative, and also helps to locate Faust as the symbol of state power, and Mephistopheles – if we want to pursue the metaphor – as the icon of global capital.

We should note that the Faustian metaphor may not fully capture the contemporary drive for development captured by the notion of "primitive globalization." Goethe's rendition of Faust as a developer was not seriously challenged by the notion of a world that was fragmented, differentiated, and specialized in numerous nation states, many of which were controlled by megalomaniac state authorities. Faust's world was a uniform and homogenous plane where the identities of city, country, nation, and beyond were conflated into a seamless space of continuity and tradition to be re-formed by imperatives of modernity and its inherent "desires of development." In this undifferentiated landscape there was no competition between nations, nor any ranking of nation states by power and wealth. But in today's world, nations and cities are in competition with each other, all vying for global capital and "foreign direct investment" (or FDI). Today there may be many Fausts competing for the attention and favor of one Mephistopheles: global capital. A country like China, it seems is in a race with time and itself, to reach the number one ranking as quickly as possible. Indeed a recent forecast by Goldman Sachs reported in *The Economist* (2007) shows China surpassing the United States in GDP by 2025, and just about doubling the US GDP by 2050.[10]

Recent events in China has shown that the provincial and local states of very large cities have taken on a life of their own, in competition with each other, often in defiance of the nation state. The Chinese State has now bred many sub-national state authorities that are all being driven by the same Faustian drive as the nation state. They are all competing with each other building, iconic monuments, exuberantly dominating city hall (to the point that the national government was compelled to put a ban on such extravagant public buildings, as reported in a recent story published in *The Economist*). Examples abound as documented by Tom Campanella in his book entitled "The Concrete Dragon".[11] It is within this frame of reference we examine the Faustian imperatives that are driving the

unprecedented transformation of not only just China, but a number of emerging economies, albeit at lesser pace, and of smaller scope.

(2) Obsession with the Ersatz

In his book Tom Campanella provides a rather rich narrative of the scale and pace of the Faustian development, drawing mainly from the thirty-plus year history of Shenzhen, from a coastal village to a booming metropolis of 15 million, today a ranking member of the Chinese urban hierarchy. Interspersed with the story of China's Faustian development, are the stories of China's obsession with the "faux" or the ersatz landscapes of new development that often, in fact typically, copy in, out of, or miniaturized scale, built forms of the West. These simulacra often include important public buildings to luxury residential palaces of the *nouveau riche*. This may include new luxury housing or new landscapes of mass consumption – amusement parks and shopping malls. Indeed the simulacra are not limited to single buildings or complexes but may comprise large urban districts or even townships. The nine new satellite towns under construction – each on a particular European country theme – are such examples. Bosker refers to them as the "simulacrascape." The following table includes a list of such ersatz or faux elements of the emerging Chinese simulacrascapes described by Campanella and Bosker with illustrations (not included here).l

In exploring the motivation of the faux, the ersatz, and the phantasmagoria it is important to note several points. First, as Campanella's and Bosker's discussion of the broader phenomenon and illustrations suggest, they are not all strictly examples of simulacra or even simulacrascapes. Some of them are inspired by a particular style or period architecture and urban form, usually of Western origin. Second, not all are copies of the Western form, a few are simulacra of native landscape and cityscapes. Third, some are inspirational copies of the ersatz, like Disneyscape, or are examples of what Umberto Eco would call "hyperreality." Finally, this is not a Chinese obsession only, Other countries, not just the developing world, but the developed world also, are also engaged in the production of such ersatz space. It will be incorrect to assume that the obsession with the faux (generically speaking) is cultural trait of the Chinese, or the Indian, or the Indonesian. Americans and Europeans are not above seeking such ersatz experiences in the cityscape. Recall that Umberto Eco's "travels in hyper-reality" was inspired by the faux and kitschy urban outcome of the economy of conspicuous consumption in the United States. If all this are an example of "consumer sovereignty" in urban design,[12] examples abound in the US as in many different parts of the world. Thus Venice, California was an ersatz copy of Venice, Italy. Now there is Venezia in the Las Vegas Strip, a casino hotel of simulacrascape of the original Venice. Then there is Paris, New York New York, the Luxor, and many other such faux environments of consumption and entertainment on the Strip. While Disneyland in California created a simulacrum of a New Orleans town square, and a seven-eighth scale simulacrascape of a generic Main Street to create a subtle "Gulliver effect", its east coast counterpart Disney World created a simulacrascape of the Hollywood of the earlier part of the last century complete with traffic signals, art deco facades, gas stations and drive-ins. Indeed the simulacarscape of

[Key: HR: hyperreality; S: simulacrum; SS:simulacrascape; DS: Disneyscape]

"invented streets"[13] of the new open air shopping malls are presumably inspired by some referent urban form, if not the urbanism of such places. Thus invented streets in Los Angels like CityWalk in the Universal City (which represents, according to architect Jon Jerde, "the quintessential Los Angeles"), or "The Grove" in the mid-Wilshire district, or "Americana" in Glendale. According to the developer Ric Caruso, consultants from Disney designed some of the details of the street furniture, streetcar and the like. Thus "The Grove" may have been a simulacrum of a simulacrascape.

In Europe there is a record of creating simulacrascape based on architecture of different part of the world. Sans Souci, the eighteenth century summer palace and gardens built by Frederick the Great, King of Prussia, in Potsdam near Berlin is indeed a carefree whimsical exuberance of hyperreality that included a Chinese pavilion presumably designed to look Chinese (See Figure 1). Similarly of King George IV of England built a summer palace in Brighton simulating of the architecture of palaces in India built in the Moghul era. Indeed Europe has a long history of rebuilding cities almost brick by brick exactly the way old city was after major disasters or wars. Rebuilding of London after the 1666 great fire was such an enterprise. The Poles rebuilt parts of Cracow and Warsaw after the World War II. The Germans recently have rebuilt the bomb damaged district of Dresden exactly the way it was. And the plan for the Innenstadt Neue Berlin is based on the principle of rebuilding the street walls of the old city (see Figure 2). Fires and wars not only destroy the built form, but also the social fabric and urbanism of the city. Rebuilding in the images of the old also becomes a simulacrum, just like the recent renovation of the Qianmen district in Beijing. Preservation or reconstruction of the shell of the old historic buildings or districts are complete simulacra because they space they enclose are now used for different purposes, and by different social class. Klaus Kunzmann discusses restoration of the façade and the main edifice of the historic Schloss in Braunschweig by developers who are using it as a front for a giant shopping mall.[14] In Berlin a collective effort is underway to rebuild the Stadtschloss which was heavily damaged by the Allied bombing during the World War II, and then taken down completely by the GDR government who chose to build a modernist structure at the site of the old Stadtschloss to hold the assembly of the socialist government. That legacy of the socialist era is now gone, unceremoniously demolished to make room for the simulacrum of the historic Stadtschloss (see Figure 3). The interiors space will be now used by commercial interest—shopping, offices, and the like.

Returning to the developing world, simulacrascapes are not uncommon in the recent urban expansion of the global south. Thus incongruously in the empty western edge of Yamoussoukro, Ivory Coast, stands the Basilica of Our Lady Peace, an imposing cathedral – a simulacrum of the St. Peters cathedral in Rome, and biggest in the world. In

the outskirts of Bandung, Indonesia, a gated community called Vila Duniya (global village) offers simulacrum houses representing different European cities: Amsterdam, London, Paris, Rome. At the edge of the Jakarta metropolitan area two new planned communities - Kota Wisata and Kota Legenda - built by the same developer are offering weekend homes for Jakarta area prosperous class, but set in multiple simulacra of tableaux from different countries and places, mainly European but a sprinkling of global south as well. Then there is Hiranandini, a new development in the northern fringe of the Mumbai metropolitan area. The design of this complex of high-rise luxury towers, complete with its own shopping center, is designed after the Western classical architecture as would have been norm in the colonial times. What is relatively unique about the project is not the identity of its simulacrascape, but its official name, which is distinctly Indian. Typically such enclaves of modern housing for well-to-do Indians, many NRI's or non-resident Indians, will be called Buckingham Gardens, or Windsor Estates, or Kensington Village, as Anthony King has pointed out previously.[15] ,

(3) Simulacra, Simulacrascape, and the Challenges of Urban Design:

What I have attempted to establish in the previous narrative is that the examples of the faux or ersatz is not peculiarly unique to China; other countries in the global south are also vulnerable to such tendencies. This is apparent especially in the urban additions comprising the higher end, upper class spaces of consumption. When I asked the young developer-architect of Kota Wisata and Kota Legenda about his choices for such ersatz non-indigenous style, his answer seem to imply: "wouldn't you rather have a good copy than a bad original?" This answer also suggests that perhaps the state of professional practice is not advanced enough to respond to the demands of the emerging consumption class in emerging markets. In other words development may have outpaced the state of architectural practice and pedagogy. Hence the tendency for the global south corporate interests (whether government of private) – or in other words, the forces behind the Faustian development – is to (a) hire "starchitects" from the global north, or (b) copy the built form of the global north, hence the preponderance of ersatz simulacra.

To test this assumption I went through *The Phaidon Atlas of Contemporary World Architecture Travel Edition* (2005) and summarized the distribution in Table 2. Of course the choices are that of the publishers, and architectural experts and observers may disagree. I have classified the architects of these chosen projects, mainly by their names, into two groups: Global South and Global North. The table shows that in Africa and Southeast Asia architects from the Global North tend to dominate the production of "world class" architecture." In China, the majority of the chosen projects are of domestic origin, although the Global North architects seem to capture a significant share. But at least the table seems to refute the notion that the local architects are not able to produce "world class" architecture. However, the scope of this analysis does not interrogate whether the world class architecture produced by architects from global south are endogenously grounded as expressions of "indigenous modernity,"[16] or simply influenced by the style and genre popular in the Global North. In other words: Is this the kind of architecture that is popularized by the "parametric design" of Frank Gehry or Zaha

Haddid, or does it reflect styles adopted, modified, and ultimately indigenously grounded? Cases in point are, for example, the architecture of Charles Correa and Balakrishna Doshi, who worked with Le Coubusier during his stint in India, and were profoundly influenced by his style, but were able to develop expressions of modernity that were grounded in the climate, culture, and customs of India.

In any event, I hope this rough analysis proves that copying and mimesis are not unique to the Chinese culture, unlike what Campanella and Bosker had implied, if inadvertently. Examples abound in other cultures, including the West. Indeed as Bosker has indicated that mimesis can be a rhetorical device as in art, often as "imitation of life," and common in the Chinese landscape and garden design tradition. Certainly the Chinese culture has a rich heritage of originality and innovation in its arts and sciences, as history books would testify.

Table 2. Distribution of contemporary world architecture (and their architects) by global regions, from *The Phaidon Atlas of Contemporary Architecture Travel Edition*.

| World Regions | Number of examples | Architects and architectural firms representing (author's best guess) | |
|---|---|---|---|
| | | Global South | Global North |
| Oceania | 64 | 64 | 0 |
| Asia (excluding China and Japan) | 18 | 14 | 4 |
| Asia (China) | 61 | 33 | 28 |
| Asia (Japan) | 69 | 56 | 13 |
| Southeast Asia | 24 | 5 | 19 |
| Europe | | Not considered | |
| Africa | 17 | 6 | 23 |
| North America | | Not considered | |
| South America | 40 | 34 | 6 |

The Chinese problematic, however, is not the mimesis but the quantum of simulacrascape that is emerging in the context of its Faustian development. The question is, who commissions such work? Who funds them? And here, Campanella's excellent and rigorous historical account suggests that it is often the wealthy developers or corporate interests that lead to such simulacrascapes. One wonders which minister or state authority thought of the nine new towns of Shanghai to be built in the images of different European

cities, and why? The answer might be obvious or known to the Chinese professional class, but remains somewhat of a mystery to the outsider.

The challenges for urban design in China, seem to be quite daunting. It is not clear that the Chinese urban designers can ban or control "simulacra" or "simulacrascapes" under some special authority granted by the local or national state. Nor would that be necessarily desirable. After all, simulacrascapes may have some appeal, and generally the public seem to enjoy them.

Elsewhere, I have argued that the practice and pedagogy of urban design has evolved in two very distinct traditions. The older of this tradition was rooted in the the Baroque and the Beaux Arts tradition and Platonic – authoritarian, dogmatic, elitist, and visionary in characteristics. Typically urban design as practiced and seen in architecture follows this trend. The younger tradition, in contrast, can be seen as Aristotlean – deliberative, democratic, organic, and pluralistic in characteristics. Urban design in the planning profession tend to be more of that type, and fits better with the public and participatory context of urban planning.[17] It is this tradition that is much needed in shaping the pace and directions of Chinese urban design. It should involve periodic interrogation, reflection, and dialog in the true Aristotlean tradition reflecting multiple views and demands for urban growth. Sustainability should be an important component of this on-going interrogation. It s possible to imagine that such interrogation would be involve research and expert observations, which then might lead to a "urban design manifesto" for China. This manifesto, in turn, can help structure a system of design guidance,[18] as common in the U.K., as well as design rules, codes, and performance standards that will create livable urban environment, and an urbanism grounded in the culture of China.

.

End Notes:

[1] I must begin with the usual disclaimers: My exposure to China is somewhat limited, although I have visited China many times, since 1980, just when China was about to embrace market economy, and start up its growth machine, much vaunted these days. My observations might be ill-informed, and shaped by the Western media coverage of China's urban development. In event I am fully aware that it is audacious, if not presumptuous, to write about a country as ancient, as complex, and as culturally rich as China.

Keywords: Soundscape, Sound Recognition, Soundmarks

## Abstract

*The aim of the study is to increase the samples in enclosed soundscape studies and as a public space; metro stations have been aimed to be included into the literature. This study is a subjective approach; examines the relationship between soundmark a space and space recognation within "degree of enclosure" context in order to gain data, sound recordings were taken from site and a listening test applied to investigate if spaces could be recognized/understood just by hearing. For each sound recording, subjects were asked to explain the recorded space (if they are open/semi open/enclosed space), and define the sound sources. Besides, in order to understand sound quality of the selected spaces, subjects were asked to choose from 17 pairs adjectives for each recording, which were selected from the previous studies. Results showed that, all of the subjects determined open spaces correctly, enclosed spaces were determined with 84% while 95% of the subjects have failed to identify the semi open spaces. Only half of the subjects were able to determine the usage of the spaces. As soundmarks, bird, wind, and water sounds were defined in the open space, pay gates and coin sounds were defined in the semi-open space, and the metro itself, as well as its brakes, doors, and announcement system were defined in the enclosed space. For open spaces, subjects tended to choose adjectives as "pleasant", "calming", "natural"; while for enclosed spaces tended to choose "unpleasant", "stressing", "artificial", etc.*

## 1 Introduction

In 2011, Brown, Kang and Gjestland suggested a taxonometric system to use as a "common framework or a checklist" that classifies all sound sources [1]. In their framework, the acoustic environment is divided into two main categories according to place: *indoor acoustic environment* and *outdoor acoustic environment*. Outdoor acoustic environment is then divided into four sub-categories: *urban acoustic environment*, *rural acoustic environment*, *wilderness acoustic environment* and *underwater acoustic environment*, but the framework only classifies sound sources in the urban acoustic environment. For the other environments, sound sources are depicted as "ditto", which means that the classifications for urban acoustic environment should be applied the other acoustic environments.

The authors maintained that the sound sources of the urban acoustic environment were sufficient as a common framework, and all studies of different acoustic environments could refer to those. However, it is known that, every space has its own unique sound environment; soundscapes, the underlying sound sources and the acoustical requirements differs [2,3]. This requirements gets varied and more complex in enclosed spaces, correspondingly, auditory perception will differ because there interferes factors such as building geometries, finishing materials, activities and reverberation (to name only a few); all contribute to the acoustic environment. [4,5]. For these reasons, the classification of sound sources should be elaborated with different case studies that consider all types of acoustic environments. And in addition to outdoor sound quality studies, indoor sound quality in different environments also needs investigation.

Until the 2000s, researchers focused on soundscapes in outdoor urban environments [6, 7, 8, 9]; there was a lack of case study on enclosed spaces. In 2007, Tardieu, Susini and Poisson became prominent

names in soundscape studies for their work in train stations [10]. They indicated that in public spaces such as metro stations, users learn how to use the space and how to understand their location in a space. Researchers then aimed to understand *how* users learn and memorize the soundscapes of such spaces. With their studies of Ankara and Warsaw metro stations, Su and Caliskan drew guidelines for acoustically measuring enclosed soundscapes [11,12]. There is a series of soundscape studies in outdoor environments, mostly investigated by the ISO-led standardization group as well as some case studies on enclosed spaces such as shopping malls and metro stations [13, 14]. However, to the best of our knowledge, there is no research in the literature that compares outdoor and indoor soundscape quality.

This study is designed to determine negative and positive aspects of the indoor acoustic environment in a metro station, and compare the station's outdoor and indoor perceived sound qualities. For this comparison, Akköprü Metro Station and Ankamall Park adjacent to it were chosen as a case study in Ankara, Turkey. The study explored the following research question: "Can users recognize a space just by hearing recordings from a location?" This study hypothesizes that open spaces and enclosed spaces different acoustic environments, and thus "Users will not be able to differentiate between semi-open and enclosed spaces from an audio recording."

## 2 Method

### 2.1 Site Description

The entrance of the Akköprü Metro Station was chosen as a semi-open public space and the platform level of the station was chosen as an indoor environment/enclosed public space. Akköprü Metro Station's attributes of being public, the Ankamall Park adjacent to it and its continuous flow of pedestrians were the main factors for its selection for this study. The station is located in Akköprü, Çankaya, one of the most crowded areas of Ankara, at the intersection of Fatih Sultan Mehmet Boulevard and Mevlana Boulevard. Ankamall Shopping Center, Ankara's municipal transportation department, the 'Turkey's veterinary services department and the Ankara fire department headquarters (Figure 1) are all nearby.

Figure 1: Site view of Akköprü Metro Station

The park sits between Akköprü Metro Station and Ankamall. It contains a small square approximately 50 metres from the station and 20 metres in diameter. The square is connected to a promenade with 18 seating areas on either side it and 11 decorative pools on the middle axis, each five metres in diameter.The square directly faces the shopping mall (Figure 2).

Figure 2. View of the Urban Park and Akköprü Metro Station from Ankamall Shopping Center

Akköprü Metro Station consists of two levels: an entrance level with pay gates and ticket offices, and a platform level. The entrance level, with its large doors that create a great flow of pedestrians and air, works as a transition between the platform level and the outside. The station is 895 meters long and 216 meters wide. The height of the entrance level is 3.19 meters and the height of the platform level is 3.36 meters from the base to under the suspended aluminum ceiling, and 7.33 meters from the metro rails to the top of the metro tunnel. The floor is artificial marble 40 cm x 40 cm. On the entrance level, walls are mostly glass brick and marble as well as columns and stairs are covered with glass brick. On the platform level, the columns are covered with acrylic paint. Ballast stone is used in the rails. There are no sound absorptive material used neither on ceiling or walls to help to control the acoustical environment of the station. (Figure 3).

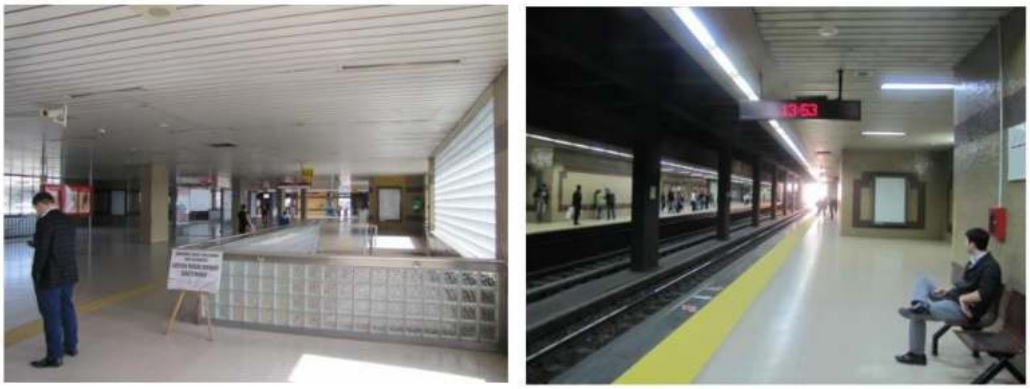

Figure 3: Entrance level (Left) and platform level (Right) of the Akköprü Metro Station

## 2.2 Methodology

### 2.2.1 Space Recognition

Sound recognition refers to a process of understanding what a specific sound is, what its source is and where it is in a specific environment. To understand this process, the relationship between sound and social context must be well understood. In *The Image of the City*, Lynch discusses the relationship among soundmarks, city images and sound and space recognition. Venot and Semidor explained that relationship with these words: "Every sound event can be preserved in a way which enables us to identify it" [15]; the authors maintained that hearing an activity creates a mental image of the sound source, the activity and the environment, which may not be as strong as a visual source but is nonetheless important.

One measurement method for sound recognition is called *soundwalking*, which aims to specify all the sound sources that form the soundscape of an area. The duration of this activity can change according

to certain factors, such as the size of the area, number of people in the group or number of sound sources. After the walking session ends, participants discuss the sound sources and architectural situations. Another way to conduct this method is to record the sound sources of an area for specific durations, then have subjects listen to the recordings and write down the sound sources they hear and whether they recognize the recorded space.

In the current study, a total of 34 sound recordings were taken from selected spaces in eight spots (Figure 4). The duration was kept short to avoid subject distraction. Listening tests were conducted in a semi-anechoic room with noise cancelling headphones.

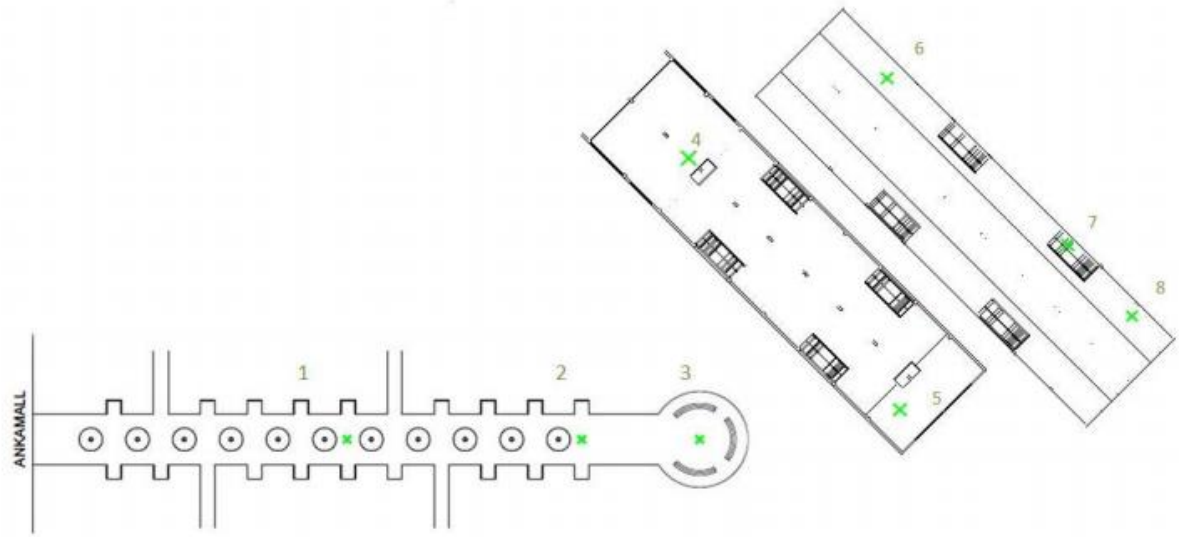

Figure 4. Eight different spots used for objective and subjective measurements (Spots 1-2-3: The park area as open space; Spots 4-5: The entrance level as semi open space; Spots 6-7-8: The platform level as enclosed space)

One recording from each spot was chosen for the listening test. Singly, the 90 uninformed subjects were taken into the semi-anechoic room and attended to the listening test (Figure 5). The participants listened to each recording twice and each session took 30 minutes. The recordings were played randomly to each subject.

Figure 5. Picture of an interviewee from the anechoic room

The questionnaire consisted of nine pages with two parts. In the first part, interviewees were asked close-ended questions about personal information such as gender, age and education level. In the second part, for each sound recording, subjects were asked to explain the purpose of the recorded spaces (usage of the spaces), guess which type of space it was (open/semi-open/enclosed) and define the sound sources.

### 2.2.2 Soundmarks

Through the listening tests and site analysis, sound sources and soundmarks of the spaces were also determined by the participants (Table 2). The order of the sound source lists written by subjects gave indications of how users perceive sounds in an environment [16].

The Overssea City Town (Shenzhen) presents a clear explanation for the diversities in ecological sound environments in big cities; nature soundscape (consists of nature sound barely man-made sound), neutral soundscape (consists of nature and man-made sound), and man-made soundscape (consists of man-made sound barely nature sound) [17].

### 2.2.3 Psychoacoustic Parameters Measured at Akköprü Metro Station/

Psychoacoustics is a scientific field that aims to explain users' psychological and physiological responses to acoustic conditions in an environment. In 1990, Zwicker and Fastl [18] proposed three basic sound metrics: loudness, sharpness and roughness. In 2013, Özçevik and Can [19] analyzed the relationship between Zwicker and Fastl's metrics and various adjective pairs (Table 1).

Table 1. Relationship between sound quality metrics, adjective pairs and soundmarks [19]

| Environmental Sound Assessment | Sound Quality Metrics | Adjective Pairs | Relationship with Soundmarks |
|---|---|---|---|
| General Assessment | Loudness (5%, 50%, 95%) | "loud-quiet" , "unpleasant-pleasant", disturbing-comfortable", "stressing-relaxing", "agitating-calming", "discordant-harmonic", "hard-soft", "crowded-uncrowded", "empty-joyful","exciting-gloomy", "loud-soft", "dark-light", "heavy-light - ", "rough-smooth" | |
| Detailed Assessment | Roughness (%10) | "far away-nearby" | Perception of the soundmarks (distance between soundmarks and the receiver) |
| | Sharpness (%10) | "sharp-not sharp" | Spectral structure of the soundmarks |
| | | "unsteady-steady" | Stability of the soundmarks in time and its effect to the space |
| | | "strange-common" | Familiarity of the soundmarks |

In the current study, Zwicker and Fastl's metrics were used with Özçevik and Can's adjective pairs. In order to understand the sound quality of the selected spaces, the subjects were asked to choose between 17 adjective pairs (see Table 1) for each recording, taking into account the relationship between sound quality metrics and all pairs of adjectives. In this study, the two adjectives were also evaluated via ***semantic differential ratings***. The frequency distributions of the adjective pairs for three different space types according to the scalar listening test results are given in Figure 7.

## 3 Results

***Sound Recognition:***

In terms of sound recognition, the listening test results show that all subjects determined the open spaces correctly and 84% of subjects determined the enclosed spaces correctly, but only 5% of subjects determined the semi-open spaces successfully. Only half the subjects were able to determine the correct usage of the spaces (Figure 6).

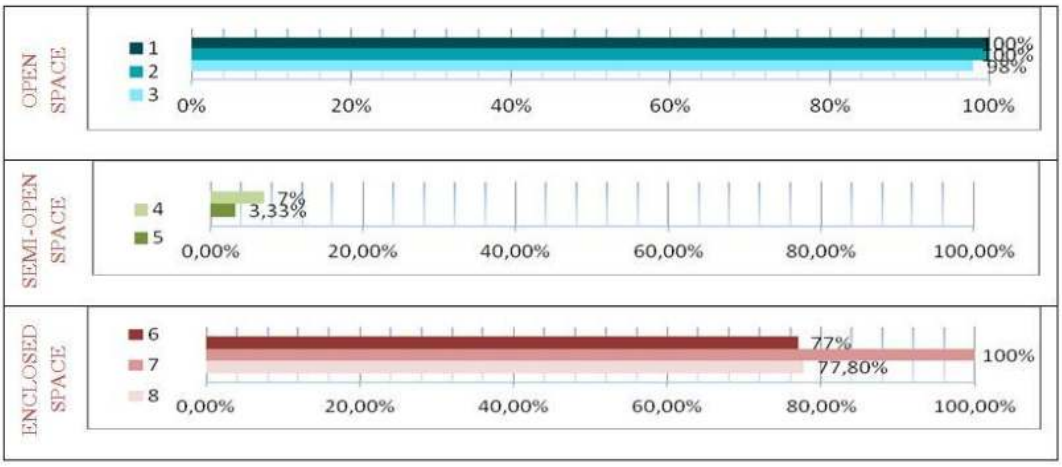

Figure 6. Listening test results - defining space types (as open (spots 1-2-3) /semi open (spots 4-5) /enclosed (spots 6-7-8) see Figure 4 for measurement points )

***Soundmarks:***

In terms of soundmarks, the sounds of marching, speech and children were perceived similarly in all three spaces. Traffic sounds such as horns and sirens were perceived similarly in open and semi-open spaces. Birds, wind and water sounds were defined as soundmarks in the open space; pay gates and coin sounds were defined in the semi-open space and the trains, brakes, doors and sound system were defined in the enclosed space (Table 2).

Results of the field studies showed that sound scape features of both three spaces differs from each other. In station (both in entrance and platform level) sound scape is all man-made; consists of metro sound, loud speaker paging, human speech etc. Sound scape of the park can be considered mostly neutral; man-made sounds such as traffic sound and human speech are as noticeable as the natural sounds such as birds, wind and water elements.

| Spaces | Sound Sources | Soundmarks |
|---|---|---|
| Open Space | Heavy Traffic | Bird Sound |
| | Decorative Pool | Wind Sound |
| | Weather Conditions | Water Sound |
| | Flow of Human | Marching Sound |
| | | Speech and Child Sound |
| | | Traffic Sound; horn and siren |
| Semi-Open Space | Ticket Office | Coin Sound |
| | Pay Gates | Pay Gate Sound |
| | Flow of Human | Marching Sound |
| | Heavy Traffic | Speech and Child Sound |
| | | Traffic Sound; horn and siren |
| Enclosed Space | Metro | Marching Sound |
| | Loudspeaker | Metro Sound; break and door |
| | Flow of Human | Paging |
| | | Speech and Child Sound |

Table 2**:** Listening Test results - Sound sources and soundmarks determined by the listening test and site analysis (see figure 4 for measurement points)

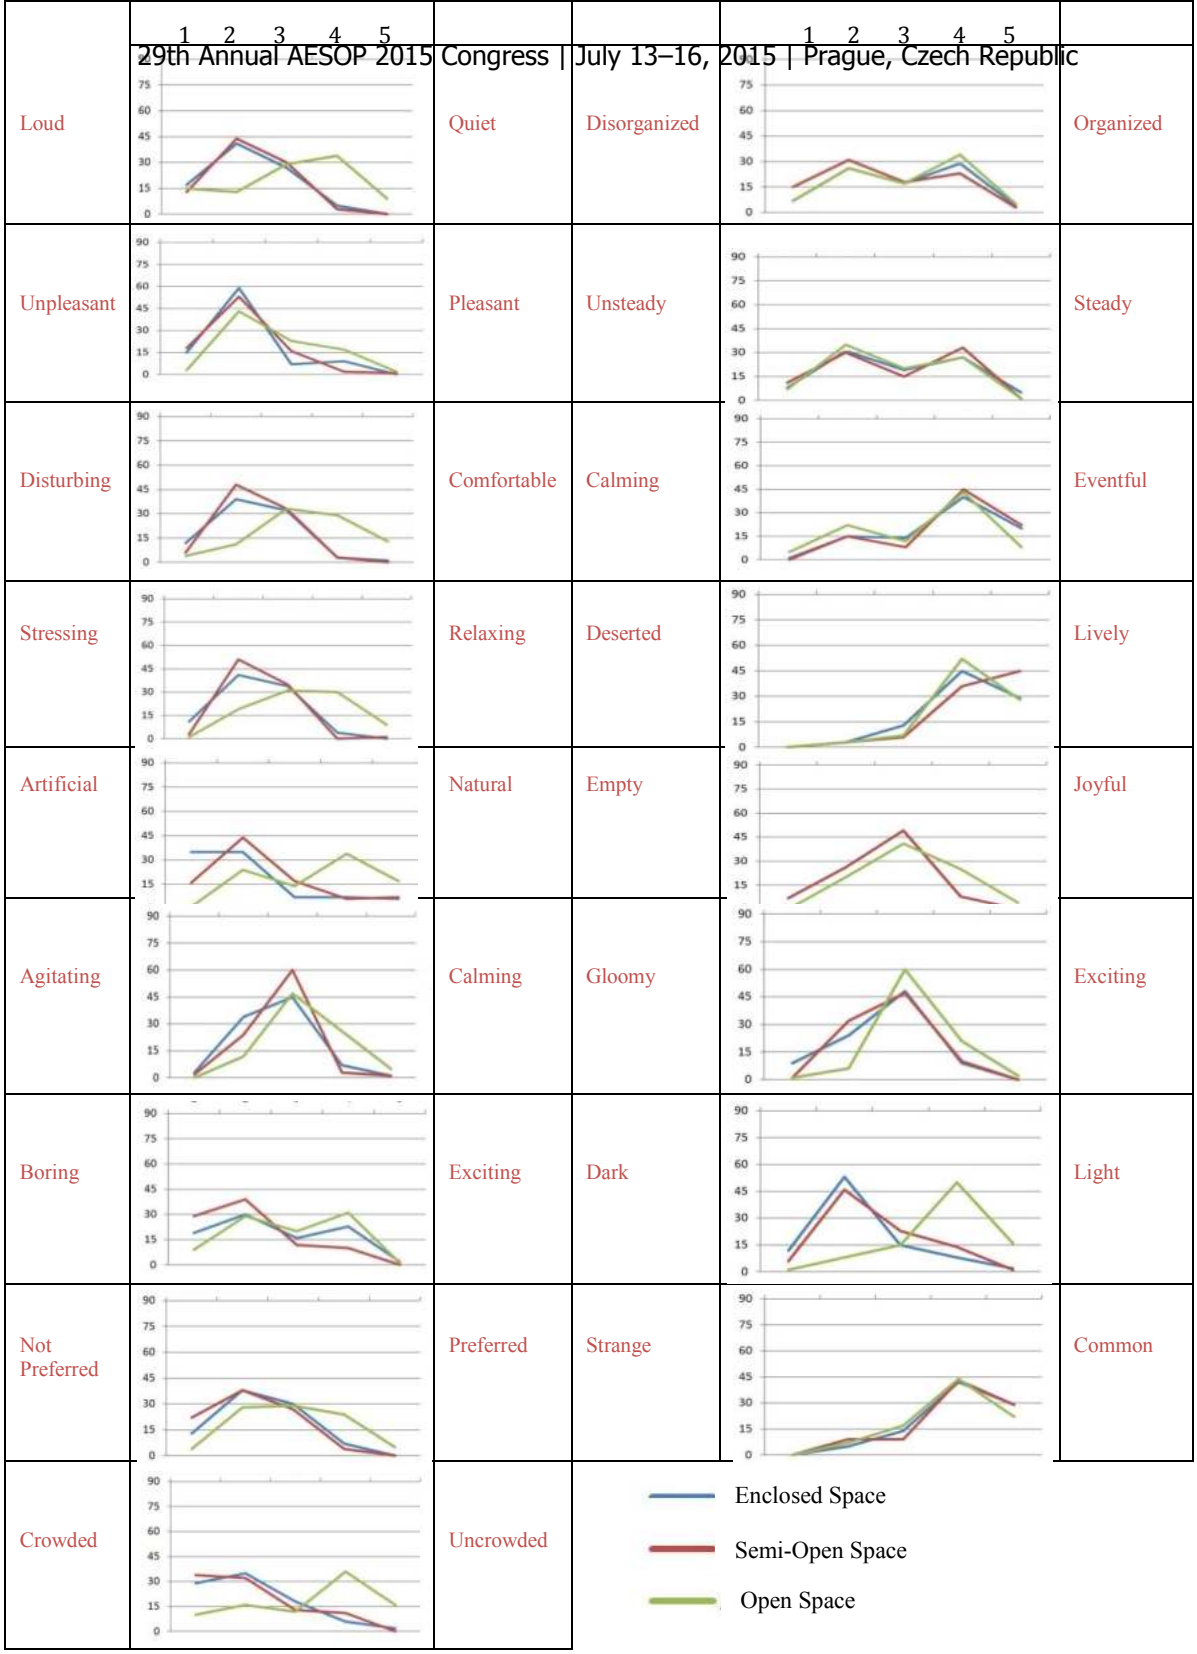

Figure 7: Listening test results- Relationships of adjective pairs / space types

### *Semantic Differential and Sound Quality Metrics*

Özçevik and Can's [18] study on the relationship between sound quality metrics, adjective pairs and soundmarks is well known. Using their pairs, the current study found that Loud-Quiet, Unpleasant-Pleasant, Disturbing-Comfortable, Stressing-Relaxing, Agitating-Calming, Uncrowded-Crowded, Unsteady-Steady, Empty-Joyful, Gloomy-Exciting, Dark-Light and Strange-Common were related with **Loudness** and that Unsteady-Steady and Strange-Common adjective pairs were related with **Sharpness**.

In other words, these adjective pairs can be explained through the related sound quality metrics (Figure 7).

***Semantic Differential and Correlations***

Correlations between the adjective pairs gained from the listening tests were also analyzed. Highly correlated adjective pairs can be seen in Table 3.

Table 3.Highly positive correlated adjective pairs

| Correlations | Loud quiet | Unp. Pleas. | Distur. Comf. | Stress. Relax. | Artific. Natur. | Agitat. Calm. | Boring excit. | Not pr. preferr. | Crowd. Uncr. | Disorg. Org. | Unste. steady | Calm. event. | Disert. lively | Empty joyful | Gloo. excit. | Dark light | Stran. Comm. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Loud - quiet | | ■ | ■ | | | | | | ■ | | | | | | | ■ | |
| Unpleasant - pleasant | | | ■ | | | | | ■ | | | | | | | | ■ | |
| Disturbing-comfortable | | | | | | | ■ | ■ | | | | | | | | ■ | |
| Stressing - relaxing | | | | | | ■ | ■ | | | | | | | | | | |
| Artificial - Natural | | | | | | | | | | | | | | | | | |
| Agitating - calming | | | | | | | | | | | | | | | | | |
| Boring - exciting | | | | | | | | ■ | | ■ | | | | ■ | ■ | | |
| Not preferred- | | | | | | | | | | | | | | | | | |
| Crowded - uncrowded | | | | | | | | | | | | | | | | | |
| Disorganized - | | | | | | | | | | | | | | | | | |
| Unsteady - steady | | | | | | | | | | | | | | | | | |
| Calming - eventful | | | | | | | | | | | | | ■ | | | | |
| Diserted - lively | | | | | | | | | | | | | | | | | |
| joyful | | | | | | | | | | | | | | | ■ | | |
| Gloomy - exciting | | | | | | | | | | | | | | | | ■ | |
| Dark - light | | | | | | | | | | | | | | | | | |
| Strange - common | | | | | | | | | | | | | | | | | |

The correlations suggest that loud environments make users feel unpleasant and disturbed. The users evaluated loud spaces as crowded. They also suggested that they feel very pleasant in comfortable spaces. Agitating environments made users highly stressed and they claimed that they got bored in stressful and disturbing spaces. Comfortable and pleasant spaces were highly preferred to uncomfortable, unpleasant and gloomy spaces. Eventful spaces were labeled as lively and joyful, but eventful, lively and joyful spaces were also labeled as loud and disorganized. Users got bored in empty spaces and found disorganized and gloomy spaces boring. Gloomy spaces were also expressed as empty. Users also found loud, deserted and gloomy spaces as dark. However, empty spaces were preferred more often than joyful spaces. Users found natural spaces gloomy and labeled artificial spaces as exciting. Users became stressed in eventful spaces. Users found eventful spaces crowded, and calming spaces related with more light.

## 4 Conclusion

The study states that, every space has its own unique sound environment and acoustical requirements. This requirements gets varied and more complex in enclosed spaces because there interferes the geometry of the enclosure, nature of the used materials, the activity takes place in etc. Correspondingly, auditory perception will differ. This statement is the most important aspect of the study's hypothesis. The study shows that there are statistically significant relationships between auditory perception and different space types. The findings prove that Brown, Kang and Gjestland's above-discussed

taxonometric system (which suggested that all sound sources can be classified using the same categories as for the urban acoustic environment) is not sufficient.

Keywords: physical accessibility, perceptual accessibility, appropriational accessibility

## Abstract

*This paper is based on the Guide that was elaborated in the context of the European INTERREG IVC programme CHARTS (Culture and Heritage Added Value to Regional Policies for Tourism Sustainability) project by the Laboratory for Tourism Planning, Research and Policy (University of Thessaly).*

*The Guide examines the Accessibility to Heritage for all people by defining three moments: a) physical accessibility: the visitor to / receiver of a cultural good uses his/her body structure and functions in order to move inside the product in its original material manifestation or experience sensorially its tangible or intangible reproductions, b) perceptual accessibility: the moment of understanding culture/heritage and it has to do with the perceptiveness of the receiver and is closely linked to the receiver's educational background, way of living and habitual mode of intellectual operation and finally c) appropriational accessibility: the apex of accessibility is the combination of the two previously acquired moments and it happens when the visitor/receiver may consider culture/heritage as part of himself/herself (familiarization) and use the adopted experience to intertwine his/her own story (narrational production).*

*The Guide supports the idea of a sustainable management of culture, heritage, tourism and it is inspired by the principles of Universal Design: all people should enjoy in the same way same benefits and high quality services offered. The Guide tries to clarify the misunderstandings connected to the notion of accessibility, proposes policies for achieving accessibility to all cultural activity and gives planning principles for the strategic management of accessibility to heritage.*

## 1. Introduction

This paper presents both a theoretical and practical approach to the issue of "Accessibility to Heritage" and it is based on the homonymous Good Practice (GP) Guide written by the scientific team of LA.RE.TOUR (Laboratory of Tourism Planning, Research and Policy) at the University of Thessaly. The GP Guide "Accessibility to Heritage" was prepared within the framework of INTERREG IVC Culture and Heritage Added-value to Regional Policies for Tourism Sustainability Program (CHARTS) and it can be used as a toolkit for achieving accessibility to culture and heritage for all, as well as for exchanging experience amongst the partners on the sustainable management of culture, heritage and landscape through communication and collaboration, keeping in mind the effects of innovation and creating a knowledge base. In addition, always in respect to the basic principles of INTERREG IVC and the objectives of Lisbon and Gothenburg agendas, the areas of support are innovation and the knowledge economy, environment and risk prevention, aiming to contribute to the economic modernization and competitiveness of Europe in cultural matters.

The paper starts with conceptual definitions. Accessibility is invoked in a generic sense as initial prerequisite for anyone to be able to reach and appreciate sites and activities of collective interest; culture as a good, situation and activity imbued with symbolic value; and heritage as the percolation of past cultural elements into epoch defining legacy. Accessibility to culture and heritage thus involves a physical moment of material access to infrastructures and sites, a perceptual moment involving an understanding of the symbolic meanings inherent in cultural products and activities, and a culminant appropriational moment when such meanings are appropriated, consciously accepted or re-presented and re-worked by those in contact with them. Two questions arise: a) how does enhanced accessibility to culture and heritage impact on the breadth, quality and value-added potential of the tourism sector, and b) how does the multiplier effect on the tourism sector become apparent.

Finally, the paper presents referential evidence of the felicitous effects of accessibility to culture and heritage on the tourism sector and lists a number of good practices from across the European Union proving the point. It ends with a set of Do's and Don'ts attempting to guide implementation of accessibility projects in an all-inclusive direction involving all irrespective of physical, intellectual or social specificity.

## 2. Objectives

This paper depicts GP Guide's "Accessibility to Heritage" output and tries to communicate its results to the European scientific audience. In the context of the current text, accessibility is approached according to a broad definition, which includes both the physical and the perceptual accessing of culture and heritage. This is because, although the term 'accessibility' usually tends to be thought of in connection to physical disability, in the particular cases of culture and heritage it also crucially involves the ability to perceive ideas and understand meanings. At a symbolic level, central to all artistic expression, a piece of visual art is much more than paints on canvas or deformed stone shapes.

The objective of this paper is to illustrate the concepts related to the central motif of accessibility, promoting the relevant problematic, examining applied good practices and addressing policy implications. Thus, the paper aims to contribute to the debate concerning the accessibility to culture and heritage. It also aims to investigate the bidirectional relationship between cultural heritage and tourism, further highlighting those issues which can supply good practices. The examination of good, in contrast with less successful, practices is included in the targets so as to highlight transferrable good practices and propose efficient transfer processes. The final aim of this paper is to suggest a series of specific recommendations and suggestions aiming at the amelioration of both physical and perceptual accessibility conditions to culture and heritage for all.

## 3. Theoretical framework

The term 'accessibility' will be defined as a generic concept and interpreted in relation to its dual articulation as physical and perceptual accessibility. In general, accessibility means the ability of everyone to use a service or a product, regardless of specificity (disability, age) or context of use. In other words, accessibility is, by definition, a matter of usability. The point is that anything that is not accessible for a user is not user- friendly. Practically, accessibility is embedded in the broader scientific field of HCI (Human Interaction) with Object/Action Design.

The term 'accessibility', in its strict definition, denotes the state in which any characteristic of the domain at issue can be accessed by anyone without discrimination based on sex, age or other characteristics (physique, strength, perceptive ability etc.), i.e. when anyone can reach and use infrastructure autonomously, safely and comfortably.

However, 'accessibility' does not refer only to infrastructure. Other aspects of accessibility have to do with accessing services, facilities and goods, engaging in activities and partaking in experiences. All

these are interacting and can give a decent degree of autonomy and security to the individual, always in relation to the environment (natural, built or virtual) [Tzanavara, 2013]. Conclusively, accessibility should apply in all fields (e.g. culture, environmental and urban planning, transport, health and welfare, research and technological development, education, labour, health and safety) and at all levels (local, regional, national, European, global) so as to ensure its generic effectiveness (Christofi, 2010).

On the other hand, a comprehensive design (integrated planning), that takes from the outset into account the needs of all citizens, including citizens with disabilities, firstly enables them to participate equally in social activities and secondly increases the level of quality and safety for all. These should exist with consistency in the everyday sense of control, cross assurance and regular maintenance of any applications in order that the uninterrupted and safe operation of access-able chains and networks is insured. Damage to a link is so obvious that devalues the overall architecture.

Actually, the theory of 'Universal Design' describes exactly the complete access of different people to different services and products and that process means 'Design for all'. The goal of universal design is accessibility for all, accessibility to buildings, structures, the classroom, internet. The application of the principles of universal design minimizes the use of assistive technologies and results in the production of products compatible with assistive technology that can be used by many groups of people, not just people with disabilities.

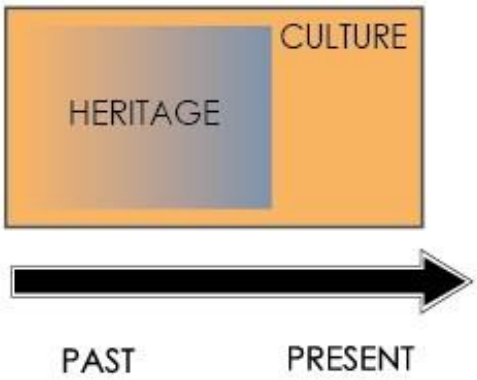
### *3.1 Accessibility to heritage: the phases of accessibility*

The term 'accessibility' is usually presented as physical disability. Nonetheless, the term can refer to very different groups of people that can face insurmountable accessibility problems. The topic is getting even more complicated when speaking about accessibility to culture and heritage. What is culture and what is heritage? How can culture and heritage be accessible? What are the reasons that prevent someone from accessing culture? Is the process of accessing culture and heritage interactive? Does physical access to culture precede mental access or does the opposite apply?

This section will attempt answering such questions by venturing into the elaboration of a theoretical model. The model depicts the phases, or moments, of accessibility to culture and heritage and is setting the background on which these can be detected, studied and addressed by policy makers and regulators aiming at accessibility maximisation.

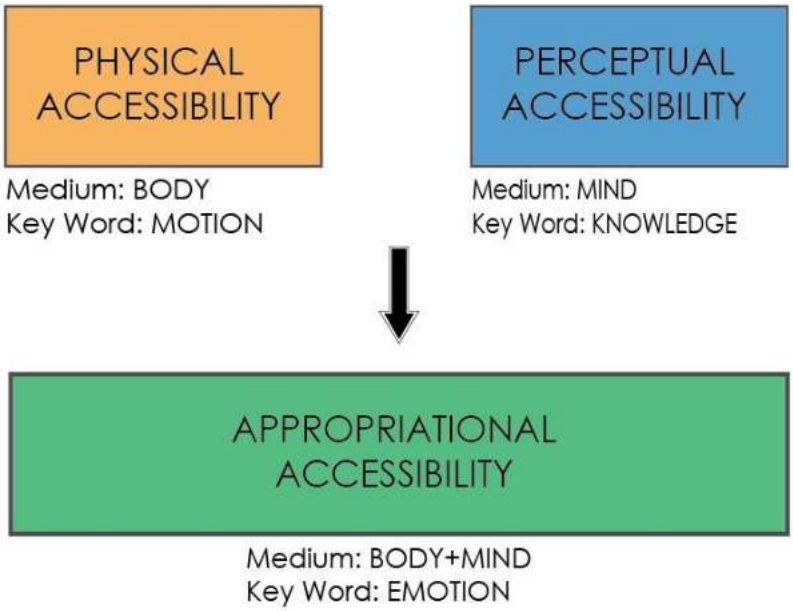
First of all, clear definitions of culture and heritage have to be given. Culture is, in this context, approached as an umbrella term including Heritage. Hence, the term Culture defined as "the arts and other manifestations of human intellectual achievement regarded collectively (through the timespan)" (http://www.oxforddictionaries.com), whereas Heritage stands for "the valued objects and qualities such as historic buildings and cultural traditions that have been passed down from previous generations" (http://www.oxforddictionaries.com). In other words, the difference between Culture and Heritage can be defined as temporal. On the one hand, Culture includes all the intellectual achievements of mankind from its beginnings to today; while, on the other, Heritage refers to non-contemporary intellectual achievements that have percolated through the ages as the past's indubitable legacy (Figure 1). But who can have access to culture and heritage?

Figure 1: Culture and Heritage according to time



As declared at the European Round Table on 'Human Rights and Cultural Policies in Europe', held in Helsinki in 1993, everyone has the right to produce, participate and access cultural life (Fisher et al., 1993). Multiculturalism, pluralism and diversity are the key words that summarize the dominant discourse on accessibility to culture and heritage. No one can be excluded from either producing or accessing culture/heritage. Here, the focus is on the phases, or moments, involved in the process (Figure 2).

Figure 2: The Moments of Accessibility to Culture and Heritage



Thus, there are two main phases of accessibility that may either precede or succeed each other:

a) **Physical Accessibility:** In this phase, the visitor to/ receiver of a cultural good uses his/ her body structure and functions in order to move inside the product in its original material manifestation or experience sensorially its tangible or intangible reproductions. Hence, through the five senses (sight, hearing, taste, smell, touch) and their combination (kinesthesia), s/he can collect either stimuli for

further interference with culture/heritage (impulse) or experiences concerning the already adapted information (integration). A crucial sub-group that is facing effects during that moment of accessibility is physically disabled people. In addition, once we talk about visiting and experiencing culture/heritage with one's body (museums, archeological sites, cultural centers), there is also an exclusion of people from culture/heritage because of economic reasons (the price of tickets).

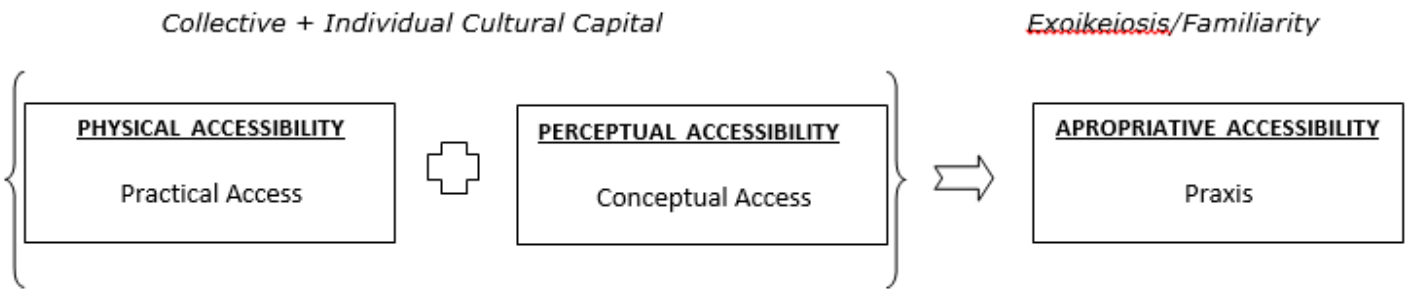
b) **Perceptual Accessibility:** This could be the definition of the phase of understanding culture and heritage and has to do with the perceptiveness of the receiver. The cornerstone is the human mind and its function. The levels of mental accessibility and perceptiveness are closely linked to the receiver's educational background, way of living and habitual mode of intellectual operation. The sub-groups that can possibly be kept out of that phase are people that are indifferent about accessing the types of culture/heritage products being offered and people with mental and learning disabilities.

The theoretical model of the moments of accessibility to culture/heritage is completed by the existence of a third phase referred to as "Appropriational Accessibility".

c) **Appropriational Accessibility:** That phase is the combination of the two previously acquired phases: those of Physical and Mental Accessibility. Firstly, the visitor/receiver may consider culture/heritage as part of himself/herself. S/he may feel emotionally attached and connected to the products of culture/heritage ("exoikeiosis" from the Greek word εξοικείωση meaning familiarization/ emotional investment). At a second level, the body and the mind of the visitor/receiver use the adopted experience and knowledge in order to intertwine his/her own story (narrational production) and, in so doing, reproduce the cultural product in novel, appropriated form. This final moment represents the apex of accessibility, the ultimate goal to be aimed for by policy makers in the field, if accessibility to culture and heritage is perceived generically.

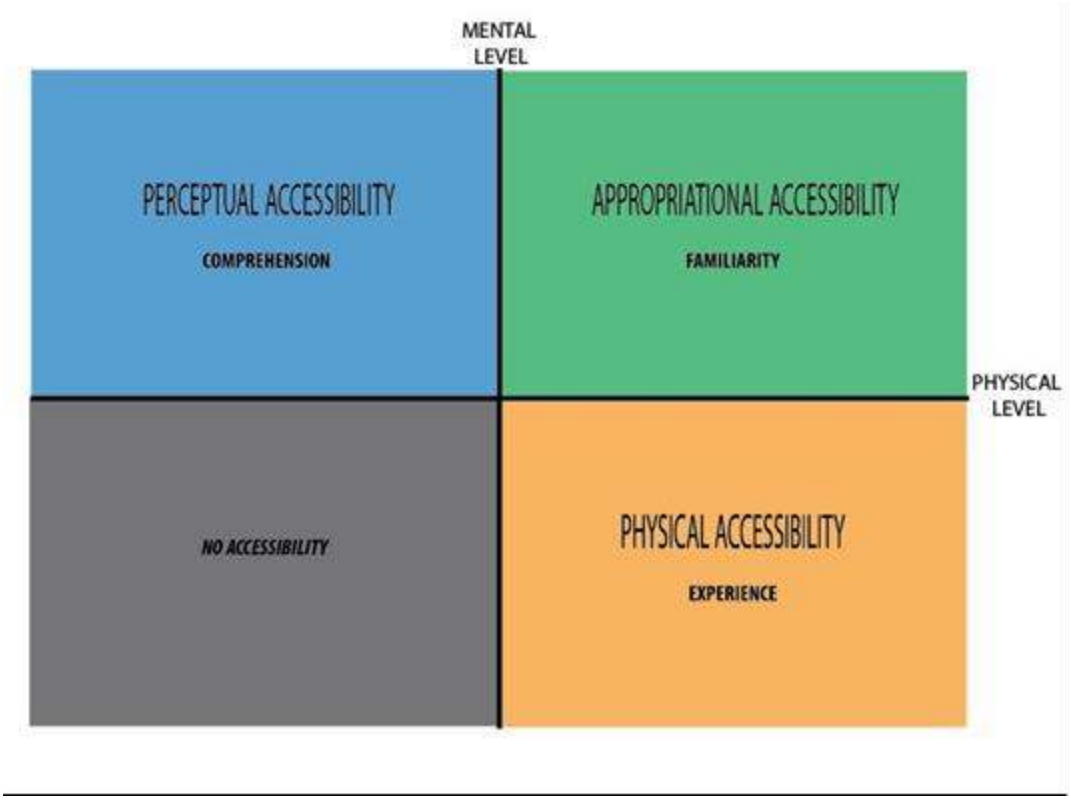
Using Pierre Bourdieu's syllogism, the theoretical model can be seen through the perspective of practice. Physical Accessibility has to do with the collective cultural capital and can be described as a matter of practical access, whereas Mental Accessibility is the individual cultural capital and can be described as a matter of practice theory (Bourdieu, 1972/1977). The third moment of accessibility (Appropriational Accessibility) indicates a continuous interaction between collective and individual cultural capital and offers the background for exercising Praxis (conscious reasonable practice) through the creative combination of practical and conceptual access (Figure 3).

Figure 3: The Moments of Accessibility to Culture and Heritage linked to Bourdieusian Syllogism



Combining the physical and perceptual level of accessibility for tracing the ultimate level of accessibility (Appropriative Accessibility), quadrants for depicting the three phases of accessibility and a fourth state of no accessibility can be used (Figure 4).

Figure 4: The Phases of Accessibility related to their Levels



During the phase of 'Appropriational Accessibility' (Physical Accessibility + Perceptual Accessibility), people get familiar with culture and heritage. They have experienced (Physical Accessibility) and comprehend (Perceptual Accessibility) culture and heritage. This guide aims to stress the importance of 'Appropriational Accessibility' and examines the practices that can promote it.

### *3.2 Accessibility impacts on tourism and key-knowledge for their management*

Tourism is a very common and widespread medium of accessing culture and heritage. Hence, the existing level of accessibility to tourism facilities and activities plays an important role in experiencing (physical accessibility) and comprehending (perceptual accessibility) culture and heritage. A sufficient level of physical and perceptual accessibility to culture and heritage through tourism can lead to the ultimate moment of accessibility (appropriational accessibility).

But what are the positive and negative impacts of accessibility on tourism? Of course, there can be a categorization of positive and negative impacts according to their sphere of influence: economic, social, cultural and environmental impacts. A good level of accessibility leads to positive economic, social, cultural and environmental impacts on tourism, whereas low accessibility levels represent and undeniable impediment to tourism development. Hence, one can observe a pro rata relation between Accessibility and Tourism Impacts.

Table 1: Positive Impacts on Tourism [High/Good Accessibility => Positive Impacts]

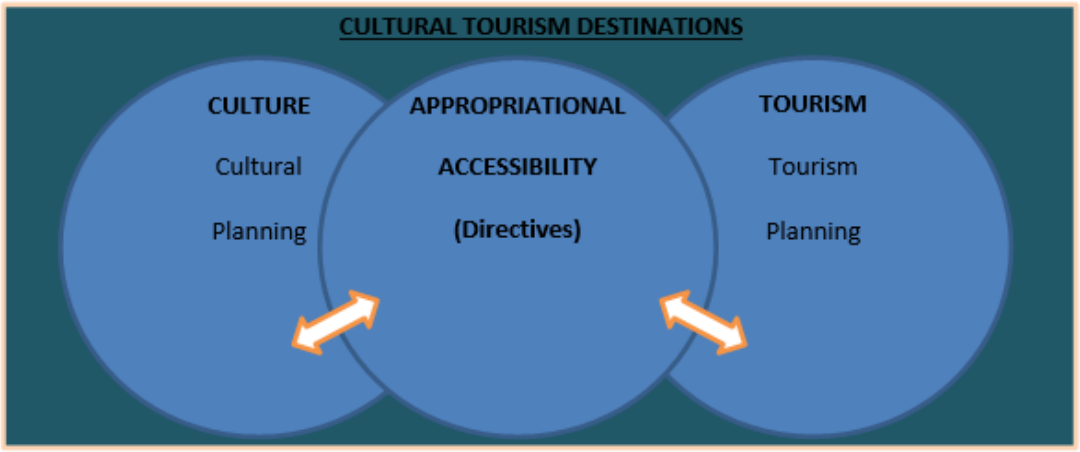
| **+ Economic Impacts** | **+Social Impacts** |
|---|---|
| ✓ Contributes to further tourism development<br>✓ Tones up local economy (zooms at investment and infrastructure development)<br>✓ Improves public utilities andtransport infrastructure<br>✓ Creates new opportunities for employment for all | ✓ Promotes social cohesion<br>✓ Improves quality of life<br>✓ Offers greater tolerance to social differences<br>✓ Reduces the feeling of social exclusion<br>✓ Satisfies psychological needs |
| **+Cultural Impacts** | **+ Environmental Impacts** |
| ✓ Offers the opportunity of gaining experience, knowledge concerning culture and heritage<br>✓ Broadens one's horizons<br>✓ Offers the feeling of being part of the collective cultural capital<br>✓ Increases individual cultural capital<br>✓ Familiarizes people with the notions of culture and heritage | ✓ Proper access for all to spaces of high cultural importance (preservation of natural and built heritage)<br>✓ Visual aesthetic improvement of cultural spaces (archaeological sites,libraries, museums etc)<br>✓ Increases aesthetic awareness of natural environments, of the threats to environmental balances and biodiversity |

Table 2: Negative Impacts on Tourism [Low/No Accessibility => Negative Impacts]

| **- Economic Impacts** | **-Social Impacts** |
|---|---|
| ✓ Fails to capture crucial segments of the tourist market (special needs visitors)<br>✓ The tourism economy fails to develop homogenously and specializes in specific types of service<br>✓ Limited target groups resulting to possible loss of revenues | ✓ Treats people in a different way without supporting social cohesion<br>✓ Stresses social differences<br>✓ Promotes the feeling of social exclusion to certain groups<br>✓ Creates unfulfilled psychological needs |
| **-Cultural Impacts** | **- Environmental Impacts** |
| ✓ Puts barriers to expanding one's individual cultural capital<br>✓ Cannot help oneself feel part of the collective cultural capital<br>✓ Cultivates indifference to cultural matters<br>✓ Drives people away from creativity | ✓ Improper access to spaces of high cultural importance downgrades them aesthetically<br>✓ Limits aesthetic awareness of natural environments<br>✓ Precludes understanding of the environmental and socio-cultural specificities of rural spatial entities<br>✓ Poorly designed accessibility infrastructure can cause accidents |

As it has been shown, there is a profound relation and interaction between accessibility to culture/heritage and accessibility of tourism. These pairs of relations and interactions constitute the core of the issue of Cultural Tourism Destinations and result to the three poles of the relevant key knowledge (Figure 5).

Figure 5: The Three Poles of Cultural Tourism Destinations (Prevention Phase)



The poles of Culture and Tourism can be studied through the concept of sustainability -main and crucial demand concerning Cultural Tourism Destinations- which can be achieved only through Planning (Cultural and Tourism Planning). Furthermore, Planning ought to be elaborated under the spectrum of accessibility and promote the ultimate moment of accessibility (Appropriational Accessibility). This phase of key knowledge can be named as "Prevention Phase".

Table 3: Key-Knowledge for Cultural Tourism Destinations

| **KEY-KNOWLEDGE FOR CULTURAL TOURISM DESTINATIONS** | | |
|---|---|---|
| POLES | CULTURE | TOURIS |
| **PREVENTION PHASE** | Cultural Planning | TourismPlanning |
| Aims | I. Protecting Culture/Heritage<br>II. Organizing Cultural Industries' Services<br>III. Providing Entertainment Choices | I. Defining the Characteristics of the Target Group(Tourists)<br>II. Stressing the ComparativeAdvantage<br>III. Promoting the Tourism Product |
| FILTERPOLE | ACCESSIBILITY TO CULTURE | ACCESSIBILITY TO TOURISM |
| Basic Directives | **UNESCO** Universal Declaration on Cultural Diversity(2001)<br>**Key-Concepts:** Diversity, Pluralism, Creativity | **UNWTO** Declaration on the Facilitation of Tourist Travel<br>**Key-Concepts:** Elimination of Tourist Travel Barriers, Facilitation of Travelling |
| | **Equal Opportunities for People with Disabilities: A European Action Plan (2004-2010)** | |

During that phase, Cultural Planning and Tourism are trying to achieve their goals, while keeping in mind the basic directives concerning accessibility. Those basic directives are declarations and action plans by specialist organizations (UNESCO UNWTO, European Council). Consequently, one can observe that "Prevention Phase" can be considered as effective when it is influenced by the general principals of Universal Design (Design for All).

More specifically, the principles of Universal Design can appear as key-knowledge for accessibility planning to Cultural Tourism Destinations. The key knowledge includes (http://www.ncsu.edu/ncsu/design/cud/pubs_p/docs/poster.pdf):

• **Equitable Use:** The design is useful and marketable to people with diverse abilities.

• **Flexibility in Use:** The design accommodates a wide range of individual preferences and abilities.

• **Simple and Intuitive Use:** Use of the design is easy to understand, regardless of the user's experience, knowledge, language skills, or current concentration level.

• **Perceptible Information:** The design communicates necessary information effectively to the user, regardless of ambient conditions or the user's sensory abilities.

• **Tolerance for Errors:** The design minimizes hazards and the adverse consequences of accidental or unintended actions.

• **Low Physical Effort:** The design can be used efficiently and comfortably and with a minimum of fatigue.

• **Size and Space for Approach and Use:** Appropriate size and space is provided for approach, reach, manipulation, and use regardless of user's body size, posture, or mobility.

## 4. Policy in practice

As theoretical construct, accessibility has been defined in Section 2, to encompass physical, perceptual and appropriational moments, at which visitors and participants gain physical access to sites and activities, perception of official (given) narratives and appropriation of such narratives so that they can rationally accept, reinterpret or amend them according to their own cultural contextuality and aspirations. Yet the pertinence of the concept lies in its practical efficacy, in its application as enabler of cultural consumption, as revealer of the symbolic as productive activity. In this respect, significant progress has been made in the course of history. From the aristocratic culture of the Renaissance, where a painting in a private collection would be seen by as many in a hundred years as one can view it nowadays hanging in a major international museum in the course of a single day, huge strides in accessibility have been made. More recently, the infinite expansion of cyberspace broadens the horizon of both physical and perceptual accessibility, new technologies, and especially ICT, offering new tools, both material and symbolic, for the mass appreciation of culture and heritage. Significantly, over the past decades, increased awareness of difference, of pluralism as interpretative category, and an insistence on the access to culture and heritage as existential imperative, transformed the closed character of culture, broke through the binary divide between a high, elitist culture of the few and a low, deprecated culture of the many. Accessibility to culture thus becoming as essential as culture itself.

Policy, at European as well national level, has adjusted accordingly. It responded to a paradigm shift regarding otherness and the nature of culture, and, in turn, reciprocated upon the transition, legitimating and enhancing it. Some significant case studies involving lobbying efforts and policy applications with respect to cultural accessibility are here presented, the selection has being limited within the borders of Europe and including examples from both physical and cyber space. Some

examples of successful initiatives, promotional techniques (awards, official sites), mechanisms (databases), guides and site-located accessibility practices are listed below:

- **Access City Award:** An innovative competition between European cities which was launched in 2010 to promote accessibility in the urban environment for persons with disabilities and to fulfill the accessibility needs of ALL citizens. The Access City Award is open to all EU cities of over 50 000 inhabitants. In Member States with less than two of such cities, urban areas composed of two or more towns may also participate if their combined population exceeds 50,000 inhabitants. The award recognizes and celebrates cities which proactively support accessibility for persons with disabilities and take exemplary steps to improve accessibility in the urban environment. The 2014 Winner of the Award was Gothenburg (Sweden), Grenoble (France) took the second prize and Poznań (Poland) the third prize.
- **Pantou.org:** a website funded by the European Commission and developed by ENAT and partners. Its aim is the connection, free-of-charge, between suppliers of accessible tourism and Europe-inbound visitors. According to the Pantou directory the goals are: a) to make it easier for tourists with any kind of access needs to find what they are looking for when planning a visit, and b) to promote European accessible tourism suppliers, showing places to go and things to do – in safety and with convenience and comfort. The target groups are Tourism Suppliers (hotels / accommodation, restaurants, transportation services, equipment suppliers) and Tourists (people with different kinds of access needs, e.g. mobility/vision/hearing impairments, people with learning difficulties, people with allergies and families with small children).
- **ACA-Accessible Culture for All:** CA aims to develop a culture which will facilitate social tourism and accessibility for people with disabilities. Appropriate structures will be set up to foster the idea of inclusion. The project will focus on ways to improve the accessibility dimension of the tourism product and the service offer for the benefit of social tourists in Europe. To address the seasonality problem of tourism demand, the intention of the project is to share best practices among the partners and to identify mechanisms which would eventually facilitate exchanges for social tourists during the off-peak season. Eventually, it will lead to exchanges for people with disabilities giving them the opportunity to experience other tourism products. The ACA project involves the following activities: a) setting up of a team within the participating National Authorities that will serve as a working group to promote social tourism and strengthening collaboration between tourism investors, b) enhancing collaboration between project partners, c) implementation of relevant studies that will improve the knowledge base to facilitate low season exchanges for people with disabilities, d) creation of a web portal as a link to the CALYPSO web platform and e) dissemination of information amongst tourists and local citizens who may be interested to travel and who fall under the category of social tourists.
- **T-Guide:** The idea of that initiative is to give Tourist Guides an awareness of the requirements of persons with learning difficulties and intellectual impairments and to equip them with the skills to extend their guiding work to these groups of visitors, thus extending the offer of the tourism sector in Europe to a wider range of customers market. The aim of the project is to produce an EU training model and Manual for training Tourist Guides in guiding people who have learning difficulties or other intellectual impairments. The promotion of integration of people with intellectual and learning difficulties by enabling them to enjoy tourism experiences and the enhancement of the role of the third sector -especially organisations of people with disabilities and their families- in developing learning programmes and tools, in order to enable the delivery of higher quality tourism products is also an crucial expectation.
- **TD-Database for Access to Public:** a database that aims at: a) citizen information and consumer empowerment, b) the stressing of obstacles and impediments of accessibility and c) the explanation/motivation of what measures should be taken for achieving a high level of accessibility. The TD is also providing different stakeholders with valuable information and its

target groups are: people with physical disabilities (vision problems; hearing problems; mobility problems, allergy problems, processing, interpreting and communicating information problems), children, elder people, foreigners and people with special sexual and religious orientation.

- **CadW-Cad Wales:** CadW -a Welsh word meaning 'to keep' or 'to protect'- is the name of the initiative for conserving Wales's heritage, helping people understand and care about history and promoting the distinctive character of Wales. It proceeds by: identifying places of special historic significance, giving advice and guidance to planning authorities as part of the statutory planning process and to other public bodies on environmental assessments and providing grants for conservation and repair to the owners of the very best historic buildings, buildings in designated conservation areas and listed ancient monuments.
- **CLEAR- Cultural Values and Leisure Environments:** an international project that includes public institutions ONGs and research centers from 7 different countries. Twelve different partners are combining knowledge and personal to achieve project aims. The lead partner is Rimini Province from Italy. Its aim is to serve as a kick-start mechanism for generating a better attitude towards Cultural Values (CVs), making them accessible to all. The project wishes to make everyone aware of the possibilities represented by the increase in accessibility for people with disability. CLEAR will provide to different stakeholders (governments, tourist representatives, cultural operators) tools and practical experiences to improve the situation and will show them how to see the obligation of addressing accessibility issues as a new opportunity. CLEAR deals with all types of accessibility: a) physical accessibility to/and in CVs as intended in more than just legal terms, b) accessibility to knowledge and information on CVs, c) economic accessibility in both its dimensions (free services and paying for personalized services), d) psycho-social accessibility, considering all learning need typologies (from learning difficulties to intellectual people requiring specific in-depth info) and e) socio-cultural accessibility, at a personal level anyone can benefit from cultural values- knowledge regardless of cultural, social, religious or ethnic background.
- **Site-Located Practices [Tivoli Gardens and Athens' Metro]:** Tivoli Gardens is an amusement park, located in Copenhagen, which in 2005 received the Accessibility Label. Tivoli Gardens provides ramps for easier access in all of the entrances, disabled parking spaces, wheelchairs without extra charge, charging points for electric wheelchairs, "show consideration" cards for children or adults with mental disabilities and also includes a Family Amenity Centre. However, there is an entrance fee that may be a reason for economic exclusion. In Greece, the Athens Metro Stations and trains are completely PSNs-friendly and they include accessibility infrastructure. There are features which are included in the Stations of Lines 2 and 3 of the Metro network, in order to accommodate Persons with Special Needs (facilities for Semi-Ambulant Users and Wheelchair Users). One of the most important characteristics of the Athens Metro is the public display of ancient artefacts and exhibits in its Stations. These information segments and ancient artifacts are inviting every rushing passenger, either Greek or foreigner, to examine and admire them. In these terms, the Athens Metro is both a physical and a perceptual accessibility practice as well as a structure with daily use that also provides access in ancient heritage.

## 5. Conclusions and recommendations

The conclusions and recommendations are consistent with some basic principles that should be followed and additionally by some common mistakes that arise from the application of these principles. The recommendations are organized in the three moments of accessibility: physical, perceptual and appropriational. The basic principles are referred as the "DO's" that each cultural destination should follow and the common mistakes that they owed to avoid are referred as the "DON'Ts" (Table 4).

Table 4: DO's and DON'Ts concerning the ensuring the Three Moments of Accessibility

| | DO'S | DON'TS |
|---|---|---|
| PHYSICAL | **Ensuring connection to all cultural activity premises with disability friendly public transport networks as well as proper road signage** | **Establishing transport services exclusively for the cultural sites, unconnected to the broader urban network** |
| | **Ensuring full physical access for all to and within every cultural activity and exhibition premises** | **Obtruding aesthetic aspects of spaces and buildings** |
| | **Offering free or price-accessible entry for all** | **Depending the realization of cultural activities on private/sponsorship funds** |
| PERCEPTUAL | **Ensuring diffusion of information regarding cultural sites and activities** | **Providing either meager, out of date information or turgid and user unfriendly material** |
| | **Providing audiovisual information in situ in all relevant languages** | **Undermining the significance of exhibits with off scale information boards** |
| | **Providing different material for different types of audiences/visitors** | **Imposing visitor alienating information overdoses** |
| APPROPRIATIONAL | **Developing interactive comprehensive and user friendly supporting initiatives enabling the user's involvement** | **Developing supporting initiatives imposing dominant or conventional narratives** |

The transfer of good practices can convey fundamental benefits to different kind of target groups. However, the barriers to overcome are numerous and difficult to ignore. An initial assessment of the cultural assets in terms of accessibility may encounter difficulties which have to be fully comprehended by all partners. The reference to accessibility to heritage is connected to quality of life issues such as social inclusion, opportunity issues and knowledge enhancement (Laquirada et al., 2013). Lack of information is usually the cause associated to accessibility problems and actions concerning learning and broadening the horizons becomes necessary. Actions should focus on the transfer of good experience.

Governance structures appear to need reforms that should be introduced in three stages. The first stage should comprise awareness for public as well as understanding of the current situation regarding tourism industry and partnerships. In order to succeed, urban governance in any scale is necessary to understand the real need, as stage two regards the direction towards enhancement of accessibility from city planners applying successful practices and achieve growth with the introduction of guidelines for statutory planning process. The third stage comprises actions for participation and cooperation between authorities, institutions and enterprises; a collaboration that can be achieved through different scale decision makers in heritage accessibility sector such as local and regional authorities, national tourism organisation and every kind of cultural industries (Centre for Strategy and Evaluation Services, 2013).

In addition, heritage and culture are inextricably connected to the tourism sector. Appropriate structures could enable the creation of networks among tourism suppliers such as travel agencies, guides, hotels and restaurants that will transfer each other creative and innovative ideas. Know-how exchange can trigger processes and set mechanisms useful to achieve extension of the tourist period. Steps towards a re-branding of the tourism product, with focus on quality, provided that professional communication tools will be enforced to attract a more targeted audience, will likely increase the possibilities of tourist repeat visits (Shaw and Williams, 2009).

Accessibility in relation to economic availability is another sector in which good practices may have a beneficial effect on. Especially, during the current socio-economic crisis, education and leisure, are witnessing severe cuts. Accessibility concerns population groups characterized by their age, abilities or disabilities, religion, economic power, etc. These people may spark the appearance of new professions that can be brought to particular regions and cultural places (Centre for Strategy and Evaluation Services, 2013).

Another aspect of accessibility enhancement is the use of IT technologies as an instrument of promoting good practices. “Technophobia” may be a constrain of its own to this effort and has to be totally surpassed, as tourism and culture institutions and industries require use of innovative technologies to facilitate processes and expand tourism demand over off-peak season or create new tourism flows.

An environment that permits the transfer of good practices is hard to be sustained, as it needs an intense groundwork to attain the sharing of experiences as a way of resolving accessibility problems. The redesign of accessibility terms at national, trans-national and European level needs a programmed operation that is considered hard enough to be succeeded completely by a single company that acts at the best practices against all measurements (Shaw and Williams, 2009).

Sharing of good practices can be reinforced by efficient and continuous information forwarding, as communication helps to ensure that the goal is set and the needs are known by all stakeholders. IT infrastructure can diminish the distance and time factors that may hamper the sharing process. However, the problem of leadership and policy making constitutes a critical factor. Administration management in different scales has to resolve issues of competence and capacity building and set common goals and objectives.

Keywords: density, public transport, mid-size city

***Abstract***

*This paper deals with the relationship between population density and public transport efficiency. It is focused on mid-size cities with a population of 100 000 inhabitants. The research question is, how strong the relationship is and if increasing residential density can be an effective tool for public transport promotion. The results indicate that increasing residential density could have an effect for public transport use only in neighbourhoods with lower density. Large part of the cities' population lives in prefabricated housing estates with high population density about 100 inhabitants per hectare. However there is no significantly effect, when the density is increasing above ca. 70 inh./ha. The results could be a contribution to the debate, under what conditions increasing residential density is an effective tool for creating sustainable city.*

## 1. Introduction

Increasing population density is one of the most important tools for creating more sustainable city (Duany et al., 2010). On the other hand a compact city can be criticized for its lower liveability – quality of environment and well-being of people is often lower in such city (Neuman, 2005). It is necessary to achieve a balance between sustainability and liveability that is appropriate to a city of a particular size. People's expectations to healthy and pleasant environment will be naturally higher in smaller cities, where are however not so good economic opportunities (Glaeser, 2012). Furthermore it is much more important to protect green spaces and recreational areas in high-density neighbourhoods, where people do not have their own gardens. Thus social responsible planning should consider negative impacts of sustainable city forms to low-income groups of inhabitants, who live very often in high-density neighbourhoods.

This paper focuses on the relationship between public transport efficiency and population density in mid-size cities (about 100 000 inhabitants). This relationship is theoretically analysed on the basis of the concept of TOD (Transit Oriented Development), however it is necessary to adjust this concept to conditions of mid-size cities. We define following research question: How much does residential density affect public transport use in mid-size city? We try to find a threshold of residential density with a positive effect on public transport use. Such limit should be then accepted in practice for balancing demand for sustainable public transportation and demand for better availability of green spaces and recreational areas.

## 2. Literature review and research project

### *2.1Literature review*

During the last few decades we can observe an escalating debate about the urban design trends associated with the movement of New Urbanism, even in the Czech Republic. There is more talk about main themes of New Urbanism, i.e. the concept of compact city, walkable neighbourhoods, reducing car traffic, public spaces restoration etc. (Duany et al., 2010). One of the key themes of the new urbanism movement is the density of the city – population density, density of job places and facilities. Compact city with higher density is promoted as more sustainable urban form (Jenks et al., 2003).

An important group of scholars are concerned with specialized field of New Urbanism movements that focuses on increasing public transport efficiency. This concept is called transit oriented development (TOD). It should lead to more efficient use of public transport and it is based on analysis of the following parameters: Density of city, diversity (mixing use), design of city environment, distance to transit (distance to the nearest stop) and destination accessibility. The authors call these parameters as 5 D's of TOD (Cervero, Ewing, 2010).

Density is considered as important variable for TOD supportive city design. Very comprehensive research from R. Ewing, R. Pendall and D. Chen (2014) analysed 83 U.S. metropolitan areas with population over 500,000 inhabitants and concluded strong relationship between density and transit commute share. The literature review from Cervero, Ferrell and Murphy (2002, pg. 80) states following: "Research consistently shows that density has a significant bearing on transit ridership. In a 1995 Transit Cooperative Research Program (TCRP) study of boardings at 261 light rail stations across 19 U.S. and Canadian cities, an elasticity of nearly 0.60 was found between ridership and population density – controlling for other factors, every 10-percent increase in population density was associated with about a 6-percent increase in boardings at LRT stations."

But there are many sources that do not share the same level of enthusiasm. Even Jenks et al. (2003) in their flagship book regarding the concept of compact city (The Compact City: A Sustainable Urban Form?) critically evaluate the effect of higher density on travel behaviour. Their results indicate only a little effect of the urban form on transit commute share. Positive Cervero and Ewing's results were relativized by their own meta-analysis showing density has one of the weakest effect on transit use: "It is sometimes said that "mass transit needs 'mass'"; however, this is not supported by the low elasticities of transit use with respect to population and job densities…" (Cervero, Ewing, 2010, pg. 276).

Also there is a discussion, what is the residential density threshold for sustainable public transport system. It is talked about at least 7 units per acre (ca. 40 inhabitants/ha) for supporting bus service every 30 minutes and about 30 units per acre (170 inh./ha) for supporting bus service every 10 minutes (Cervero, 1993). R. Ewing (1999) sets lower value of 15 units per acre (85 inh./ha) for premium bus service. P. Hnilička (2012) sets the minimum of population density for economically sustainable bus service in Czech conditions on 50 inh./ha. Walkable city starts on 100 inh./ha.

It is obvious that different values will be relevant in smaller, mid-size cities. Most of researches concerning TOD focus on big cities or metropolitan areas. Jones, Mock and Cearley (2006, pg. 24) define the difference between travel behaviour in bigger and smaller cities as following: "In large metropolitan areas with well-utilized public transit systems, riders are more diverse in regard to socioeconomic status. However, in small to mid-size cities, riders tend to be predominantly poor and live in the innercity."

*2.2 Research project*

Our research analyses relationship between public transport use and the population density in three Czech mid-size cities with a population of 100 000 inhabitants. The purpose of this work is to contribute to the discussion, to what extent it is appropriate to apply the principles of the compact city in mid-size cities conditions. There are not such a good economic and career opportunities in these cities as in big metropolitan areas (Glaeser, 2012). On the other hand people in mid-size cities expect better environment and better access to public greenery. And the critics of compact city point out the "compact city paradox" – city with higher density could be more sustainable, but it is also less liveable (Neuman, 2005). Lot of people is still dreaming about living in more sprawled city, in houses with gardens or with access to free landscape and they are going to migrate to suburbia (Howley, 2009). So it is necessary to increase density only in that way that we would not discourage mid-size cities' inhabitants from living in a core city.

Our previous research has showed that access to free landscape, suitable for short-term recreation, could be in the Czech mid-size cities very unequal (Felcman, Franke, 2013; Felcman, 2014). There are big differences between individual neighbourhoods in their density. Over 3 million from a total 10 million people in Czech Republic live in prefabricated housing estates with high population density and this causes the inequality mentioned above. Implementation of compact city principles should not worsen the conditions of the people living in the housing estates, on the contrary, it should contribute to more social responsible planning of the cities. Identification of the residential density threshold will help to implement compact city principles in the appropriate neighbourhoods.

*2.3 Research method*

We collected data of public transport use from three Czech regional cities: Liberec, Czech Budejovice and Olomouc. The structure of the data was different. In Liberec and Olomouc we processed number of passengers using various public transport stops (number of getting on and off). There was available only occupancy of public transport vehicles between the stops in Czech Budejovice. In both cases we transformed the data in that way, we connected them with demographic data of individual basic administrative units (BAUs). According to their size of built-up area, number of inhabitants and population density we derived data of public transport use among individual BAUs.

Built-up areas of those cities contain contiguous area of settlement including connected settlements of neighbouring municipalities, without fragmented parts of built-up area. We used the method from previous research, where these central polygons were created (Felcman, Franke, 2013). Since we have focused on the housing areas only, we have eliminated those BAUs with less than 100 inhabitants. Also we eliminated those BAUs, which had more than 100 inhabitants, but their built-up area had mostly a non-housing character. According to land use plans those BAUs consist mostly of production areas, recreational areas etc. The population density of these BAUs was misrepresented, because most of their built-up area was not determined for housing. At the end we eliminated central parts of the cities – data of public transport use are misrepresented by high number of changing passengers in central parts, there is high mix of use and it could be expected that many residents do not use public transport and walk in these parts of the city (see fig. 1).

After this elimination we got into analysis 64 BAUs in Liberec, 44 in Olomouc and 36 in Czech Budejovice. We tested the relationship between the population density and public transport use index that is based on the ratio between the population and the use of public transport.

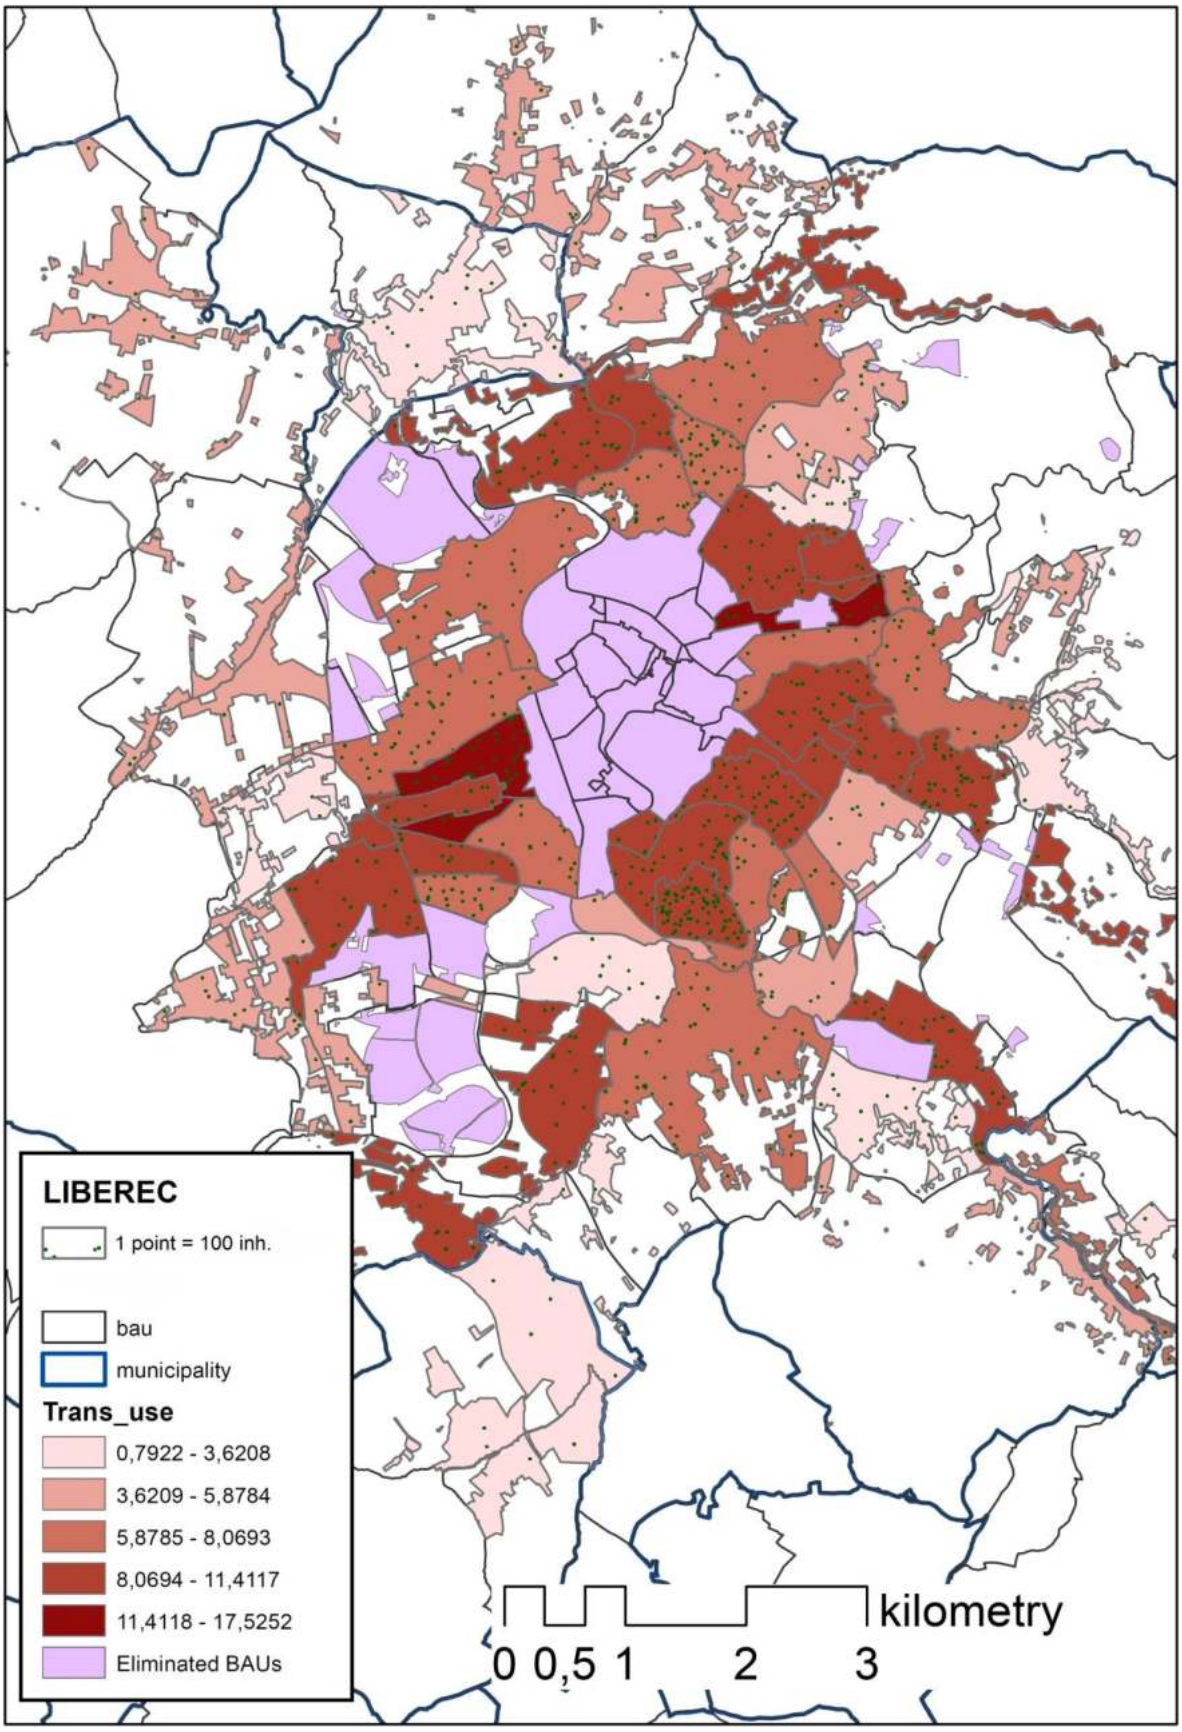

Figure 1. Results in Liberec – analysed BAUs without eliminated parts of the city (central parts, non-housing neighbourhoods).

*2.4 Statistic processing*

The goal of the statistical analysis was to establish statistically significant regression models for each city that would explain the use of public transport on the basis of population density in a given BAU. Then we focused on the appropriate adjustment of data and creation of a single set of data for regression analysis and the model of addiction between explained and the explanatory variable across cities.

The data of residential density and public transport use are available in three data sets distributed by town. The first step was the basic data editing, including compensation and reunification records in the data set to an initial value 0 and maximum value of index of public transport use around 18 for the planned unification of data. Followed by the basic statistical evaluation (e.g. to determine the median, standard deviation, skewness, kurtosis, etc.) and Shapiro-Wilk test was considered normality. Normality has not been proved; this has an impact on our conclusions that can be deduced from the statistical evaluation.

Variances hypothesis was tested for unified data for all three cities. The test showed equality of variances in relationship between public transport use and the residential density in all cities. The exception is the relationship of Liberec and Olomouc, where the hypothesis of equality of variances was not confirmed, but compliance was close.

Then we created 21 regression models with different settings and we selected the best four of them based on the most suitable parameters RMSE, $R^2$ and the test values characteristic "Pr > F". We have chosen, if possible, a model where the value "Pr > F" indicates its significance.

All tests were confirmed at a significance level $\alpha = 0.05$ and as statistical software was used SAS in version 9.2.

*2.5 Results*

Czech Budejovice

Six models were constructed for the data from Czech Budejovice. The best values was showed by a model, which is defined by a second order polynomial levelling, and it achieves the coefficient of determination $R^2 = 0.22$. According to this model the use of public transport is indicated by population density from 22%. RMSE (Root Mean Squared Error) has also relatively low value of 3.3 in this model. Value "Pr > F" reaches 0.02, therefore the null hypothesis is not rejected and the model can be considered as significant. The functional relationship is shown in the formula below (y – use of public transport, x – population density):

$y = -0{,}0009x^2 + 0{,}1508x - 0{,}8773$

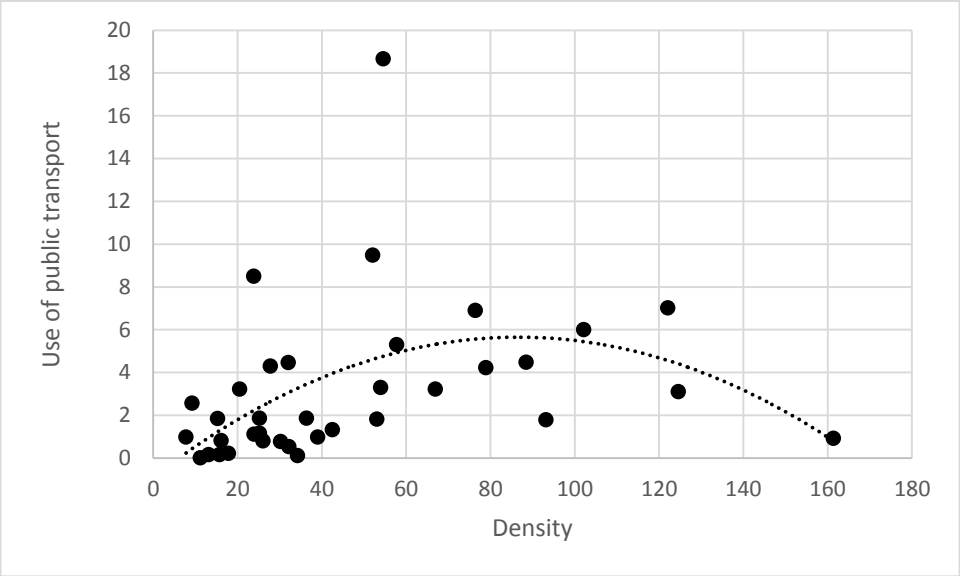

Figure 2. The relationship between residential density and public transport use in individual neighbourhoods in Czech Budejovice.

Liberec

The most appropriate model for Liberec was again selected on the basis of the best indicators value from six created models. The best values were showed by a model, which is defined by a third order polynomial levelling, and it achieves the coefficient of determination $R^2 = 0.357$. According to this model the use of public transport is indicated by population density from 35.7 %. RMSE showed by this model is also relatively low with value of 2.85. Value "Pr > F" is close to zero, therefore the null hypothesis is not rejected and the model can be considered as significant. The functional relationship is shown in the formula below (y – use of public transport, x – population density):

$y = 0.00001x^3 - 0{,}0035x^2 + 0{,}2931x + 1{,}6529$

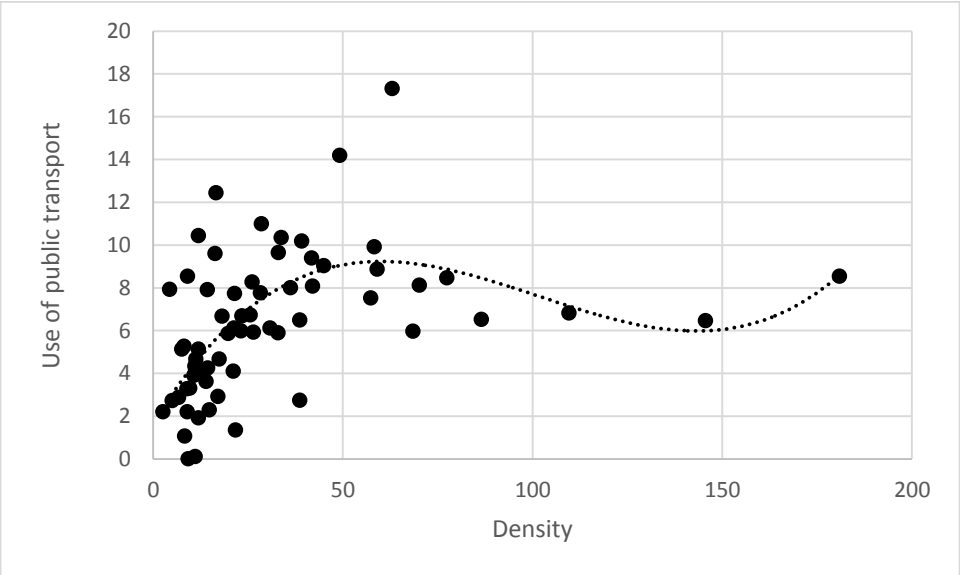

Figure 3. The relationship between residential density and public transport use in individual neighbourhoods in Liberec.

Olomouc

Six different regression models were created also for the city of Olomouc. None of them showed statistical significance. It can be chosen as the best second-order polynomial model from the available models that achieves a low coefficient of determination $R^2 = 0.06$. RMSE for this model reaches value of 3.6. Value "Pr > F" is very high (0.28) and therefore it is not statistically significant. For completeness, the following functional relationship designated by model below (y – use of public transport, x – population density):

$y = -0{,}0002x^2 + 0{,}0495x + 3{,}9064$

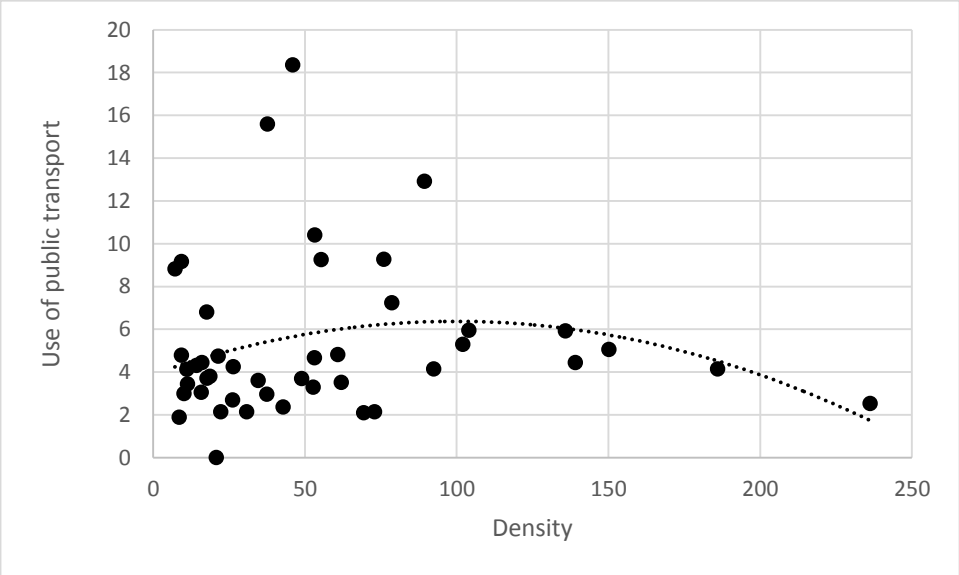

Figure 4. The relationship between residential density and public transport use in individual neighbourhoods in Olomouc.

The regression model for aggregated data from all analysed cities

Three models were created for aggregated data from all three cities. According to the indicators it was chosen model, which is defined by a third-order polynomial levelling. It achieves the coefficient of determination $R^2 = 0.1$. According to this model the use public transport is determined by population density from 10%. RMSE for this model reaches the value of 3.57. Value "Pr > F" is close to zero (0.0019) and therefore the model can be considered as significant. The functional relationship is shown in the formula below (y – use of public transport, x – population density):

$y = 3E\text{-}06x3 - 0{,}0012x2 + 0{,}1335x + 2{,}5327$

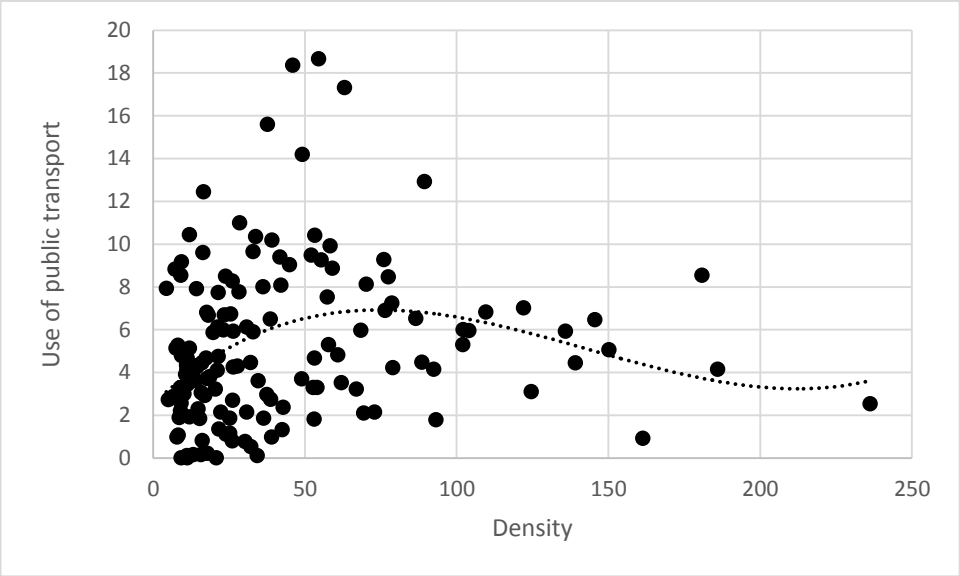

Figure 5. The relationship between residential density and public transport use in individual neighbourhoods of all three cities.

*2.6 Discussion*

Our study is limited by number of analysed cities and neighbourhoods. Furthermore the data of public transport use had different structure in all three cities and it was necessary to transform them. Only in Liberec we could analyse clear residential public transport use, because we had data derived by day time. So we made the analysis only with data of getting on passengers between 0:00 and 12:00 AM. It could be expected that those people are largely residents and not visitors and workers. The results could be more precise, if we could work with data of such structure from all cities.

The results are however quite similar in all three cities. We could observe that BAUs with density above ca. 70 inh./ha do not have significantly higher rate of public transport use in relative numbers (ratio of riders to number of inhabitants). The positive influence of increasing density is noted primarily in neighbourhoods with lower residential density. What could be consequences of such results?

At first we should mention that Czech mid-size cities are rather monocentric. People from peripheral areas make a large proportion of trips just to the central zones. All three cities have extraordinarily high numbers of passengers at stops in one central zone of a city. Also their system of public transport is concentric with one or couple of main transfer stops in central zone of a city. If we consider size of the urban area of the cities and distance between most of analysed neighbourhoods and central zones, we could not expect larger share of commuting by walk; the distance is largely more than 1 km. The monocentricity and the size of urban area together imply that principles of walkable city with residential density above 100 inh./ha (Hnilička, 2012) cannot be successfully applied in whole area of mid-size city. Such higher density could be appropriate in central zone, but there is no strong positive effect of such high density in peripheral neighbourhoods. On the contrary increasing residential density could decrease quality of environment in these neighbourhoods (Neuman, 2005).

Our previous research showed inequalities in free landscape accessibility in Czech mid-size cities. 64% of Liberec inhabitants live without direct contact with free landscape, although in Czech Budejovice it is only 37% (Felcman, 2014). In many cases development of new family houses cut off inhabitants of housing estates from free landscape in Liberec. Our results indicate now that

increasing residential density of those housing estates probably will not promote public transport use. Based on that, it could be recommended to protect green spaces close to prefabricated housing estates in Czech mid-size cities. Tools for increasing residential density should be targeted on neighbourhoods with lower density.

## 3 Conclusions

The results of our study indicate that increasing residential density positively affects public transport use rather in neighbourhoods with low density. Neighbourhoods with density above ca. 70 inh./ha – primarily prefabricated housing estates – do not have significantly higher rate of public transport use. We focused on Czech mid-size cities and we conclude that tools for increasing residential density should be targeted rather on neighbourhoods with lower density in these cities.

# 'Definite space, fuzzy chronology - the planning history of the 20C street revisited'

Michael Hebbert
Bartlett School of Planning, UCL <m.hebbert@ucl.ac.uk>

Keywords : streets, urban design, planning history

**Abstract**

*The street is a definite space but a strange category of object - void rather than solid. It is multifunctional: a public realm for trade, display, communication and social encounter; a channel for every kind of movement and a highway for vehicles; an architectural environment with distinctive aesthetic of enclosure, perspective and 'townscape'; an outdoor environment and part of the urban eco-system; a micro-climate with distinctive patterns of temperature, wind, sun and shade and humidity; a public infrastructure, a political economy in miniature with a unique combination of ownership and governance; a place with a name, address and identity - a locus of collective memory.*

*The standard chronology of 20C street history is a three-step 'Death and Life' narrative, based on the evolution of design theory, that sees it embraced by fin-de-siècle urbanism, rejected by the Modern Movement, rediscovered by postmodern urbanism. By reviewing this narrative from the perspective of the many distinct functions that streets perform, my paper reveals a fuzzy and overlapping chronology that puts both the death of the 20C street and its resurrection into question. The paper will also directly address the overall conference theme of the multiple governance of geographical space.*

## 1. Introduction

The street is a definite space with fuzzy responsibility - a microcosm of our conference theme. Its *definiteness* is physical and unambiguous: streets are contained by the vertical frontages of the buildings that line them and give shape and character to their space - *Stadtraum* - the characteristic enclosed realm of urban public life. They are named and mapped and mostly outlast the buildings for which they provide an address, just as buildings tend to outlast their human occupants. The older a town, the greater the age of its streets. giving them historical as well as contemporary definition.

The *fuzziness* of streets derives from the multiple roles that they perform. A street is a multifunctional space: a public realm for trade, display, communication and social encounter; a channel for every kind of movement and a highway for vehicles; a way-leave for public infrastructure; an architectural setting with a distinctive aesthetic of enclosure, perspective and townscape; an outdoor environment and part of the urban eco-system; a micro-climate with distinctive patterns of temperature, wind, sun and shade and humidity; and a public realm and locus of collective memory. Each aspect involves different issues of policy and brings its own set of rules. So the street which is such a definite space is also a regulatory fuzz, a complex political economy of ownership, use and governance.

## 2. Biographies

Each street has an individual life-history beginning from the moment when its lines are first traced on the surface of the earth. Some streets have distant origins as farm-tracks or animal pathways, others are formed by state authority and laid out with the force of a military action, some are commercial ventures developed to create urban value for the plots that make up its frontage and provide its economic rationale, others again originate in the spontaneous actions of citizens, marking out sites for informal settlement.

Narratives of the life and times of individual streets are a fascinating literary genre, whether written from a perspective of fiction, history, geography or ethnography. Street biographies can also be told cartographically through maps and visually through photographs taken from a fixed vantage point, revealing the shifting balance between vehicles and pedestrians, and the changing relationship between building facades and the public realm. 'Double Vision', a recent exhibition of archival and contemporary photographs of the forcibly removed neighbourhood of South End in Port Elizabeth compiled by former resident Yusuf Agherdien, shows the impact of the 1950 Group Areas Act, before and after the forcible removal of residents from a culturally diverse neighbourhood to segregated townships, and the replacement of vibrant streets with highway landscapes and gated townhouse complexes for whites only.

**3. The Grand Narrative**

However, the focus of this paper is not on individual streets but on the overarching history of the street as a design type situated right at the heart of twentieth century urbanism. The paper follows a simple structure, first setting out a standard, definite narrative as it might be taught to first year undergraduate students, then introducing the qualifying factors that make it fuzzy.

The received narrative of the history of the street can be readily assembled from standard texts - Stephen Ward, Spiro Kostof, Jonathan Barnett. The narrative begins in the pre-1900 world of the 'traditional' street, a term that encompasses many differences while expressing a shared reality of movement by hoof and foot on public thoroughfares framed by the frontage private frontage. This immemorial typology undergoes four transitions in the short space of the twentieth century.

First at the turn of the century comes the concept of town planning or urbanism, implying the application of collective action and technical rationality to the ancient practices of the street. Joseph Stübben's *Der Städtebau* (1907), Eugen Fassbender's *Grundzüge der modernen Stadtbaukunde*

[Foundations of the Modern Science of Urban Planning] (1912), Raymond Unwin's *Town Planning in Practice: an introduction to the art of designing cities and suburbs* (1909), Nelson Lewis's *The Planning of the Modern City* (1916), John Nolen's *City Planning* (1916), Edouard Joyant's *Traité d'Urbanisme* (1923). Joyant provides a complete manual of street-building which begins with the dimensions of every major boulevard in France, and proceeds to explain the formation of blocks and the technique of parcelling land, controlling building alignment and height, and placing public buildings. Common to all these early texts of 20C urbanism is the idea of a progressive transformation of the attributes of 'traditional' urbanism.

What happened next was a true example of a paradigm shift. The Modern Movement rejected the assumption of continuity in urban design. Corbusier's *Urbanisme* of 1925 derides the corridor-street - the *rue-fissure* - as unwholesome and unworthy of twentieth-century man. Under his tutelage the International Congress of Modern Architecture (CIAM) develops and disseminates a theory of the streetless city, in which wheeled traffic moves freely on its own road hierarchy, architecture is liberated from the servitude of facades, and nature penetrates everywhere. Monumental towers, clean geometrical architecture, unornamented whitewash and iconic landscapes combine with a compelling verbal narrative of machine-age progress. State patronage in East and West Transforms drawings and maquettes into full-scale city-building experiments.

But around the mid-point of the century another dialectical shift occurs. Wartime destruction and the beginning of postwar urban clearances heightened younger modernists' awareness of the significance of the physical settings of everyday life, and the power of people's attachment to particular places and local identities. Aldo Van Eyck, Jacob Bakema, Louis Kahn, Georges Candilis, Shadrach Woods and Alison and Peter Smithson broke away from CIAM and launched Team 10, shifting the emphasis from function to human association and quality of the everyday habitat. This generation reinstates the traditional street as object of emulation though their models of urbanity were no longer sought in boulevards but in the dense, picturesque, intimate environments of the casbah and the slum, the Italian hill-town, the Cornish fishing village. Separate but convergent movements for 'townscape' and for 'urban design' are launched in the postwar decade, and Gordon Cullen, Kevin Lynch, Edmund Bacon are among those who provide the necessary technique and terminology. It is a strange phase of design theory in which a fascination with the layout and human dynamics of the street finds physical expression in multi-level megastructures and pedestrian decks or in pocket parks under the lee of office towers. Writing in 1975, the best Shadrach Woods can hope for in *The Man in the Street: a Polemic on Urbanism* are street-like opportunities for pedestrianism and face-to-face encounter within a world of free-flow highway engineering and widely-spaced superblocks.

The fourth step in the dialectic takes urbanism full circle to address the agenda of modern living in a *rue-fissure*. As Nan Ellin shows in *Postmodern Urbanism* (1998) the return to the street originates in grassroots activism against the bulldozer in Paris, New York, Toronto, Brussels, Berlin, Barcelona. Community struggle against planned modernisation produces a considered defence of the conventional mixed street - the real thing, not the *ersatz* urbanism of Team 10. Using the powerful black-and-white simplicity of figure-ground maps, Aldo Rossi and Colin Rowe teach architects to 'forget architecture' and appreciate their role as urbanists, shaping space through the outer walls of buildings. Intellectuals such as Henri Lefebvre and Ed Berman find words to articulate the contribution of the street to political pluralism, cultural creativity, economic growth, and erotic possibility. Jane Jacobs and W H Whyte, in the distinctive tradition of American pragmatism, contribute micro-observations of layout and human behaviour in 'streets that work'. Whyte is also one of the first to articulate the economic rationale for street revival, that as the city lost industrial and commercial functions for which it was no longer competitive it would reassert its ancient role as the place where people come together face to face, human congress being 'the city's true export' (1988 341). So, revival of the street was supported from multiple perspectives. A planning theory based upon the shared public realm of central places harmonised equally with the emerging pattern of postmodern, x-generation life-style, and with growing awareness of CO2-induced climate change and the significance of the sustainability principle for transport and urban form.

By the last decade of the twentieth century we had arrived at a robust consensus around the principles of urban design. The mixed-use street was once again endorsed, indeed encouraged by official policy. The Blair government convened a Task Force chaired by Lord Rogers to promote the recovery of urban over suburban areas. Sir Peter Hall, who sat on the commission, spent the next decade demonstrating how the sustainable city was being realized in progressive urban projects around Europe, at Freiburg, in Stockholm's Hammarby Sjostadt, in the tram-based perimeter extensions to Dutch cities. All are street-based.

**4. Towards a Conclusion**

But here, in mid-May 2015, my paper ends on a note of incompletion. So far I have only described the definite. By the time we reach Prague in mid-July 2015 I will have added the fuzzy - which is the real point of the paper. Come and hear why the apparent consensus of the Urban Task Force has proved illusory, and why the clear-cut narrative we teach to first year undergraduates is alas mendacious.

# Research on the Relationship between the Accessibility to the Public Space of Communities and the Sense of Community

Gangyu HU[1] Qian ZHAO[2] Yujin ZHANG[2]

[1] Tongji University College of Architecture and Urban Planning hugangyu1991@163.com

[2] Tongji University College of Architecture and Urban Planning 594081886@qq.com

Abstract: This paper mainly pays attention to the physical and psychological accessibility to the public space of three different types of communities in Shanghai, which are the Lilong area around Hefei Road, the worker housing around Sujiatun Road and the superblocks around Liyuan Road. After the investigation of the three areas, the physical accessibility of the three communities would be analyzed from two aspects: the physical structure and the boundaries. After the interview with the residents living here, the psychological accessibility which is more closely connected to the sense of community would be summarized and analyzed to the three communities respectively. And then a good community example—Hearthstone Cohousing Community would be given as the comparison. Finally, based on the analysis above, the relationship between the accessibility to the public space and the sense of community would be preliminarily concluded. And also some suggestions would be given to help enhance the sense of community.

Keywords: Sense of Community Physical Accessibility Psychological Accessibility

## 1. Introduction

Sense of community (or psychological sense of community) is a concept which focuses on the experience of community rather than its structure, formation, setting, or other features. Sarason summed up sense of community as "the sense that one was part of a readily available, mutually supportive network of relationships upon which one could depend and as a result of which one did not experience sustained feelings of loneliness" (Sarason, 1974) . Actually, citizen participation in community organizations has been viewed as a major method for getting strong sense of community through improving the quality of the physical environment, enhancing services, preventing crime, and improving social conditions ( e.g., Ahlbrandt & Cunningham, 1979; Churchman, 1987; Florin,1989). And citizen participation is mainly done in public space. Consequently, the accessibility for citizens to public space of communities is considered as an important factor in the formation of sense of community. That's the reason why this paper focuses on the physical and psychological accessibility to the public space of three types of communities based on our investigation.

## 2. Physical Accessibility

2.1 Physical Structure

From the layout map, it is easy to be found that these three communities have their special distinguishing features. Lilong area (Hefei Road area) is a small scale community with narrow lanes through it. The Worker Housing area (Sujiatun Road area) has a bigger scale with mostly multi-storey buildings in it. And the Superblock area(Liyuan Road area) has a huge scale with high-rise housing in it. (Figure 1)

Lilong Housing Worker Housing Superblock

Figure 1. The Layout of Three Different Types of Communities (Source: http://map.baidu.com)

In Lilong， the public space and living space is mixed together, and people can go inside randomly. So activities occur freely outside and inside the area. In the Worker Housing Sujiatun Road area, public space is along the street, so it has high accessibility. Activities mostly happen along the street in the greenery. And in the Superblock area, the public space is inside the community and available only for residents, so it has low accessibility for people outside. Activities show an intensive aggregation in the middle courtyard. (Table 1)

Table 1. Physical Accessibility Comparison of Three Types of Communities

| Site | Lilong Housing<br>Hefei Road Area | Worker Housing<br>Sujiatun Road Area | Superblock<br>Liyuan Road Area |
|---|---|---|---|
| Physical Accessibility<br>Street<br>Greenery<br>Buildings<br>Flow of People(inside)<br>Flow of People(outside) |  |  |  |

2.2 Boundary

In Lilong, no specific boundaries exist. No walls, no fences, just these stores around this area working as boundaries. Entrances spread along the street. So it is kind of totally open. In Sujiatun Road Area, fences and greenery are boundaries. The greenery working as public space is outside the fence facing to social people. In the meantime, the fences separate living space of the community from the social public space outside. So the life in the community is comparatively private. In the Superblock, fences as boundaries keep the greenery totally inside like walls. These boundaries separate people and activities inside from outside, which makes it a relatively closed community. (Table 2)

Table 2. Boundaries of Three Types of Communities

| Site | Boundary Schematic Diagram | Boundary Forms |
|---|---|---|
| Lilong Housing |  | Stores |
| Worker Housing |  | Fence and Greenery |
| Super-block |  | Fence |

## 3. Psychological Accessibility

Psychological accessibility is different from physical accessibility in these three communities. It is more about how people feel when they get into this place. As to how you get here, easily or hard, that doesn't matter so much. So psychological accessibility is more closely connected to the sense of community. Here, we have interviewed a few people who were opportunely in the public space when we were doing the investigation. And the information has been summarized in the table below. (Table 3)

Table 3. Interview Information Summary

| Site | Main types of users | Frequency of utilization | Activities | Users' living place | Neighbor relationship |
|---|---|---|---|---|---|
| Lilong Housing | The old<br>The mid-aged<br>The young<br>Children | often | Social<br>and<br>Private | around<br>inside | familiar |
| Worker Housing | Old people | often | Social | inside<br>nearby<br>far away | Not too familiar |
| Super-block | Old people<br>Children | often | Social | inside | not familiar |

As we take the "neighbor relationship" as an important factor of the sense of community, we could preliminarily recognize that the sense of community in Lilong and the Worker Housing is stronger than that in the Superblock.

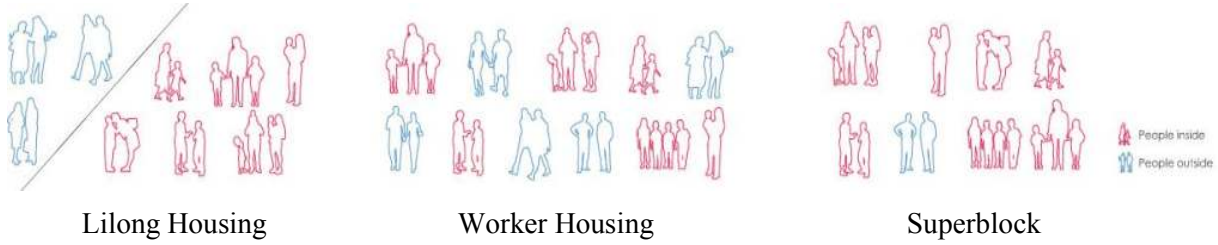
### 3.1 Lilong Housing

The Lilong itself is a very special kind of community. Here, the narrow lanes work as public and semi-public space. It doesn't have clear borders between public space and private space. Because of the incapacious living space and some kind of tradition, residents here always do private things in public space, such as doing the laundry and having dinner. To people living here, the second they step outside their houses, they get into the public space. Because of the small space scale, they can easily talk with each other even just stretching heads outside the windows, therefore making them more familiar and more intimate. Most of them have been living here for a long time. And thanks to the longtime brotherly communication, they almost know everyone living around this place. Somehow they get closely bound up with each other, and in this way the strong sense of community comes up.

To the people living outside, because the Lilong doesn't have boundaries like walls and fences, so it does have high physical accessibility, which means people can go inside randomly. But the thing is,

when you go into a Lilong house-block, you would have a strong feeling that you don't belong here. Even though the lanes inside are public space, it has a more private feeling, which makes Lilong space not so welcoming to people outside. Even if you are a new renter living here, you will find it very hard to integrate into the original residents. So the Lilong has high physical accessibility but low psychological accessibility to people living outside. This also reflects the strong sense of community in Lilong, which is some kind of exclusive and which is spontaneously formed not depending on physical boundary.

But on the other side, boundaries really can support the safety of a community. The sense of safety which is affected by the many strangers coming and going in the lanes is a big problem existed in the Lilong space.



Lilong Housing Worker Housing Superblock

Figure 2. People Mixing in Three Kinds of Public Space

3.2 Worker Housing

In Sujiatun Road area, the public space is along the street around the community. It has high physical accessibility to both the residents here and people living outside. This dynamic space which offers enough room for social meeting, is more welcoming than Lilong and the Superblock. It welcomes to different meetings with friends and strangers. Thus the public space in Sujiatun area has both high physical and high psychological accessibility.

But here comes the question. More welcoming, more strangers. Does it lead to less sense of community? Actually, these "strangers" are mostly from the communities nearby. They gather together sharing the public space to chat, to play cards, to do exercise and so on. People from different communities mix together harmoniously here. In this way, the sense of community goes outside one community and expands to more house-blocks, which consequently forms the sense of "big community".

Since the fences separate the living space inside from the outside public space, this Sujiatun area somehow creates a big sense of community while still preserving privacy. And because of the boundary, it has a good sense of safety too.

3.3 Superblock

The Superblock has very firm boundaries, which proclaims that it is totally not welcoming to the outside people. So the public space inside has both low physical and low psychological accessibility to the people outside. Even if boundaries sometimes can support the sense of community, it obviously doesn't work here. According to our investigation, most residents here are not familiar with their neighbors and they can hardly recognize each other. The sense of community here is very weak. Some old people moving out from Lilong to this Superblock express that they miss their old life in Lilong very much.

What makes this community get so little cohesion? The sense of belonging is a main problem. Originally, McMillan and Chavis identified one element of sense of belonging as "expectation of belonging"(McMillan & Chavis, 1986). At this time, that concept seems best described as the "faith that I will belong." Acceptance remains unchanged. These two elements emphasize the two points of reference that are constant in sense of community theory—the member and the community. In Lilong, the moment the residents step into the lanes, they get a strong sense of belonging thinking that they have already reached their homes. However, in the Superblock, only when they get into their houses, can they feel the sense of belonging and relax themselves.

The scale is also a factor which influences the sense of community. Compared with Lilong, all these narrow lanes and small houses, such tall buildings in the Superblock seem like huge living machines. People here get very weak sense of presence. The Superblock gives much attention to the community itself instead of the members living in it. (Figure 3)

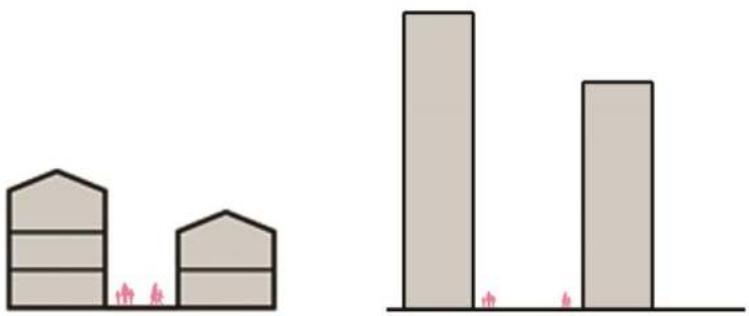


Figure 3. People's Sense of Presence

## 4. A Good Community Example—Hearthstone Cohousing Community

Hearthstone Cohousing Community has six characteristics. Firstly, all the community members participate in the community design, sharing their requirements. Secondly, neighboring building layout should reflect the sense of community, including household orientation, the setting of the pedestrian space, etc. Thirdly, the public facilities such as public kitchen, dining room, activity room, etc. should be free for every household with the management and use. Fourthly, Community residents

jointly maintain the community property, and hold regular meetings to make decisions for community development. Fifthly, there is no hierarchy in the social structure and decision-making principles. Lastly, every member should make a contribution in the collective labor showing that you are part of the community.

In the three kinds of communities we have mentioned above, Hearthstone Community is more like the Lilong. They both get small scale and some lanes. But the lanes of Hearthstone Community is much wider than that of Lilong. And Hearthstone doesn't have many stores around it. The walls of the houses form the boundaries of the community, which makes it have a good sense of safety. Residents here design this community and protect it together, and thus they get a very strong sense of belonging. Public space in the community which has high accessibility is open and welcoming to social people. All these elements set up a strong sense of community and make this community a practical reference case of the concept "Utopia". (Figure 4)

Figure 4. Hearthstone Cohousing Community (Source: http://www.hearthstonecohousing.com)

## 5. Conclusion

The sense of community is actually very complicated and has many influence factors. The accessibility to the public space is just one factor but gets some certain importance to it. The physical accessibility to the public space is mainly related to the physical structure and boundaries of the community. However, the psychological accessibility is more about people's feelings when they are in it. To people living outside the community, the psychological accessibility is mainly reflected by whether the public space is welcoming to them or not. And to people living inside, namely the residents, the psychological accessibility is more about the safety, the sense of belonging, and the sense of presence, etc.

From our investigation, Lilong Housing, Worker Housing and the Superblock all have their specific characteristics in sense of community. The Lilong has a strong sense of community, and meanwhile it has low psychological accessibility to the people outside (not welcoming). Therefore, the sense of community of Lilong is exclusive to some extent, and it is the sense of community in a small scale. The Worker Housing (Sujiatun area), its public space has high physical and psychological accessibility

to both the residents and people living outside. It somehow forms a great sense of community in a big scale, expanding the sense of community to more house-blocks. That is the most precious spirit of the Sujiatun community. As to the Superblock, a good sense of community is really hard to form according to its current situation. Maybe the managers of the community could hold some different kinds of activities for the residents to take part in. In this way, residents may communicate more with each other, and be familiar with each other little by little. It is time for the Superblock to put more attention to the members in the community emotionally, rather than just be a living machine providing them with living space.

To form a good sense of community, it is better that the scale of the community is well controlled from the sight of human scale. Boundaries can exist to keep the community safe and enjoying privacy. But the forms of the boundaries could be abundant and interesting, like fences, greenery, shops, not have to be cold walls. High accessibility to the public place makes contribution to form a great sense of community which breaks out the limit of community unit. The greenery ,some of which combine with pedestrian trails, some of which work as physical locations for social contacts and public events ,and some of which connect people to parks and playgrounds, promote good community identity and a neighborhood sense of community. Local authorities should take some measures to maintain the safety and good environment both in and outside the community. In the meantime, they could summarize and spread the good experience to more communities. This should cover not just green space or the outdoor public space but also public facilities such as shops, pubs and community centers. This information could then be used to inform planning decisions and public spending decisions.

# A CASE FOR RECONSIDERING THE INCLUSIVE URBAN DESIGN DEBATE

Elisabeta G. Ilie

UCL Bartlett School of Planning, elisabetailie@yahoo.co.uk

*Abstract*

*Mainstream theory and practice of inclusive urban design focus predominantly on the free access and use of the built environment. This becomes problematic when set against the homonymous theory which argues for places for all, under what appears to be a holistic, yet vague definition of 'inclusivity'. Moreover, a design focus on physical accessibility leaves unaddressed questions on users who are to benefit from inclusive design practices, to what extent and how that is to be achieved.*

*The present paper argues that in order to legitimately discuss issues of inclusivity in an urban design context, the discipline needs to consider not only urban design process and outcome, but also mechanisms behind exclusion/ inclusion processes and how these are embedded in everyday urban practices, artefacts and spaces.*

*This can only be attained by re-considering and re-phrasing the very concept of inclusive urban design. Building on a critique of the purpose and the function of the discipline, the paper challenges in-place notions of inclusive urban design and explores its limitations against taken-for-granted notions of everyday urban reality. This is done by drawing on sociological theories of socio-cultural production of space/place and of the body in space, with the aim to outline a more comprehensive and, potentially, more effective understanding of inclusive urban design.*

Keywords: inclusive urban design, (urban) reality as a socio-cultural construct

## 1. Introduction

Over the past decades, the discipline of urban design has aimed to step away from traditionally architectural concerns with the purely built form (Le Corbusier, W. Morris, F. L. Wright). Instead, attempts have been made to account for urban experiences as part of the design process (Jacobs, 1961; Lefebvre, 1991; Lynch, 1960). These endeavours have picked up in recent years with emerging reflections on urban design as a potential catalyst for urban (social) change (Boano in Carmona, 2014a; Harvey, 2003; Madanipour, 2006; Mayer, 2009).

These ideals feed into the contemporary debate of inclusive urban design. Although with a relatively vague theoretical base and a methodology inadequate for its declared purpose, the discussion on inclusive urban environments is gaining momentum on policy agendas (Gov.UK, OECD). Moreover, it reflects disciplinary (urban design) changes in understanding city-making processes with implications on the urban design process itself (Carmona,2010; Gehl, 2010; Healey, 1997). For these reasons it is opportune to critically assess the principles and framework of the inclusive urban design debate, if inclusivity is to be not a mere buzz-word, but an effectively working concept.

In its current form, the theory of inclusive urban design has a number of limitations, namely that it targets a narrow segment of end users and it engages only partially with principles of urban design. As a result, in practice, solutions of inclusion by (urban) design are predominantly ineffective, while the public realm remains, to a large extent, exclusionary of certain social groups.

Therefore, this paper explores an alternative conceptual framework for inclusive urban design with the purpose of informing both theory and practice towards more inclusive built environments. The alternative conceptual framework considers the urban design process and its outcome alike; the paper starts from challenging the existing limitations within the inclusive urban design debate and continues by building on social theories of socio-

cultural construction of reality/identity and phenomenology. This is done in order to better understand the mechanisms behind processes of exclusion and the potential pre-sets of inclusive practices. It is hereby suggested that exclusion from the built environment is not only physical as proposed by the mainstream literature on the subject, but also experiential. Consequently, it is argued that exclusion processes materialise in hindered access and use of the public space, as well as in design features which further re-enforce and reproduce social stigma – the central driver of exclusion practices. By understanding how the latter practices come into being and take a spatial form, it becomes possible to outline design tools and methods likely to counteract the inaccessibility of the public realm to certain social groups.

## 2. Emerging critique to the inclusive urban design debate

The on-going inclusive urban design debate focuses predominantly on the physical accessibility of the built environment. As a result of this, the available body of literature (CABE, 2006; Goldsmith, 2000; Dong et. al, 2000) and policy recommendations on the topic (GOV.UK) center on issues of mobility within public space and engage only marginally with other forms of physical exclusion from public space. It can therefore be argued that the inclusive urban design theory and practice engages only marginally with notions of inclusivity. In doing so, the inclusive urban design debate reproduces exclusionary practices which overlook (lived-in) experiences of the urban (Relph, 2008; Tuan, 1977; Rodaway, 1994).

The purely physical approach to inclusive urban design attracted a number of criticisms (Hanson, 2004; Imrie & Hall, 2001, 2003) and led to a re-evaluation of the relationship between users with disabilities and space, and its implications on urban design theory and practice.

The ideal behind the inclusive urban design (InUD) debate, as suggested by the available literature, is design devoid of barriers to access and use public space, a design which facilitates '*users having the ability to take control over their environments'* (Hatch, 1984, p. 4 in Imrie & Hall, 2003, p. 18). S. Goldsmith's 'Universal design' (2000), the Department of Transport's publication on 'Inclusive mobility' (2005), CABE's 'The principles of Inclusive Design' (2006) or Part M of the Building Regulations, are all referential documents for the practice of inclusive urban design. The principal argument behind contemporary InUD is that of a universal design (Goldsmith, 2000) that promotes the '*flexibility, adaptability and interchangeability of fittings and fixtures'* (Imrie & Hall, 2003, p. 16). Notwithstanding, this approach to inclusive design has been extensively criticized for being vague as to how user differences – of gender, race, physical needs - are to be accommodated (Hanson, 2004; Imrie & Hall, 2003). The principal issue arising from here is that inclusive (urban) design targets a rather limited number of excluded groups (the non-able bodied) while overlooking a diversity of other groups excluded from the free use of public space. This is mostly due to a unilateral understanding of inclusion/exclusion processes within the city. In its current form, the InUD debate lacks a conceptual framework which could potentially lead to a more comprehensive theory of inclusive urban design to inform more effectively inclusive practices.

Complementary to the theoretical limitation, a secondary critique takes form regarding the practice of inclusive urban design. The latter is aimed at the barriers in implementing features of inclusive urban design. The documents listed above, although intended to inform more inclusive urban design practices, remain simple guidelines with no design monitoring structure in place. Furthermore, with designers' tendency to overlook a large number of end users and with developers' prime interest in profit and cost margins of new projects (Imrie & Hall, 2001), there is a limited concern in investing in inclusive design solutions. Consequently, '*most places are bereft of basic design features, such as tactile paving, colour contrasts, clear signage and induction loops*' (Imrie & Hall, 2001, p. 233). This state of fact is supported by the lack of incentives in investing in inclusive solutions, by the particularities of the urban design theory, as argued above, and by the downfalls of operationalising notions of InUD when implementing inclusive urban design solutions. Although explorations of inclusive design are still incipient in the context of the built environment, there is a strong argument for broadening the field of this endeavour. '*[T]he focus (of inclusive design) to date has been on products, buildings and physical access to*

*buildings. Now it needs to broaden to whole neighbourhoods, villages and towns.*' (Burton and Mitchell, 2006, p.9).

Drawing on the above, it could be argued that a truly inclusive urban design is yet far from being attained, given the limitations of both theory and practice of InUD. Inclusive design '*is as much about process as products*' (Imrie & Hall, 2003, p. 24), which is why the present paper aims to challenge notions of inclusive urban design both in terms of process and outcomes with the aim of re-conceptualising the theory and practice of InUD. The three limitations to be hereby explored, as identified in the previous sections are first, the narrow segment of targeted end users, second, the inclusive urban design conceptual framework and third, the operationalisation of 'inclusive urban design' as a concept translated into tools and methods specific to the urban design discipline.

## 3. Outcasts of the public realm

The question of *who* is to be included in/by the inclusive urban design process is at the heart of emerging critical thinking in the field (CABE, web archives; Hanson, 2004; Imrie & Hall, 2003).

Recent endeavours to theorise the inclusion of marginalised individuals (disabled or elderly) within the design of public space propose a change in traditional understandings of disability (Hanson, 2004; Imrie & Hall, 2003). Previously regarded as an inability to use the built environment due to personal constraints/ restrictions, disability is nowadays reviewed from a socio-cultural perspective, by adopting models '*which propose that the environment itself actively produces disability. According to these models, a person becomes disabled by the barriers they face, not by their impairment'* (Hanson, 2004, p. 5).

In an attempt to move beyond existing stereotypes of disability associated predominantly with wheelchair users (Goldsmith, 2000; Imrie & Hall, 2003), studies of inclusive design broaden their scope and consider a wider range of dis-abilities, such as motion, sensory and cognitive related capabilities (Dong et. al, 2000, p. 47). The main purpose of this is to understand the users' specificities and respond to them rather than over impose a universal solution to all contexts. This approach led to researches more broken down into user requirements. For example, adding to an increasing body of literature on elderly experience in public space, E. Burton and L. Mitchell (2006) give special attention to a group segment suffering from dementia.

The underlining argument behind the socio-cultural model is that disability is socially defined, where the 'disabled' is labelled as such when set against the 'ideal' of the full-bodied space user. '*[A] focus on disabled people necessarily draws attention to the body and the diverse ways in which it is entwined with socio-spatial practices*' (Imrie, 2001, p. 233) is a different manner of describing the normative able-body, a body which is socially accepted and redefined. Discussions on the inclusion of bodily disabled users are often framed by socio-cultural notions of abnormality, dirt and disorder (Douglas, 2003; Foucault, 1977; Parr, 2000, 2006). '*[T]he (re)production of barriered and bounded spaces [...] reinforce the efficacy of <civilised and normal bodies>*' (Imrie, 2001, p. 233), thus the out of place character of an element is given by its deviant or disruptive nature. *'"Normality" is defined, to a significant degree, geographically, and deviance from this normality is also shot through with geographical assumptions concerning what and who belongs where*' (Cresswell, 1996, p.27).

There can be no discussion of the 'normal' in the absence of the 'deviant'; space and place as such have no inherent connotation of either concept but they are, nonetheless, '*used to structure a normative landscape*' (Cresswell, 1996, p.3) both in theory and practice. Moreover, they feed into larger notions of individuals referred to as being in and out-of-place.

The recurrent themes in the existing literature on the topic indicates that a debate on inclusion by (urban) design cannot be carried out outside social theories of socially-constructed notions of the normative and the body (Butler, 1999; Douglas, 2003) all falling under the wider concept of 'stigma' (Goffman, 2009). E. Goffman theorised three categories of social stigma: physically visible (noticeable deformations such as scars or certain disabilities),

deviations in some traits of character (mental illness or forms of addiction) and 'tribal' (cultural notions of ethnicity, nationality or religion). What all three forms have in common is that they are socially agreed upon as deviances from 'normality'. C. de Albuquerque (2012) writes about 'stigma' as an instrument of social differentiation and re-enactment of the social norm; it has an informative, reiterative and controlling role. In everyday life, stigma acts as a means to define the socially deviant, the unwanted 'other'.
Understanding the mechanisms behind stigma and, therefore, behind processes of exclusion is a pre-requisite, given that in-place stereotypes of the abnormal inform social and attitudinal barriers to inclusive design (Imrie & Hall, 2003).

Because from an urban design perspective, inclusion/exclusion processes are fundamentally spatial (Cresswell, 1996) and they are regarded as forms of physical accessibility to the built environment, partly explains the fact that the main approach to inclusion by urban design is centred around the able-body. This basic premise of urban design is further validated by more general approaches which frame social exclusion structurally – around employment, housing, minority (Social Exclusion Unit, 2000, 2001, 2004).

However, forms of social exclusion, other than those of the physically/ mentally disabled, are spatial as well, although little discussed in these terms (Power & Wilson, 2000; Wacquant, 2008). The reason for this is that the socially excluded are, although physically capable of using public space, refused access.
Experience has shown repeatedly that their bodies, associated with different forms of stigma, are labelled as out-of-place elements and denied opportunities of being in one place or another. This is the case of, for example, racially and gender exclusive spaces where space and place become *'useful surrogates for more direct forms of power*' (Cresswell, 1996, p.163) and elements of design are often '*used to control people and things*' (idem).

Within the inclusive urban design debate, scarce attempts have been made to explore social exclusion in the context of the city and thus anchoring it spatially. This is the case of C. de Albuquerques's (2012) report on the stigmatisation of Dalits and women with fistulas, of D. H. Nadal's (in Pancetti et al., 2012) study on the marginalised Rocinha favela, of M. C. Loschiavo dos Santos' (2007) project on integrating scavengers in Sao Paulo in a local economy cycle and C. Rishbeth's (2010) work on designing for ethnic diversity. The above studies are noteworthy because they make the link between the socially excluded and their spatial-cultural context. They illustrate that marginalisation is first, socio-culturally constructed, determined by the social norms/ values of the place where it takes form and second, spatially articulated in the design of places which they occupy/ appropriate or from which they are excluded.

In the case of disabled individuals, it has been argued that the lack of access ramps or tactile paving prevents them from freely using public space. Similarly, the lack of public seating or the presence of control signage prevents particular users from safe and comfortable access. *'[W]e are all potential or actual victims of architectural discrimination as a result of conventional building design*' (Hanson, 2004, p. 10) and the best example of this is that of the 'away from home toilets'; the absence of this element of street furniture is associated with discrimination by design on different accounts – able-bodied, age, gender (Greed, 2003; Hanson, 2004). It can therefore be concurred that an inclusive urban design, aimed at removing barriers to uses of public space, ought to engage with a diversity of socially excluded groups which are either overlooked or even banned from different public spaces.

Broadening the InUD target groups onto the socially excluded in more general terms is not here an argument for a built environment equally accessible to all users in the traditional understanding of inclusive urban design (CABE, 2006; Hanson, 2004). The claim is to acknowledge the diversity and plurality of urban users as part of the urban design process and to pursue a non-hindering built environment; a built environment which does not aim to re-produce and validate existing stereotypes that re-enforce stigmas and lead to the further marginalisation of certain social groups.

## 4. Re-assessing the urban design principles behind the 'inclusive' debate

As the existing body of literature indicates, current theory of inclusive urban design has looked extensively into questions of physical use/ access of the built environment. However, from an urban design perspective, this approach responds only partially to the core principles of the discipline. Questions of human (excluded) experiences in the city are not accounted for by mainstream InUD discussions.

This constitutes an inherent limitation to the quest for a more inclusive urban environment, all the more so as physical exclusion is always accompanied by an experiential exclusion. In other words, marginalised individuals are not merely denied the use of public space, but also a range of urban experiences, of enjoying the public realm, of appropriating it and of developing feelings of identity and belonging.

Understanding the mechanisms behind exclusion processes and how these processes become spatial is essential for developing a comprising theory and a capable practice of inclusive urban design.
The physical – experiential binary of being in the city is rooted in the urban design concept of 'place' as an ultimately social space (Cresswell, 1996; Lefebvre, 1991). Therefore, arguably, the city is simultaneously built form, everyday practices - 'performativity' and lived-in experiences – 'lifeworld'. This triad is fundamental for understanding processes of inclusion/ exclusion in the public realm. The reason for this is that it accounts for the co-contruction of the excluded subject, who is both created and creates himself and the (urban) reality which he inhabits.

If the 'built form' has fairly clear references to the materiality of the urban environment, the two latter notions, 'performativity' and 'lifeworld', require somewhat of a more detailed understanding before moving forward with re-conceptualising InUD. Both 'performativity' and 'lifeworld' are concepts traditionally anchored in the social sciences. However, they provide a twofold understanding of city-making processes which is fundamental to any discussion on cities inclusive of a diversity of end users. While ''performativity'' accounts for the socio-cultural (re)construction of (urban) reality and of social identities, the 'lifeworld' encompasses the phenomenological human experience of being bodily and emotionally immersed in (urban) places (Seamon, 1979).
Performance is theorised as the enactment of everyday practices which reinforce accepted uses and ways of being in place (Butler, 1990, 1999; Goffman, 1959). If for E. Goffman practices are scripted, played out and consequently consumed, for J. Butler they are the enactment of identity – the social 'self'. By performing the everyday – through actions, gestures and habits - we aim to add meaning to our lives and to define our place in the world.

> *'The city is soft, shapeable, moldable, like clay. It 'awaits the imprint of an identity'. It invites the individual to remake it, and the 'self' too; this process, of the formation of identity and the shaping/remaking of the city, is a dialogic process [ . . . ] in which the formation of identity is simultaneously the shaping of the city*.' (Nentwick, 2004, cited in Makeham, 2005, p. 152)

Building on the idea of performing the everyday, J. Butler phrased her own concept of 'performativity' as a way of being in the world. She defines it as *'that reiterative power of discourse to produce the phenomena that it regulates and constrains'* (Butler, 1993, p.4) and uses 'performativity' to argue for a socio-culturally constructed notion of the gendered body – i.e. being a *woman* means taking on a particular behaviour, values and presentation of the self as socially prescribed and accepted for a woman.

> '*The universal conception of the person, however, is displaced as a point of departure for a social theory of gender by those historical and anthropological positions that understand gender as a relation among socially constituted subjects in specifiable contexts. This relational or contextual point of view suggests that what the person< is>, and, indeed, what gender <is>, is always relative to the constructed relations in which it is determined*' (Butler, 1999, p. 15).

Analogously, if the female body can thus be defined and enacted, so can other types of (excluded) bodies, be produced socio-culturally, as argued previously. It could therefore be inferred that social identities as such are partly socio-culturally produced. J. Butler herself links her theory of 'performativity' to the deviant, stigmatised body: '*The abject for me is in no way restricted to sex and hetero-normativity. It relates to all kinds of bodies whose lives are not considered to be 'lives' and whose materiality is understood not to matter*' (Butler in Meijer & Prins, 1998, p. 281). The rationale applies to different categories potentially subject to social exclusion – i.e. disability (Hanson, 2004), race and ethnicity (Smaje, 1997). These identities are reproduced through performances of the everyday – gestures, actions, enactments. This performance of identity is simultaneously a performance of being 'the other' and it is both an expression and reiteration of identity, of *being oneself*, through repetition of manifestations by which one is discursively (self)defined (Urbinati & Warren, 2008). As spaces are moulded into places precisely through the agency of these performances, the attributes that they are invested with in turn re-shape users resulting into a city in a continuous process of spatial transformation (Shaftoe, 2008; Wylie, 2009; Gehl, 2010 etc.). This dialectical relation is considered here to be inherent to re-producing stereotypes of social stigma by means of exclusionary urban design practices.

The second concept in need of clarity for the purpose of the present paper is that of 'lifeworld' which, together with 'performativity', co-creates the urban experience and accounts for being-in-place in the city. 'Lifeworld' is the expression of phenomenologically inhabited (urban) space. While phenomenology is theorised as exploring *'the things and events of daily experience*' (Seamon, 1979, p. 9), one's 'lifeworld' is defined as the '*daily world of taken-for-grantedness*' (Seamon, 1979, p. 91), '*a concept developed in order to grasp the horizon of understanding the everyday, as well as life's threshold events, and thus also life's different perspectives'* (Madsen & Plunz, 2005). 'Lifeworlds' are characterised by memories, affect, personal values and sensorial experience; in other words, 'lifeworlds' are immersions in the surrounding physical environment.

Traditionally, the city was regarded as a container for everyday activities and experiences of the urban were understood as behavioural patterns that the urban design professionals could observe and integrate in good quality design solutions (Lynch, 1960; Whyte, 2001). In more recent decades, the post-modernist approach to social sciences has unveiled a narrow understanding of the human experience per se within the built environment. Including layers of experiencing the urban within the urban design process accounts more accurately for urban diversity and is likely to lead to a richer range of urban solutions and a good quality of public space. Consequently, by introducing the concept of 'lifeworld' next to the built environment and 'performativity' when discussing city processes, accounts for the lived-in experience of urban users (Buttimer, 2010; Seamon, 1979).

Both concepts of 'performativity' and that of 'lifeworld' are relevant to the inclusive urban design debate because they help understand processes of exclusion by design – where they take place, who is excluded and by what means – and subsequently to inform more inclusive urban design solutions – how to counteract, in InUD practice, social stereotypes and denied access to the public realm. If 'performativity' accounts for the socio-cultural construction of reality, 'lifeworlds' explain being in place as an immersion (Rodaway, 1994; May & Thrift, 2003) where individuals are understood as inhabiting '*the world before they represent that world to themselves and others*' (Anderson & Harrison, 2010, p. 10), as being '*part of the on-going becoming of worlds*' (idem, p. 11). Although 'performativity' is somewhat captured in InUD theory when discussing excluded identities as socio-culturally constructed, notions of 'lifeworld' are entirely absent from the debate. This is reflected in Gleeson's (2001) critique of existing solutions for disabled individuals, solutions which reflect no understanding and recognition of disabled experiential knowledge. As the inclusive projects discussed previously (de Albuquerque, 2012; Pancetti et al., 2012; Loschiavo dos Santos, 2007) illustrate, working with target individuals , rather than treating them as passive users, can potentially lead to successful inclusive solutions.

A concept that partially incorporates the built environment – 'performativity' – 'lifeworld' triad is R. Shields (1991) 'imaginary geographies'. Defined as a '*purely discursive (i.e. ideational, symbolic, and linguistic)*' (Shields, 1991, p.64) concept, the term of 'imaginary geographies is used by R. Shields to denote images or 'myths' of what/ how places are like, of self and of community identity. The argument is that the image a place

acquires in the eyes of the general public is dictated by the typical users encountered there and the specific form of activities with which they are to engage. '*The world is cognitively territorialised so that on the datum of physical geographic knowledge, the world is recoded as a set of spaces and places which are infinitely shaded with connotative characteristics and emotive associations*' (idem, p.264). According to this frame of thought, it is argued that the image the public holds of a particular place appears to be a discursive construction, product of collective and individual processes of signification alike. *'[I]n these recordings of geographic space, sites become associated with particular values, historical events and feelings'* (idem, p.29).These associated meanings inform socio-spatial practices and are being enacted by means of everyday performances. The latter are interlinked with lived-in experiences which further consolidate the constructed image of what a place is; in doing so, locally established spatial and social norms are being continuously re-enforced.

R. Shields suggests that 'imaginary geographies' incorporate the different facets of the place-making process where places, as 'centers of meanings' (Cresswell, 1996, p.13) have both physical and mental coordinates. The first takes the spatial form of the built environment, while the latter encompasses the subject's association with a multitude of urban places – such as accepted behaviour, customs, habits, memories, affect, attached meaning. For R. Shields the experienced 'reality' of the built environment remains subject to imagined, taken-for-granted 'truths' of where, when and how is space to be occupied or used (Butler, 1999; Gowan, 2010; Lefebvre, 1996), what makes it in post-structuralism terms a socio-cultural construct.

Overimposed to this generally accepted understanding of a place is the lived-in experience (Relph, 2008; Tuan, 1977), the subjective notions which each individual is likely to attach to a particular place; '*[b]ecause places are meaningful and because we always exist and act in places, we are constantly engaged in acts of interpretation'* (Cresswell, 1996, p.13). Normative in nature, this censorship of *being* in public space is reflective not only of accepted ways of appropriating space. As such, there is always a subject – the producer and an object – the product in every discursive urban reality of what a place/the city is, of how to behave in it or who is allowed to be there. The imaginary duality extends beyond the user – space dialectic, to that of the 'self' and 'other' as defined at both collective and individual levels. As discussed in the previous section, this is in line with contemporary theories of social identity – gender, race, class – being themselves socio-cultural constructs (Goffman, 1959; Butler, 1999) enacted through (self) performances of the body in place. As space is being reconfigured so as to correspond to mainstream notions of a good public space it becomes a means to delineate the norm-al from the deviant.

'Imaginary geographies' have also a spatial component which is the physical form of an enacted image of reality. '*Place is produced by practice that adheres to (ideological) beliefs about what is the appropriate thing to do'* (Cresswell, 1996, p.16), '*place reproduces the beliefs that produce it*' (idem). In other words, performing space by conforming to rooted ideas about them assigns each place with taken-for-granted characteristics, characteristics which in turn reproduce and regulate ways of performing place (Cresswell, 1996; Hetherington, 1997; Shields, 1991). Common understandings of who is to go, how to behave and what is accepted to do in Brighton or in a high luxury sea resort are very different. By subscribing to unwritten 'rules' of conduct and attitudes individuals further validate the image that the resort has for the general public – they 'construct' it as the type of resort that it is thought to be. Analogous, in the specific case of excluded groups, the accepted social norm operates with opposing notions of 'normality' vs 'deviance'. *'<Normality> is defined, to a significant degree, geographically, and deviance from this normality is also shot through with geographical assumptions concerning what and who belongs where*' (Cresswell, 1996, p.27). There can be no discussion of the 'normal' in the absence of the 'deviant'; space and place as such have no inherent connotation of either concept but they are, nonetheless, '*used to structure a normative landscape*' (Cresswell, 1996, p.3) and feed into larger notions of in and out-of-place.

The concept of 'imaginary geographies' is valuable for a potentially more comprehensive conceptual framework of inclusive urban design. Its relevance lies in the fact that it successfully bridges over social theories of understanding and inhabiting the world and the actual spatial reality of the built environment. This bridge is essential in the context of wider principles of urban design which are concerned with the physical form as much as

with experiencing the city – feelings of safety and security, community and belonging. Consequently, 'imaginary geographies' can be understood as records and narratives of place, deeply rooted in a physical setting. In the context of InUD, they could be used to describe and understand the particularities of place and place-experience where the quality of exclusion/inclusion is considered.

These are strong arguments for borrowing the concept of 'imaginary geographies' from the social sciences into the inclusive urban design debate.

Nevertheless, in order for this concept to respond adequately to the discipline's pursuits, an additional dimension is required. The reason for this is that while processes of constructing place by both socio-cultural and phenomenological means are accounted for, the built environment is dealt with as a passive container for everyday activities and meanings to be attached. However, '*places encompass the physical setting, as well as human experience and interpretation'* (Stedman, 2011, p. 672). Empirical evidence and InUD critique (Hanson, 2004; Imrie, 2001) suggest that characteristics of the built environment condition everyday performances in public space. Moreover, the same broader design characteristics (i.e. the absence of certain artefacts, spatial layouts, aesthetics, discouraged/preferred uses, processes of management and shaping the physical environment) contribute to the type and quality of experience of place and, as a result of this, to what could be referred to as exclusive/inclusive spaces. Drawing on this, it can be argued that features of the physical environment influence the type of urban experience users have (Stedman, 2011). Whether these are aesthetic qualities intrinsic to the architectural/ urban landscape object (Norberg-Schulz, 1980) or over imposed by means of the design process (Joerges, 1999), the built environment plays an active role in constructing experiences of exclusion/ inclusion from the public realm.

Understanding this particular aspect is essential because there can be little efficacy stemming from a well-defined inclusive urban design theory, if its products debilitate public space users while simultaneously re-enforcing social stereotypes and reproducing practices of exclusion.

## 5. Operationalising the 'inclusive' in inclusive urban design

The emerging critique of current inclusive urban design solutions extends from product to producers of public spaces. '*[D]evelopers, architects and designers tend to operate in ways which are inattentive to end users'* (Imrie & Hall, 2001, p. 3) partly because they '*have limited knowledge of disabled people and their needs*' (Imrie & Hall, 2001, p. 347), partly because the focus is on construction costs and development profit (Imrie & Hall, 2001, 2003). Arguably however, these are symptoms of a professional frame of thought deeply rooted in taken-for-granted social understandings of good quality public space and its users (idem). In practice, this leads to a widespread assumption across professionals of '*<sameness>, of normality, amongst the people*' (Imrie & Hall, 2003) with inherent repercussions on different forms of designing the urban.

This professional frame of thought is a key barrier to achieving a more inclusive public realm, as in urban design practice '[s]*pace [is] often used to control people and things'* T. Cresswell (1996, p.163). For this reason, a more inclusive urban design is likely to start from revising basic urban design principles – such as safety and security - that feed into notions of unwanted behaviour/ users in public space (Cresswell, 1996; Hanson, 2004) and, subsequently, into behaviour-controlling architecture (Savicic & Savic, 2013). Is hereby suggested that this essentially implies a review of the socio-culturally constructed border between the 'normal' and the 'deviant' within the urban design discipline. In other words, an inclusive public space comes with no pre-requisites of who is intended to use it and in what way this should be done. Rather than thinking of everyday performances and ways of experiencing the city in terms of 'right' versus 'wrong', design of would-be inclusive spaces can be looked upon as a mode of ordering space alternative to traditional forms of public spaces where designers and users alike conform to normative ideas of 'normality'(Douglas, 2003).

A different mode of ordering space is a pre-set of most urban spaces occupied by often socially excluded groups who have '*their own codes, rules, and symbols and they generate their own relations of power*' (Hetherington, 1997, p.54). As '*modern forms of social ordering*' (Hetherington, 1997, p.54) spaces occupied by the excluded become '*spaces apart, defined by the ambivalence or difference of their modes of ordering'* (idem, p.68). By no longer distinguishing between the 'normal' and the 'deviant' in urban design, disappears also the duality of behaviours, action and people being out of place for not complying with generally accepted social norms.
A separation of design theory and practice from established social norms is worthwhile discussing particularly in the context on inclusive urban design given the fact that given that certain discussions around extensively excluded groups (such as the urban homeless) are particularly hard to tackle in the current market-oriented design framework. Whether it lies within the urban design discipline's responsibility and resources to reshape social attitudes and behaviour is something that requires further critical reflection, this is not the subject of the present paper.

Notwithstanding the above, urban design practice is unlikely to effectively tackle spatial exclusion in the absence of different, more inclusive, parameters with an aim different to that of either controlling or disabling both access and use. The potential implications of this on the discipline's code of practice and design principles can be notable.

Bearing in mind this permeability of an inclusive urban design theory, it can nonetheless be argued that an inclusive space is difficult to achieve in the absence of an InUD process inclusive throughout. What is understood here by an inclusive urban design process means a reflection of inclusivity principles at all stages: designing, developing, using and managing (Carmona, 2014b).

As argued previously, inclusive outcomes fall outside traditional understandings of good design principles, functional spaces and end users. As such, the established state-of-the-arts tools and methods are potentially problematic in the case of, until recently, little understood groups of urban users. This could be one of the reasons why inclusive urban design practice has progressed slowly over time and is clearly illustrated in successful inclusive projects (Burton & Mitchell, 2006; Loschiavo dos Santos, 2007) where the methodologies used were not customary to the discipline. The underling argument for engaging with alternative methodologies is that a presumably inclusive urban design product – space or artefact - is unlikely to be successful if it is the mere result of a blueprint exercise.

It is therefore suggested that the in-place knowledge of excluded groups is invaluable to an operating inclusive principle (Imrie & hall, 2001). This in-place knowledge has a twofold purpose: it reports on the 'imaginary geographies' of exclusive places, as discussed previously, and informs inclusive solutions for a better quality of public space design. What this means is that an inclusive principle is fundamentally an empowering principle. Empowering is to be understood here partly as non-disabling (Hanson, 2004; Imrie & Hall, 2001, 2003) and partly as endowing agency to the target group (CABE, 2006; Imrie & Hall, 2001; Loschiavo dos Santos, 2007). Endowing agency means working *with* rather than *for*, like in traditional urban design practice, excluded groups; this is to say that so far marginalised groups are no longer likely to be treated as passive space users, but pro-active agents with the possibility of being involved at different stages of the urban design process.

In order for this to be attainable, existing tools and methods need to be tailored with the specificities of each target group in mind. Upheld methodologies such as public participation (Healey, 1997) require readjustment for this purpose, given that working with more vulnerable groups may well be problematic in practice. Social studies are rich in group engagement methods which could be adapted to the field of (inclusive) urban design, for example talking in place (Anderson, 2004; Gowan, 2010) or photovoice (Cappello, 2005; Wang et al., 2000). Similar alternative modes of engagement and the possibility of transferring them to InUD require further exploration so that the inclusive urban design framework is put to practical use.

## 6. Conclusion

The present paper proposes a re-assessment of the core principles and outcomes of the inclusive urban design debate. Challenging limitations identified both in theory and practice is the first step towards a re-conceptualisation of inclusive urban design.

A redefinition of inclusive urban design is built partly on social theories of socio-cultural constructs of (public) space, its normative users and uses and partly on a phenomenological – subjective - approach to documenting urban experiences. Arguably, an inclusive approach to urban design needs to be estranged from 'normal'/'deviant' space dichotomies and aimed at achieving places that are flexible in design and respond to a diversity of site specific urban users. Spatially, exclusive and inclusive places may well overlap – a space which allows for the presence of certain users may 'reject' the presence of others. For this reason, an inclusive design is not equivalent with a type of universal design. It is difficult to assume that a form of urban design can accommodate the conflicting needs and experiences of a plurality of space users. However, it will ideally pose no intentional barriers to the use of public space and will acknowledge, if not account, by means of the urban design process the diversity of public space users.

A critical reflection on both theoretical and methodological frameworks of inclusive urban design illustrated that inclusive urban design as a discipline branch holds insufficient comprehension of exclusion experiences and how these are embedded in the built environment. This relationship is all the more difficult to integrate in the urban design process given that the discipline's established tools and methods are not suited for this purpose. Therefore, the hereby proposed conceptual framework puts emphasis on understanding processes of urban exclusion and the spatial forms that this exclusion takes by primarily engaging actively with targeted excluded groups.

Urban exclusion is a factor which cannot be overlooked when discussing good quality built environments, nor feelings of community and belonging in the city. For this reason, the debate on the inclusivity of the public realm is underlining to all discussions on city-making processes and, subsequently, to practices of urban design.

# Rethinking Urban Design Processes in Framing Public Places

*The case of Western Harbour waterfront development in Malmö, Sweden*

Elahe Karimnia[1]

**Abstract**

*This paper addresses the process of transformation of urban spaces and the contribution of urban design to framing public life. It manifests the multiplicities of interests towards good urban form, and people's experiences and engagements, as outcomes. The study acknowledges places as process and meanings, which require 'relational' and 'contextual' analysis. Reviewing the design processes, and the unintended consequences in associating use value highlights that engagement with place as an experiential quality needs high level of publicness that can be achieved at some levels within 'meaningful urban design'. However, the gap between experiential qualities and spatial aspects, which influence the meanings of places, should be sought in the place-shaping process: intentions and outcomes to find out how public spaces are: intended to be, physically built and socially used and experienced; in becoming places. The study area is the regeneration of the waterfront in Western Harbour, in Malmö, Sweden. By interviewing the key actors in planning and design process, and reviewing documents the paper highlights that the public spaces were not into focus as visual aspects of place However, the reality of everyday use in public space unfolded other qualities: that public space can be a catalyst for regeneration process. The study revealed the urban design potentials for place-making and suggests rethinking about design practice to act temporal and associated in the long-term process in cities. It highlights that a meaningful design should also concern the 'scale' of relations in space and time; and potentials of planning in place-making.*

**Key words**

Urban design, public space, place-making

## 1. Introduction

In recent years, discussions around complex societies and associating life in urban public places have been the interest for many academics and scholars as well as activists and city makers. The question was constantly asking how urban context can solve so many economic, social, political, economic and environmental issues; while not being problematic for its users. Therefore, studying urban form and human behaviour experiences has been central to understanding how material production interplays with social and economic arrangements. Most of the research produced as the result often takes disparate positions. In academic literature, public space has been argued within physical decline, which can no longer provide public life (Sorkin, 1992). Furthermore, new trends in communication expect to take new forms of social life that less matter in public spaces (Banerjee, 2001; Castells, 2001). From urban planning and design perspective, social life in public spaces is interrelated with the quality of spaces. On the other hand, quality of space is framed by social norms and cultural values interwoven with political-economic relations too. The provision of public life by design of urban spaces therefore becomes a provocative topic, and forms critical theories around the relation between spatiality and sociality in different scales (Lefebvre, 1991).

Urban design has an integral role in production of the built environment, yet as a discipline has ambiguous term and broad definitions (Madanipour 1996 & 2014). Urban design practice in positioning public life in urban places was criticized for its limited and partial theories, and detachment from the laws that construct the society (Cuthbert, 2006), as 'amalgam of several disciplines' (Inam 2002, 35), and obsessed with the final product (Sorkin, 2009) and with the truth of the experts' knowledge as power of authority (Foucault, 1967). There is a frustration with the dominating language and the level of interpretations, which may present intentions in the form of 'valid' facts or as the most efficient ways of doing things. The tendency of urban design to uncritically adopt, combine and use theories without testing them enough clarifies why Marshall (2012, p.267) positions urban design at least in part *pseudo-scientific discipline*.

One of the reason urban design and its normative theories established was the intention to re-build the lost quality of places in the public realm, which nowadays it is being criticized for its achievements. Urban design should be reinvigorated from within, as Marshall (2012, 268) suggests. Carmona (2014) offers generating of a new knowledge around a unique subject and practice. Recent literature recommends a shift in thinking of urban design towards more 'pragmatism' (Inam, 2014), and as an 'on-going long-term process' (Inam, 2002). This perspective reflects the critical social sciences perspective, that urban design should seek an open-ended meaning (Sennet, 1990), concerning the urban changes in use and values (Madanipour, 1996). The same threats and potentials stand for place-making, regarding the subjectivity and complexity of sense of places and meanings. Places, in urban design, should be understood within multiple identities and avoid reductionism (Dovey, 2010) and be sensitive to the contextual relations in space and time (Massey, 1994). The socio-spatial relations in places, provided by urban design are therefore not 'deterministic' and 'linear' (Urry, 2005). As a result, meaningful and responsive urban design is an endeavour to bridge the gap between the theories and practice, and to reflect the reality of everyday life and learning from different experiences (Crawford, 1999, 2004). Madanipour (2014) suggests focusing on 'urban' than 'design' of urban design; and Inam (2014) proposes a radical shift towards 'pragmatism', empowered understanding of urbanism and exploring the potential of inclusive field of thinking and action.

Urban design, not by definition, profession, or responsibilities (which varies in different contexts [1]) but as a field of practice, is facing a big shift. 'Relational thinking' is recommended to study public space (Tornaghi and Knierbein, 2014), as the real object of this practice (Cuthbert, 2006), and thinking of 'place-shaping' as a process that reviews the post-occupancy of the place and the process of its delivery between 'design, development, space in use (place) and management' (Carmona 2014).

Accordingly, place is investigated as 'material-relational' (Dovey, 2010), as both 'product' with its micro-scale values, and 'process', within network of macro-scale values, thus reflecting experiential qualities (Arefi & Triantafillou, 2005).

Towards the goal of process and relational thinking and to enrich public life in urban spaces, as well as to investigate the gap between design and everyday use in public spaces, this paper examines a contemporary urban transformation project in Western Harbour (Västra Hamnen in Swedish), in Malmö, Sweden; where the production of waterfront public spaces was in nexus. To understand the potentials and limits of urban design and its contribution to place-making, this paper reviews the place by act of wondering about intentions and outcomes: How intentions were formed, how public space was physically built, socially and spatially used and practiced. The outcomes were sought in everyday life of the place, meanings and experiences; if public space becomes a place.

## 2. Conceptual framework

*2.1 Transforming urban spaces*

Public life, as a value of living together, has been specifically conceptualized in public spaces and regarded in different disciplines with different concerns. In urban design, mantras of urban qualities such as liveability, vitality, attractiveness, and safety are pouring in cities. To achieve these qualities, the modalities of urban design should develop to balance between these – sometimes conflicting-values.

However, in practice, urban design strategies are framed within the purpose/problem they get involved to propose/solve. Due to global economy, cities are adjusted with their markets in particular periods of time. Therefore, urban design in the production of the built environment has become a part of the urban development and central in the economy process that are supposed to be used as goods and services, as economic values (Lefebvre, 1991; Madanipour, 2003, 2014). Regeneration of public spaces is accordingly adapted as a response to such fundamental changes and contextual demands. Creating public spaces is framed by their effectiveness in economic process and its social consequences. Madanipour (1996 & 2003) posed this tension between use value and exchange value rises when economic transition and spatial transformation intensifies. He contends that leisure is the only major function has left in most of European public spaces.

Focusing on the new spaces of leisure and consumption, this is a phenomenon of regeneration of industrial cities (see examples in Melbourne in Dovey and Sandercock, 2002). For the cities in transition, if the market leads the development such as examples in UK, public spaces should be attractive and liveable places where use value is identified by number of activities and consumption and the provision of extra safety and security, and over-managed public spaces to guarantee the long-term investment (Carmona, 2008). In this case, spatial configuration is a tool to address economic demands, to manipulate people's access, movement or presence in public, as 'privatization' and 'exclusion' (Madanipour, 2003; Banerjee, 2001) which results loss of meaningful use in public spaces as pseudo-public spaces.

In transformation of the urban spaces spatial planning has an important role in territorializing of values and services and to shape future socio-spatial relation in places (Graham & Healey, 1999). Relational theories have un-linear conception of development and consider multiple time-space and meanings within different network (Healey, 2004).

*2.2 Urban design process and place-making*

Agreeing on the values of places between the process of globalization and localization, place still matters, though complex and multi-layered, beyond visual aspects and a product (Arefi & Triantafillou, 2005; Dovey, 2010; Arefi, 2014). Meanings of places are formed through time and highly subjective, embedded in people's narratives and experiences and interpreted by cultural and social context. Meanings are multiple and require deep human studies to be detected. The challenge for urban design is then to understand how socio-spatial attributes assign meanings to places, to be perceived and collectively experienced.

Urban design has a history for such contribution with place-making. In micro-scale, it was initiated by Jane Jacobs, praised the lively streets of Greenwich Village as an example of safe and diverse urban environment (Jacobs, 1961). William H. Whyte's Street Life Project, was one of America's most influential on cities, people and public spaces, conducted as pioneering studies on human behaviour in urban plazas in New York. Through deep observation, he showed how built environment contribute to people's different activities and behaviour. Human needs in public space was identified by Carr et al. (1992), as 'comfort', 'relaxation', 'passive engagement', 'active engagement', and 'discovery'. From human perspective, a 'responsive environment' was identified as accessible, connective, permeable and visible (Bentley et al. 1985). A human-scale environment offers a level of satisfaction and comfort, and that 'optional' and 'social' activities can take place (Gehl, 1996). In macro-scale, human needs and experiences were conventionally regarded in cities, where support places if they are well-located, visually accessible without any physical barriers (Hillier, 1996). Lynch (1981) emphasized on city unique image, both through physical elements and people's perception, and applied them in his *Theory of Good City Form*. Gordon Cullen named sense of place as '*the sense of being here- in a particular place'* (Cullen, 1961). Christopher Alexander acknowledged different scale of socio-spatial relationship (Alexander et al., 1977), and *'the timeless way of* building' (Alexander, 1979). In the mid-1980s, Jacobs & Appleyard characterized environmental urban design by 'liveable streets and neighbourhoods, minimum densities, functional integration and proximity, positive urban space, and human scale and variation' (Jacobs & Appleyard, 2000). Such studies admit the contribution of human experiences and narratives to urban design, in both micro and macro scales. Yet, such paradigm shift has been opposed for being utopian in a contemporary social context, and by underestimating the 'epistemological, political and ideological' aspects (Dovey, 1999), or by obsession with the power of architecture and people as objects, and consequently for reduction of complex reality of everyday life.

Urban design should concern place as a 'process' and assign the values it produces within the larger network. Meanings and senses as part of these values should be challenged not only through micro-scale of human perception but within particular relations of the context in macro-scale. The result of other disciplines' findings about sense of place such as human geography and political economy are required for meaningful urban design. Sense of place is an inseparable interwoven relation between physical attributes (material and location), activities (practices- social production and construction) and conceptions (meanings/phenomenological) in space and time (see for example Canter, 1977; Relph, 1976; Tuan, 1977; Cresswell, 2004; Agnew, 2004). People's experiences are at the heart of these studies. So, place is both subjective and objective, and the meaning embedded in places, are both produced and producers. It draws the attention of urban designers to manifest the multiplicity of senses and meanings by Looking into people's use of space, their action, perception and experiences. The city design and urbanism is emerged out of the demands of everyday use and realities that does not exist as taken-for-granted (Crawford, 2004).

There are studies that show how urban design in its history has failed because of focusing distinctively on physical aspects while expecting place-making as an outcome (e.g. branding/marketing and re-imagination strategies, Ashworth & Voogd, 1990). Yet, urban design role in place-making should be

discussed as a valid contribution in planning discussion, *if* urban design attempts to apply new methods to study human perception and experiences and pertain them to formal theories; and *if* urban design regards relations as the materials.

In this paper, the process of framing public life in public space is investigated through a contemporary urban design practice, to find out the functions and roles, and responsibilities in assigning values. Together with understanding the context and power relations, this is a systematic study across the entire process of creating and recreating places.

## 3. Methodology

*3.1 Research Design*

Since contemporary public spaces are built within a larger development, and urban development processes cannot be studied itself as an object; this 'phenomenon' should be studied in its 'context' (Campbell, 1998:2). Therefore the empirical data about urban design is explored within qualitative strategies and case study to handle complex urban processes. The case is 'illustrative and exploratory tool that nevertheless cannot easily be generalized or consistently replicated' (ibid). This case investigates a 'contemporary phenomenon within its real-life context' by posing *'how'* and *'why'* questions (Yin, 1994) about the waterfront public space as part of the development of Western Harbour (Västra Hamnen in Swedish) in the city of Malmö, south of Sweden. It is a 'unique case' in which the city aims at transforming an industrial harbour to a 'knowledge city'. The development was initiated by a housing exhibition (Bo01- stands for living 2001) in two phases. The case is characterized as a "best practice", a "prescient case" (Yin 1994, Campbell, 1998) because it is ahead of its time as national pilot for *sustainable urban development*.

The need of process thinking and analysis, led the research material to be collected by meta-tactics in the two areas of theory and practice (empirical data of the observable events of the cases, as well as literature review). Various sources provided different types of information, which called for 'triangulating evidence' (Yin, 1994) and alternative types of analysis and interpretation. It helped observing the establishment of design and development process, while keeping distance of what has been echoed either by designers' intentions, or reflected in the document, which sometimes not coinciding with the actual practices in place. Qualitative interviews were conducted in the form of *dialogue* and *open* in order to exchange views. To understand the design intentions, interviewing the key actors of the projects in planning office and consultants brought a valuable insight to the research and supported some of the (pre-found) facts, while revealed different levels of interpretation, trades-off and unexpected changes and consequences in the process of development. Online reports or published in [local professional] journals were supplementary sources to find out the challenges of the development, which urban design practice has been able to overcome, criticized for, or appraised by, was studied by reviewing documents, reflected as. To go beyond abstract intentions and to understand the reality of everyday use, this study applied participant observation while documenting realities by photography. The patterns of behaviours, practices and repetitions were studied without expectations, while evaluating them critically as urban design outcome and if there is any unintended consequence.

## 4. Result: Malmö's experience in waterfront development

*4.1. The Historic and political context*

The city of Malmö is Sweden's third largest city, located at the southern tip of the country with 300,000 inhabitants, which includes a high immigrant population of around 29%. The city's dockyards formed in reclaimed land in 1840, and Malmö evolved as a thriving industrial town. By the early

1980's, the Kockums shipbuilding industry was in decline and in 1990's vanished completely from the Malmö dockyards. The SAAB factory was replaced there in the 1990s, yet closed down soon. The city's future was in crisis. As a result, the City of Malmö (the municipality) decided the phenomenon of urban regeneration in the industrial area of Western Harbour, within a major strategy for the whole city (Malmö Stad, 2006; Larsson, 2015).

In January 1995 the municipal government initiated a comprehensive vision work 'Project Malmö 2000'. The intention was to formulate a possible positive image for Malmö, for the promotion of in-migration and entrepreneurial start-ups (Malmö Stad, 1999), a dramatized journey into the 'knowledge city'. Strategic spatial planning played a vital role for primarily shift and repositioning Malmö. The decision was in line with the establishment of the Öresund link- road and rail bridge- connecting Sweden to Denmark, and to the rest of the Europe, means positioning Malmö in Öresund region, which gave Malmö more opportunities to be re-imagined as the *knowledge city*. The two other strategies were the initiation of the housing exhibition: Bo01 - Living 2001- as part of the European Housing Expo in 2001 and the establishment a new university. Territorializing of both strategies was negotiated by the City of Malmö. Through spatial planning Western Harbour, an industrial site was proposed to be the *place* for new image of the city, close to city centre to get integrated with its potentials (Figure 1).

Malmö's period of industrial decline overlapped with a number of environmental disasters that had a particular impact on Sweden. This was parallel with new political interest in issues of sustainability discussed in 1992 Rio by United Nations, which highlighted the important role for local government in tackling climate change, which Sweden has a long tradition in that. In a climate of increased urban competitiveness, the condition was prepared for Malmö to choose particular 'environmental vision' and 'sustainable development' for the transformation of Western Harbour.

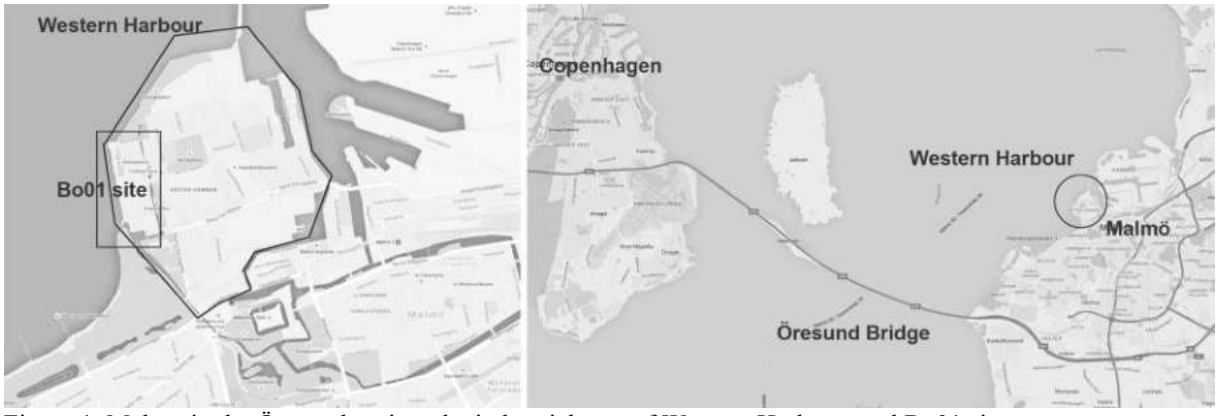

Figure 1, Malmö in the Öresund region, the industrial area of Western Harbour, and Bo01 site

*4.2 Design Intentions*

*4.2.1 Bo01 Vision & Development: City of tomorrow*

The design and development of Bo01, named as 'City of Tomorrow', was the first part in the process of transforming the former industrial harbour to a brand new living urban district (figure 2). A determined visionary and strategic work initiated in 1996 for the creation of attractive living and urban environments 'to build an ecologically sustainable information and welfare society' (Malmö Stad, 1999), to draw people's attention to Malmö after a severe emigration.

The site has unique spatial qualities, natural values and proximity to the city centre and to the future university that could invite new businesses and prospective developers for long-term investment to be economically profitable. Urban design had an integral role for regeneration and transformation process, for the provision of sustainable city to be *"more comfortable, economical, secure, and pleasant, exciting and beautiful* ... [through urban form which should meet] ... *people's aesthetic, emotional and social needs* ... [as]… *necessary conditions for tomorrow's wise buildings* (Tham, 2015).

Such visionary idea established a rational design process and was presented through a master plan, which the natural potentials of the site, climate restraints, and human well-being (biological and cultural needs) were central concepts to form the built environment. The master plan and leading the whole Bo01 project was accomplished by an experienced trustworthy Swedish architect, Klas tham, who is well-known for his ambition and experiences to shape the environment based on 'unmeasurable needs: comfort, safety, and environmental experience' (Tham, 1997). He put particular attention to human-scale environment, aesthetics and visual qualities, inspired by the old European cities to foster 'small-scale intimacy, awareness, security, complexity, mystique and surprise' (ibid, p.10). A mutual agreement from all actors involved in the project provided a legally binding document named 'Quality Programme', as a common platform between Bo01, the City of Malmö and the developers' representatives, to ensure the quality and attractiveness of the outcome as a legible and coherent built environment (Malmö Stad, 1999).

Figure 2, The regeneration of Western Harbour, left 1969, right 2001: Bo01Expo opening

4.2.2 *'Public space' and Social life as requirements for the 'city of tomorrow'*

One out of ten percent of the Quality Program underlined the 'public spaces', yet unclearly categorized, either by the location or by design requirements. What has been highlighted the most in this guideline was to reinforce the 'coherent urbane and unified identity' of all public (open) spaces. To achieve this goal, responsibilities were shared between developers, City of Malmö and Local Streets and Parks Department (Malmö Stad, 1999, pp.33-40). Physical legibility and coherency was essentially required through different facilities such as lighting, recycled material, colour and decoration, traffic prioritization, or standards for tree planting (ibid).

The scope of this paper, on public space is on the seashore (figure 3), which was designed through a competition process and by different designers in three parts: Dania Park (Daniaparken) in the northern part of Bo01, Citizens' Square, (Scaniaplatsen) in the middle of the site, and Promenade (Sundspromenaden) that connects the Citizens' Square to the marina at the end south of Bo01.

However, restricted guidelines of the Quality Program as well as the Scandinavian's philosophy about the landscape and nature have caused a uniform and legible outcome. A minimal design with rich and

durable materials arose from the Scandinavian landscape design philosophy for being in the nature and enjoying the view (Andersson, 2014; Anderssen, 2015).

In the quality program, the waterfront public space was intended for 'public recreation' as 'attractive destination where access and publicity are assured' (Malmö Stad, 1999, p 26). 'Social life' and 'needs for meeting and socialising' were aimed yet not scrutinized in the quality program. It was identified as 'safety access to activities' in public spaces and through services, besides using the technology and local network in the district for better communication'. 'Meeting points' were proposed in public places where public activities and services are triangulations for social encounters. Public places, e.g. cafés, library, laundry rooms, playgrounds, were intended to be situated at the entrance of each block, on the ground floor level.

The value of green spaces was described widely through human health, and rich spatial experience, and knowledge of biological diversity. Planning high intention to include vast green spaces along the waterfront was negotiated between the actors and the City of Malmö, which resulted changes in the master plan. Dania Park was intended to be a park, which makes culturally different value in Swedish culture of being out in the nature.

*4.3 The Outcomes*

*4.3.1 Public Life: The site becomes the place*

Bathing in cities in some cases have caused by coincidence when people spontaneously started to swim in some part of cities. This phenomenon happened in Western Harbour waterfront after Bo01 was inaugurated. The shoreline public space offered visitors access to the water; the right, which the city and its citizens were deprived for a long time. The stairs, which were expected for sun bathing and enjoying the view, shortly, connected people to the water. It was a challenging circumstance for the City of Malmö, because swimming was banned in this site due to the safety issues. It was recognized that citizens' main interest and the need of this place had been ignored (figure 4&5).

The City of Malmö was about making decision in this particular situation: should citizens be prepared to accept planning 'reasonable decision' or if planning should accept social justice and act reasonable

(Campbell, 2006). The public use, as an unexpected outcome, turned to be an opportunity for Bo01 actors, struggling with the gentrified and not affordable development. Therefore, the city adopted approaches to accommodate public use where possible and changed the physical elements as well as the management policies. Paved stairs lead users into new wooden platforms with jetties, which enabled people to get in and out of the water. The popularity of the waterfront increased, and people's use of space gradually influenced their spatial knowledge and perception about the industrial identity of the harbour. They got access to the site where would not be possible unless the new development. They were enjoying an attractive environment at Western Harbour, which aimed at high quality urban form to increase the market value through its new inhabitants.

Figure 4, swimming just happened as an unexpected consequence on the site, photos: Thorbjörn Andersson

The public space, in which the least social values were expected to allocate, exceeded the city and even the urban designer's expectations (Tham, 2015). Accordingly, the 'public space' turned into a place, where public life could develop, and "the drama of communal life unfolded" (Carr et al 1992, p.3).

Another unintended consequence happened at the management and surveillance level. The trees in Dania Park, which aimed to reinforce the sense of place, sense of enclosure, climate protection and seasonal variation, were disappeared after some years (Andersson, 2014 & 2015). The trees did not survive even after a second try planting with an excessive cost. The management responsibility was not clear in the park, where the public access and used the space unexpectedly (ibid) like almost 20,000 people in a sunny summer day.

Figure 5, the gap between vision and reality; trees on the sketch of Thorbjörn Andersson, right: added platforms

*4.3.2. Spatial experiences and experiential qualities*

The waterfront has four areas that punctuate the edge of boulders and access to the water; three in the park, and one in Promenade. The land in Dania Park has been intentionally elevated to create different 'spatial experiences' in different location. In the middle of the park, three platforms are rebounded on a higher elevation in the form of terraces, looking to both green lawn and allies provide space for individuals and groups. Two large open plazas bound Dania Park. A grand hard platform in the north captures the best view of the site, which is left deliberately empty, as a flexible space. A projected platform out on the water in this point stands as a statue and landmark for the waterfront. All the ledges, stairs and edges are comfortable for seating. It was observed that most people visiting the park walk up to this point and spend some times there. The open square hosts several events and initiated activities by the City (Figure 6). Changes in flooring materials and patterns have high visual and aesthetic quality. The Citizen's Square situated at the middle of the site is the main entrance of Bo01 to the water and opens the view to Turning Torso tower (built in 2005) as the new landmark of Western Harbour, replaced the industrial image.

Figure 6, Various optional and social activities; Both left: Dania Park, right top: Citizens Square, right bottom: Promenade

wooden long steps of Promenade after seating and stretching out for individual or groups on both sides, either facing the sun and towards the horizon, or facing the promenade and protected from the wind. The whole waterfront is prioritized for pedestrians with extensive and safe walking and biking routes.

The high quality of the physical space encourages people for different optional activities, which are carried out by wish (Gehl, 1996). Taking a walk, standing around enjoying life, watching the view, sitting and checking phone, taking picture and sunbathing in the summer are the most observed activities. Although planners had aimed for more public places on the ground floor level, not the same interest for developers, therefore urban design reconciled developers' interest with limited

implementation of public places. The City of Malmö, perused the strategy for public spaces to be liveable and become meeting places. Following this strategy, the City took the initiative and runs regularly different social and cultural events in this public space, in which people do not only access to this place but can participate and be actively engaged with it. The public space is open to all Malmö citizens who do not necessary know each other, to exercise their interest and to express their feelings. The Waterfront public space became an ideal place for striking up acquaintances increases the possibility for social activities. Citizens' engagement and practices in the public space shaped a new image for Malmö on top of the branded sustainable identity of Bo01.

Bordering buildings, along the public space are relatively higher to reduce the wind; therefore the interior part of Bo01 is perceived more private and secure. For the same reason, permeability of the peripheral blocks along the public space is low and through the narrow internal streets and frequent plot lines (Figure 7). As a result, there is a weak continuous visibility through the blocks, which is less inviting for the regulars. The robust impression of public/private influences natural movement and avoid wandering freely through the blocks; otherwise in some areas there are signs of soft control of the privacy.

Figure 7, left: limited visibility to the public space; right: the privatized neighbourhood inside.

The buildings typology along the waterfront varies in the northern and southern part relatively to the time they were built (figure 8). The physical edge of Dania Park was built during the second phase of the development after the park had been formed and used. All are residential buildings have semi-private interface, in a form of front yards, whereas in the southern part, private doors and windows are directly opened to the public space. The high level of publicness of the waterfront and diverse group of users on one hand, and no interface between public and private in the southern part on the other hand, had made conflict for some local residents who had paid extra money to get the sea view, while other citizens who *'hated'* this gentrified area *'[…] just walked up and pressed their noses against the glass all the time'* says Scott, an American, who lived on a sixth-floor seafront apartment in 2005. He continued that *'[…] if I was on the first level or the ground level, I'd move out, and many people have done just that, six or eight months after moving in. Others have blocked their windows with shades […]* (Rose, 2005).

## 5. Discussion

*5.1 Towards meaningful places and meaningful urban design*

The case illustrated the rational planning and design process with the aim at identifying high quality sustainable environment, in two main focuses of green living and human-scale form. Development and use of the public space, as part of regeneration process, became a key point and catalyst for an inclusive and liveable environment to stimulate social life. The findings of the study showed that people got the intended environmental qualities gradually through their engagement in public spaces. Their engagement at a certain time - when the Western Harbour turned to be a liveable place- was the result of unordinary public life which was unfolded and turned into formal outcome, like the way everyday urbanism aims to contribute to urban design (Crawford, 2004).The case study showed that the public space became the meaningful place when people's presence made a different, their practice was repeated and adopted to the physical place; as the process of social production and social construction of space (see more in Low, 2009, p.28).

This study highlighted that places are about urban processes, people, power and institutions. Places and meanings are more complicated object to be finite, they change through time. In addition, other direct or indirect factors and connections in macro-scale network and planning level such as spatializing public good, socio-economic dynamics, and political reasons influence people's knowledge and attitude and accordingly experience of the place. Urban planning and design assessed the social need as an unintended consequence, changed the regulation, facilitated the place by design and upgraded it with initiating more social activities.

The big lesson was that the citizens' voice was heard, and due to high planning ethics they were responded immediately, which fostered a democratic process. Later on, the City proposed new places and facilities for swimming, designed by the same designer and rich material as Promenade, in Western Harbour. Through this process – and following strategies for public spaces- the City is regarded by its simple but powerful definition as 'a human settlement in which strangers are likely to meet' (Sennett, 1977, 39). From planning perspective public space potentially becomes the site where different actors and their influences meet. Place-making then was a post-development effort, based on needs for cultural development, was a big step to rehearse civility where there is lack of friction, togetherness and any deeper reason to communicate (Bauman, 2001). That was a great achievement for Malmö with almost 170 different nationalities to gather a large group of people together. This is as much of the literature on city design and urbanism aims to address at the best of public space development.

'Towards opens attitudes', the City of Malmö is strongly aiming at 'rethinking about public spaces' for multiple social usages (Larsson, 2015). Place shaping then can be interpreted as production of space for 'collaboration and dialogue between diverse groups of users', which is in planning level (ibid). Besides, provision of constructive space in urban design perspective, is through place-shaping for 'complex forms of freedom' for individuals and groups, 'not only as an expression of distance and absence (…) but for connection, presence and mutual support' (Madanipour, 2014, p.247). To achieve freedom and democracy in public space is an integral point that should be addressed further in multicultural and super-modern societies.

## 6. Conclusion

Places and people both form meanings, by materials and relations, 'roots and routes' (Dovey, 2010): the former is shaped by urban designers' attempts and knowledge to create physical quality, visual identity and social activities, while the latter is limited by 'utilizing the affordances that particular material structure offers' (Cresswell, 2009, p.2). The former is traditionally addressed by standards and necessary criteria required to shape a good urban form, which determine human needs and patterns of behaviour (Kostof, 1991; Lynch, 1981; Alexander et al., 1977). However, this case study revealed that meaningful places are beyond *good urban form*, which is not necessary out-there. Urban design should rethink the approach of *what it would be,* also their attitudes towards provision and evaluation of *meaningful* public places (Crawford, 2004, Inam, 2014). Urban design should be contextually fit for specific culture and time.

Summarizing the major potentials and limits of urban design in framing public life and its contribution to place-making, the points are:

- Urban design has an integral role in solving economic and social problems by production of space but not only through shaping the form (design) but also through the use and management. Therefore, the success of urban design should be through only evaluation the form and outcome, but through the process of shaping, between intentions and outcomes, design and use, actors and users, macro-scale relations and micro-scale perceptions.
- Urban design should have a broad moral vision in solving problems in solving social problems.
- The social and cultural norms and values are reflected through the normative positions and experts' experiences and preferences in urban design practice.
- Unintended consequences are not necessarily negative outcomes if urban design is positioned within an informative environment with long-term urban planning, and if it has pluralistic approach to alter the solutions.
- Urban design practice involves experts in different scales and diverse roles to materialize planning visions: plans; frameworks and regulation, mediating between different actors and developers, trade-offs.
- Studying contemporary public spaces highlights the power of public authority and their relation in place-making.

I conclude this paper by addressing a critical question: how can urban design better navigate the contextual needs in transformation process, and in which scale the outcomes can be predicted in advance.

[1] Urban design (or in Swedish Stadsbyggnad) is described as 'the methodology of ordering and shaping, composing, designing buildings, streets and public spaces in their entirety'. However, urban design in Swedish context follow special regards to 'natural and cultural values' and promotes 'aesthetically pleasing design of built-up areas, green belts, routes of communication and other construction' (Planning and Building act: Chapter 2, section 2, Quoted in Loew 2012, p97).

# Embodied practice and relational public space. Bridging critical social practice, planning and design through education

Knierbein, Sabine and Tornaghi, Chiara[1]

[1]A1 Ass. Prof. for Urban Culture and Public Space, Department of Spatial Planning, Faculty of Architecture and Planning (TU Wien, Austria), knierbein@skuor.tuwien.ac.at

Keywords: public space, counter planning, critical pedagogy

## 0. Abstract

*Traditional approaches to understand space tend to view public space mainly as a shell or container, focussing on its morphological structures and functional uses. That way, its ever-changing meanings, contested or challenged uses have been largely ignored, as well as the contextual and ongoing dynamics between social actors, their cultures, and struggles. The key role of space in enabling spatial opportunities for social action, the fluidity of its social meaning and the changing degree of "publicness" of a space remain unexplored fields of academic inquiry and professional practice. This paper offers a different understanding of public spaces in the city. Its objective is to (re)introduce the embodied experiences in public life into the teaching curricula of those academic disciplines which deal with public space and the built environment (architecture, planning, urban design, the social sciences, etc.).*

*Relational theories of public spaces have been frequently discussed over the last decade, with differences in their way of addressing the relations between city materialities and social practice. The paper gives an insight into a recently evolving stream of relational pedagogy of public space, where theory of space is informed by perspectives and abstractions taken from human action constitiuting space, and related bodily encounters. Taking the example of the unexplored potentials of embodied cultures in public space, this presentation seeks to bridge theoretical approaches in urban studies and an introduction to performative tools in planning and architecture with the objective to highlight the everyday patterns and rhythms as starting point for theory building.*

## 1. Relational conceptions of public space

This paper discusses relational perspectives on public space in order to present a way forward in dealing with new challenges in architecture and planning education. Developing a pedagogical approach based on urban life and difference in public space is a crucial and a much needed challenge in an increasingly complex and accelerated urbanised world. Considering the ramifications of spatial practice and strategic interventions on urban everyday life, this is a key task for the education of urban professionals. Alternative (relational) ways of envisioning space are particularly needed in architecture and planning schools in order to reflect critically on the crucial role of academics and to amend historical patterns in the production of space.

While urban collectives and urban movements might not always reach the point of becoming 'critical counter publics' (Fraser, 1990), there are many ways in which theory and practice can be informed by the effervescence of daily life, and by the way people both engage with and signify

[1] This paper summarizes and adds on to the findings of the book: Tornaghi, C. and Knierbein, S., 2015. Public space and relational perspectives – New challenges for architecture and planning. New York/London: Routledge.

space. To some extent current debates on public space are aware of multiple emerging social dynamics that spontaneously evoke new patterns of public life or challenge existing ones. Contributions such as "Loose Space" (Franck and Stevens, 2006) or "Insurgent Public Spaces" (Hou, 2010) stress the power and innovation emerging from grassroots practices. Madanipour (2010) also feels that 'the complexity of the urban design, development and management processes (…), and of the configuration of urban societies in which they are located, makes it impossible to find simple answers' (p.237). In "Public Space and the Challenges of Urban Transformation in Europe", Madanipour, Knierbein and Degros (2014) emphasize the challenges faced by municipalities and urban populations in different European cities in terms of policies and programmes, and analyse the multiple roles of public space as a catalyst for urban change. An entire section is dedicated to public space in everyday urban life, revealing its multifarious potential for accommodating the changing patterns of everyday urban routines. This can be linked to Stevens' (2007, p.7) view that "urban experience and social needs are more than mere conceptual abstractions; they can be understood by looking at everyday life on the streets, at its specific and diverse qualities, (…) and in particular at the complex tensions which arise between different needs, different meanings and different users in spaces." Public space is understood as those places where public life unfolds (Madanipour, 2010). Public life relates to the (dis)enchantments of urban encounters, in which there are many and diverse ways of 'how people rub along, or don't, in the public spaces of a city' (Watson, 2006, p.2). However, the built arrangements (that is, their physical shape) of public space can only be interpreted as a snapshot of complex socio-historic processes of space production.

Philosophers, social scientists and other professionals have long tried to understand the workings of the relationships between society and urban space (see Schmid, 2005, p.194 for an introduction to absolute and relational space, and its philosophical history). In the course of these debates, so-called positivist conceptions of space have been challenged by relational conceptions of space. The first group of positivist approaches tend to consider space as existing more or less independently of human existence. Absolute conceptions of space are criticised as 'bedrock' concepts because they 'shift only slightly and move only slowly, despite increasing criticism of their usefulness and appropriateness' (Graham and Healey, 1999, p.625, citing King, 1996). The second group, concerning relational conceptions of space, tries to grasp the built space we perceive and touch as something that has grown over time and is constantly changing, as an outcome of the specific mutual relations between people and places, and their contexts. Here, we consider the material quality of the city as one aspect of such socio-historic processes. We look at space, firstly, as constantly generated by people – individuals or social groups – and, secondly, as indirectly affecting the everyday life of people, and in turn being transformed by changing everyday life patterns and thus by social dynamics. To put it simply, relational space approaches involve concepts that define 'lived spaces' as phenomena that can only be explained by their social, political and cultural context and by the relations between people and objects, both at a given moment in time and in the course of history.

Why is such an exploration necessary within architecture and planning? The modernist approach in these disciplines tended to view public space mainly as a shell or container, focusing on its physical and material structures, and functions. It ignored its ever-changing meaning, contested uses, social conflicts, and more generally the fact that public space is an outcome of contextual and on-going dynamics between social actors, their cultures and power relations. Today, absolute space concepts are still prevalent (as in the aforementioned bedrock concepts) in theory and practice, and tend to reduce public space to a conceptual container (without life and human experience). Such narrow concepts of space are influenced by perceived geometries that can be quantified by measuring and counting. The criticism directed at their proponents emphasises that architects,

planners and colleagues from related fi elds of the spatial arts run risk of disregarding social circumstances, political alternatives and cultural values when intervening in public space. Such a positivist, technocratic understanding of public space does not help in the search for a broadly accepted social path of urban change; indeed it contributes to the tightening of structural conflicts.

Since 1974, this contradictory situation has been explained as partly caused by the segmented and segmenting approaches to analysis and conceptualisation of modernist space among (and within) academic disciplines, but particularly in architecture and planning (Lefebvre, 2009; Stanek, 2008). The challenge is to find ways of dealing with the neglected human aspects in those disciplines that cast spatial visions into steel and stone, and provide the associated instruments for implementation. It promises a stimulating contest at the interface of theory and practice in cities, where interests in designing material change usually collide and confront interests wishing to produce scientific insights. These collisions and confrontations are immanent in capitalist urban planning and design, which treats space as an abstract two- or three-dimensional object to be sliced into workable pieces (Stanek, 2008). These pieces are then tailored by specialised disciplines, that is, by transport planners, landscape architects, light and urban furniture designers, regional planners, urban designers, architects, and the like.

This division of labour in shaping space leads to the alienation and marginalisation of citizens and critical scholars in ordinary practices: place is ripped out of its social and cultural meaning and origin. Since professionals in these specialised spatial arts' disciplines have been taught to understand themselves as neutral technical experts rather than as agents responsible for the spatial aspects of social change (a wider perspective in engaging with space), they hardly touch on the political or epistemological ramifications of their actions (a narrow perspective in engaging with space). These segmented and compartmentalised conceptions of space are constantly (re)produced and prevent a necessary understanding of spatial complexity and the political consequences and social impacts of strategic spatial interventions for urban societies. Above all, they lead to the incapacitation of local dwellers with everyday knowledge and experience of the values and symbolism inscribed within historically grown public space. Today, four decades after Lefebvre's critique, these discrepancies are still prevalent. As Lehtovuori (2010, p.4) states, 'space is conceived of as something separate both, from the meaning people give to it and the actual uses and practices taking place in space'. He considers this to be 'the main problem in architecture and planning's space-conception'. Academic division of labour and life-worldly alienation separate both politics and science from more accurate accounts of the complex nature of socially produced public space. The key role of public space in determining the structures of opportunity for social action, the fluidity of its social meaning and its changing public nature remain neglected fields in the academic education of future planners and architects.

Despite contributions that have provided conceptual tools to counter this trend, for example the latest evolutions of structure-agency debates, in the form of strategic relational approaches (Jessop, 2001; Jessop, Brenner and Jones, 2008), relational understanding of space and place (Graham and Healey, 1999; Tonkiss, 2005; Healey, 2006) and, more recently, neo-structuralist epistemologies of space quality (Moulaert et al., 2013), their degree of abstraction, and lack of relationship to the specific settings of everyday life and spatial practice often prevent them from being of use to a wider group of academics. This applies even more to practitioners who shape the built environment and design the institutional architectures that could enhance social processes. This 'rich texture of relational-space-theorising' does not (yet) lead to substantial change in planning and architectural practice as 'practitioners understand public (…) space predominantly as a visual (…) stage-set, not as a socially rich entity or realm, even less a process' (Lehtovuori, 2010, pp.4-5).

A way needs to be paved to frame space simultaneously by its built and social qualities, and the relationships between them. In applying relational conceptions of space to planning and design education, there must be a strong emphasis on spatial practice to serve as a transdisciplinary catalyst for sustaining social change in spatial terms. Simply put, relational conceptions of space help the understanding of material and immaterial aspects of different urban development phenomena by focusing on social processes, as well as on their cultural and political contexts and inequalities. But why would trained architects and planners find it useful to approach space relationally? As Harvey (2004, p.5) explains: 'There are certain topics, such as the political role of collective memories in urban processes, that can only be approached this way. I cannot box political and collective memories in some absolute space (clearly situate them on a grid or a map).'

On the other hand, the complexity and the abstract nature of relational conceptions of space are still greatly criticised in architecture and planning (Lehtovuori, 2010, p.18), and 'the relational terrain is an extremely challenging and difficult terrain upon which to work' (Harvey, 2004, p.4). Architecture, urban design and planning schools are inherently divided communities, encompassing advocates of positivist approaches as well as proponents of relational conceptions of space. The latter are usually assigned an overly theoretical, abstract and inapplicable impetus, whereas the former are often stigmatised as prescriptive, descriptive, and socially indifferent. Following Harvey (2004, p.6), rather than interpreting relational perspectives as merely contrasting absolute conceptions of space, we seek to understand them through a wider approach to (socially produced) public space which allows for self-reflexivity, criticism, proactive recognition of the marginalised, and the relevance of the everyday in all its social and material manifestations. It is in academic education in architecture and planning that absolute conceptions of space and different counter conceptions collide on a daily basis. It is here, where a dialectical relational approach seeks to overcome thinking in such dichotomies, that there is promise of new insights and innovative results. These efforts might contribute to enrich and revise academic curricula in architecture and planning will provide a useful way of enhancing interaction and collective reflection between academic institutions, governmental departments and planning practice, and within them.

A relational approach to public space can be an influential sphere of life in which to enact an alternative, and socio-environmentally just, coexistence of living beings, and that built environment professionals have a crucial role to play in making this happen. In a world where cultural, political and social hegemonies tend to influence public perception and 'where the story of city life as mixing and mingling is replaced by a story of antagonism, fear and exclusion' (Watson, 2006, p.1), we see a powerful tool in a socially grounded and radically different architectural and planning practice to counteract processes of neoliberal spatialisation (Brenner and Theodore, 2002). Closely linked to the above is the belief that public space is a crossroads where different knowledge fields overlap and connections can be made among them. It is therefore particularly important in establishing spatial practices to enhance lived space qualities, to develop trans-disciplinary dialogues – that is to say collaboration between academics (and academic inquiry) and non-academics (wide ranging forms of knowing) – in the endeavour to rethink the role of education in the field of public space.

In addition to academic approaches advocating a relational praxis, a plethora of grassroots and activist practices have emerged in the form of insurgent planning spheres, which implicitly involve relational approaches to space, without their potential being necessarily recognised by institutionalised planners and designers and their institutions. By learning from these emerging, spontaneous, critical and insurgent practices, and by experimenting with innovative pedagogical tools inspired by them, we seek to address and bridge the gap between relational approaches to space and relational spatial practices.

## 2. Educational Reflections on Relational Practice and Critical Pedagogy

Public space is created wherever learning is possible between various disciplines, between different communities and expertise fi elds – particularly those relating to everyday life. The following educational challenges echoe a practice-oriented trend that has gained momentum in the last decade and expands the notion of planning and designing beyond architects, designers and planners to include inhabitants of the city. Tonkiss (2014, p.2 and p.11) has recently emphasised a 'critical understanding of design in terms of both formal processes and informal (or less formal) practices'. Relating the concept of 'ordinary urbanism' (Amin and Graham, 1997) to public space research, she takes into account diverse forms of agency and activism within the processes of city-making. Similarly, there are various conceptualisations that value spontaneous and radical practices, which aim at reconciling aspects of planning, design and everyday life, for example: 'everyday urbanism', (Chase et al., 2008), 'guerrilla urbanism' (Hou, 2010) or 'insurgent planning' (Sandercock, 1998; Miraftab, 2009). Most of them deal with insurgencies and their geographies as a response to neoliberal tendencies through inclusive practices (Miraftab, 2009, p.32). These relevant contributions tackle public space as a core arena of participation, action and reflection.

Other than this general theoretical turn towards practice-oriented and inclusive approaches to city-making, the immense potential of learning from everyday life is neither acknowledged nor explicitly and sufficiently reflected upon in those disciplines that shape the built environment: existing insights have hardly ever been translated into practice, and have even been negated, ignored or circumvented by educators. This has produced noteworthy conflicts and tensions between urban populations and urban planning and design institutions in Europe and beyond (see Stuttgart protests in 2011; Occupy Gezi Movement in 2013). Planning and design professionals have not made systematic efforts to overcome the evident weaknesses of their formalised procedures, nor have relational thinkers succeeded in translating abstract theory into educational principles in order to raise future professional awareness in favour of inclusive social practices. In elaborating specific relational perspectives for planning education, this contribution substantiates the view that critical reflection and critical action need to develop out of mutual dialogue between those involved in practical interventions and those busy gaining scientific insights about its nature.

### 2.1 Learning and designing: Creating spatial conditions for relational learning

In public space, learning and designing can mutually enrich each other on a practical level: pedagogical approaches to design that include ludic elements of play can trigger fantasy and help in learning with less fear of failure. Playful interventions leave room for student experiences and values, and – when undertaken in direct contact and interaction with urban dwellers and space users – can help establish empathy between (future) urban professionals and 'the public'. Such pedagogical approaches are based on a number of innovations: they provide access to alternative places of learning; use irritation to provoke attention; seek opportunities to renegotiate spatial interests; work with repetition to enhance learning effects and leave room for (self) emancipatory action. These experiences correspond to ideas of education that see learning as an immersion process in the complexity of the daily life of local communities, i.e., as relational learning.

There are already a number of educational practices that transcend the boundaries of abstract space, partly under the influence of the educational turn in those professional areas dealing with the material qualities of public space (for example, public art). Alongside the benefit to students, urban professionals and teachers can become informed about (relational) theories of learning and related objectives of spatial emancipation and justice, and thus can establish a transfer between concepts in

education and pedagogy, and urban design and planning approaches. Scientific insights so gained about the minutiae of everyday life are grounded in local social practice, yet can enhance understanding of issues that are relevant for urban societies generally. Knowledge generated from relational practices is not just 'embedded', but first and foremost 'embodied' (Madanipour, 2013, p.378). Learning is understood as being both embedded and embodied in social relations; it emerges out of the interplay between individual motivation and collective stimulus, (for example, interactions between tutors and learners, learners and learners, public and learners). Pedagogically, this means supporting situations of co-participation, studying the proper social and spatial contexts of learning and helping learners engage in social practice that would foster socially innovative outcomes in a certain place. Place-based learning is coined as situated learning.

Action-orientated pedagogy has been used as an opportunity to activate a more horizontal and experiential way of learning: students learn outside the traditional classroom, from peers, from citizens, and in dialogue with teachers. Understanding planning and designing as practices of learning means going beyond an individual and unilateral understanding of the phenomena of social change, and offers a step forward towards collectively co-produced knowledge that is experience-based, materially embodied and multilaterally embedded in social relations.

## 2.2 Emerging and embedding: Acknowledging spaces of emergence and spontaneity

The collective pedagogical experiment in the making of public space means systematically exploring unplanned side paths and fostering student capacity to engage with the unexpected. Lived space becomes an open and experimental seminar room in which to teach these skills as students can try to test conceived planning strategies and defined design goals. Based on self-organisation, collegiality and open dialogue at eye level, pathways of self-organisation can be explored within the 'messy' environment of lived urban space. In this way, rather than thinking of teachers/lecturers as those directing students through educational activities, the social richness of public space can be acknowledged and explored at its fullest. Here, students learn to combine the achievement of procedural goals with a general openness towards substantial changes in strategies and goals during the process, while considering the range of possibilities of building or not building. Such an approach, based on the particularities of place, will not produce generalisable solutions, but rather situated strategies geared to respecting the peculiarities of specific people and places, and the precise social practices from which they emerge and on which they impact.

Learning about social relations can be fostered by employing dialectical learning fields that go beyond project demarcations. This means adopting a working practice that values and is embedded in locally existing socio-historic contexts, and that introduces perspective from the margin. In such peripheral contexts, there is the opportunity to experience the richness of spontaneous human interaction, such as often happens before or after process-oriented practices like street theatre events. Integrative and interactive public life situations can be valuable learning experiences. Embedding these (marginal, peripheral) lived space perspectives into urban professional curricula makes spontaneity and improvisation a normal part of the learning experience. In so doing, the peripheries produced by these demarcations can be turned into productive fields of learning from the margins. Yet a full transfer of these educational insights into practice has yet to be made: urban professionals are asked to leave the expert's pedestal and accept the evident limits of any skilful intervention in lived space. By reinterpreting these limitations as a potential, practitioners might be able to envision procedural goals, to deal spontaneously with emerging spaces and to work constructively with the clashes between collective and individual interests.

By recognising the ever-changing nature of public space, open-ended processes embrace the variety, novelty and surprise that the 'banality of mundane' or ordinary everyday life entails, and makes space for these practices to hold a legitimate place in planning and design practice. On a more abstract level, the study of changing spatial practices offers an understanding of public space as a core field for conceptual innovation based on insurgent practices. Instead of zooming out into meta-disciplinary accounts, researchers may look to both empirically informed and theoretically abstracted forms of cross- and transdisciplinary knowledge, gained via public space, and connected to the insurgent materialities of spaces of emerging (counter) publics.

## 2.3 Opening and sharing: Learning about new forms of inclusiveness from the open source movement

Public space is increasingly recognised as a place of open source-knowledge production where cultures of sharing may be conveyed. Many contemporary ideas for establishing and self-organising urban collectives and public movements, which try to unravel structural power relations or related controversies, have been adopted from the open source movement. Elsewhere, game prototypes are 'tested' through multiple user-feedback loops where public users are systematically invited to criticise and contribute at all stages of development, thus becoming the real developers themselves. Such endeavours acknowledge that public space is as endlessly completed as it is fully incomplete: incomplete because it is generated by unpredictable patterns of unknown and constantly changing user communities, which both interact with and constitute the open source movement.

Game designers can only draw near-ideal solutions; so do architects and planners. By linking emancipatory practices of open source-based game design to spatial planning skills, students are encouraged to focus on the imaginary, inventive, immersive and subversive features of any spatial intervention.. By contrast to new ways of global learning (such as MOOCS) and despite their advantages in reaching many people in different world regions, face-to-face learning in local public space is much more open to questioning, amending and reforming structural access to knowledge production, even though public space is anything but free from structural power relations. Since public space is saturated with power dynamics, it is where the constant development of new ways of thinking and new ideas, inspired by the creativeness of the open source movement, can be brought to light. Therefore, the material and embodied facets of power relations can be more openly and radically addressed, challenged and changed in place-based education.

We believe that from an engaged relationship with open source principles students can critically rethink the traditional positions of place-makers and instigate collective communication and action via public encounters, collective collaboration and face-to-face communication. In this sense, publics and collectives are considered as makers, producers and owners, rather than as spectators, consumers or passive users. Moving a step in this direction means promoting an open culture in public space education per se. It can be worth transferring knowledge about digital practices, based on open culture as a core principle, to non-digital public space as it helps experimentation with new dimensions of inclusiveness in mutually entangled urban and digital commons. Yet the open character of user-centred approaches in digital public space does not automatically lead to shaping urban public spaces in a more inclusive and just way. Rather, it is the professional habitus of the urban professional, his/her ethical disposition and epistemic finesse that helps to develop a professional 'position' for public space.

## 2.4 Activating and appropriating: Developing positionality while learning about politics of (public) space and time

In formal planning, practitioners often find it hard to react to the dynamics of social change, the pressures of migratory waves and the rhythms of everyday life. Everyday practices in public space may fluctuate between tranquillity and peace as well as between moments of open dissent, ambivalent behaviours and situations of spatial insurgence. Yet it is in public space where the conflictive nature of structural inequality and injustice results in local disputes. Our suggestion is that urban professionals can take inspiration from the work of activists and artists engaged in a plethora of forms of everyday urbanism, insurgent planning, and the creation of alternative counter publics. As non-state and non-profit actors, NGOs and activists are key to establishing transparency and to introducing socio-political dimensions into inclusive processes of city making. Student exposure to this range of experiences in public space can sharpen observational skills as well as place them in contingent situations where they will need to develop their own positionality.

Positionality refers to consciousness and willingness to take part in professional practice, starting with the mere act of considering planning and design not just as a neutral, apolitical or technological skill, but rather as a field where agents behave according to their own ideas, values and beliefs. Acknowledging their situated and embodied specificities means understanding their position and the distance that needs to be 'covered' to address, negotiate and bridge these differences. This acknowledgment can only happen when professional practices are informed by a socio-political mission aimed at enabling a diversity of values and at fostering inclusive and non-discriminatory processes. This change in perspective inevitably challenges students to abandon a supposedly neutral position from which to observe urban life and to conceive alternative plans for new urban spaces. On the same lines, a relational approach to public space needs to start with a critical appraisal of the institutionalised hegemonies, structures and systems of values (and interests) that tend to inhabit mainstream professional practices. This acknowledgement can take various forms: from supporting counter-movements or residual, marginalised practices and helping them to gain momentum, to more conceptual approaches that disentangle any forms of injustice and exclusion embedded in design and planning approaches.

On a theoretical level, the critique is that planners, architects and their related institutions often lack information about and tools to acknowledge civic claims and needs – some of them outspoken, others silent or oppressed – and the time(s) these demands seek to (politically) gain momentum. So far, canonised, orchestrated and strictly choreographed time lines for project life cycles are hardly ever synchronised with the diverse and changing patterns of collective time and public life. In that sense, the politics of public space needs to embrace both the spatiality and temporality of existing claims of spatial appropriation. This leads back to the initial consideration that social unrest sparked by urban design and planning interventions is a key conflict area from which all space related researchers can learn important lessons.

## 2.5 Overcoming othering and nesting: Reflecting and overcoming own biases and accepting difference in public space

Hegemonies over the (material, social, symbolical) use and (political) appropriation of public space do find their intellectual expression in planning and design classrooms as well as in the urban realm. Certain social groups in the marginalised (for example, 'migrants', 'drug addicts', 'the urban poor', 'the homeless'). 'Othering' – understood as a set of discriminative practices usually realised between individuals and groups pertaining to the majority society – is considered as being inherently nested in structures of thinking in academic education concerning space. This is illustrated in cases where ethnic and religious diversity is openly and bureaucratically oppressed by planning authorities, or by city and state officials.

On a theoretical level, post-colonial studies have long paved educational pathways in order to critically reflect on and react to such practices as 'othering' (Said, 2012, pp.173-174). However, in planning and design education teachers are often unaware of, or do not sufficiently care about, the same social stigmas they frequently (re)produce. Any processes of building awareness on the potentials of difference and tolerance need to be systematically and structurally initiated in order to open up inward looking disciplines to meet the challenges of collectively co-shaping public spaces. Historically, urban life has been characterised by difference in many ways (religion, ethnicity, gender, language, etc.). Thinking relationally about public space carries the potential to foster an awareness of social difference and a tolerant, fair and supportive inclusion of marginalised voices and weak interests. The introduction of public space-oriented acts of performative, experiential or counter planning is likely to produce professional policies of social justice and critical practice that may travel through very different contexts and find expression in the symbolic and discursive as well the embodied and material dimensions of public space.

Limits to altruistic practices in planning and design become obvious once their proponents are accused of quixotic romanticism and utopian idealism. But how, in the end, can we not just seek but also achieve a lived space-based planning and design ethos, thus trying to enhance practices that refuse spatial strategies and interventions that (openly or silently) expel, scorn or discriminate against 'others'? Planning and design, currently, is far from close to just and human practice, and there are fundamental reasons for this situation, which we need to disclose, denounce and oppose. A first step is to start from self awareness in public space, where students are asked to discover, enlarge and finally leave their own individual comfort zones, first by extending the individual to a group exploration and, secondly, by transferring this experience into the study of the existing urban life patterns of unknown social groups or political collectives and their spaces. In this way, students and teachers can learn about inner limitations (which we all carry), (relationally) understand how to deal with them and, most importantly, challenge them systematically.

## 2.6 Acting and reflecting: Collectively learning from the ethics of transdisciplinary exchange

With a plea for action-based research formats and a focus on the importance of practice for 'emergent concepts' we approach public space-related academic education as dialogical by nature. By combining social experiences and thought, planners and designers might learn from what the Brazilian educational scientist Paulo Freire, as early as the mid-nineteenth century, coined as a confluence of 'action' and 'reflection'. Reflection, for Freire (1973), is the critical component of education, resulting in a 'critical consciousness' in which learners become actors – not observers – and authors of their own decisions. When teachers and learners fail to reflect upon their own spatial relations or critically evaluate the nature of the information presented to them, they run risk of becoming passive and superficial by accepting dehumanising rationalities and de-contextualised ideas. Thus, they allow themselves to be swayed by deceptive arguments and political polemics. Freire thus proposed combining action and reflection into praxis, an idea that links back to earlier Marxist thinking on social praxis as the starting point of any theoretical consideration.

A transfer of Freire's educational studies to public space education implies that opportunities for reflection should occur not only after but also before and during student interventions in public space. Students take note of their learning starting point, assess their progress in the midst of the class unit and critically evaluate their own learning, both at the end of each intervention and at some time later. In this way bridges between theory and praxis are already embedded in dialogical, reflexive, forms of teaching, which anticipate and prepare the students for trans-disciplinary practice. The training of future professionals to master trans-disciplinary practice can therefore

start from reframing university education as not only a social institution with a public mission (see the eighth educational challenge) but also as a place where social innovation and knowledge is gained in dialogue and joint working with local communities, and where inclusive methods and tools are taught that carry practical relevance for improving everyday life realities.

These findings bring relational public space close to constructivist pedagogy and emphasise the relational character of learning, where teachers start from what they have rather than what they expect. Such approaches acknowledge that learners bring unique prior knowledge and beliefs to a learning situation and that knowledge is constructed uniquely and individually, in multiple ways and through a variety of embedded tools and embodied practices. At the same time, experiences of collective learning in public space enable students to dialogise and negotiate between different and partly contradictory positions and knowledge fields (reflection), and to enter into processes of active exchange and mutual enabling (action). This dialectical approach helps overcome situations where practitioners get stuck in project based rationales (i.e. budget constraints) or where scholars gripe in theoretical debates without linking back to everyday life questions and challenges, losing connection with wider societal questions. While training in dialogical and dialectical practices does not prevent potential conflicts or contrasting views from emerging, it will undoubtedly help create a working climate of trust and tolerance.

## 2.7 Collaborating and countering: Dealing with heterogeneous interests and resulting conflicts

Tolerance and trust, however, are aspects that urban professionals hardly ever come across in their education; rather, they are trained to serve their (party politics, profit-oriented or just passive) clients and to provide them with singular or individual spatial benefits. What happens, however, if the commissioner, client or – maybe more pertinently – the 'partner' in developing public space is a collective that is self-organised and whose primary goals and strategies are driven by non-profit and non-governmental motives and beliefs? Collectives, similar to emergent publics, do not represent one clear and singular interest, but heterogeneous and partly conflictual values and beliefs. Their self-organisation is not usually top-down. By contrast, they often seek to use horizontal and networked forms of operation, sometimes alongside (contradictory) forms of hierarchical management. At other times and when organised in a more ambitious way, they favour consensual ways of decision making, by trying to mediate antagonistic views in long-term negotiation processes.

In a nutshell, urban collectives and urban publics are uneasy 'partners'. Yet their role is as promising as it is demanding, since it allows stunning insights into the power of a plethora of social practices and concrete spatial claims. Results from planning and design processes that include collectives and publics as 'partners' range from social acceptance to cultural identification and ideally foster an activation of sleeping or silent resources such as social and cultural capital and local everyday knowledge. Yet such approaches need to be framed by (self)critical reflection on the risks of dogmatism, counter exclusion or exploitation, in order to make them suited to processes in which incremental objectives are jointly negotiated. Self-critical approaches in academic education facilitate the development of acts of critical practice. They allow and encourage the questions: 'why plan, why design'?

In public space, conflicts offer moments of intense learning about real interests, new appropriations and crucial socio-political questions. They can also be understood as burgeoning seeds that open momentary political spaces and help emerging cultures and publics express their spatial and temporal needs. They might even serve to activate local competencies and resources for an

outcome yet unknown. Studying conflicts in relation to counter publics and their spatial expressions in particular neighbourhoods, and collaborating with activist groups and NGOs in order to overcome certain conflicts, requires not just 'taking into account' civil society perspectives and goals, but also implies these as the essential starting point. Counter planning, in this sense, helps focus on emerging counter publics. Their study enables constant testing and reframing of the educational standards of those disciplines where people are trained to intervene in lived spaces. However, the potential of counter publics is not yet sufficiently understood by urban professionals, with the result that counter publics and counter spaces still remain a hidden and uncharted academic domain in architecture and planning.

### 2.8 Theorising and changing: Learning from the everyday and reinterpreting education as inclusion, participation and action

Theorising from everyday life in public space makes for the last and maybe the most ambitious of the educational challenges addressed in this paper. As public space changes, educational landscapes change too. Where earlier modes of education have largely rested on rigid divisions between learners and teachers exerted in the mono-functional spaces of the classroom, where relations were based on the premise of one to the few, and stimuli were offered within a teacher-centric 'push culture', contemporary landscapes of learning converge around a non-linear sharing model based on the premise of many to the many. In this networked model, a more diverse 'pull culture' of learning is promoted as learner-centric, where investigative forms of learning span from individual towards the collective. Here, space is assigned key significance, as changing learning strategies and practices require a fundamentally different approach to understanding and appropriating space.

Public space, in this respect, has been rediscovered as an arena where dialogue between the diverse epistemologies of the everyday can be created at the interface of theory and practice, as well as within these fields. Given this fertile potential, urban professionals need to overcome limiting approaches which combine or prioritise various positivist aspects belonging to multifunctional open space design. Following participatory action research principles, the core educational challenge here is to make students engage with practical notions such as investigating and developing relationships, yet in an open and non-determinist way. This means critically analysing the voices that both agree and disagree with their own vision, while also embracing those that challenge and contest them. Urban interventions in public space are therefore a very delicate issue for urban professionals, because the key skills they need to acquire are no longer goal-oriented and focused on structured action in an architectural or planned space. Rather, educational curricula need to focus on ethical aspects of building trust in, and becoming a medium for, communities and civil society, on acknowledgement of the limitations of their own professional role in the light of embodied knowledge, everyday life experience and political pressures.

## 3. Conclusion

### 3. 1 Changes from within the academia

By having explored educational reflections relating to relational public space we aim to put forward a radically different way of conceptualising, researching and teaching about public space, in the hope that this will impact on future practitioners' roles in policy design and professional practice. While the type of change that we envision for the future of urban public space is much wider than the reach of this paper, we nonetheless believe that much social innovation can be foreseen through the reflexive practice of academics, academic-activists and academic-practitioners. At the same time, the educational focus developed within such a relational

perspective needs to consider the current capitalist institutional frame prevalent in academia itself. As Merrifield (2000, p.181) underlines, 'In our own daily practice, we deal more and more with abstract representations and codifications of society which are wrenched out of the lived experience of both ourselves and others outside the academy'. This contribution has aimed to show that counter scenarios are already lived, experienced and practised in public spaces, embracing both urban places outside in the city, and inside universities' seminar rooms and lecture halls.

Rather than being a mere theme in urban research, planning and design, investigating public space helps overcome and bridge practice-oriented approaches and theoretical accounts to explain the abstract patterns of space production. A consideration of the relational ethics of public spaces has a key role to play in establishing these connections in a socially just way. With the aim of expanding these approaches and contributing to a change in urban education via public space, a sequence of pedagogical implications, challenges and opportunities have been elaborated that illustrate research results from an exploratory and experimental teaching and research practice in Vienna. Building on the reflections, the following eight transversal perspectives can contribute towards facing the manifold educational challenges that are inherent in relational public spaces.

## 3. 1 Educational challenges

The first educational challenge is to establish educational contexts, conditions and situations characterised by trust and respect and to start from the experiences that students bring into the learning process. That way, students are being made aware of the need to create spatial situations where they are able to respect people's local beliefs, routines and experiences, develop professional empathy and acknowledge the potential resources that urban dwellers might bring along. The emotional and practical aspects of the manifold relations implicated in these learning processes in public space need to be considered. The shift from co-learning to jointly changing the material arrangements of public space with urban dwellers requires the ability to acknowledge ethical, ontological and epistemic considerations implied in these forms of dialogic learning.

The second educational challenge is to engage with intuitive ways of learning based on the encounter with the unexpected and to acknowledge the patterns of social emergence as a core characteristic of public life. Appropriate tools and procedures that can capture the situated, context-specific and idiosyncratic nature of collective places and their social dynamics need to be developed. These tools both emerge from, and address, the context, problem and given situation, and ideally explore public space as relational space. Students will learn to link these dynamics back to the material dimension of public space, specifically to its emerging materialities, while they are encouraged to deal with the unpredictability and spontaneity of material claims and spatial appropriations.

The third educational challenge is to create a general openness to sharing different perspectives and ways of working within the daily life of the students. Public space, in this respect, can serve as an experimental arena where alternative ways of pooling resources for urban change can be envisioned, developed and practised as if real. Enabling alternative spatial appropriations that use public space as a common good beyond private fragmentations needs to start from the resources that lived space already offers. Welcoming attitudes to new perspectives (for example introducing public feedback loops) need to be cultivated as they offer a good opportunity for integrating new forms of inclusiveness.

The fourth educational challenge is to encourage students to take an informed stance and to develop a professional positionality towards their socio-political role as urban professionals by

developing their own ethically informed position. That way the politics of space and time of public space will be acknowledged as given ground for any professional action. Planning and design studios need to radically incorporate a new cronopolitical thinking, and its translations into practical project rationales, to enable the plethora of everyday life rhythms of space appropriations and re-appropriations to fully unfold. Both politics of space and politics of time are therefore central to relationally thinking of public space as lived space.

The fifth educational challenge is to train the ability to overcome individual, intimate and private comfort zones in order to develop professional skills of acknowledging, integrating and respecting social and cultural difference in urban space. This concerns the ethics of intervention in lived space as well as the ethics of the seminar room. A core educational aspect here is to focus on experiential learning in non-discriminatory situations where teachers include and appreciate as many different perspectives, languages and disciplinary frames as possible. Group formation for studio work can be organised along aspects of difference in order to stimulate self-experience and dialogue. On a theoretical level, postcolonial accounts of (public) space can help in revisiting current approaches, unravelling and opposing practices of 'othering'.

The sixth educational challenge is to combine argumentative debates linked to the public sphere (reflection) to the embodied interventions and public address in public space (action) in all pedagogic formats. On a practical level, this helps to develop experiential ways of public intervention and tools to induce processes of co-shaping public spaces. For students in these self-developed formats the analysis of the realised interventions is one core aspect: for this reason it is important that sufficient time is allocated for reflection before, during and after the participatory intervention in public space. Particular emphasis needs to be put on the de-briefing phase, when the ethical and epistemic implications of practical action can be unravelled, discussed and challenged, and the political character of any intervention in public space can be jointly exemplified.

The seventh educational challenge is to start from a study of and collaboration with collective claims, counter publics and their acts of resistance and contestations when developing an idea about their role as urban professionals intervening in public space. This way, students learn to develop their own politics of action in contested areas of social interaction, as well as to recognise already existing activist tools, knowledge and practices. Consideration of conflicts as normal opportunities to learn about socio-political aspects of public space rather than as exceptional risks to the formal and often canonised (party) politics of public space, can be a key component for socially-just decision making, where the involvement of civil society actors is not considered as a risk to urban development processes, but as their enriching precondition.

A good way to start dealing with this eighth and concluding challenge is to declare universities as public spaces where not only rational discourses are framed and perpetuated, but also professional practice is reinterpreted in its original and embodied sense: re-rooting the notion of educational politics to 'the collective', the public in its earliest connotation. This means addressing public space not merely as a theme but rather as a vehicle for gaining knowledge based on epistemologies and ontologies of the everyday. It implies considering research and teaching not just as ways of generating data and conveying information, but as politically informed processes to embed inclusion, participation and action into the life of the scholar with the aim of generating socially innovative insights and relevant knowledge on public space as lived space. This means nothing less than shifting the focus of urban professionals back to the shaping of everyday places of public and collective concern.

# URBAN MORPHOLOGY AND SOCIAL REPRESENTATION: THE CASE OF MODERNISTIC HOUSING ESTATES

Michal Kohout[1], David Tichý[2] and Filip Tittl[2]

[1] Department of Building Theory, Faculty of architecture, Czech Technical University in Prague, Prague, Czech Republic, kohout@unitarch.eu
[2] Department of Building Theory, Faculty of architecture, Czech Technical University in Prague, Prague, Czech Republic

Keywords: urban morphology, housing estates, transformation

*Abstract:*

*The spatial representation of community is present through different levels of built environment – from single dwelling unit and buildings with specific shared spaces to neighbourhoods and districts. In urban level the spatial representation of community is manifested in public spaces. Traditional urban public spaces - rooted in human cognitive and sensual capacities and cultivated for centuries-long development of adopting, using and identifying one self with a place – can be perceived as most natural field for public social interaction.*

*The paper describes the problems of legibility of modernistic urban patterns, its spatial and social dimension. Modernistic housing estates represent specific morphological structures where identity in urban level is generated by solitary buildings instead of public spaces. Public space is often designed as an open space without any specific content and with uniformity lacking social meanings. This setting can easily lead to disorientation and lack of inhabitant's identification with the environment. Based on problem analyses the study explores the possibility of reorganizing the public space in favour of legible public space without the necessity of massive changes in built mass. It presents the results of comprehensive research project "Housing Estates, What's Next?", which has taken place at the Faculty of Architecture CTU in Prague. During the process six specific modernistic neighbourhoods in Czech Republic were analyzed and more then 20 model solutions have been produced and evaluated.*

## 1. Introduction – Built Environment and its Social Dimension

Spatial organization of built environment and its social dimension are closely related (Doxiadis, 1966). Humans identify with their living environment and that respectively constitutes a strong part of their own identity (Lewicka, 2011). This interaction is to be found not only on a personal level but is true for different forms of social organization - these being personal, interfamilial, civic, national etc. (Kohout et al., 2011). In a common sense we often identify a given social entity (being a single person, family, community, nation or even an institution or corporation) with its home or seat. This relation plays, no doubts, an important role in constituting and maintaining social relations, it shapes their forms and allows for their continuity, further it plays an essential part in their representation.

In a way built environment represents a dynamic balance of several contradictory tendencies. That of stability and flexibility, control and openness, readability and need for richness and depth. To allow for all this it tends to organize itself in spatial units each of which usually representing a certain social phenomena (Doxiadis, 1966). Based on the ability of human senses to recognize certain physical phenomena, these spatial units tend to appear in certain given physical dimensions (Hall, 1966; Gehl, 1987). As was pointed out by John Habraken (1998) these spatial units also represent certain decision making levels in the process of environment creation and management. To manage their different duration periodicity through their clear separation plays also an essential role in environment ability to withstand time changes (Kendall, 2000).

In a standard municipal built environment we can thus usually recognize the following ascending line of environmental units: rooms – dwelling units – houses – blocks – enclaves – neighbourhoods – districts etc. (Kendall, 2000; Kohout and Tittl, 2012; Lewicka, 2011; Galster, 2001). By rule the units of a higher scale usually consists of several units of a lower scale and specific extra elements which usually tie the composing units together (Berghauser Pont and Haupt, 2010). This "adhesive" role is usually played by communication spaces, being private shared in units of a lower scale levels (such as apartment corridors), semiprivate (inner staircase in an apartment house) or public in units of higher order (streets, squares etc.). It is usually these spaces which allow a user to perceive the situation and give him basic orientation of the unit given. I.e. a corridor or a hall in apartment unit enables one not only to move through the apartment, but also to get a certain overview. The same can be said about inner communication spaces of a tenement house or in even more obvious form in the public spaces on urban scale. Main streets or squares usually allow not only for circulation, but at the same time offer basic navigation and further more give a sense of presence and identification with a particular place.

Common spaces therefore play important role in providing the unit with an ability to offer a sense of identity. Such identity is closely connected to the setting of its communication spaces. This is true to the degree that the unit common spaces often are the main discriminatory feature of certain typological forms: so we recognize corridor or hall apartment setting, staircase, corridor or gallery setting of an apartment house radial or grid urban patterns. Seeing common spaces merely in their circulation role as secondary (serving) as opposed to the functioning (served) role of the composing units, means overlooking completely their organizational role (organizing as opposed to organized) and equally important communication (in broader sense) and representational role (as identity bearing elements).

## 2. Housing-Estates - Characteristics and Defects

Czech housing-estates built roughly from the middle of the 20$^{th}$ century were planned like so many others in Europe and elsewhere in the world at that time with several underlying ideas. One was the spatial Modernistic concept of a free continuous park-like landscape with houses placed in this space as free-standing objects. These objects "freed" from the traditional formative mass/public space relation were first positioned in a rational row of slabs system, to be later substituted for more random composed types of massing.

As for their social concept, bigger housing estates were usually subdivided into so-called dwelling groups (roughly 1 500 inhabitants), neighbourhoods (ca 5 – 6 000 inhabitants) and districts (with tens of thousands of inhabitants). These units were served by corresponding planned public and commercial facilities (kindergartens, schools, shopping centres etc.). The unit system was usually applied directively often regardless of particular settings of the site and its individual character.

As for the planning-in-time aspect, housing estates were in a way built as "timeless" compositions with no clear concept of gradual change, future adaptation or renewal. This, together with the fact that from technical as well as ownership point of view these were often single planner, single-client and single-builder undertakings, proved to be a mayor limiting factors in their further re-/development. Especially in a situation when the ownership structure became massively fragmented in the privatisation processes following the social changes after the fall of Communism.

Despite broad range of applied urban patterns, when compared with the compact city forms, housing estates as a system tend to show certain characteristic deficiencies which tend to repeat in practically all cases and be therefore considered as inherent for this particular type of environment:

*2.1 Undefined public spaces*

Probably the most obvious characteristic of housing-estates urban fabric is the oversized public space. In comparison with traditional urban structure, where public spaces comprise about 25-35% of overall area, in housing estates this figure rises to some 60-80% (fig. 01). The modernistic vision of "living in park" brought along a new way of organizing urban fabric. Traditional municipal spaces were substituted by a concept of a free space without any specific content. It can be seen as symptomatic that in the nearly 70 years of living and using housing-estates no adequate and generally accepted names for their public spaces were adopted. The most often used word "greenery" for this "between-house-area" expresses sufficiently the helplessness of the situation and the lack of closer understanding and more structured use. The phenomenology of space which works with such terms as park, garden, orchard, playground, meadow, forest, but also parkway, alley, square with trees helps to understand particular space better. And such understanding not only facilitates identification but most of all helps to realize how to use such space, how to behave in it and consequently who is responsible for the space, who cares for it (Kohout, Tichý and Tittl, 2015). Unfortunately, the public spaces of housing-estates usually do not allow for their clear articulation and this decreased legibility results in their lower overall quality.

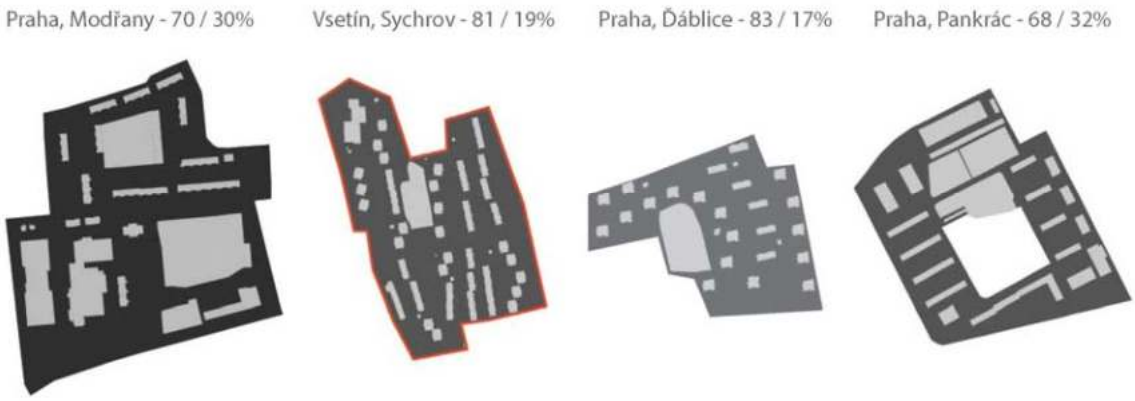

Fig. 01. Proportion of public and non-public space in typical housing-estates localities in Prague

*2.2. Unclear composition of units and the reversed mass/space relation*

Despite the fact that Housing-Estates and their strictly organised system of planning units and public facilities (kindergarten units, school precincts, neighbourhood shopping facilities etc.) represent in a way even more orthodox hierarchical system than standard municipal environment, these abstract units - due to the continuously floating public spaces – remain often undefined and unrecognizable from users perspective. Also public spaces with no clear delimitation can hardly become representations of any morphological units. It is often the case that such identification role is played rather than by public spaces by buildings themselves, usually those which play a public role, i.e. shopping centres, public facilities etc. However, such setting brings along several complications. Such buildings are often not authentically public (often they are privately owned). Also they can hardly orient a user in a way public spaces can (buildings usually do not offer any panoramic overview and therefore do not allow for better understanding of urban layout). But most importantly, the life cycle of buildings is by rule shorter (decades) than that of public spaces (centuries). They can therefore hardly become a stabilizing factor of the urban structure mental image.

*2.3. Absence of readable spatial pattern*

Public spaces do not represent only shared space of local communities with its programmatic content and symbolic meanings, they play as well a key role in forming urban pattern. In the spatial setting of traditional town the key part of public space system is usually performed by communications (streets) and their intersections (corners, squares). The public spaces are naturally defined by building mass and together they constitute a coherent pattern. On the contrary, in most of housing estates localities, the traffic network does not correspond to the spatial arrangement of buildings themselves and the spaces they form (fig. 02). The space is not oriented longitudinally in the communication direction (i.e. in the sense "from" and "to" somewhere), nor is it oriented perpendicularly (i.e. in the front – back sense). Further, housing estates public spaces do not form a comprehensible hierarchical system where the more and the less important elements would be clearly distinguishable. The communications do not take on the character of streets but they rather resemble roads, i.e. a phenomenon more characteristic for rural areas rather than a city (Kohout and Tittl, 2012).

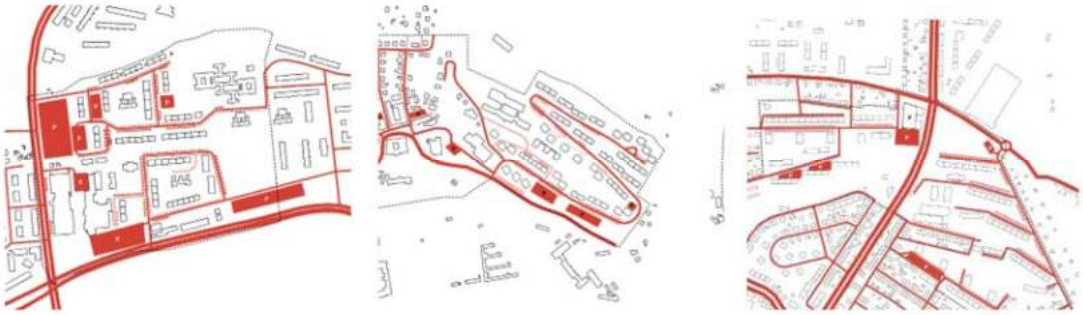

Fig. 02. Relation between built mass and traffic network; left: Modřany in Prague, middle: Sychrov in Vsetín, right: Skalka in Prague

*2.4. Lack of active parterre*

The fact that housing estates public spaces do not channel general movement (being of pedestrians, bicycles or cars) into clearly recognizable corridors supported visually by building mass has further two fold effect on formation of neighbouring private spaces and buildings. It brings along a lack of clearly distinguishable semiprivate space, suitable for certain types of outdoor activities (independent movement of small children, some types of house works etc.). Perhaps even more importantly, such arrangement negatively influences the possibility of commercial activities on ground floor inhibiting thus the creation of an active parterre – a living interface which would further stimulate public life of the neighbourhood and bring about their functional diversity.

## 3. Housing-Estates - Tools of improvement

Following section describes possible interventions in housing estates fabric targeting legibility of urban layout with adequate social meanings. It presents selected results of comprehensive research project *Housing Estates, What's Next?*, which has taken place at the Faculty of Architecture CTU in Prague. The project's general aim is to search for long-term and sustainable development strategies, which would result in housing-estates transformation into areas with adequate social status, stable mental image and functional arrangement. Six housing estates localities in Czech Republic (in Mladá Boleslav, Karlovy Vary, Vsetín and 3 in Prague) were chosen with aim to cover broad range of areas with different morphological, historical, sociological characteristics and regions with different level of development potential. Spatial, demographic, functional, traffic and other surveys were carried out on the basis of which 20 model solutions were produced with the aim of showing possible town planning strategies tackling the problems identified as the most pressing in respect to the areas future development.

Despite the diversity of housing estates spatial arrangement as well as their present development potential (pressure for further development in areas like Prague (Němec, 2014) or Mladá Boleslav, or on the other hand depopulation, in case of for example Vsetín), some general tendencies and themes can be drawn from the case studies executed. Most have a direct relation to the people-place relation and the social dimension of planning. They can be summarised into the following list arranged according to the scale of intervention:

### *3.1. Delimitation of spatial and planning units*

Referring back to a standard urban environment organisation (and its social meanings) described in the introduction, the key step in enhancing the legibility of housing-estates spatial structure represents delimiting distinguishable spatial and planning units - urban blocks, neighbourhoods, districts etc.

On the district level, neighbourhood arrangement is the main task. During this process critical parameters (number of inhabitants, dwelling units, public facilities etc.) were verified and corrections were made to match better their theoretical standard. Nevertheless this constitutes no dogma, divergences are possible, but they should be well-founded and their reasons should be preferably understandable from the environments context (terrain morphology etc.). Neighbourhood identity is usually carried by overall character of built mass and – in this case perhaps even more importantly – by key local public spaces. During the process these spaces were identified and set as a key element of public spaces pattern (fig. 03).

On the neighbourhood level, particularly critical is to define urban blocks (meaning block as a unit of urban environment). Predictably, the predetermined mass setting proved to be challenging when readable block structure was to be created. As a response, a highly diversified block typology was introduced, which manifested itself in different mass patterns as well as different sizes of the blocks. These ranged from small *urban islands* with only one side defined by a building mass, the other side usually articulated only by landscaping or fencing, to large *superblock* arrangements usually subdivided and with system of secondary permeability. Standard urban blocks with central semiprivate or semi-public space determined by building mass on all sides (though massing itself was usually with a less orthodox and more open arrangements) were of course also an option (fig. 04). Wide variety of block typology resulting from the effort to save most of the present built mass can be perceived not only as practical, viewed from economical and ownership aspects, but take into consideration also existing character and its mental meanings. Furthermore, specific block typologies can also provide for neighbourhood's specific character and as such are often found in examples of contemporary housing.

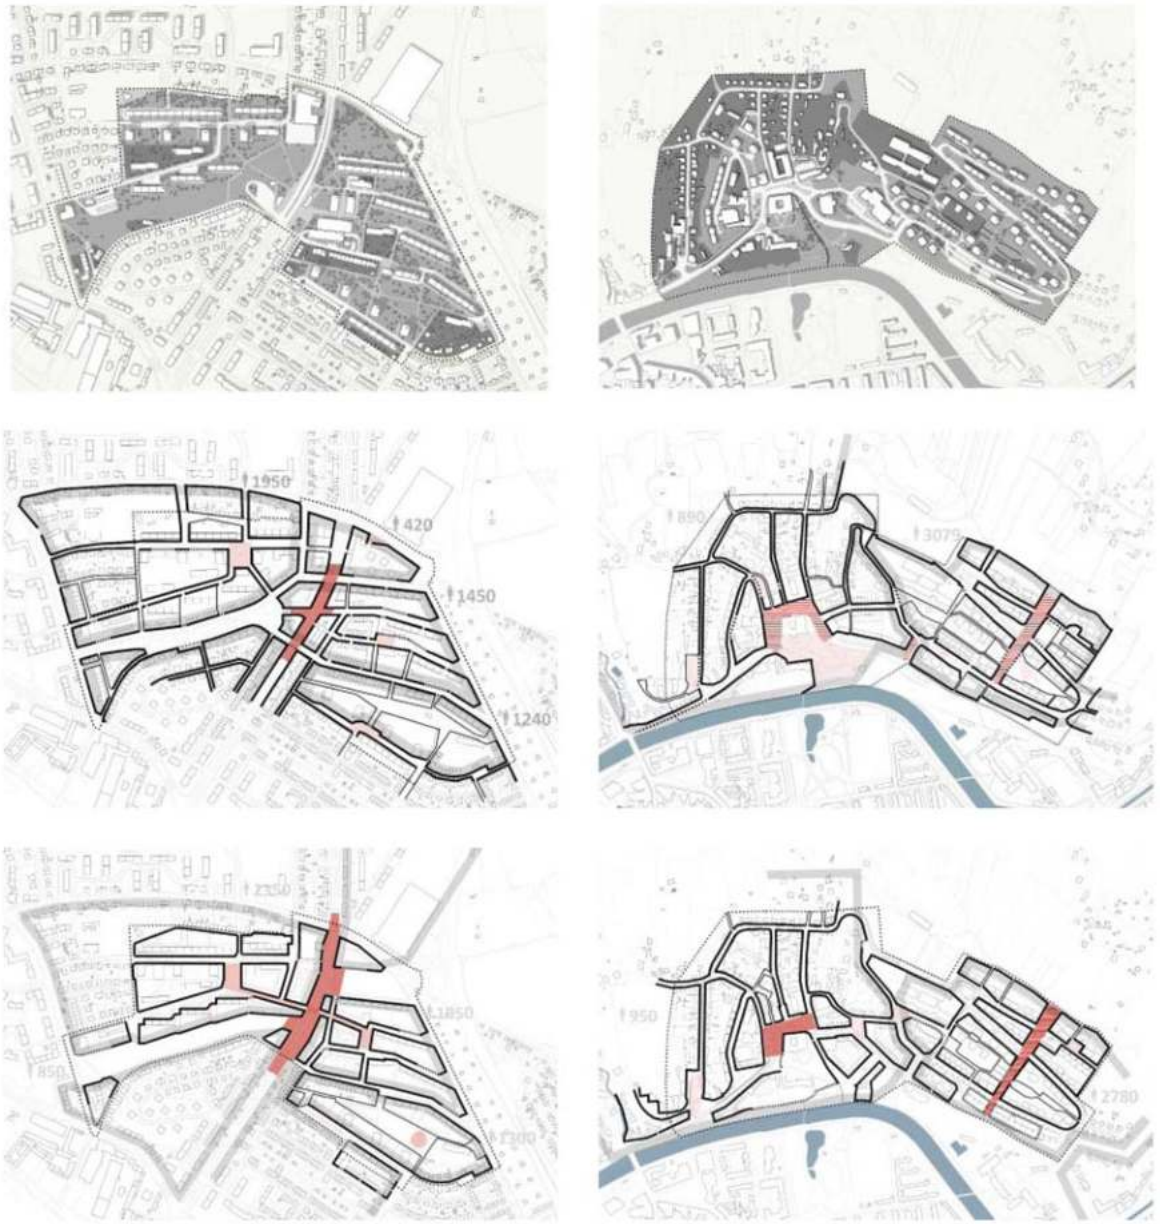

Fig. 03. Delimitation of comprehensible units (blocks and neighbourhoods) in two examples of housing estates – Skalka in Prague (left) and Sychrov in Vsetín (right); top - present state, bottom – two examples of possible unit delimitation for each locality in relation with number of inhabitants representing the neighbourhood community; source: Housing estates, what's next project case studies, Kohout–Tichý studio FA CTU in Prague, M. Decker, M. Marada (Skalka), R. Paulus, F. Bačuvčík (Vsetín)

Block arrangement possibilities related to housing estates built-mass organisation; left – superblock (Modřany in Prague), middle – standard urban block (Růžový vrch in Karlovy Vary, right – urban island (Skalka in Prague); top: current state, middle: rearrangement proposal (block delimitation and detail parterre organisation), bottom: diagram of hierarchy of privacy (for the key see fig. 05); source: Housing estates, what's next project case studies, Kohout–Tichý studio FA CTU in Prague, J. Sládek, T. Kafková, M. Decker

*3.2. Intelligible network of public spaces*

The basic characteristic of housing estate urban layout – the continuous unlimited space was assessed as one of environment's main disorientating factors. Individual case studies were therefore testing the possibility of its structuring into legible, nameable and limited spatial phenomena: streets, squares, parks etc. Effort was made to link these spaces into patterns, which spatial logic would be based not only on abstract compositional principles but would rather follow the underlying natural social meaning.

What was usually necessary to overcome in this process was the often unintuitive traffic system based on the principle of dead-end side streets connected to circling boulevards. Traffic connections have as a rule little to do with overall orientation of spaces indicated by building mass arrangement. It is therefore desirable to complement present communication into a more intuitive network by linking of the dead-end-streets. Different public spaces should have their natural continuation – they have to navigate the visitors and their orientation has to be clear and logical. Traffic intensity (the original reason behind the unintuitive traffic arrangement) can be effectively regulated by other means (mixed traffic streets or other types of reduced car-traffic on local communications) while avoiding the negative disorienting effect (Kohout and Tittl, 2012).

*3.3. Introducing broader variety of open spaces regarding hierarchy of privacy*

Urban fabric does not necessarily have to be composed of strictly private or strictly public spaces. *Semiprivate* open space shared only by inhabitants (e.g. yards of apartment houses), can be complemented by *semi-public* spaces (e.g. publicly accessible parts of blocks) with a more intimate character. Different level of privacy within the built environment stems from its distinguishable character. Such comprehensible heterogeneity caters for different ways of usage and helps inhabitants to identify themselves better with a place. Hierarchical sequence of outside spaces from public, semi-public, semi-private to private therefore fundamentally increases users capacity to „read", comprehend and patronize environment by different ways of usage (Kohout, Tichý and Tittl, 2015).

Such articulation of open space does not have to be related with introduction of new built mass (fig. 05). In the housing estates areas it can be in fact achieved only by relatively simple interventions: in many cases by plain landscape rearrangement (see section 3.4). This solution can not only enrich the quality of environment and bring more life into open spaces, but also help to find new use for the oversized public spaces and to distribute more evenly the maintenance costs. Despite this significant change in open space organisation, present character of „houses in a park" does not have to be changed fundamentally.

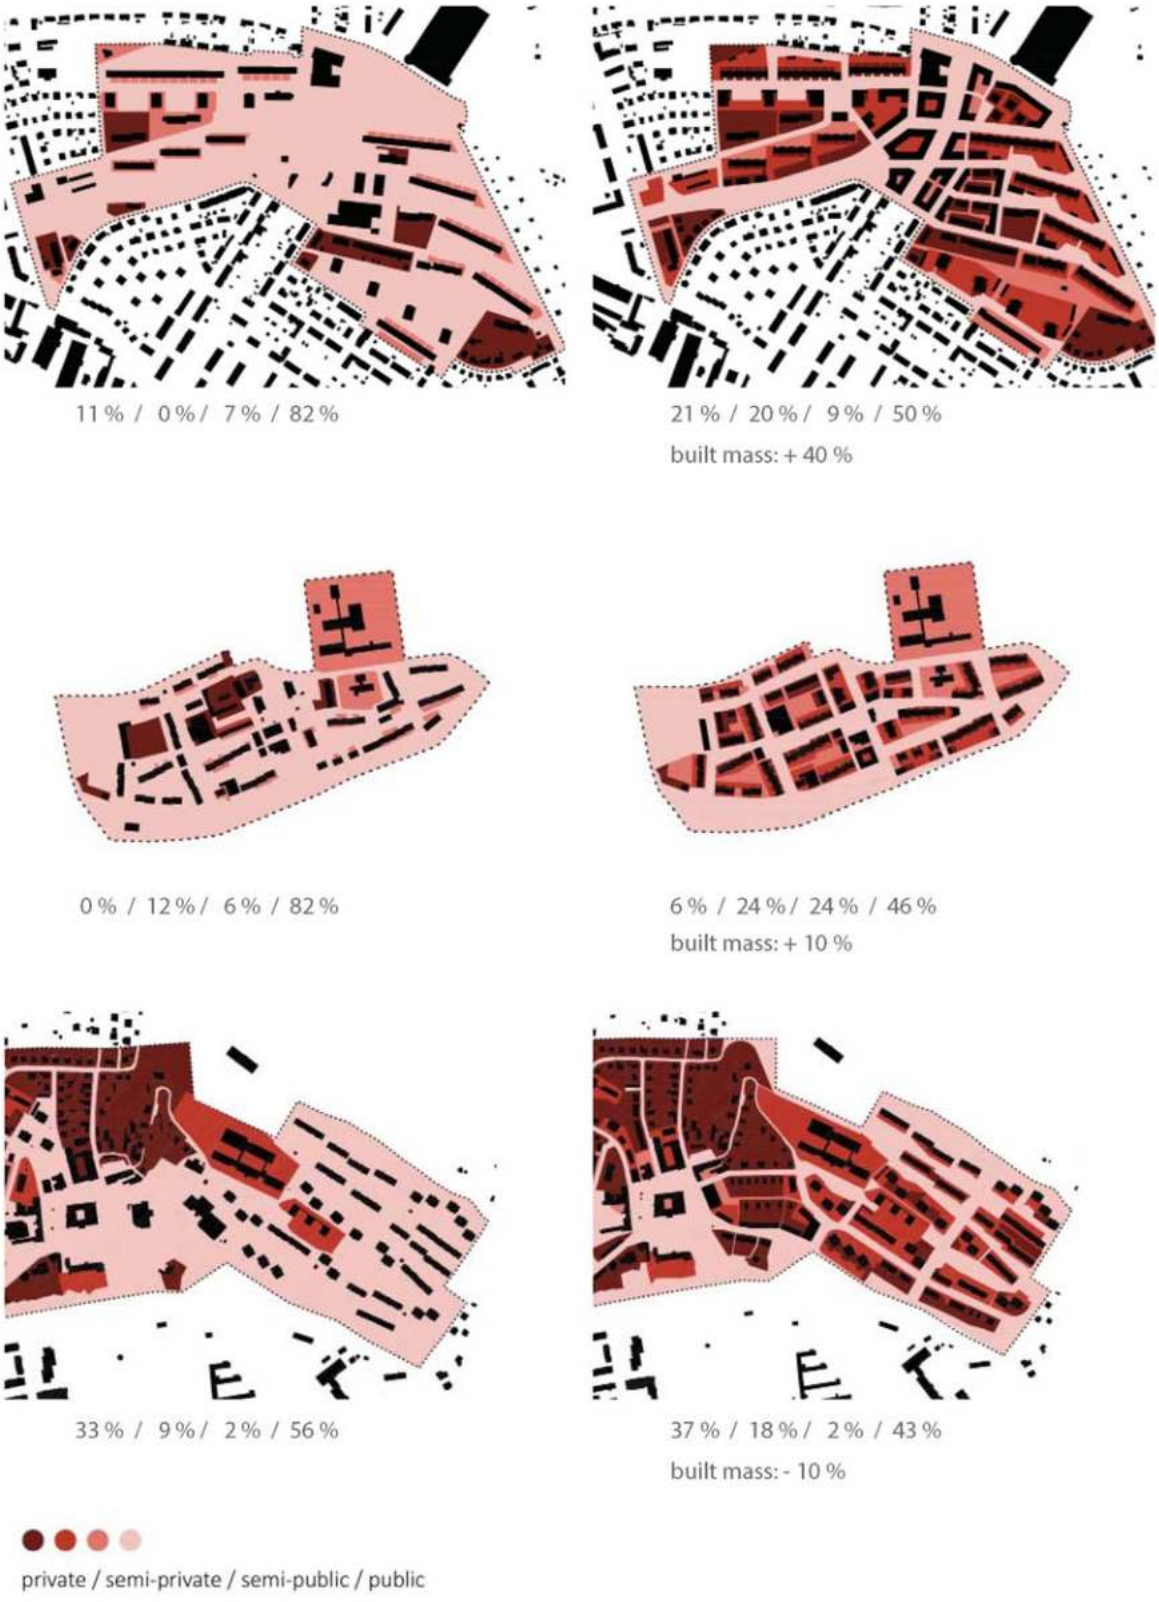

Fig. 05. Introducing broader variety of spaces with different level of privacy into housing estates fabric; top — Skalka in Prague, middle – Růžový Vrch in Karlovy Vary, bottom – Sychrov in Vsetín; left: current state, right: rearrangement proposal; source: Housing estates, what's next project case studies, Kohout–Tichý studio FA CTU in Prague, M. Decker, T. Kafková, T. Vrbová

*3.4. Articulation of the boundary between public and private*

From the point of view of direct impact on the user, the elements on a lower planning level play an essential role. This is even more important when adaptation of an existing urban fabric is being planned as due to pre-determined conditions the possibilities of later adjustments are decisively limited. Critically important in this sense are the boundaries between different types of spaces, which delimitate and define different units and determine the level in which a visitor can actually distinguish these urban elements. Most of all, the chosen type of boundary modulates the level of communication between the public and the private sphere and is therefore essential in moderating visitor's behaviour.

Probably the most important boundary represents the demarcation between block and street space. In the plan it is determined by street line, usually visible through edges of built environment, i.e. through buildings themselves or their articulated surroundings, such as front garden fencing. In any case, level of such articulation might vary dramatically in different areas. In housing estates context milder solution can be adopted regarding both respect to the "openness" of its character and predefined arrangement of built mass limiting range of possible solutions. Physical expression of the boundary can also manifest itself only through parterre organization (fig. 06). What is, however, critical is relation to ownership arrangement, i.e. division of lots, which should correspond to the real visible arrangement, in particular to positioning of street alignment.

At the similar importance as natural legibility of the boundary is its role as an active interface. Inhabited shared spaces or private gardens can introduce natural social control to public space, distinctive features of different activities in shops and services on the ground level led further identification to the spaces they address. In the housing estates context active commercial parterre can be introduced only by small additions in ground floor level (fig. 07).

Fig. 07. Introducing interactive interface in ground floor level – example of small addition to existing prefab slab; source: Housing estates, what's next project case studies, Kohout–Tichý studio FA CTU in Prague, L. Havelka

## 4. Conclusion

Despite the drain of more affluent inhabitants (Ouředníček and Temelová, 2012) Czech housing estates still remain socially manifold. But even in these relatively favourable conditions the environment shows some systemic deficiencies which, if not taken care of, could in future jeopardize today's relatively favourable situation.

As it was described in the analytical part of the text, housing estates environment is often conceived as disorienting. This lack of orientation means not only that people have sometimes difficulty to find their way (this happens mostly to visitors), but perhaps more importantly it means that it is difficult to understand the functional designation of certain, mostly open, spaces - i.e. what activities are or are not suitable. This is true not only on short term level (for instance where is it possible to behave in a more relaxed way, what places are suitable for more formal activities etc.), but also for long term activities (where is it advantageous to open a shop, where is it possible to add or substitute a building mass).

The freely running continuous park-like public space represent therefore not only much higher running costs, but also in connection with its anonymous character, lower social status, at the same time it brings along a higher potential for negative social behaviour (vandalism etc.). In a negative spiral effect disorientation leads to lower identification with spatial units and loosening of the person-to-place relation.

*Possible interventions*

The research project has brought forth planning models which show, that by decisive reorganization of the land ownership and adequately changes of landscaping and parterre a spatial organization of the environment can introduce higher level of legibility and intuitive orientation - a clear structure of graspable phenomena of building mass (blocks, neighbourhoods) and readable public spaces (streets, squares, parks, etc.) both arranged in corresponding hierarchical order. Further, such changes can also allow for relatively independent development of manageable lots mostly of the size of urban blocks. These critical goals can be often achieved without large scale changes in overall building massing. Also the areas can most often retain certain visual openness and a "garden" character - qualities valued highly by their inhabitants. As a result the environment's physical structure can reflect and absorb better elements of its social structure and adapt more flexibly to their ongoing changes.

# 'BECOMING LOCAL' IN AMSTERDAM: THE SYNERGY BETWEEN CREATIVITY AND CITY BRANDING IN STRENGTHENING LOCAL IDENTITY

Georgia Lalou[1] and Alex Deffner[2]

[1] Department of Planning and Regional Development, University of Thessaly, Greece, geo.lalou@gmail.com

Keywords: creative city, city branding, Amsterdam

## Abstract

*Cities are continuously changing due to economic conditions, demographic changes, urban planning policies etc. Newly emerging economies contribute to the consolidation of different outlooks in urban planning practices such as city branding, which has been widely connected with cultural policies. Nevertheless, this approach has been widely criticized since there have often been negative outcomes for the existing places and residents, as for example gentrification or loss of local identity. During the last years, a shift is observed towards the emphasis on the social aspect of city branding. Also, a new economy based on creative professionals appeared, enriching the theoretical approaches of the creative city and adding new dimensions in cultural policies. Strategies are now observed to be directed more to the preservation of the local identity and the collective memory of the city.*

*Two case studies in Amsterdam show two different ways of 'becoming local' processes. The first refers to the 'broedplaatsen' initiative – the 'Art Factories' program. This creative policy led to the construction of meaningful places with multiple uses, housing the creative professionals of the city and hosting multiple activities. Besides, the abandoned places were part of the history of the city and this evolution resulted in the preservation and strengthening of local identity. The second case study concerns Amsterdam's festivals, combining both global and local characteristics. Festivals are mostly situated in public spaces and offer an easy access for the visitor to the life of the city, thus a different way of 'becoming local'.*

## 1. Introduction

Cities are continuously evolving due to factors such as economic conditions, demographic changes, and urban planning policies. Newly emerging economies contribute to the consolidation of different outlooks in urban planning practices such as city branding, which has been widely connected with cultural policies. The idea of the creative city and the practices of city marketing and branding have been widely criticised as expressions of neoliberal ideas in the capitalist city. The literature offers a variety of city marketing and branding cases as well as the controversial discourse of the creative city. This paper analyses the linkage between the social approach of city branding and the creative city idea.

Passing from a theoretical framework to the analysis of specific cases from the marketing of Amsterdam as a creative city, the main hypothesis to be tested is if, and how, local identity is reinforced through the aforementioned processes. The first case refers to the 'broedplaatsen' initiative – the 'Art Factories' program. This creative policy led to the construction of meaningful places with multiple uses, housing the creative professionals of the city and hosting multiple activities. The second case study concerns Amsterdam's festivals, combining both global and local

characteristics. Festivals are mostly situated in public spaces and offer an easy access for the visitor to the livelihood of the city.

## 2. City Branding: cultural and creative approaches

Following the rise of the new leisure, cultural and knowledge urban economies, there was a growing need for cities to obtain distinctive characteristics in the post-industrial city and the economically globalized context (Cox, 1995; Beriatos and Gospodini, 2004). The new 'product' (good) of the city to be projected was its image and the new means in urban development was the city marketing process (Hannigan, 2003; Kavaratzis, 2004). During the years, city marketing passed through many phases, from a simple place adevertisement or promotion to an integrated city branding procedure, aiming at the production and distribution of an attractive city image (Kavaratzis and Ashworth, 2008). The outcome of the city branding procedure is the construction of a strong place identity, acknowledged by the target groups, belonging either to the internal environment (local community) or to the external environment.

Place branding has a variety of expressions, as for example destination branding or place of origin branding (Kavaratzis, 2005). Nevertheless, city branding is considered to be a strategic approach through which the place's image is improved, involving materiality, institutions, practices and representations (Kalandides, 2012). This offers an integrated version of city branding, taking under consideration all parts of the social context, trying to enhance the city's image. As Mommaas (2002) cites 'it is a strategy through which cities gain an image, a cultural value which ideally functions as a source of added symbolic and economic value'.

The place image to be created is strongly interwoven with the cultural psyche of the city. Peoples' culture (not necessarily coinciding with popular culture) is almost the most authentic element that defines the identity of the place. Thus, city branding that is based upon culture has gained ground, enhanced by the fact that a cultural image contributes to touristic growth. Cultural branding (Kavaratzis, 2005) became a very well renowned practice in the age of the flagship projects and led to the massive production of cultural projects, destined for cultural consumption. This approach was adopted by lots of cities around the world, integrating 'aggressive' cultural policies in their urban development agenda, and more specifically applying practices that intensified the 'cultural consumption' orientation. The 'Bilbao effect' has always been the desideratum, whereas reverse procedures often took place.

All these factors led to the 'hard branding' of the cities (Evans, 2003), with eventually homogenized cultural images and identities, without taking into account local distinctive characteristics (Knox, 2011). Gentrification and social exclusion were the most usual impacts after such actions, along with the loss of the collective memory, as many times flagship cultural projects replaced the authenticity of neighbourhoods (often slum or workers' neighbourhoods), with the gentrifying effects. The case of Barcelona is representative of this effect, with 'Poble Nou' and 'El Raval' districts being violently gentrified after the Barcelonetta redesign and the cultural redevelopment through MACBA, thus losing their historic local identity and the collective memory of the place. Numerous examples of cities around the world with similar characteristics can be spotted. Moreover, as Kunzmann (2004) says 'the cultural content remains the last bastion of local identity'. So, cultural branding could have a twofold and ambiguous role; on one side, negative outcomes for the social context of the city could emerge and on the other side strengthening local identity could be at work. The key is to define practices that could differentiate the effect favourably towards local identity and collective memory.

To avoid the negative results of aggressive city branding tactics, during the last years a more social aspect of city marketing emerged. Based primarily on participatory planning procedures and bottom-up processes, the 4R's place branding approach became quite popular (Aitken and Campello, 2011). Referring to the rights, roles, relationships and responsibilities of community's members, the city's image isn't now managed as a 'commercial product' that needs to be communicated. On the contrary, it is created by the true members of a community, hence linking the place's true identity and collective memory to the desired image and strategies. In this way, a place's cultural memory (Olick, 2007) can be preserved, safeguarding collective representations and urban symbols.

During the last decades, interest on urban development has shifted from mere cultural strategies towards the creative class and the creative city discourse (Landry, 2000/2008; Florida, 2002/2012). Creativity and innovation became the keywords in the 2000s EU's policies for an attractive urban image. This resulted in the anguished quest and adoption of the 'creative city' label from many cities. The catching idea, according to Florida's work, was the return to the human capital, entitled as the driving force of the new economy. On the other hand, Landry and Hyams define the creative city in relation to the creative and imaginative thinking at all urban levels, along with a set of attributes that mould a creative milieu (Landry and Hyams, 2012). Landry's ideas are more widely acceptable because of his holistic approach of the city as a complex and multi-faceted entity.

Nevertheless, the creative city rhetoric has been widely criticized, since the relevant strategies and proposals were connected to neoliberalist ideas, leading to 'creative destruction', slum clearance, gentrification, ambiguity of urban policies, etc. (Peck, 2005; Vanolo, 2008; Zimmerman, 2008). More specifically, Pratt (2011) describes Florida's creative city as 'hard branding with soft edge'. On the other hand, there can be a differentiated viewpoint concerning the linkage between city branding and creativity. Creative places can be spotted in cities that try to attract creative professionals or implement creative policies, involving public space, with positive effects on the social milieu.

## 3. Creativity in Amsterdam: Art factories, festivals and the public realm

Amsterdam is one of the most famous European capitals concerning its city marketing and branding strategy. The successful strategy goes through many stages and at many levels. The strong, but currently obsolete, image of sex, drugs and drinks on which tourism was based since the 1970s, had to be replaced by another image covering various domains in order to maintain and enhance the competitiveness of the city at the international level. Nonetheless, through participatory methods, certain 'priority dimensions' associated mostly with the residents' quality of life and cultural issues, were selected, concluding in three 'core values, namely creativity, innovation and the spirit of commerce on which the brand of the city should be based' (Kavaratzis and Ashworth, 2007). Nowadays, Amsterdam is considered to be the creative capital of the Netherlands, with the relevant policies, professionals, industries, networks, organisations and events.

### *3.1 The 'Broedplaatsen' initiative*

One of the most interesting policies, especially in the way that it had been evolved, was the 'Art Factories' programme – 'Broedplaatsen' initiative, designated as a 'socially inclusive' creative initiative (Peck, 2012). In the 1990s, Amsterdam had already developed the appropriate environment, where cultural and creative industries could flourish. An open, diverse and vital city along with dynamic, urban culture set the scenery for a prosperous 'creative era'. In the late 1990s, a squatters' movement set the breeding ground for this creative initiative, destined to be one of the most influential

creative policies in the city of Amsterdam and abroad. Vacant, occupied warehouses by artists and anarchists became the beginning of a controversy between them and the property-development bloc, 'between the soul of the city and the specter of gentrification' (Peck, 2012). Following violent interactions, a kind of negotiations occurred between the squatters and the municipality, with the squatting movement setting the foundations for the 'Art Factories' programme. The final outcome was the emergence of a new creative policy, based on the re-use of abandoned space by start-ups, dealing with culture and creativity.

The 'Bureau Broedplaatsen' is the main agency that undertook the coordination of this new venture since 1999. Its goal is to attract young creative professionals, who are considered to be the basis of the creative industry to be grown in Amsterdam. Primary responsibilities are the housing of all these professionals, taking into account the property crisis that offers a vast buildings' stock, available to re-use, and the precarious nature of creative jobs, thus searching for affordable and inspiring living and working spaces (Bureau Broedplaatsen, 2012). What is more important now for Bureau Broedplaatsen and the city is that the accumulation of such creative professionals attracts international companies, specialised in the creative sector, in order to establish themselves in Amsterdam. This concludes to the combined situation of urban development and the configuration of competitive characteristics in relation to the transformation of abandoned spaces in synergy with the local community.

The facts show that every year approximately 500 young creative professionals look for suitable living and/or working space in Amsterdam, and by 2012 more than 3500 living and/or working places have been created for them (Bureau Broedplaatsen, 2012). The Broedplaatsen Programme in its implementation affects urban environment in four ways: *cultural* – Amsterdam as a laboratory of talent; *economic* – attraction of international corporations; *social* - linking with the neighbourhood and bottom-up approach and *spatial* – avoiding gentrification and reuse of derelict space. The most interesting part is the adoption of the bottom-up approach in the way Art Factories are being created and the interaction with the local community. The 'NDSM Wharf' in Amsterdam is a representative case.

NDSM (Nederlandsche Dok en Scheepsbouw Maatschappij) was constructed in a derelict site in docklands, through bottom-up processes. It is about a 'self-made city that has developed naturally, driven by its residents'[1]. A private initiative, comprised of artists and other creative professionals, asked for the redevelopment of the former industrial area. After the supply of a financial budget, the total site of 80.000m$^2$ was redeveloped by them to an incubator of creativity, culture and talent (Creative Metropoles, 2010). Nowadays, NDSM hosts a variety of creative professionals and events, transforming a semi-private place to public space. Additionally, the self-organised initiative, derived from the squatters' esprit, avoided the shortcomings of possible gentrification, whilst allowed the productive usage of abandoned space, yet useful and important to the local community. Being the centre of underground culture and becoming one of the most vivid civic spaces in Amsterdam through creation, innovation and events, the NDSM 'Art City' safeguards the heritage, memories and identity of the city, moving from the industrial production to the creative production.

### *3.2 'Festivalisation' in Amsterdam*

Experiences, additionally to 'products' and goods, have long been targeted as the new cultural goods. The experience economy that emerged in the 1990s intensified the need for organising events in the city as experiences that could emotionally engage the consumer (Klingmann, 2007). Events are widely considered to be of the most important city marketing tools (Kavaratzis, 2004). Mega-events, cultural

[1] http://www.vandejong.com/en/#!/en/case/ndsm/

events and festivals of all kinds are being recruited for the configuration and promotion of the city's cultural image. Particularly during the branding of the 'creative city', the production of spectacular urban events has undeniably become a presumption (Harcup, 2000). The plethora of events in a city has once again been accused for cultural 'hard branding' of the city, whilst cities end up being 'festival marketplaces' (Harvey, 1991). Also, festivals are accused to transform the city, altering its spatial configuration and attributing the city with a particular identity, offering a sanitised version of it (Johansson and Kociatkiewicz, 2011).

There exists a variety of impacts of festivals on cities, but festivals serve not only economic development as well as induce erratic symbolisms. Positive social effects can be the residents' or visitors' socialisation, the community's boost of self-confidence and the residents' cultural quest. Some of the events rely on the cultural past or the collective memory of the city, trying to recreate the city's image relating the authenticity of the past to the imaginary present. In the case of Amsterdam, festivals are regarded as the strongest tool to strengthen the city's profile, as they can attract international attention (Kavaratzis and Ashworth, 2007). Along with the principal goal that the city's marketing plan has to serve, the events are considered to be the mirage of Amsterdam's tradition as cultural centre. This old image intermingles with the contemporary cultural image coming from the creative city identity, thus offering a plethora of urban events.

It can be said that Amsterdam 'suffers' from 'festivalisation': quick look on the city's official portal leaves the visitor stunned by the plurality of festivals, organised by various partners. The events are numerous, categorized in many genres, such as music, dance, culinary, theatre festivals etc. Surely, it is the place for a visitor to be from any background and in any time of the year. But do the same also apply for the residents of the city? It is certain that eventually the physical form of public space will be temporarily altered, but this is something required for the proper implementation of the event. What is more important is the representation of the real identity of the city's population through the plethora of festivals. Amsterdam's population is characterized by diversity and openness, with more than 170 different nationalities and 45% ethnic minorities, with great tolerance towards the LGBT community and a large percentage of young and active population[2]. The plurality of festivals reflects this image of the social context of the city, along with the contemporary creativity that defines the city.

Another viewpoint on the contribution of the festivals to the city is that a visitor becomes local and a resident rediscovers local identity or the collective memory of his/her city. Three festivals, amongst others, demonstrate this assumption. 'Grachtenfestival' (Canal Festival) is a classical music festival, open-air situated on the canals of the city providing stage for young, talented musicians. The festival is realized in public space, dominated by the city's history (canals), culture (classical music) and contemporary creative people (young and talented musicians). 'Roots Open Air Festival' is a world music festival, situated on an open park with free entry. The festival gives the opportunity of socialisation (open-air park), 'occupying' public space, yet for culture transmission through music and promoting diversity, supporting local ethnic minorities (world music). 'Amsterdam Heritage Days' is a celebration of the city's history with open doors of important buildings, monuments and private homes, tours, exhibitions and lectures, free of charge. The event features the built heritage of the city, part of its history, giving the opportunity to the resident for a cultural quest of his city and to the visitor a chance to 'become local'[3].

[3] All information for Amsterdam's three festivals are driven from the site: http://www.iamsterdam.com/en/

## 4. Conclusions

City marketing and branding practices have been widely connected to the creative city idea in recent years. The need for cities to establish themselves in the global hierarchy demands new ways of celebrating their uniqueness and distinctive characteristics. Nevertheless, this nervy pursue of rise in the global rankings leads, in general, to serious impacts on the social context of the city. Cultural 'hard-branding' of the city, through flagship projects or spectacular events, can result to gentrified neighbourhoods and social exclusion. Local identity and collective memory are lost and residents feel alienated from the public realm, and not attached to the local community.

With the leading case of Amsterdam, as a city that carried out one of the most famous city marketing plans and place branding tactics along with the domination of creative identity, it has been shown that these practices, usually linked to 'creative destruction', don't only serve economic and urban development, but also serve and respect the culture and identity of the human capital of the city. The 'Broedplaatsen' initiative designated the inspiring Art Factories policy, through which the city supported cultural endeavours, subsidizing young creative people to develop their own space in derelict sites. The most important part was the adoption of participatory methods and the bottom-up approach in the process of the whole venture. The spillovers covered all parties and the policy seems to have been successful: the city gained a strong creative community that it was looking for; the squatters and creative professionals acquired officially their own, collective, artistic space, constituting an active community; the abandoned industrial heritage was redeveloped through new cultural uses and a bottom-up approach has been encouraged. The case of the Art Factories policy and NDSM demonstrates the image of the creative city as a multi-faceted entity with intertwined characteristics.

Additionally, festivals and events comprise the most important tools of Amsterdam's marketing, thus creating a city of spectacle. Nonetheless, local identity, in combination with the distinctive characteristics of the social context of the city, are depicted and celebrated by the plurality of the festivals and their themes. Besides negative outcomes that follow the city's 'festivalisation', people and their cultural diversities are represented through the events, along with the emergence of a collective memory. As a final conclusion, cultural branding of the cities has always been controversial. What is crucial for a socially oriented creative city branding, is the adoption of good practices, involving social inclusion and integration of local communities.

# The research on the impact of the physical environment in the high rise residential complex on the local inhabitants' meeting place[1]

LI Qing

**Abstract:** Due to the scarcity of the land resource, more and more new development or redevelopment in China takes high rise as its building form. The large-scale development of the high rise residential complex has dramatically changed the urban fabric and the daily lifestyle of many Chinese inhabitants, particularly the way by which inhabitants meet together. The paper attempts to evaluate how the shift of the physical environment affects the mode of the inhabitants' behavior in the public meeting space. Based on the case of Houxiandaicheng, a typical residential complex in Beijing with the distinctive varieties of the layout of the high rise building clusters, the paper first describe the general features of the inhabitants' daily life in their leisure time and maps the features of the daily activities of the residents in the meeting place. Then it illustrates the relation between open place and the flat location of each inhabitant who plays in the outsider place and analyzes the correlation between the features of the open space and social relation based on the site. The study finds that there is a weak correlation between the size of the meeting place and the social behavior and neighborhood relationship; but a high-positive correlation between the types of the meeting place and the social behavior and neighborhood relationship; the quality of the meeting place has some impacts on the social behavior and neighborhood relationship, but the quality is not the decisive factor in the high rise residential complex. Besides the literature examination, the research methodology primarily consists of site observation, interview, behavior mapping and social network analysis.

**Key words:** the meeting place, the high rise residential complex, social network, neighborhood relation

## 1 Introduction

Because of the rapid urbanization and the scarcity of the land resources, high rise residential areas have become more and more common in not only coastal cities but also inland cities of China. This kind of complex has not only changed the appearance of the urban space, but has also affected the residents' daily life in the neighborhood. This kind of area sometimes leaves us a deep impression with some words like "high rise ", " less sky exposition", and "depress". However, when we walk into the area, the space between two high-rise buildings is much more wider than the one between two multistoried buildings, partly because of the planning ordinance to the basic sunlight demands. In some complex, the distance between high-rise buildings can even reach 80-100 meters, and makes it a "huge courtyard " which can be shared by the hundreds of residents in those buildings. However, the high density of population in the complex doesn't indicate people getting more contacts with each other. Actually, they meet on the road like strangers, and live without any words to their neighbors, which reflect an apathetic neighborhood relationship and a lack of the inner social cohesion to a certain extent. Due to the development of the modern transportation、 network and information technology, the traditional neighborhood which is regarded as " local entity" has entered a recession， but the place identity, local organization, and social capital in residential area are still playing important roles according to

[1] The research is funded by China National Natural Science Foundation (NO. 51378359).

some relevant studies. Lots of residents at different ages are eager for enjoying a certain contact with their neighbors. B. Wellman once took a long-time investigation on the residents of Toronto in Canada, through which he found that the proportion in the active network in local neighborhood would increase dramatically when "contacts" is used as the factor of analysis instead of "tie", and so does the number of individual friendship with the feature of active contact originated from "locality". Although neighborhood has been liberated from "traditional constraint" which is all-inclusive and with highly solidarity, it still embodies some features derived from sociability, supportability, and identity.

Although those literatures have helped us a lot to understand the social structure deeply, however, there are few study connecting the social network with social space, and even fewer with the high rise residential areas. The open space in high rise residential area is totally different from the one in multistoried residential area. The differences on the horizontal and vertical scales between the two kinds of residential areas are big. Therefore, how much of an impact can the high rise residential area have on the residents' social neighborhood? Which features of open space in high rise residential area are related to the neighborhood social network? And how can those features affect the neighborhood social network? Those questions form the point of departure for the study.

2 The theory of space-based social network analysis

The earliest social network analysis is about in 1930s, a famous anthropologist of the United Kingdom named A. R. Brown concerned on the research of social structure. During 1930s to 60s, a serial of research, such as K. Kewin on the group structure, Moreno on sociogram, F. Heider on the social attitude, those researches promoted the discussion of social structure, and kinds of net concepts such as centralization, density, structure balance, and block etc. went deeper. Along with the theory, method and technology of social network analysis are being mature, social network analysis has become one of the important social structure research models. Social network can be used to analyze the strong ties and weak ties of one group. In 1970s,M. Granovetter proposed "the strength of weak ties", he suggested the weak ties would build a bond among groups and organizations, meanwhile the strong ties would maintain the inner relationship of the organization; Burt raised the theory of the structural hole, and proposed that there wasn't a necessary relationship between the tie strength and the amount of the social resources; L. Nan put forward that： the weaker the social network is, the more instrumental it will be in getting social capital, and also, individuals will get heterogeneous capital much easier. On the neighborhood level, the meeting place, mixed land-use, good design for houses, neighbors' walking suitability, the individual motives for others, limited individuals' choices, and the dependence among groups and so on, all those factors could affect the contacts among neighbors.

Based on the theory of social network analysis, the paper regards the open space in residential area as a special "actor", which becomes a key node in the social network. The paper will explore the relationship between the special "actor" and other actors (residents) with the social network methods. Firstly, I surveyed the social activities of the residents in open space, and had an analysis on their regularities; then, I mapped the residents' activities which took place in open space and the neighborhood social network between the special "actor"— place and other actors (residents), and calculated the density and centrality of the network; at last, I analyzed the relationship between the features of the open space and neighborhood social network. Based on

the observation of the basic characteristics of the open space in residential area, I present the research assumption as follows: the larger the scale of open space in residential area is, the stronger neighborhood social network will be; the richer the functional types of open space are disposed, the stronger the neighborhood social network will be; the higher the environmental quality of open space is, the stronger the neighborhood social network is.

The relevant data and materials are gotten mainly by on-the-scene observation, activities mapping and semi-open structured interview, the date of the field survey is from March 28 to April 7 (both workdays and weekends are included) with 97 effective questionnaires. The interviewees are the residents at different ages and on different income levels.. The case of our investigation is "Houxiandaicheng (HC)"—a typical high rise residential complex in Beijing, a middle and top grade residential area built in 2004 and located on the 4th Ring Road at the east of CBD. The site area is about 20.63 hectares with the floor area ratio 2.54 and 12500 or so population, among which 65% is migrant tenants. Youth and middle-aged people comprise about 70% of the HC population, and the rest 12% and 18% are respectively old people and children. This residential area is divided into four districts by local streets. The northeast district is district A with the area of 2.5 hectares and about 2600 residents; the northwest district, district B, is the smallest with about 1.8 hectares and 1900 residents; the southeast district, district C, is the largest with about 4.5 hectares and 4800 residents; the southwest district is district D with about 2.5 hectares and 2900 residents. There are clear differences in the layout of the open space in the four districts, which makes it more convenient to compare the space features of the four blocks and its neighborhood social network.

## 3 The features of the social activities in the public space in the residential area

As the social activities of residents are a media which connects the public space and neighborhood social network, the paper focuses on the social activities of residents first.

The developed public transportation, high owning rate of automobile, and amounts of beautiful parks, those factors attract Beijing citizens to go around in their leisure time. So do the residents in HC. Sometimes, they enjoy views, breath fresh air, play, meet friends and etc. in Caoyang park, Beihai, Temple of Heaven, even on the Fragrant Hill in their weekends, 30 minutes away from the complex by car, But at most time, residents have their social activities in the public space in their residential area. There same regularities present on the residents' behaviors through their weekends activities. According to the activity mapping of the 4 districts, the residents of district D have the highest activity intensity. There are even 70 persons playing in its open space during the peak moment; and on the contrary, the residents of district B have the lowest with only 15 persons during the peak moment; although district C owns most residents and largest land scale, there are only 30 persons during the peak moment. Compared with district C, district D has almost more than twice number of people playing in the public space (fig. 1, 2). It indicated that residents' activity intensity has a certain relationship with the open space in residential area.

The daily activities of residents can be divided into 8 kinds: playing balls (basketball, tennis, ping pong)、 fitness (jogging, doing tai chi, equipment exercises), walking dogs, playing games (children), taking care of children (parents), chatting, having a rest and taking a walk. Different activities perform different laws, and there are 3 kinds of activities last for the longest time: playing games, taking care of children and playing basketball. When enjoying those 3 kinds of activities, many people are gathering in the public space. And chatting, having a rest, taking a

walk and walking dogs, these 4 kinds of activities have a changeable performance in the public space. The interesting thing is that residents would form a familiar group as soon as they share the have same activities, which leads to a high familiar lever. Majority of residents who have social activities in the open space says that the number of the familiar neighbors is about 70% among the neighbors who they know to each other, which means they generally have closer contacts during playing in the open space and children who take part in the activities know each other well. The number of neighbors playing outside who don't know to each other is less than 5% (Tab. 1). And the neighbors having same activities make a subgroup of social network, partly because the relationship would be improved through chatting with each other while they take part in same activities. And also, when they walk dogs or take care of children, dogs and children often act as a medium for them to start talking, and neighbors would get even more familiar as they play balls. And these may generate deeper relationship in the neighborhood, such as: a mum asks another one to take care of her child by the way; or teenagers communicate with each other before playing balls together, or neighbor A leaves his keys to neighbor B when A is out, and so on. This reminds us that neighbors still keep a collective memory and warm neighborhood relation among Beijing citizens which happened before the start of open and reform policy, Actually, it's a long absence relationship for many other neighbors nowadays in modern society.

4 The analysis of the correlation between the public space and the space-based social network in the residential area.

On the basis of the analysis of the features of the residents' behavior in high rise residential area's public space, now, we will have a deeper study on the relevance between features of open public, such as size, the functional type and the environmental quality, and neighborhood social network.

4.1 The correlation between the size and neighborhood social network

By referencing the social network analysis theory, the study regards the open space as a special "actor", called "place node"; and the address of resident who has social activities in the public space is regarded as "flat node". After matching the relevant "place node" and "flat node" with line, we can get "relation line". Through intercepting a typical moment of residents' social activities in the public space, we mapped the "spots" and "lines", and got a graph of the space-based social network in the residential network (fig. 3). In the graph, the relevant "relation lines" perform a subgroup deriving from the place node. We can find from the graph of the space-based neighborhood social network that there isn't a strong relevance between the space size and the number of residents having social activities (tab.1). For example, district D owns 50 "relation lines", and 28 of them (about 56% of the total lines) come from the same block with the "flat nodes", while 22 of them (about 44% of the total flat nodes) are not from district D, among which 17 flat nodes are from the other 3 districts, and the rest 5 are from other complexes at the west of the HC. It shows that district D has a much more attractive for the neighbors in other districts. District C owns the largest area and population, but there are only 18 "relation lines" which is much less than district D. And actually, there are 22 "flat nodes" in district C, and 8 of them are relevant with district D, main for playing balls and taking a walk, it means that 36% of the district C's "flat nodes" prefers having social activities in other districts. District A illustrates more obviously at this point. As the courtyard is separated by a wall, the number of people having social activities in district A decreased sharply. As a result, there are 21 "flat nodes" in this district,

and only 9 of them have activities in district A, which comprise only about 43% of total flat nodes in district A. Most “flat nodes” appear in district D and B, main for playing balls, taking a walk, play games (children) and walking dogs. Also, district D gets the highest score in measureing the centrality (tab. 2, 3).

4.2 The relationship between the functional type of the public space and neighborhood social network

According to the map of the social activities in the public space, the functional type of the open space presents an obvious influence on the residents' social activities, because each functional type of place matches relevant residents' social activities. Overall, walking dogs, taking a walk and having a rest, such activities don't need high requirements for space disposition. However, physical exercises need a certain requirements for the space disposition generally. When children play, it would need a certain size of hard ground for running, riding tri-cycles and playing ball. Also, a playground with a small pool, sand holes, and slides, would help improve the attraction of the place to children. In terms of sociogram, district A has 5 subgroup: playing games (children), taking care of children (parents) , walking dogs, having a rest and taking a walk, the number is as the same as the one in district B; district C has 6 (one more with ping pong), and district D has 7 (two more with basketball and tennis compared with district C). The subgroup of basketball gets the most "flat nodes" about 12 where there is an informal basketball competition being held on one of the basketball sites. The number of "flat nodes" related to playing games is also big about 9 in district D, and the number of "flat nodes" related for parents to taking care of children is about 7. In all, children and parents are the main users of the open space. However, there isn't a big difference for walking dogs and taking a walk in the four districes.

4.3 The correlation between the environmental quality and the neighborhood social network

The four blocks of the HC belong to one residential complex, but they perform a certain differences because of the distinct planning and layout, later-stage management and property maintenance. In district A, the greenbelt between 2 buildings is comparatively attractive, and the trees there make a pleasant shade with a walking line and pergolas. Anyway, the environmental quality is good in district A. District B is a highly mixed block with the southern part for residents, the northern for SOHO and the eastern for business. As a result of management, there is a wall to separate the southern part and other parts, and to make the space break into pieces. In addition, because of the bad smelling from the trash cans by the main lane at the north of the residential area, the environmental quality is affected seriously. Although the northern part in district B is designed well, the property maintainers change majority of its hard ground into a parking site, that also lead a worsen quality. District C has a comparatively nice environment, but the hard ground is designed too boring and without careful maintenance; District D has a comparatively good maintenance, and majority of its open space is hard ground with a few trees. According to the evaluation from residents, the environmental quality of district A gets a highest score, district D follows behind, and district B gets a lowest one.

After having an analysis on the subgroups of playing games and taking care of children, we know that district B owns the fewest "flat nodes", and district A gets the most (fig. 4). It seems to

have improved the proposal that residents tend to have social activities in a better environment. But as we studied on the subgroup of having a rest (sitting), we found that district D owns most "flat nodes"(fig. 5). There is a certain number of elms out of the safety net of the basketball ground and tennis ground in district D, and under the elms, there are flower beds and chairs. Between two closed basketball grounds, there is a main lane which is 5 meters wide. So, residents would be attracted by the youth playing basketball unconsciously when they pass by, and maybe they would sit down to be their audiences. The old persons with some trouble in walking or sitting on wheelchairs, often prefer to stop under the elms to enjoy the warm sunshine while watching the basketball game.

Thus it can be seen that the environmental quality of place is a complex variable, and residents tend to choose a better open space, but meanwhile, rich humanity landscape is much more welcomed by residents. Such as the case of GC the sports places act as catalyst for the vitality of the open place.

6 Conclusion

Through regarding the open space in residential area as a main "actor" of the neighborhood, the paper establishes a kind of social network built by the "actor" and other "actors" (residents). The research found that: (1) the scale of the open space in high rise residential area does not have a clear correlation with the residents' neighborhood social network. Partly because of the relevant ordinance of the sunshine standard, there is a large distance between 2 rows of buildings, so it couldn't affect much on residents' daily activities even if the scale of open space is expanded. For instance, in the case of "HC" in Beijing, the open space scale of district C is 1.5 times as big as the one of district A, however, during the peak moments, the observed number of inhabitants in the open space in district A is a little more than the number in district C. (2) The functional type of open space in high rise residential area has a clear correlation with the neighborhood social network. Through the research, I found that different functional type of open space could build different neighborhood groups. Neighbors have high familiarity in a same neighborhood group, that's because those neighbors in the same group has lived in the same space for a long time, as a result, it's easier for them to get contacts. A free, open space with sport facilities could gather residents easily. For example, youth and middle-aged people are always seen in district D as it owns 2 basketball courts. This proves a proposal similar to Y. Gail—open space will be popular if there are things for residents to do. And it's also very important if the space is open and free, so that the utilization of the space will be fairly high. Sometimes, children rushed into the basketball court when there weren't any adults. They stumbled, lifted the ball up and tried to throw into the basket net like the elders under the attention of parents, this kind of humanity scene is not only a help for the children' socialization, but also reflects human nature, maternal love and the spirit of brave adventure. At the same time, it increases the compounded use of the space naturally, making the open space in high rise residential area be popular. (3) The quality of the open space has a certain impact on neighborhood social network. Good atmosphere of open space would attract many residents. For example, district A in "HC" has a good environment, and trees there make a

pleasant shade, so it's quite popular in the nice evenings. But in district B which has worse environment, the residents have much less activities there. However, the quality of the environment is not the main factor affecting residents' activities in open space. District D is payed more attention on hard ground environment with fewer trees, but more residents are willing to take a rest in district D than district A, although district A gets higher grades in the evaluation of the environmental quality. It indicates that although the green disposition is important in open space, we should also consider the function of open space, especially the demand of residents for contacts and "humanity landscape".

Although the open of the residential area and the basic building function of "courtyard" are not the key point in this research, they have a certain impact on neighborhood social network. In a word, the neighbors in high rise residential area can build much closer neighborhood social network through a right open space design. Lots of open space in high rise residential area has a huge potential on stimulating the neighborhood social activities in high rise residential area. Although the key point in my research is the social weak ties among neighbors, how to improve the social strong ties among neighbors with the open space in residential area should still be explored.

Keywords: Privately Owned Public Space (POPS), Spatial Point Pattern Analysis, Systematic Open Space

## Abstract

*In Taiwan, to achieve the goal of improving urban environment and disaster prevention capacity, some urban renewal development projects could apply for additional floor area bonus and result in part of the private property turn into the privately owned public space (POPS). Certain properties have become a unique existence in the open space system.*

*From 1980s, Taiwan government have provided incentives in exchange for more public open space through legal system, i.e. Zoning Code, Urban Renewal Act and Land Use Regulation, as a result, 483 POPS had developed from 1983 to 2013. Many local research have explored the effect of the individual POPS to the regular open space and proposed better usage and management of POPS. However, there is lack of debate about private property and the relevance of entire POPS system with open space network. Moreover, in most cases, the lack of proper and flexible design guidelines and review system could also result in poor design and limited usage due to the unwillingness of private owners. Accordingly, POPS could not serve better function to the surrounding built environment and citizens.*

*Hence, this paper will discuss the relationship between existing POPS and public open space system based on spatial point pattern analysis, choosing Taipei City, Taiwan as a case study area. This paper will expect to provide some information for better policy of public space system in Taipei.*

## 1. Research background

To achieve the goal of improving the urban environment and the capacity for disaster prevention, some building site owners can apply for additional floor area bonuses that results in part of the private property being converted into privately owned public spaces (POPSs). A lot of POPSs started up after the Taipei City government formulated the Regulations on Taipei Land Use Control in 1983. Then, some regulations, the Detail Plan for Keelung River Surrounding Area in 1994 and the Regulations of Bulk Reward for Urban Renewal in 1999, followed. The number of POPSs increased to 483 from 1983 to 2013.

The concept for the POPS regulations is good, but many people have questioned the openness of POPSs in residential zones. In 1997, POPSs became a social issue related to the applicability of their location and management. After that, the Regulations on Taipei Land Use Control were amended to cancel the bulk reward, extra floor area rewards for new building construction project, for residential zones. In 2014, the same issue arose, and it was reported that people wouldn't want to be converted to POPSs. Therefore, it is necessary to review whether the conversion to POPSs was able to achieve the primary goal for such spaces. In addition, the locations of POPSs were chosen on the basis of the laws without considering the entire planning scope. Hence, this paper discusses the relationship between existing POPSs and the public open space system itself.

## 2. Literature review

### 2.1 The relationship between POPS and public open space system in Taipei

In high density cities, it is difficult to get extra open spaces. In order to improve the existing open space system, one solution has been to create building lots to provide open spaces. In New York City, since the 1890's, a lot of skyscrapers have emerged in order to gain height and volume, resulting in some problems in the urban environment. As a result, the 1916 zoning resolution created a sense of openness, also known as "light and air," at the street level. Further, the Voorhees draft in 1958 proposed the first concept related to POPSs. "In order to bring more light and air into streets surrounded by tall buildings, as well as to create more usable open space, a bonus device has been established to encourage the setting back of buildings from the street line." (Kayden, J, S., 2000). Likewise, Taipei, as the capital of Taiwan, faces same problems related to the environment in open spaces. In addition, the city cannot expand its borders due to limitations related to basin and range topography. The urban growth is close to a saturation point, so it cannot afford more construction in open space land. That is to say, it is more important to improve open space system by putting in a strategic number of POPSs. The POPS policy has been in operation for 30 years. However, the question remains as to whether it has actually achieved the goal of improving the open space system. The literature review makes it clear that there has been limited discussion of the entire POPS system. Therefore, this paper discusses the contribution of POPS to the open space system. In the next section, we review the legal and planning purposes of POPS.

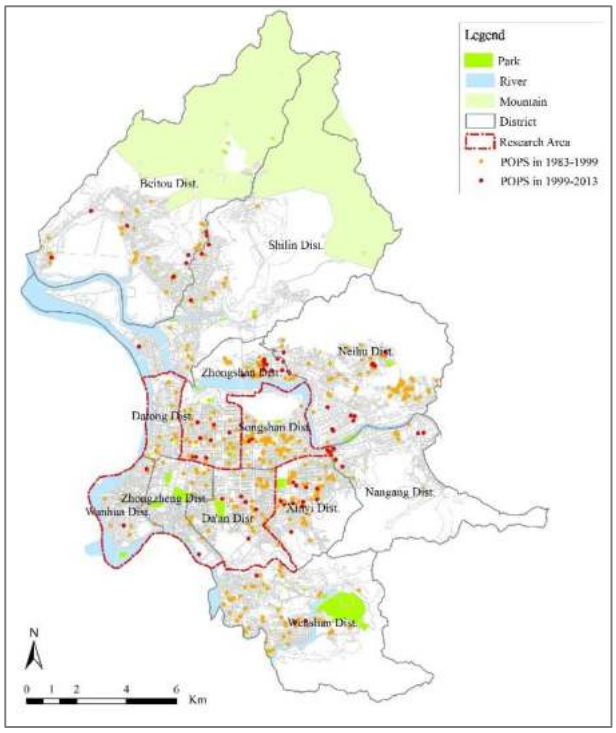

Figure 1. Location of existing open space and POPS in Taipei

### 2.2 Legal and planning purpose of POPS

The legal ground of POPS with a bulk reward in Taipei includes the Regulations on Taipei Land Use Control, Regulations of Bulk Reward for Urban Renewal and Detail Plan. The purpose of these laws is to improve the urban environment and to shape an open space network.

In 1983, Article 26 of Taipei City's Enforcement Rules of Urban Planning Law, Taipei first executed Land Use Control in Taiwan. In Chapter 11, the Comprehensive Design and Bulk Reward Regulations encouraged small building lots to merge into entire blocks in order to provide centralized open spaces for the public. The government use a carrot-and-stick approach to establish the rules of operation, management and rewards for POPS. In order to prevent budget increases, the urban environment had shared open public spaces (Huang, J. N., 2004). The locations of POPSs were ordered in residential zones, commercial zones and market land. However, POPSs located in residential zones caused many management problems at that time. Hence, residential zones were canceled as reward sites in 1999. After 1994, some planned areas had more design standards for POPSs but were still limited to commercial zones and high density land use as reward areas. Regulations of Bulk Reward for Urban Renewal was published in 1999. Among the rewards for planning and design (△F5), it was encouraged that building lots remain open spaces or plazas. In addition, sites could get bulk rewards by redeveloping urban renewal areas.

According to the policy review, we can classify the POPS policy into two phases. The first phase is the initial period from 1983 to 1999. It delineated general rules for locations and specifications at that time. However, the second phase started after 1999 and incorporated strategic rules. High density land use and urban renewal areas were its bulk reward objects. Table 1 shows the open space type. There are strip-type, plaza-type, pedestrian decks, arcades, sidewalks, etc.

After a review the three legal grounds of POPSs, the role of POPS laws in the entire open space system is discussed. Figure 2 shows the legal hierarchy of open space planning. In the open space system, POPS can remedy the weaknesses of the parks planning and green fields systems in order to improve environmental quality and the capacity for disaster prevention. Lin (1995) defended the open space system. POPS is part of the patch elements of the open space system. In addition, open spaces in building lots can be divided into two types: statutory open spaces and POPSs. Extra bulk rewards can be used to exchange more open spaces for public as POPS (Shie, Y. C., 2006). However, the exchange between public interest and private profit in POPSs has extended the debate on this subject. That is to say, it is necessary to review the contribution of POPS to open space environments from a legal standpoint.

POPS as provided in the form of bulk rewards is one of the tools implemented for open space planning in the legal hierarchy (Huang, J. N., 2004). POPS, as a patch type, increases the completeness of the entire open space network. However, the competition between three legal grounds causes developers to prefer building lots with higher bulk rewards and fewer specifications (Yang, S. Y., 2007). POPS cannot be located in areas with poor environmental quality as a result of the legal specifications. Next, we compare domestic and foreign policy.

Table 1. Legal and planning specification of POPS

| Related laws and plans | Purpose | Locations | Open space type (specification) |
|---|---|---|---|
| **Regulations on Taipei Land Use Control** | • To increase park and sidewalk construction<br>• To connect with existing open space | **1983-1999**<br>- Residential zone, Commercial zone, Market land<br>**After 1999**<br>- Commercial zone, Market land | • Strip-type (50 $m^2$ minimum area)<br>• Plaza-type(100$m^2$ minimum area)<br>• Pedestrian deck (4.5m maximum height difference)<br>• The atrium space on the first floor of the building |

| Related laws and plans | | Purpose | Locations | Open space type (specification) |
|---|---|---|---|---|
| **Regulations of Bulk Reward for Urban Renewal** | | • To improve poor environment<br>• To reward sites with good design | **After 1999**<br>- Urban renewal area | • Plaza<br>(200m$^2$ minimum area) |
| **Detail Plan** | **Keelung River Surrounding Area** | • To fulfill open space demand for increasing resident | **After 1994**<br>- Commercial zone, Entertainment zone (part of residential use is allowed) | • Plaza<br>(200m$^2$ minimum area) |
| | **Xinyi District** | • To shape open space network | **After 2000**<br>- Business facility zone, Special business zone (located in the main road) | • Strip-type (for 10-20m)<br>• Plaza-type (accounting for more than 15% of site)<br>• Plaza at street corner<br>• Arcades and Sidewalk |

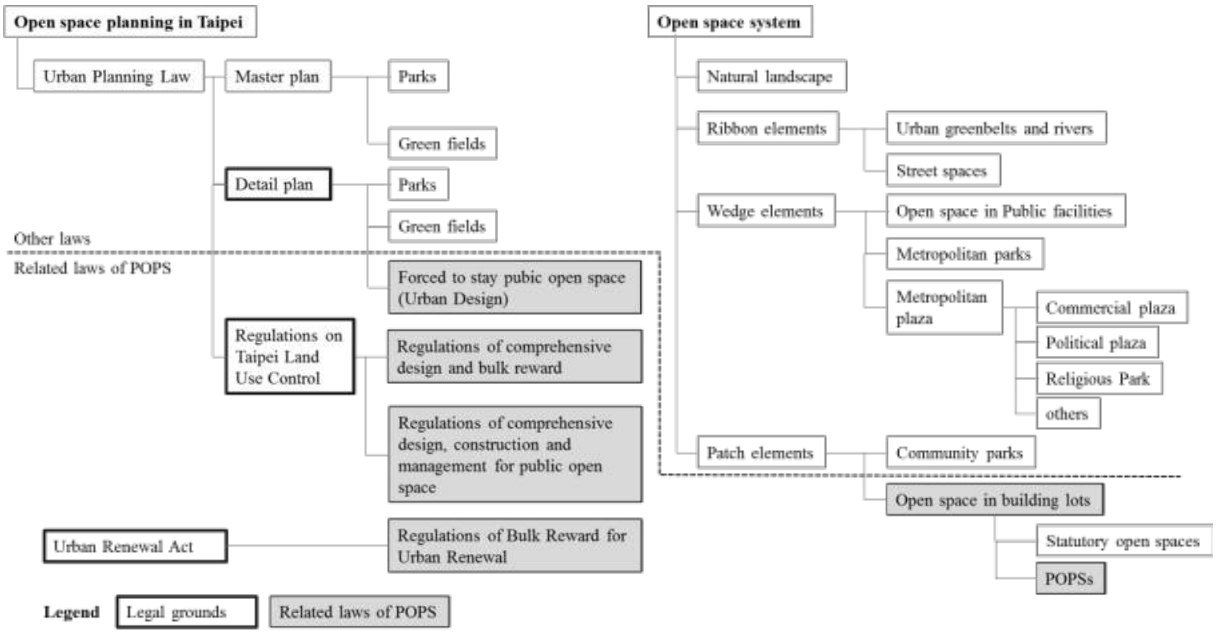

Figure 2. The relationship between POPS regulations and the open space system

## 2.3 Comparison of domestic and foreign policy

Because the USA was the first to use bulk rewards to encourage the private sector to retain open spaces, the Regulations of Land Use Control became more elastic. Furthermore, urban planning in Taiwan was also influenced by Japan. The regulations from Japan for comprehensive design and bulk reward were studied. Thus, in this section, we introduce the related policies in New York and Tokyo and then compare them with domestic policies.

Since the 1890's, a lot of skyscrapers have emerged in New York to incorporate a larger volume of people and activities, causing some problems in the urban environment. As a result, the 1916 zoning resolution created a sense of openness, also known as "light and air," at the street level. In 1961, New York City published The 1961 Zoning Resolution to establish bulk rewards and to give additional floor

areas a bonus, less than 20% of the original floor area ratio (FAR), for building lots providing plazas or arcades. It was the first case of a POPS bulk reward. Then the period of special purpose district from 1967-1973, the open space type became diversified, i.e. elevated plazas, through block arcades, covered pedestrian spaces, sunken plazas, open air concourses, etc. To achieve a specific goal according to an ideal situation, the New York City government formulated five special purpose districts. After 14 years of experience, in 1975, an "as-of-right" plaza was imposed with higher design standards. Then, in 1977, the "residential plaza" was proposed to differentiate it from urban plazas (Kayden, J, S., 2000). However, New York City Mayor Koch imposed overall laws in 1982. The points of the revised laws are shown as follows (Shou D. G., 1993):

1. The open space type of planning changed from a concept into a definite type with a regional planning system.
2. Forced specifications existed for some welfare facilities, i.e. locations of green fields.
3. The functions of space were required to suit daily life activities.
4. The concept of POPS standards changed from single into multiple, emphasizing functional rewards.

In Japan, the bulk rewards for open space design had two classifications: a Specific Block System and a Comprehensive Design System. In 1968, urban planning laws for land use control formulated the idea of specific blocks, having spatial standards about FAR, height, and building lines. The Building Standard Laws were revised in 1970 to enhance the Comprehensive Design System. If building lots with enough site area retained a certain percent of the area as open space and contributed to the urban environment, they were allowed more liberal specifications for FAR and height (Chen, L. F., 1995). The government of Tokyo formulated Tokyo Comprehensive Design Permission Regulations in 1988. To merge building lots into large-scale areas and keep adequate open space, the regulations liberalize the FAR and building type and ensured the environmental quality of open spaces and urban areas. However, due to the lower standards for site area (Specific Block: 5,000 m2; Comprehensive Design: 1,000-3,000 m2) in the Comprehensive Design System and the fact that it involves a simple process, it has higher usage.

After the case review, POPS foreign policy is compared with domestic policy. Due to different historical backgrounds, the primary subject of POPS development is different in each country. In New York, the USA case, POPSs play the role of improving building environmental quality in commercial zones i.e. CBD. In the case of Tokyo, Japan, the program assists with urban disaster prevention. In Taipei, Taiwan, urban renewal areas are included in reward area specification. Although the objectives are different in each country, the same goal for better open space environments is shared by all of them. However, the regulations specified for the locations of POPSs in Taiwan are generally applicable and result in uncertainty with regard to the sites developed for POPS.

Table 2. Comparison of domestic and foreign policy of POPS

| Country/ Area | Purpose | Locations | Open space type (specification) |
|---|---|---|---|
| **USA/ New York** | **1961**<br>• To improve urban environment | • Commercial zone, Business zone<br>• Special purpose district | • Plazas, Arcades, Urban plazas, Residential plazas, Sidewalk widening, Open air concourses, Covered pedestrian spaces, Through block arcades, Through block gallerias, Elevated plazas, Sunken plazas |

| Country/ Area | Purpose | Locations | Open space type (specification) |
|---|---|---|---|
| **Japan/ Tokyo** | **1968**<br>• To improve urban environment<br>• Development of merged building lots<br>• Urban disaster prevention | • Commercial district, Business zone, Residential zone, Industrial zone<br>• 1,000m$^2$ minimum area and open space should more than 65% of site | • Plazas, Green field, Sidewalk (100-300 m$^2$ minimum area) |
| **Taiwan/ Taipei** | **1983**<br>• To improve urban environment<br>• To shape open space network | • Commercial zone, Market land<br>• High density land use in detail plan<br>• Urban renewal area | • Strip-type (50 m$^2$ minimum area)<br>• Plaza-type (100m$^2$ minimum area)<br>• Pedestrian deck (4.5m maximum height difference)<br>• The atrium space on the first floor of the building<br>• Plaza at street corner<br>• Arcades and Sidewalk |

## 2.4 Related research

Many local researchers have explored the effect of individual POPSs on regular open spaces and have as a result proposed better usage and management of POPSs. However, there is less debate about private property and the relevance of the entire POPS system in the open space network. Most methodology use questionnaires or observed phenomena for such studies, and therefore, using quantitative analysis for the study of POPSs is unusual.

From a design and management perspective, law reviews and case studies are usually the research methods (He, S. B., 1988; Lu, G. B., 1989; CPAM, 1991). From the user behavior perspective, policy advice is provided by establishing evaluation subjects and surveying properties to investigate user behavior (Chiang, W. C., 1993; Chang, W. Z., 1994; Chiu, H. Y., 1995). From the effect of openness perspective, some researchers have conducted analysis by describing phenomena, comparing cases, or by doing law reviews and case studies in order to propose improvements (Tung, Y. Y., 1999; Rou, R. H., 2003).

In the past, the main discussion of POPS-related research in Taiwan was individual spaces; nevertheless, the debate on site locations and the influence of open space systems are rare. Moreover, a successful reward system should have systemic feedback instead of patch feedback. Depending on the complete plan and management system, a carrot-and-stick approach should work (Marcus & Carolyn, 1990: 13-15).

## 2.5 Open space system review in Taipei City

Table 3 reviews the developed ratio of open spaces in Taipei. Over the past decade, the developed ratio increased by 7.9%, from 43.0% to 50.9%, but half of the areas planned for open spaces have not been developed. That is to say, planning areas in open space systems cannot provide expected effect, and the differences are shown in Figure 3. Furthermore, each district is compared according to its green resources per capita in Taipei. The green resources per capita in the five districts, Wanhua, Zhongzheng, Songshan, Da'an, and Datong, are lower than 10 m2. These districts are mostly located in the western area, the old developed area, which lacks public facilities. In a situation where no open spaces can be developed, it is important to increase and connect the open space network efficiently.

Current policies encourage building lots to remain as open spaces through the use of bulk rewards, but the contribution of POPS in areas with poor environments is still a question. Subsequent analysis will take these five districts as the research area to allow discussion of this point.

## 3. Methodology

The research process uses four scenarios and then compares the results of the scenario analysis. Average nearest neighbor and kernel density estimation are used as the research methods due to the spatial data type of point pattern. Through a global analysis, we can determine the intensity of clusters with POPS and open spaces in Taipei. In the average nearest neighbor analysis, the distribution of POPS and open spaces will show as clustered, random or dispersed. If the average nearest neighbor ratio is clustered, then hot spots are analyzed using a kernel density estimation in order to determine the differences among the districts. The result will show that the open space environment is improved whether or not through formulating the POPS policy, especially Wanhua, Zhongzheng, Songshan, Da'an, and Datong district.

### 3.1 Scenario Analysis

The literature review clarifies the planning and development of open spaces through the two phases of POPS policy. Therefore, the open space system is classified into four scenarios and shown as below. Subsequent analysis will involve a spatial point pattern analysis for four scenarios in order to compare the differences among the different scenarios and to verify whether the environment improved after executing the two phases of POPS policy.

- Scenario 1: Open space planning system (a total of 1,165; an area of 1,510.02 ha)
- Scenario 2: Existing open space system (a total of 253; an area of 397.63 ha)
- Scenario 3: Scenario 2 adds the first phase of POPS from 1983-1999 (a total of 634; an area of 466.41 ha)
- Scenario 4: Scenario 2 adds the existing POPS from 1983-2013 (a total of 736; an area of 481.11 ha)

### 3.2 Average Nearest Neighbor (ANN)

The null hypothesis of average nearest neighbor in hypothesis testing states that "the events are randomly distribution without clustering." The Nearest Neighbor Index is a distance statistic for point pattern data sets that gives the analyst an indication of the degree of the clustering of points (Chainey & Ratcliffe, 2005). In Average Nearest Neighbor, $\overline{D}_O$ is the average nearest neighbor distance; d is the nearest distance of dot i to dot j; n is the number of event points in study area. R is s nearest neighbor index; D¯_E is the average distance between the nearest neighbor and point.

$$\overline{D}_O = \frac{\sum d_{ij}}{n} \qquad R = \frac{\overline{D}_O}{\overline{D}_E} \tag{1}$$

The Average Nearest Neighbor is an index for evaluating point pattern distribution. If the index (Average Nearest Neighbor ratio) is less than 1, the pattern exhibits clustering. If the index is greater than 1, the trend is toward dispersion (Mitchell, A., 2005). If the index is near 1, the pattern is random.

### 3.3 Kernel Density Estimation (KDE)

Kernel Density is used to estimate the intensity of a spatial point pattern. Kernel Density Estimation represents the core area of design k1, k2, and uses points s1, s2 for the number of events within a core computing radius. The majority of events are assigned to different event groups, and then the density surface, the core area with a radius length τ1, τ2, will affect the accuracy of the estimates. Conceptually, a smooth, curved surface is fitted over each point. The surface value is highest at the location of the point and diminishes with increasing distance from the point, reaching zero at the search radius distance from the point (Silverman, B. W., 1986). If s represents a general location in R, and s1,…, sn are the locations of the n observed events, then density, λ(S), at s is estimated by (Bailey & Gatrell, 1995):

$$\hat{\lambda}_\tau(s) = \frac{1}{\delta_\tau(s)} \sum_{i=1}^{n} \frac{1}{\tau^2} k\left(\frac{s-s_i}{\tau}\right) \tag{2}$$

* $k()$ is a suitably chosen bivariate probability density function, known as the *kernel.*
* The parameter $\tau > 0$ is known as the *bandwidth* and determines the amount of smoothing.

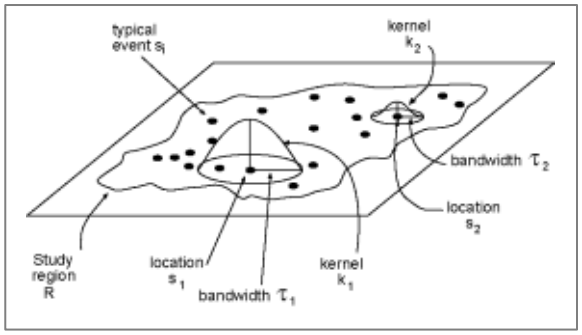

Figure 4. Kernel estimation of a point pattern
Reference: Bailey & Gatrell, 1995

## 4. Analysis

### 4.1 Average Nearest Neighbor Analysis

Table 5 shows that all of the average nearest neighbor ratios are less than 1 and that the Z-Score is less than -2.58 (P-Vale= 0.0000). That is to say, the point is a clustered distribution and allows the kernel estimation of the open space. In addition, reviewing the value of the four scenarios, the ratio of scenario 1, open space planning system, is 0.6155 more than the other scenarios. The case of scenario 1 shows that open space ideally tends toward an average distribution. In scenarios 2 to 4, the ratio become gradually smaller (from 0.6784 to 0.5541). The entire open space become more clustered after executing the different phases of POPS policy.

Table 5. Average Nearest Neighbor Analysis

| Scenario | Ratio | Z-Score | P-Value | Expected Distance | Observed Distance |
|---|---|---|---|---|---|
| **1** | 0.6155 | -25.1049 | 0.0000 | 243.1777 | 149.6825 |
| **2** | 0.6784 | -9.7868 | 0.0000 | 513.1923 | 348.1369 |
| **3** | 0.5585 | -21.2525 | 0.0000 | 331.9157 | 185.3595 |
| **4** | 0.5541 | -22.8559 | 0.0000 | 312.4617 | 173.1455 |

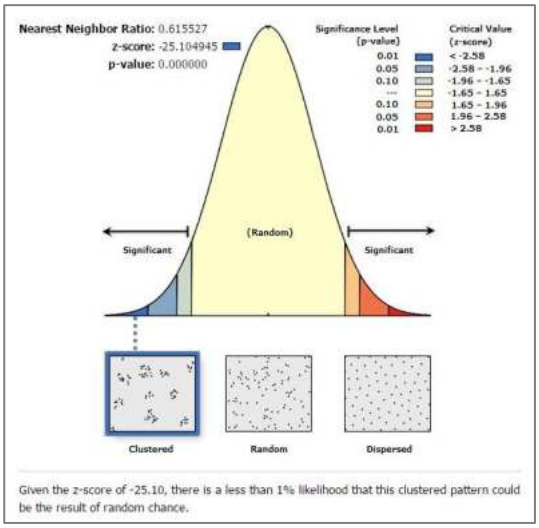

Figure 5. Scenario 1: average nearest neighbor analysis

### 4.2 Kernel Density Estimation

Analyzing the point pattern using kernel density estimation can determine open space hot spots. Furthermore, the change tendencies for open spaces can illustrate the differences in open spaces in each district. Figure 6 shows the intensity of density. Red represents a high density open space area. White represents a low density open space area. The parameter setting is that the center of each open space is the kernel, the value of $\tau$ (bandwidth) is 600m, and grid size is $60m^2$. In the different scenarios, the open space is used for hotspot maps.

To compare the different open space scenarios, the ranking in the kernel density estimation is revised

as the same in each scenario. From the overall perspective of open space service density in Taipei, the service density of scenario 1 distributes even locations according to population density close to ideal conditions. The policy of POPS is to effectively increase the service density of open spaces because of changes in the different phases from scenario 2 to 4. Although, the POPS policy of has more strategic standard, the POPS tends to be developed in certain area with either higher bulk reward or less rigid requirements due to the different policies. Even though increasing the POPSs amount of 100, the area of 25 ha, from scenario 3 to 4, the entire open space system cannot be improve. Ideal planning cannot be realized in the case of some old community.

Moreover, the poor green resources districts, Wanhua, Zhongzheng, Songshan, Da'an, and Datong, are the research areas. In planning open space in scenario 1, there is a lack of open space facilities in the Wanhua and Zhongzheng districts. Some districts, Songshan, Da'an, and Datong, improved when moving from scenario 2 to scenario 4, but this was not the case in the Wanhua and Zhongzheng districts. The goal of a better urban environment was not met. Although the result of the POPS development did not fulfill original expectations, but from scenario 2 to 4 the POPS did contribute a bit to those areas need open space most. Still, if we want the POPS to contribute more to the entire open space network, then the open space type and development specifications should be made in order to attract private developers more.

## 5. Conclusions

In high density cities, it is hard to create open spaces. This is why governments consider offering bulk rewards for creating open spaces. By developing strategic points for open spaces, urban environments will ideally be improved. According to the literature review, the policy at the first phase was generally about setting locations, but the policy became guiding principles in the second phase. However, different POPS specifications in regulations caused competition between regulations. Based on the analysis conducted in this study, the POPS policy actually improved urban environments according to the average nearest neighbor analysis. However, there have been little effects if the policy in the case of some districts with poor environment according to the kernel density estimation. In order to create better policies, it is necessary to increase rewards for areas with poor environments. On the other hand, rewards should be decreased for other areas. It is therefore possible to guide the development of POPS and achieve the goal of improving environmental quality.

# TEMPORARY PUBLIC SPACES IN UNSTABLE CONTEXTS: PRACTICES, LESSONS AND TOOLS

Christine Mady
Notre Dame University Louaize, christine.mady@ndu.edu.lb

Keywords: temporary public space, rhythms, Beirut

*Interdisciplinary approaches to research on public spaces indicate the broad interest in understanding their complexity and roles as stages but also resultants of social interactions. Despite their ever changing nature (Tornaghi, and Knierbein, 2015), public spaces persist over time as expressions, experiences and relations of urban contexts with their urban dwellers, while being stamped by local particularities, and affected by global waves. In particular, the role of public spaces in unstable contexts is becoming one urgent strand for research. The paper focuses on temporary public spaces, which provide insights on how their temporariness reinstates common values towards mitigating unstable contexts. The paper first utilises the triad of space production by Lefebvre to explain the dialectics of the production of conventional and temporary urban public spaces, and explain how public spaces are affected by instability. Rhythm analysis (Lefebvre) is used as the framework explaining how the context-specific tools and processes of temporary public spaces address instability. An ongoing study since 2006 on Beirut's temporary public spaces serves to illustrate the role of temporary public spaces in mitigating social instability. Finally, the conclusion presents some lessons learned on temporary public spaces, which act as an impulse for urban recovery and social integration within unstable contexts.*

## 1. Introduction

Interdisciplinary approaches to research on public spaces indicate the broad interest in understanding their complexity and roles as stages but also resultants of social interactions. Despite their ever changing nature (Tornaghi, and Knierbein, 2015), public spaces persist over time as expressions, experiences and relations of urban contexts with their urban dwellers, while being stamped by local particularities, and affected by global waves. The global-local on the one hand refers to neoliberal spaces that are showcased, and the mundane urban spaces used by locals in their everyday routines. On the other hand, the global-local refers to the exchange and use values of these coexisting spaces (Lefebvre, 1991), and in turn projects spaces of possession and control versus appropriated spaces that meet social needs (Lefebvre, 2008). Appropriated spaces relate to time, rhythm, symbols, and practice (Lefebvre, 1991, p. 356). The more the space is programmed for a specific function and controlled, the less it lends itself to appropriation, and alternative uses by different users (Madanipour, 2004; Loukaitou-Sideris and Banerjee, 1998; Lefebvre, 1991).

While spaces with exchange value help in city branding for global competitiveness, and act as commodities, and showcases for attracting tourists, and other exclusive members of the consumer society (Madanipour, 2004), spaces with use value cater for different people's rhythmic urban activities based on context-specific values. The latter spaces are in constant change. Understanding spaces as changing, requires a relational perspective lens, which magnifies intertwined and sometimes tense cultural, social, economic, political, and other context-specific factors that produce these spaces (Tornaghi and Knierbein, 2015). The need to understand public spaces is augmented in unstable situations where disruptions to daily rhythms, common meanings, and practices occur. This is due to the spaces' potential to address drastic change (Degros, Knierbein and Madanipour, 2014), and consequently instability. This paper focuses on temporary public spaces, which provide insights on how their temporariness reinstates common values towards mitigating unstable contexts.

To unpack this relational view in the cases of unstable contexts, the paper first utilises the triad of space production by Lefebvre (1991) to explain the dialectics of the production of conventional and temporary urban public spaces, and to explain how public spaces are affected by instability. The next section presents rhythm analysis (Lefebvre, 2004) as a frame to explain how the context-specific tools and processes of temporary public spaces help in addressing instability. An ongoing study since 2006 on Beirut's temporary public spaces is used to illustrate the mobilisation of people to reinstate the city's public life in an unstable context. Finally, the conclusion presents some lessons learned on temporary public spaces, which act as an impulse for urban recovery and social integration within unstable contexts.

## 2. Productions of Public Spaces

There is a co-presence of public spaces delivered through the tools of design and planning, and those that are temporary. Each category has different characteristics presented in the literature. The former are currently affected by privatisation, and commodification, and the latter are characterised by their ability to enhance public life through creative space appropriation. Lefebvre's (1991) space production triad is useful in explaining what leads to these differences in public spaces, especially that 'space and society are closely intertwined, and the processes that shape space are at the heart of what characterizes societies' (Madanipour, 2004, p. 282). Moreover, this slant on public spaces interprets them as ever changing entities, which are closely knit to dynamic social, political, economic, and other factors (Knierbein, 2015). Shifting research from public space as object to research on these relations allows for establishing congruence between what is intended in the space and what is socially needed (Knierbein, 2015), especially in unstable contexts with high uncertainties, and constant change.

*Representations of space:* correspond to the tool that urban planners and designers use to communicate about urban space. Representations of space fall into the danger of becoming abstract spaces, devoid of meaning (Knierbein, 2015, p. 55). As discussed earlier, these are spaces with exchange value, which could fit in any time-space (Knierbein, 2015: 46). Examples are abundant, including cities in the UK where the main pedestrian streets are flanked by an almost identical series of chain stores, or in the case of Lebanon and its shopping malls that house similar content of identical chain stores that are equally available in shopping malls globally.

Representations of public space do not always meet social needs, as they are distanced from the users of public space. Madanipour (2004, p. 271) refers to 'cracks' in public spaces and defines them as 'neglect and decline, as well as tensions along the lines of social fragmentation and stratification.' If there is no sense of attachment or emotional belonging (as the exchange value prevails over the use value), public spaces could be dominated by specific rather than all user groups, could easily be changed to other uses or simply stay neglected.

Representations of public space are often out of pace with users' changing identities due to population mobilities, but also social fragmentation as in cases of conflict and war. Differences emerge at 'fault lines' in cities, where multiplicities occur (Holston, 1995, p. 444). Moreover, in cases of political instability, and raised security alert, control often results in the 'city's disintegrating public spaces and abandoned public sphere.' (Holston, 1995, p. 447) This is manifested in the erosion of public space by protective concrete elements and barbed wire (Németh and Hollander, 2010) that are a common sight in Beirut and other cities nowadays. Other forms of disintegration of these spaces include long-lasting effects of misuse, or even leaving these spaces on drawings without ever being executed and implemented as planned. Therefore, in the case of representations of space, instability is reflected spatially (cracks), socially (fragmentation, discrimination, exclusion even within members of the same

population), and also temporally (breaking rhythms or disappearing rhythms of everyday activities, festivals, events, holidays, curfews, and so on). However, mitigation in the form of the new and unforeseen manages to reappear (Lefebvre, 2004) in cities struggling with instabilities, such as in the case of temporary public spaces.

*Representational space:* correspond to the assembly of symbols, signs and values assigned to a space, including their dissipation through social media, billboards or even 'iconic elements, soundscapes, graffiti, media contents' (Tornaghi, 2015, p. 30). These signs, symbols and their dissipation customise a space according to its local culture and society. It is theis network of non-verbal communication, which informs people about the space. In contexts of instability, and with different symbols and signs the coding and hence perception of a space changes. One example in the case of Beirut is the demarcation line, which changed how people referred to the eastern and western city parts (Yahya, 1993; Fregonese, 2009).

*Spatial practice:* refers to the everyday practices taking place in urban space, and also the routines of urban life including elements of surprise and encounter that support the development of 'social relations' (Knierbein, 2015, p. 42). Spatial practices occur in lived space over time, and are essential to healing schisms occurring in unstable contexts. The everyday traffic, buzzing and flow of people are an indication of 'balanced' life, as opposed to calm periods following a natural or manmade disaster, where city life comes to a halt.

Thinking of public space as combining non-verbal communication and social practices allows for the production of public space, which includes possibilities for social change (Holston, 1995), since this approach incorporates the study of public space and the panoply of factors affecting it. Therefore, 'public space can be a catalyst for change, through actions initiated by residents, as well as public authorities and others' (Madanipour, 2004, p. 279).

Meeting social needs in situations of uncertainty requires experimentation, acquisition of knowledge, and creativity to understand the context, its specificities and constraints, and to arrive at desirable solutions (Christensen, 1985). Through informal networks of communication (Hillier, 2000), and exchange of information, individuals and groups are able to identify social needs, especially in unstable contexts, and search for opportunities to materialise those needs (Holston, 1995). Over time these needs might be claimed as rights that were not initially defined by regulation (Holston, 1995). In other terms, these groups create new tools for meeting common yet unrealised 'social needs' (Lefebvre, 2008, p .147). One tool is temporary public space, which provides the opportunity to meet 'the unintended and the unforeseeable' (Holston, 1995, p.443) in everyday urban life. In the context of Beirut as in other cities worldwide (Bishop and Williams, 2012; Franck and Stevens, 2007; Haydn and Temel, 2006), temporary public spaces reflect effectiveness in meeting social needs, implementing transformative actions (Walliser, 2013) and enhancing urban life. Literature on these spaces highlights several aspects: first, their various interim uses (see Drake and Lawson, 2013; Langegger, 2013; Pearsall and Lucas, 2013). In Germany interim use is part of the planning system, and indicates a time-limited occupation of vacant land for an alternative activity (Blumner, 2006); second, how they seize the situation of deindustrialisation, shrinking population (Madanipour, 2004), weak planning (Andres, 2013) and/or gaps in unresolved ownership (Colomb, 2012; Mady, 2012a), all of which often result in vacant urban land in highly accessible locations (Trancik, 1986; Loukaitou-Sideris, 1996; Foo et al., 2013; Németh and Langhorst, 2013). This contributes to the temporary spaces' success in terms of high accessibility (Madanipour, 2004), and in bringing vibrancy into urban life (Stevens and Ambler, 2010). These spaces provide opportunities for urbanites, be they economic, environmental or social (Foster, 2013; Pearsall et al., 2013; Drake and Lawson, 2013).

There are few references indicating how temporary public spaces could be a response to natural disasters (Karen, 2011), or manmade disasters inflicting social schisms (Mady, 2013), and the ability of these spaces to absorb distortions caused by disasters and mitigate instability by reintroducing various rhythms of urban everyday life.

## 3. Rhythm, unstable contexts and temporary public spaces

Rhythm analysis as defined by Lefebvre (2004) includes learning from cyclical and linear time patterns that recur yet generate differences. As events, actions, movements, and outcomes are repeated- yet not identically- they are always compared or measured against what is established as known within a specific context. What is established is built through history and common values, and what occurs refers to present time actions, for example response to instability. Rhythm facilitates appropriation through recurrence, yet allows for variations. Rhythm empowers, and gives right, allows for differences to coexist, introduces elements of surprise, discovery and encounter. Rhythm analysis facilitates the understanding of the link between current, intended, and past needs, top down interventions, mundane practices, and expressions of needs, which are then manifested in space appropriation.

Disasters and conflicts cause changes, and yield contexts with environmental, economic, political, social and other instabilities. These instabilities affect contextual rhythms of everyday urban life by annihilating the rhythms, disrupting them or completely altering them. Also, these instabilities could affect the use and exchange values of urban spaces, in turn affecting how people experience their cities. Spaces with use value imply appropriation, which is tied to time, rhythm, symbols and practice, or in other words to representational and lived spaces (whereas exchange value implies the representation of space). Through time, these symbols and practices along with their rhythms need to be reinstated, and this requires some form of power. On the one hand, for conventional public spaces, this power is reflected in celebrations, parades, group activities, public arts, staging public events, and festivals that are temporary yet change the spatial experience (Madanipour, 2004, pp. 279-283). On the other hand, this power is provided as a use-right in temporary public spaces (Mady, 2012a), as it gives the opportunity to representations of space to accommodate representational dimensions and lived practices. One of these practices refers to contact and communication during which ‘meanings and uses of public space are transformed through practice during social movements, the symbolic dimension of public space is decoded and reloaded, thus providing fertile ground for redirecting (political, medial) attention to silent claims and emerging needs.’ (Knierbein, 2015, p. 59) Reinstating social practices also means changing the perceptions of a space and its context, which is necessary in unstable situations. The reinstatement means regaining confidence, promoting a sense of attachment, and reversing a stigma that could become associated with a space or locale (Madanipour, 2004, p. 283) To achieve this, three aspects must be considered over time ‘resources, spatial situations, and strategies’ (Lefebvre, 1991, p. 356), which are implemented integral to the production of temporary public spaces, and explained in the next section.

An exploration of temporary public spaces through the lens of rhythm reveals how those spaces are able to cope with dynamic situations, facilitate users’ acceptance of change inflicted by instability, and continuation of their routine urban lives with positive emotions despite other disruptions, and uncertainties (Magis, 2010; Tidball and Krasny, 2014; Wilson, 2012). Temporary public spaces form one the medium bridging differences, platforms for dialogue, adaptation and even transformation (Walliser, 2013). They reinstate previously existing rhythms or introduce new ones with the result of mitigating instability. In these spaces, temporality ceases to be a time-span consideration and is transformed into ‘a prototypical phenomenon [that] tends to counteract temporality itself’, that is, it exists because of its transience and does not seek permanence (Haydn and Temel, 2006:17). In this

sense, temporary spaces challenge the idea of planned spaces (Groth and Corijn, 2005). These spaces respond to emerging needs linked to changes in culture, functions, activities and people, especially in light of increased global mobility (Low et al., 2005: 3; Cuthbert, 2006; Carr et al., 1992; Trip, 2007). Temporary public spaces fill gaps, and generate 'counter spaces' or 'public spaces where alternative paths of urban development beyond capitalist growth scenarios can be imagined, invented and explored' (Knierbein, 2015, p. 53), and spaces whose use value overwhelms their exchange value, as stated in Lefebvre (1991).

## 4. Lessons from Beirut's temporary public spaces

Beirut is a city, which has and still is experiencing ongoing political, spatial, social, economic, environmental and other instabilities, which expedite urban dynamics (Tabet, 1993) and render it a laboratory for actively experiencing and experimenting with public space production. Moreover, Beirut was specifically referred to in Lefebvre's writings (2004, pp. 99-100; 2008, pp. 239-240) on Mediterranean cities, but only to indicate the 'arrhythmic' everyday life that instability inflicted on this previously harmonious 'polyrhythmic' city. The disruption of rhythms manifested first spatially in Beirut's public spaces (whose genesis was based on imported representations of space such as the garden and square during the Ottoman and French Mandate periods), which were annihilated during the war period, and second socially through segregation that happened along sectarian and political divides (see Mady, 2012b for a brief overview of Beirut's public spaces). Reconstruction efforts in the city centre concentrated on providing transportation infrastructure[1], which only degrades public space (Lefebvre, 1991, p. 359), and different polarised groups then established their commodified spaces within their territories (Deeb and Harb, 2013), while other groups managed to produce spaces with common social values (Mady, 2013). Nowadays these concerns with rhythmic public spaces move beyond Beirut, and other contested cities (Gaffikin et al., 2013; Nagle, 2013) to encompass specifically in the Middle East and North Africa region (El-Husseiny, and Kesseiba, 2012), and broadly cities worldwide.

Before unpacking constituents of temporary public spaces, here is a brief note on the methodology. The data for this paper is taken from research on Beirut and temporary public space case studies, which included mapping, interviews with various stakeholders, and observations of these spaces. This research was conducted between 2006 and 2008 in Beirut (Mady, 2010), and observations of some of these spaces are still ongoing to present. The case studies include: one farmers' market, one flower market, an urban stairs with artists' exhibition, and six sports sites (refer to Mady, 2010 for detailed explanations on the case studies). The data is used to identify temporary public space users, and the experiences, expressions, and values that they attach to these spaces. It is equally used to learn about tools and processes for temporary spatial appropriation in Beirut. Also, comparing the cases in Beirut to those in other cities responds to the question on temporary public spaces' appropriation within unstable contexts, by reinstating and/ or introducing rhythms through 'resources, spatial situations, and strategies' (Lefebvre, 1991, p. 356). Different unstable contexts seem to give rise to creative solutions on the appropriation of urban public spaces.

*Resources:* in this case refer to the individuals and groups who produce temporary public spaces, and any materials or capital used to activate the temporary public space. In Beirut social exclusion occurs

[1] The real estate company Solidere who reconstructed the long sealed-off city centre re-established vehicular access with its surroundings, creating tunnels and bridges, thus severing the previous link from its surroundings (Lefebvre, 1991), which used to be tightly-knit neighbourhoods around the centre. Solidere conducted extensive land acquisition, reparcellised land, set urban design guidelines, and incorporated plans for public spaces, which are managed by Solidere yet owned by the municipality of Beirut. The realised public spaces were valorised for their exchange rather than use value.

on the basis of vulnerability, which could equally affect foreign migrants or the local native population (Madanipour, 2004). A public space, which mitigates social instability, is then able to serve Beirut's 'mosaic of different publics' (Deeb and Harb, 2013, p. 85). Examples include the two markets, which use their economic activities as a pre-requisite for social integration (Madanipour, 2004). These markets offer job opportunities for people (Walliser, 2013) who have difficulties competing in the market, and provide them with the opportunity to cope with stress, remain active, learn new skills, establish social networks, be empowered rather than stay dependent thus strengthening social capital (Wilson, 2013) in the form of collaborations between experts and everyday people through collective action (Mady, 2013). The organisers of these markets were identified as social entrepreneurs (Mady, 2013) who are open to experimentation and innovation (Christensen, 1985), and who work in small interest groups to produce these spaces. Note that sometimes the organisers operate at different scales, and network with influential individuals to gain power in promoting the proposed public activity. One example is the case of the farmers' market, which gets its certification for organic products from the Italian government, thus bridging the global with the local (Roy, 2005) to give credibility to the market, and perpetuate it.

*Spatial situations:* refer to the state of vacancy of urban spaces, rendering them available to host temporary public uses. As mentioned in the introduction to temporary public spaces, these vacant urban spaces are resultants of an absence of construction due to weak planning (Andres, 2013), a stagnating economy, or ownership disputes. In each case, this vacancy is time-limited, and once this temporal status changes, the temporary public space then has to relocate. In the cases from Beirut and to present, the temporary sports sites have been used for periods spanning 19-40 years, whereas the markets moved two to three locations in the span of 11-15 years. The urban stair has been used for the artists' exhibitions for 29 years. Note that the urban stair is seasonally used, the markets are periodically used on weekends, and the sports spaces are used either seasonally or periodically since they also serve as car parking spaces on weekdays. Each of these examples has its own rhythm, and contributes differently to urban life in Beirut.

The fifteen-year war in Lebanon meant that people were frequently on the run, adapting to new circumstances, and living with the unknown. Change and mobility became usual companions to everyday life, and to some extent, change was accepted as a constant (Wilson, 2012). Whereas cases of temporary public spaces in European and American cities presented the limitation of being terminated due to the switch of vacant land to construction land, in Beirut this switch meant the mobility of the temporary public activity and a search for a new location, as illustrated in the cases of the two markets. These temporary activities partly owe their flexibility to the simplicity and flexibility of their dismountable structures, and partly to the determination of their users to continue with the activity irrespective of the location (as reflected in the interviews within both markets). The temporary public spaces in Beirut, and unlike their counterparts in Europe and the USA, do not seek permanence, and are rather aware of their temporariness as a feature of the space. This is reflected in the agreement with the property owner, the municipal permit, and the creativity in mantling the markets every time (Mady, 2013). To what extent is the limited lifespan of the space worth investing in? Will these spaces disappear, and will their creativity stop? Beirut's temporary spaces show that the existence and use values overshadow the ephemerality of the lifespan. Not only do these spaces change location without losing their impetus, they have initiated similar temporary space mutations with other creative activities in different city parts, and on different week days. Moreover, the visitors of the two markets now visit the farmers outside Beirut, and explore parts of the country, which they had not visited before (Mady, 2013). The spaces have generated other rhythms within and outside the city. To some extent, these temporary spaces have raised people's awareness on the right to public space in Beirut. The case of the urban stair developed awareness of stairs as public spaces, and citizen campaigns to protect them as heritage.

Another difference with their foreign counterparts is that vacant spaces in Europe or the USA await the implementation of the plans designated for them, turning them into spaces with exchange value, or awaiting the arrival of an investor in the absence of any plans (Andres, 2013); in the meantime local authorities realise the opportunity of and support the temporary activities. In Beirut, the temporary public spaces are not part of an official city plan, and are not considered opportunities by the municipality; they are simply vacant properties (according to an interview with a municipal authority). However, the real estate company Solidere that is in charge of the city centre's reconstruction, has endorsed these initiatives for temporary public spaces to promote the return of the 'public' to the reconstructed city centre, and has mediated the use of vacant spaces for temporary public uses.

*Strategies:* refer to the tools and processes that the individuals and groups devise to gain access and right to temporarily use the vacant urban spaces for public activities. Note that unlike the example of squatting spaces, all the case studies in Beirut present temporary public spaces that are legally used, and which obtain municipal permits if required, as in the case of the two markets and the arts' exhibition. The sports activities do not require municipal permits, yet have the permission of the property owners to temporarily use the spaces.

The strategies listed in this paper are not exhaustive, yet they highlight those that are highly pertinent to unstable contexts: valorising local tradition, and local culture (for example the village spirit in the food market[2]; capitalising on what is Lebanese including: cuisine, flowers or paintings or in other words on shared beliefs and values (Hillier, 2000); organising events in response to different interests in addition to the routine activities (such as competitions, concerts, awareness campaigns, children's activities); choosing locations that are highly accessible, and not associated with a specific political or sectarian territory within Beirut[3]; using social networks as a 'coping strategy' (Hillier, 2000, p. 293), and building power to increase the space's use value and consequently lead to its change or reproduction (Hillier, 2000, p. 297) from a vacant site to an active public space. The effect in mitigating instability through these strategies is illustrated through one statement by one of the respondents at the flower market:

> 'People of different ages and sects, veiled women from different parts of the country come here. Beauty and values bring people together'

Examples on similar strategies are present worldwide; in Barcelona economic competitiveness is used as a strategy for social cohesion, in Wuppertal artists accentuated the role of urban stairs as public spaces, and in Coventry football was transformed into an activity that brought people together (Madanipour, 2004). Other examples reflect how similar temporary spaces provide opportunities to have positive emotions (Tidball and Krasny, 2014), similar to those indicated by users of the two markets through the interviews (convivial, refreshing, simple, different, interesting, emotional, friendly, and other).

Among the limitations of temporary public spaces is the risk of these spaces to fall into the 'common path of economic gentrification (Andres, 20113, p.771), and lose their intended social values. In this case, the spaces become club goods (Webster and Lai, 2003), which are selective spaces privileging (Hillier, 2000) some members of the consumer society. Here representations of space become instrumental in preventing such a direction towards exclusion, yet no universal solution exists.

[2] The village spirit is equally appreciated in other contexts in Beirut such as the decoration of cafés with a village spirit (Deeb and Harb, 2013, p. 118) because it moves away from the divides of politics and sectarianism.

[3] These are mainly spaces within the reconstructed city centre, which became no-man's land during the war years, as opposed to the polarised eastern and western Beirut districts (see Chapter 8 in Mady, 2010 for further explanation).

Understanding the context becomes of high significance (Lefebvre, 1991) in limiting global influences that are superimposed on local spaces, and preventing them from transforming the spaces' use value to exchange value. 'Therefore, context-specificity means that a place of public life needs to be analysed, interpreted and shaped according to its local embededness in a specific social, political and cultural context' (Knierbein, 2015, p. 51).

## 5. Conclusion

This paper presented the possibility of informing the production of urban public spaces especially in unstable contexts through lessons learned from the analysis of temporary public spaces. Case studies of temporary public spaces in Beirut, Lebanon were used to illustrate the relational reading of these spaces, and how they mitigate contextual instabilities.

While generally 'public spaces can be used to bring people together to improve the quality of life and to project a positive image...' (Madanipour, 2004, p. 281), temporary public spaces mitigate instability that is manifested spatially, socially, and temporally in the daily practices and representations of the city. These spaces reinstate or introduce rhythms in everyday urban life, and generate social values that lead to social integration and conviviality. Temporary public spaces achieve this while tapping on resources, spatial situations, and devising strategies. With little capital and a lot of dedication (Mady, 2012a; Walliser, 2013) these spaces present 'opportunities for sustainable and dynamic urban development' (BMVBS, and BBR, 2008, p. 5).

The analysis of everyday life and its rhythms moves away from merely observing practices ranging from the mundane everyday actions in public space, to norms followed by a whole society (Lefebvre, 2014, p. 232). This analysis is considered as a tool for understanding social meaning in everyday urban life (Knierbein, 2015, p. 54). This tool informs the conceived spaces of designers and planners that are not necessarily immersed in the concrete reality of the lived, perceived spaces, and are in turn lost in their abstract representations on plans and other related documents.

Temporary public spaces as tools for establishing long-term values and meeting future challenges could be integrated within planning systems and used as a response to instabilities, be they economic, political, social or other. Beirut's cases indicate that such spaces leave positive social memory (Wilson, 2013, p. 208) within a volatile and highly fragmented society, and even project a positive image (Madanipour, 2004) of Beirut especially after its war reputation. However, the analysis presented in this paper is specific to the context of Beirut, where instabilities and the production of Beirut's public spaces are contingent to the context specificities and factors affecting the city's stability and urban life. Further practices and research on temporary public spaces in different contexts are necessary for a broader understanding and further development of this tool.

Keywords: soundscape, sound source mapping, sound perception

## Abstract

*According to the recently published ISO 12913-1, soundscape differs from the acoustic environment, since the first refers to a perceptual construct, whilst the latter to a physical phenomenon. Noise exposure has been a main concern over the last decades, but from the planning viewpoint limited attention has been given to the perception of the acoustic environment and its representation at a city scale. This paper aims to establish a method for representing soundscape through source-related maps and secondly to correlate the sound sources with the urban context in terms of specific activities. Using a grid-based sampling methodology within the broader area of Sheffield city centre, soundscape data were collected in 90 spots, during morning and evening hours. Afterwards, soundscape variability for technological, anthropic and natural sounds was represented by maps using a Kriging interpolation technique in GIS. Preliminary results show how sound sources' spatial variation in urban soundscapes is closely related to urban contexts and activities, therefore urban activities can be relevant for designing the soundscape of the urban realm. The paper ultimately points out how soundscape mapping can be used as a tool for planning purposes and urges to rethink the design process of the built environment also from the sonic viewpoint.*

## 1. Introduction

Soundscape has recently been defined in an international standard as an "acoustic environment as perceived or experienced and/or understood by a person or people, in context" (ISO, 2014). Such a definition is somewhat comparable to the European Landscape Convention (Council of Europe, 2000) that defines 'landscape' in similar terms (Brown, 2012). Hence, there is a general agreement that soundscape – as well as landscape – concerns human perception of the environment.

The soundscape philosophy implied a paradigm shift from a 'reactive' approach to noise to a 'proactive' attitude towards sound, considering this element as a resource rather than a waste. Indeed, community noise has been a main concern over the last decades, but from the planning and design perspective, limited attention has been given to the perception of the acoustic environment in its positive aspects and its representation at a city scale.

There is a current need to position soundscape management into planning policies (Kang 2007; Andringa, et al., 2013). For this purpose, new operative tools are required to be used by planners and policy-makers. Some researchers investigated the possibility to use spatial analysis to study the sound environment of urban contexts (Ge and Hokao, 2005) and possible ways to record and represent the soundscape (Ge et al. 2009). Furthermore, a number of studies investigated the relationship between

soundscape and landscape as well as land use metrics and urban morphology (Hao and Kang 2013; Liu et al. 2013a; Liu et al. 2014a; Liu et al. 2014b; Hao et al. 2015).

Apart from that, numerous studies have started visualising soundscape using GIS tools to map sound sources in urban areas or parks (Irvine et al. 2009; Liu et al. 2013b; Hong and Jeon, 2014). The mapping process is usually performed using various interpolation techniques (Li and Heap, 2008). The most widely known such as Kriging and Inverse Distance Weighting (IDW), have previously been tested for noise assessment purposes (Can et al. 2014). Nevertheless, there is still no clear consensus about what soundscape-related information is relevant and should be collected for planning and design purposes and how soundscape and urban contexts relate to each other.

This paper aims to propose a method for representing soundscape through source-related maps and secondly to correlate the sound sources with the urban context in terms of specific activities. For these purposes, soundscape data and audio recordings were collected in 90 spots in a typical European city, Sheffield (UK), according to a grid-based sampling methodology. Afterwards, a laboratory experiment was carried out with 20 participants, in order to investigate possible relationships between the individual assessments of the acoustic environments and a set of urban activities.

## 2. Soundscape mapping

### *2.1 Study area and data collection*

A study area was selected in Sheffield city centre, since it combines many different land use characteristics and can also be considered a typical example of a post-industrial average-size European city. Furthermore the area is characterised by a dense and varied network of local and national level of streets as well as transport infrastructures (e.g. railway, tram, buses). The total area extends to 3.6 $km^2$. A grid of 200 × 200m was implemented, segregating the region in 90 tiles. The measurement points were defined at the centroids of all tiles, as shown in Figure 1. In case a centroid resulted to be non-accessible due to legal or physical restrictions (e.g. buildings), the closest publicly accessible point was selected.

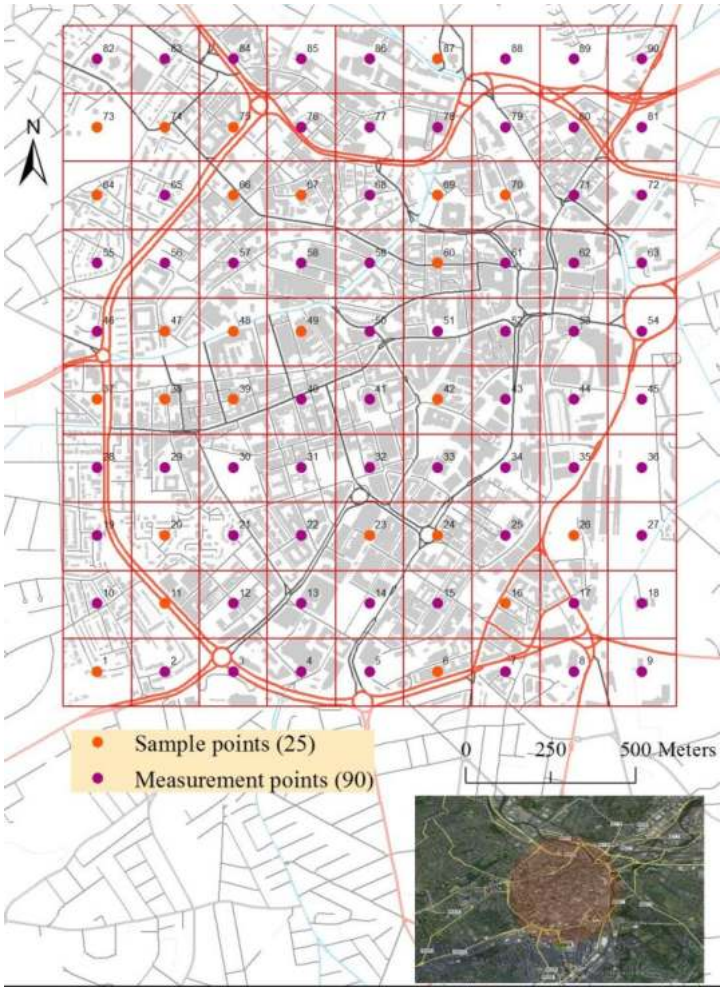

Figure 1. Study area with measurement and sampling points in Sheffield

A researcher collected data at each spot twice over 4 working weeks: during mornings (09:00–12:00) and afternoons (14:00–17:00). For each measurement session the researcher recorded the equivalent sound level ($L_{Aeq}$-2min) with a sound level meter (MicW i436 - class 2) and carried out 2-minute audio recordings of the sound environment by means of a binaural kit connected to a portable recording device (Edirol R-44). Furthermore, the researcher reported "what sound sources it was possible to hear" by ticking off on a form with possible sound sources selected during a pilot on site campaign, as shown in Table 1.

Table 1. List of sound sources used during the soundscape data collection

| Category | Sound sources | |
|---|---|---|
| Technological | Cars | Alarms |
| | Buses | Grass Mowing |
| | Trucks | Industries - Fans |
| | Trains | Industries - Other Machines |
| | Airplanes | Construction |
| | Bicycles | Domestic |
| | Fireworks | Recreation |
| | | Miscellaneous |
| Natural | Wind | Rain |
| | Trees Rustling | Birds |
| | Grass Rustling | Dogs |
| | Water Sounds | Insects |
| | Thunder | Frogs |
| | | Miscellaneous |
| Anthropic | Human Speech | Roller-skating |
| | Human Singing | Music - Live |
| | Human Laughter | Music - Recorded |
| | Crowd of People | Music - Shops |
| | Footsteps | Church Bells |
| | | Miscellaneous |

*2.2 Mapping methods*

After the data collection was finalised, all the information related to the audible sound sources was transferred in the ArcGIS software (v.10.1) for further processing. The audible sources' occurrences were aggregated per type and these values were averaged over the morning and afternoon conditions. Then a prediction surface was created using the kriging interpolation method for the technological, natural and anthropic sound sources accordingly. The surfaces were created based on the Ordinary Kriging method and the spherical semivariogram model, considering all the 90 points of the study area.

*2.3 Characteristics of sound sources*

According to the perceptual data, 3 soundscape maps were created for the study area. Figures 2–4 show the spatial variability of audible technological, natural and anthropic sound sources respectively.

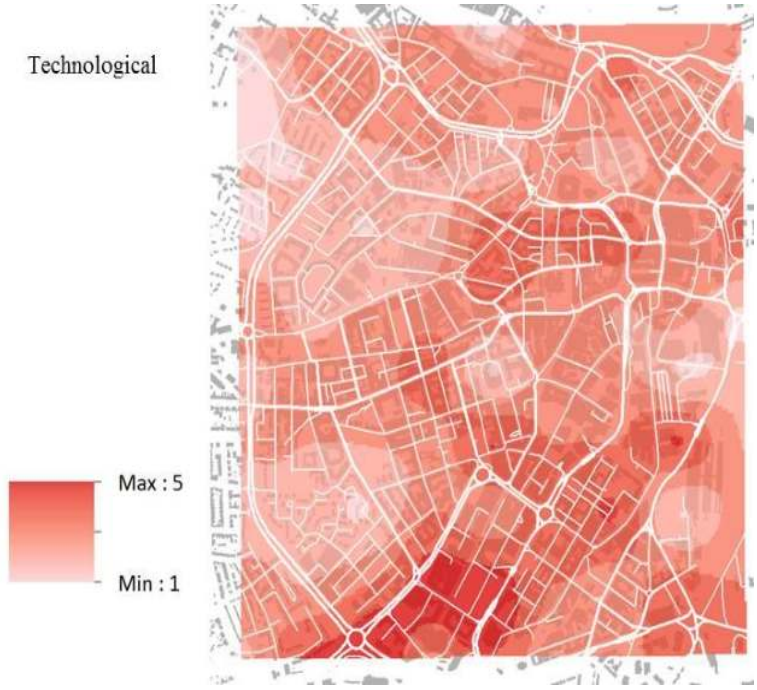

Figure 2. Spatial variability of the audible technological sound sources

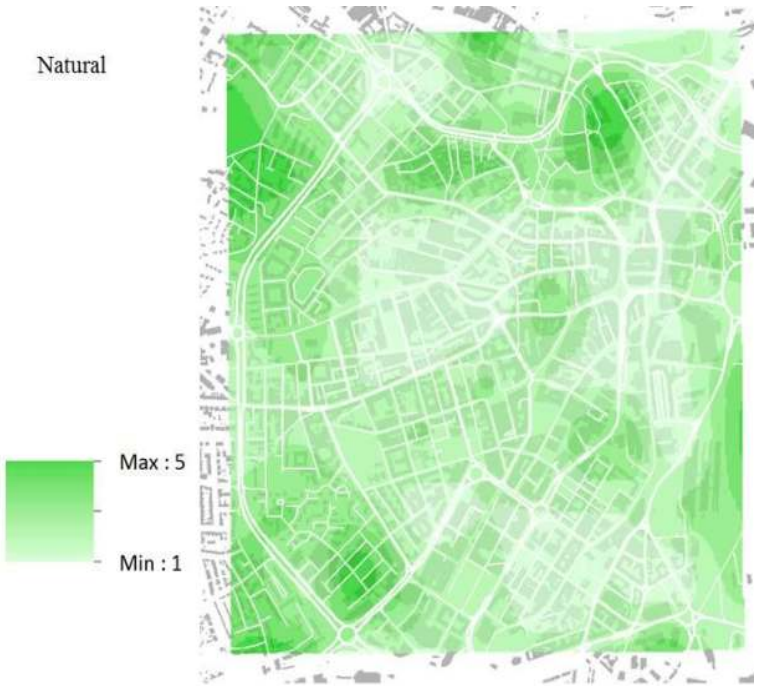

Figure 3. Spatial variability of the audible natural sound sources

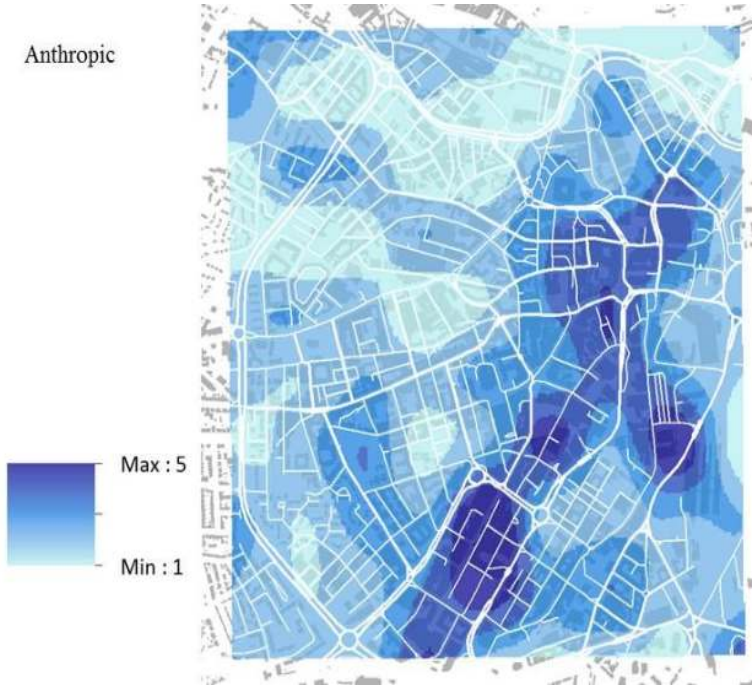

Figure 4. Spatial variability of the audible anthropic sound sources

According to Figure 2, areas on the north-west side of the ring road – mainly covered by University buildings, parks and residential houses – present low level of technological sources. The same happens on the south-west side of the ring road, which is a purely residential area. Low technological sources are also present in the east side, close to the train station because of the natural area on the east. Similarly, another small area with absence of technological sounds can be identified in the city center, with many pedestrian areas. High concentration of technological sources was observed in the roundabouts of the ring road and along the main roads in the central zone of the study area. The highest number of sources was observed in the southern part, which was expected due to the combination of traffic and light industrial activity.

From Figure 3 it can be seen that increased number of natural sources is evident in specific areas around the ring road which constitute parks, exclusive residential areas or places close to the river on the north. The west side of the study area is more privileged in terms of natural sounds because of the proximity to urban green spaces and playgrounds, while the house type with backyards or front yards enhances the presence of birds and animals. The city center presents the lowest aggregation of natural sounds with a small presence in various squares. It is also surprising that most of these places are along the main highway creating a contradictory soundscape environment with increased number of technological and natural sources very close to one another.

Lastly in Figure 4, anthropic sources seem to create a corridor from north to south starting from the river and continuing along the commercial and former industrial area of the city center. These are areas with many shops, services, entertaining activities and active social life during the greatest part of the day. Another vital point is the train station on the east as well as the corridor on the west close to the student's accommodation houses and the Devonshire Green square. The presence of human sources is limited on the rest of the study area apart from some small exceptions close to the river on the north and the green area of Ponderosa on the north-west.

## 3. Relationship between soundscape and urban context

In order to investigate the relationship between the soundscape of a place and the urban activities that are likely to occur in such a place, an audio-visual laboratory experiment was designed. For the experiment, 25 out of the initial 90 spots were selected around Sheffield (See Figure 1). The first selection criterion was to choose sites representative of all the possible land use categories according to the Local Plan of Sheffield within the study area. Consequently, areas appropriate for residential, industrial, open green space, commercial and educational purposes were selected. The second criterion accounts for the availability of the street view option in Google Earth in order to create the videos.

*3.1 Experimental set-up and procedure*

Twenty undergraduate and postgraduate students from the University of Ghent (Belgium) aged between 23 and 33 years old, took part in the experiment (16 males, 4 females; $M_{age}$ = 27.5 years, SD = 2.82). All of them were citizens of Ghent, while 16 participants had previously visited England at least one time in the past. However none of them had been to Sheffield before. The auditory conditions were the same for the total duration of the experiment, since it took part in a listening room using specific equipment. Each participant received a reward of 5 euros in cash after completing the experiment.

From the initial audio file, a 30sec audio part was extracted representative of the sound environment at each spot. Then the audio excerpts – previously recorded on site – were combined with the visual excerpts in order to create 25 audio-visual representations of 360$^o$ view. This process was performed using Camtasia Studio software. The audio excerpts were also calibrated so as to be as representative as possible with the on-site conditions. For the calibration, a test sound of 30 seconds was used from the initial recordings. The dB value of the test sound was measured using Matlab and the calibration was made based on the dB level of the original signal. Then the volume was adjusted based on calibrated equipment and a dummy head with 0.1” microphones, as shown in Figure 5.

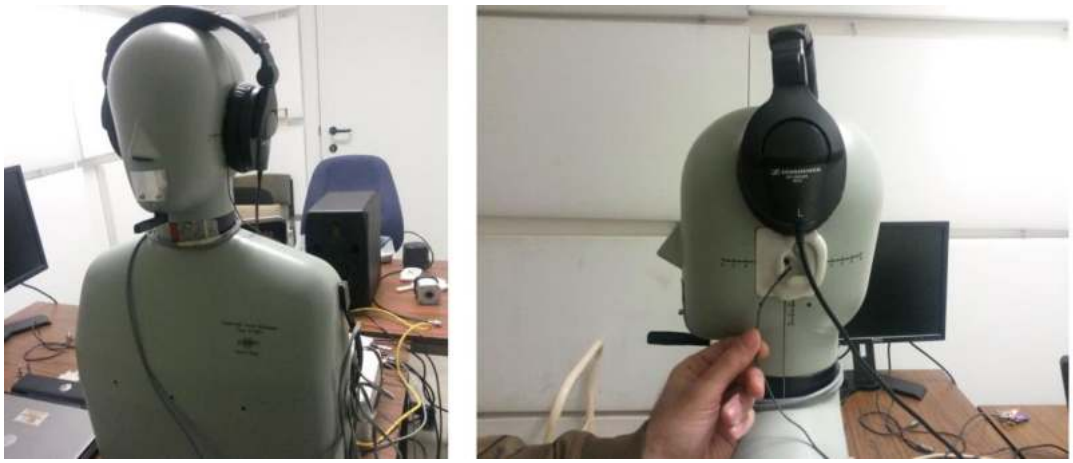

Figure 5. Calibration test on the left ear of the dummy head and the 0.1” microphones

A structured questionnaire consisting of two main questions was prepared based on the soundscape model proposed by Axellson et al. (2009, 2010). On one hand there was a list of 23 urban activities;

namely: outdoor informal games, walking, jogging or running, socialising-conversing-chatting, picnic or barbecue, experiencing active street life, individual outdoor activities, spending time with friends or family, escaping city stress, experiencing peace and quiet in general, nature appreciation, school and student work, residence, offices, shops, shopping, restaurants or cafés, industrial activity, road or rail transportation, parking a car, appreciating inland water, boating or fishing, swimming or bathing, appreciating cultural heritage. For each urban activity participants were required to assess on a scale ranging from 0 to 100 its suitability (i.e. kind of activities that would fit in this place), as shown in Figure 6. On the other hand, a list of 4 sound sources types was presented to participants; namely: traffic sounds, sounds from people, natural sounds, and construction sounds. Similarly, the participants were asked to assess the audio stimuli by defining on a 0-100 scale the extent to which they could hear each sound source type (0 = "Do not hear at all", 100 = "Dominates completely"). The audio-visual stimuli were presented to participants using the SurveyGizmo software, with randomized answers for both questions and different video sequences for each participant. The numbers in the scale bar for all the answers were invisible so as to avoid possible rounding tendencies from the participants. The average duration of the experiment was one hour, while the participants were able to watch the videos more than one time in order to answer the questions.

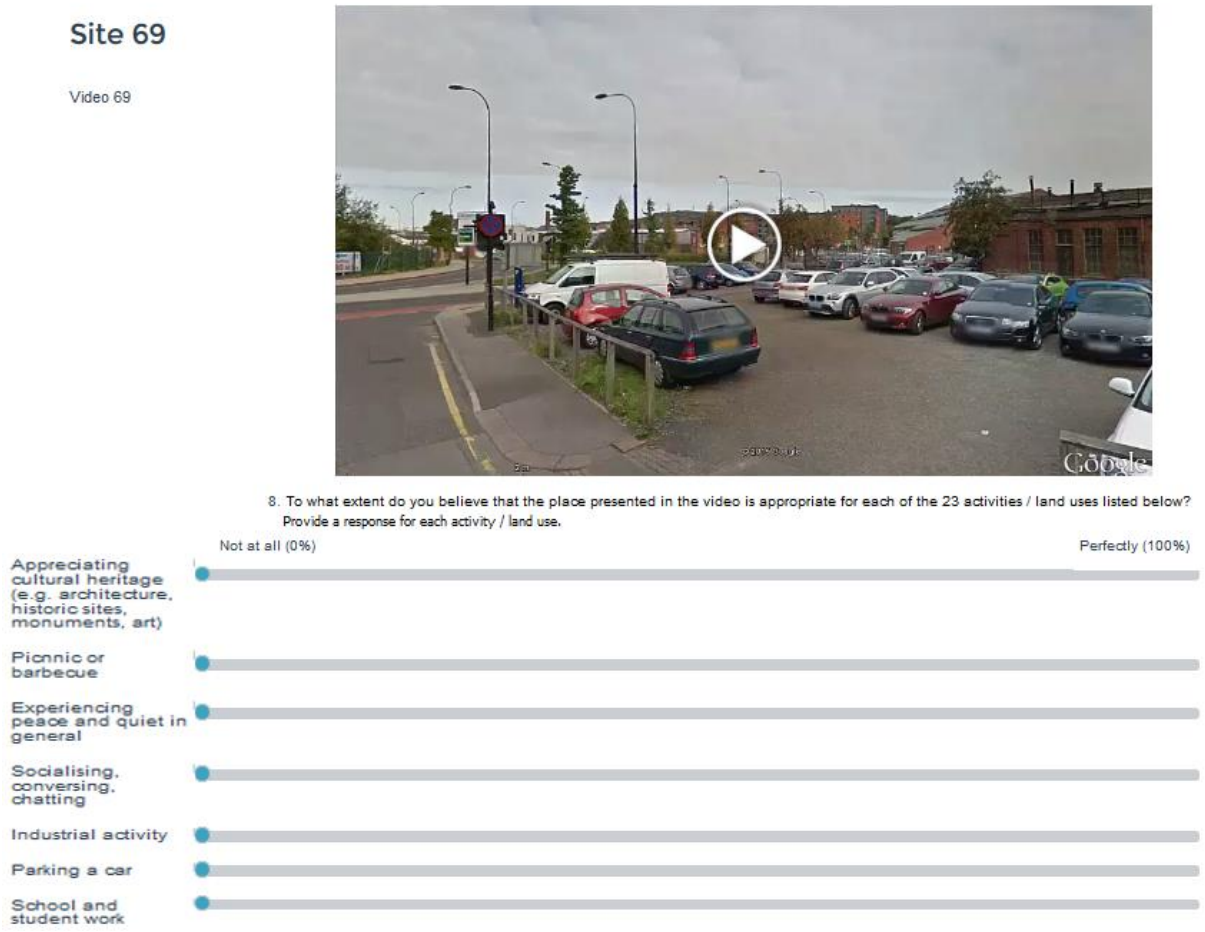

Figure 6. Sample from the questionnaire structure concerning the urban activities assessment

*3.2 Clustering of sound sources profiles and urban activities profiles*

For the purpose of this study, a cluster analysis was performed on the individual responses using the Ward method. This method is particularly useful when the ideal number of groups to form is not known and needs to be estimated as an output variable. Such a method discriminates attributes based only on their distance from their centroids. In this analysis, the agglomerative hierarchical clustering procedure is applied to the 25 spots. Firstly, the attributes related to the sound sources were used as variables. The algorithm merges two groups at each step, until all elements end up in a single group. The method minimizes the sum of squared distances between the points and the centroids of their respective groups, summed over the resulting groups. The same clustering process was applied considering the urban activities. For both cases, the interpretation of the agglomeration schedule table from the hierarchical analysis (not shown in the paper), suggested that the use of three clusters would be suitable to describe relevant sound sources and urban activities profiles (Can and Gauvreau, 2015). The aim of this process was to identify plausible profiles of sound sources types as well as urban activities' profiles and define the cluster membership to those for the 25 selected spots.

Once the optimal number of clusters was defined, the K-means clustering algorithm was used in order to identify the cluster centres. Regarding the sound sources as presented in Table 2, spots which belong to Cluster 1 are typical of more natural sounds and a balanced combination between traffic and construction. The presence of anthropic sources in these sites is limited mainly due to time variations over the day. Spots which belong in Cluster 2 are highly dominated by traffic and occasional construction sources with a very low presence of people and natural sounds. Finally the presence of people and traffic is highly evident and equally balanced in Cluster 3 with a low contribution of natural or construction sounds.

Table 2. Cluster centers using K-means clustering method

| | **Clusters** | | |
|---|---|---|---|
| **Sources** | **1** | **2** | **3** |
| Traffic | 25.3 | 81.9 | 47.6 |
| People | 11.3 | 3.2 | 63.1 |
| Natural sounds | 50.9 | 6.2 | 10.4 |
| Construction | 20.2 | 11.3 | 13.4 |

From the urban activities perspective, spots which belong in Cluster 1 are placed in areas surrounded by greenery or open spaces as it can be seen in the sample pictures of Figure 7a. These places are primarily suitable for residential purposes, outdoor activities, relaxation, socialising and nature appreciation. To a lesser extent they can also be considered appropriate for educational activities, however they are inappropriate for commercial and industrial amenities or offices.

Spots in Cluster 2 as shown in Figure 7b are mainly appropriate for commercial activities involving shops, restaurants or cafes. They are usually squares; pedestrian or small commercial streets with an active street life where people can spend time shopping, chatting and socializing. Working spaces such as offices are less appropriate there as well as residential and educational facilities. Finally natural green elements and transport have a secondary role in these places.

Points in Cluster 3 presented in Figure 7c indicate a mixture of uses comprising of residential, educational, parking and office facilities. The presence of transportation infrastructure is also obvious in these places combined with small industrial facilities. Overall, commercial and educational services are not suitable there, neither outdoor nor social activities.

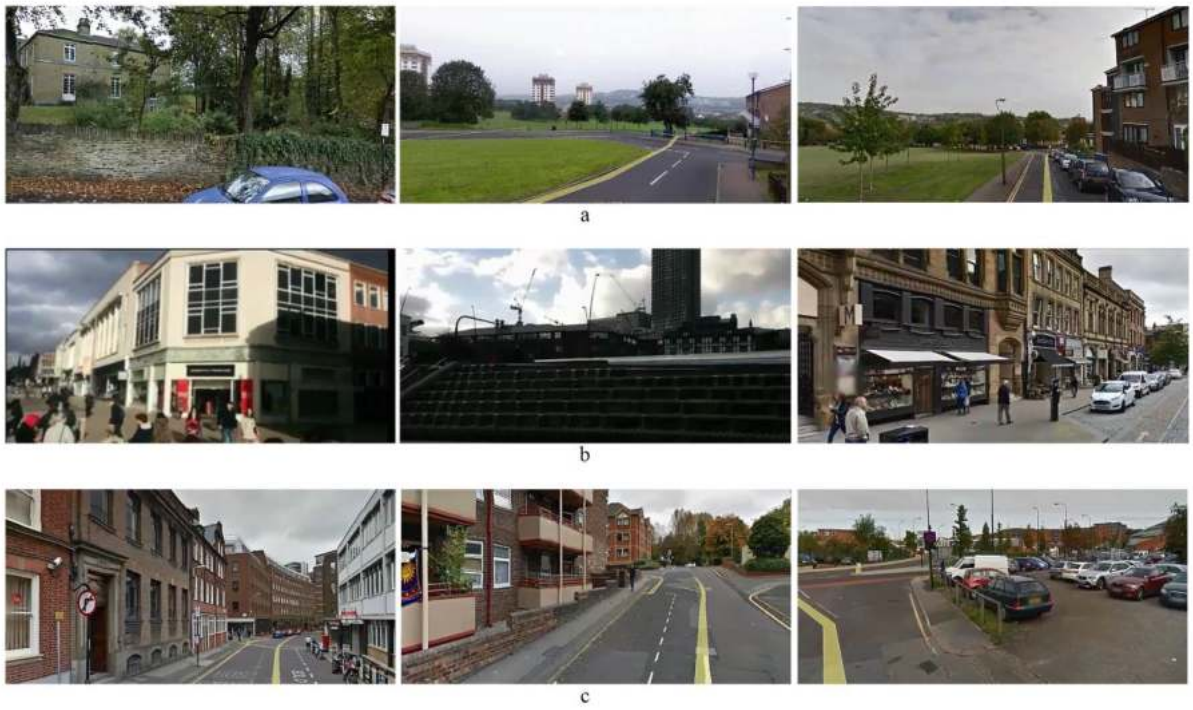

Figure 7. Activity profiles: (a) Cluster 1: Residential areas, (b) Cluster 2: Commercial areas, (c) Cluster 3: Mixed land use

*3.3 Relationship between soundscape and urban context*

A chi-square test of independence was performed to examine the relation between sound sources profiles' membership and urban activities profiles' membership as presented in Figure 8. Results proved that the sound sources profiles were not equally distributed (random) in the activity profiles, $\chi^2$ (4, N = 25) = 11.389, $p$ = 0.023. Detailed results presented in Table 3 denote that the expected frequencies of all sound sources were either higher or lower than the expected ones with a maximum variation of 3.1 in absolute values between the traffic sounds and the mixed class of urban activities. On the contrary, the lowest variation (0.4) was detected between the human sounds and the residential profile.

A comparative analysis of the videos which belong in each cluster revealed that the majority of the places belong to the expected sound profiles. For example residential areas are equally distributed between the natural and the human sound profiles. Mixed activity areas, which include residencies, offices, education and parking spaces; are split among the sound profiles where traffic sounds prevail, while natural or human sounds are present to a smaller extent. Finally, all the places with commercial activities are related to human sounds; denoting an active street life during the recording period. However there were also other places where there was a disparity between the expected and the actual

sound classification. In two cases there were activities which were combined with natural sounds, while they were expected to be combined more with traffic. Another example is the prevalence of human sounds in places which were also expected to be combined with traffic such as mixed residential and office spots.

Table 3. Cross tabulation of sound sources profiles and urban activities profiles

| | | | **Urban Activities Profiles** | | | |
|---|---|---|---|---|---|---|

## 4. Conclusions

The aim of this paper was initially to describe a methodology for mapping different kinds of sources and visualise their spatial distribution in the study area. From the results it was possible to detect the peaks and lows of each sound source and have a visual representation of the source variability. In spite of the fact that the methodology which was followed can be used only for short time representations; the average of morning and afternoon values provides more robust results for the study area.

Secondly an attempt to correlate sound sources and urban activities was investigated. According to the results the correlation between the sound sources profiles and the urban activities was statistically significant and not random. All the activities corresponded with the expected sound profiles with some exceptions. This happened either because of the time variation in the soundscape during the day or due to the absence of human sources in both recording periods (morning, afternoon). Furthermore, a positive effect in urban design can occur from the correlation between sound sources and activities. Since it is usually difficult to change the land use character of a place; targeted actions towards the modification of one or more sources – such as traffic – can improve the soundscape of a place and change the balance of the perceived sounds. Consequently a defined urban context can be improved according to the balanced combination between the character of the place and the proportion of the audible sound sources.

To conclude, soundscape mapping as a tool should be considered together with the landscape and urban design at a certain stage. As the management of the urban environment is not just a land use process, but also a human-related process, an interdisciplinary approach has to be applied, combining the land use policy with landscape design and human perception.

## 5. Acknowledgments

The research leading to these results has received funding from the People Programme (Marie Curie Actions) of the European Union's Seventh Framework Programme FP7/2007-2013 under REA grant agreement n° 290110, SONORUS "Urban Sound Planner". The last author received funding within the Sheffield Undergraduate Research Experience (SURE) scheme 2014. The study was conducted while the third author was a Newton International Fellow at School of Architecture, University of Sheffield, sponsored jointly by the Royal Society and British Academy. The authors are also grateful to all the participants who contributed with their responses to the audio-visual experiment as well as to Karlo Filipan and Bert De Coencel who helped in the audio files processing.

# Spatial Requirements on University Sites of the 1960s and 1970s

Dipl.-Ing. Ilka Mecklenbrauck
Department of Urban Design | Faculty of Spatial Planning | TU Dortmund
ilka.mecklenbrauck@tu-dortmund.de

Keywords: Knowledge transfer, Campus Universities, Innovation

*There is consensus in regional economic literature that urban structures are stimulating innovations by knowledge transfer. Creating knowledge is no longer exclusively generated by scientists but produced by combining practitioners, scientists, creatives and highly qualified manpower. Knowledge, particularly research and science knowledge, is available inside and outside the 'laboratory' and is created in different locations and conditions.*

*Universities are grave components of cities relating to innovation, regional and global knowledge transfer and by responding to society shifts. Assuming that knowledge society has specific demands on space and urban structures, I argue that knowledge society causes spatial demands on university sites as well.*

*The research project considers a special type of universities – the large-scaled campus universities, founded in the 1960s and 1970s outside the city centres. Challenges and measures for advancing the sites rise on different scales of urban design: constructional, spatial and strategic. Based on own research the speech gives answers on different levels:*

- *How do spatial conditions influence the inter-relation of university and society in context of innovation processes?*
- *According to social dynamics, university sites have changed under spatial and architectural aspects. Especially the campus universities of the 1960s/1970s do not meet the spatial demands of today's knowledge society. Which measures of urban design help to stimulate interaction between 'creatives' to create knowledge and innovation?*
- *Regarding the local and regional policy, how can different stakeholders be involved in these processes to combine the interests and goals?*

## 1. Introduction – Cause and Focus

Universities as parts of cities and regions are of vital importance to face the structural change from industrial society to knowledge society. As locations of informational and social exchange processes universities contribute the alliance of knowledge intensive players and institutions with their regional and local conditions.

In urban and spatial research the role of universities within regional and urban context and their importance as attractive locations for working, culture, living and life for employees of knowledge-intensive branches are broadly investigated (Florida, 2005; Matthiesen, 2009). In contrast the structural and spatial impact of universities, their impact on the urban fabric as well as the (spatial) requirements the knowledge society has on university sites are not yet deeply explored. An academic void in current spatial and regional research is raising the question of the importance of the structural and spatial character of university sites and the character's impact on the attractiveness in context of knowledge-society.

This research project presents a part of the findings of a PhD research, which dealt with a special type

of universities: Universities which were founded as new universities in the western part of Germany in the 1960s and 1970s. The research acts on the assumption, that universities and their spatial conditions and surroundings – each location offers specific circumstances and needs – do play a leading role for facing the structural change from industrial society to knowledge society. The focus of research is set on the structural and spatial components of university sites. In principal the sites are faced with the same challenges, but depending on the specific type of site – different dates of origin offer a different pattern and integration into the urban fabric as well as varying types of uses and spaces –, different measures, implications and strategies have to be implemented individually.

One of the main targets of the research was to find principles for the conceptual and strategic development of the universities of the 1960s and 1970s. The explanation of structural and spatial features within university sites and their impact on the urban fabric are the main value proposition.

## 2. Theoretical Background

2.1 *Knowledge Society – basics and spatial demands*

Although the concept of knowledge society is discussed differentiated and controversial, it is more than a buzz-phrase (Wiesner/Wolter, 2005 p. 34). It is consensus, that society is changing from an informational-based to a knowledge-based society, but different positions are assuming whether this change is already accomplished or still processing.

Within the knowledge society theoretical or research knowledge is a central, dominating factor regarding not only economical growth and production, but moreover it is influencing social behaviour and public life (Wiesner/Wolter, 2005, p. 35). Research and knowledge are transformed to production factors, universities are economic location factors and knowledge is the trading good which can be „sold“ (Elm, 2002, p. 17). Based on the complex attributes a multidimensional reflection of the knowledge society is necessary to understand its economical, technical, historical, social and cultural features (Höhne, 2003, p. 62). Global availability of knowledge, permanent dynamic and diversification of knowledge production, transdiciplinary, the influence on different features and the concluding demand of “lifelong learning” are of most importance (Wiesner/Wolter, 2005, pp. 36–37).

Within the knowledge society the implicit form of knowledge, intimated connected with persons, is the central value. This tacit knowledge is created through exchange. For this reason space is gaining importance to create, advance and transfer the knowledge (‘learning by doing’; interaction). Boarderlines between science and society are fading and getting more permeable (Nowotny, 2006, p. 27). Characterizing knowledge society, three main attributes can be summarized:

- *Human capital* in combination with its knowledge is an important resource in 21st century, as factor of production and as immaterial economical and tradable good or service.
- The distinguishing mark of this form of knowledge production is that creating knowledge is no longer done by scientists exclusively. It comes into existence through combining practitioners, scientists, creatives and highly qualified manpower. In this context highly qualified and creative people and their requirements are the main driver in the environment of innovation competition and for the economical power of cities and regions which are competing in acquiring the „smartest heads“. *Space* in which highly qualified and creative people are meeting is increasing in importance. Knowledge, particularly research and science knowledge, is available in and outside the ‘laboratory’, that means that the context of knowledge and its practice and implementation is enlarging and it is used by experts and laypersons. Knowledge is expanding and is produced in different locations and conditions.

- A City, or *urban structures* in general, as interaction platform for knowledge owners and knowledge environment is getting more and more attention to develop knowledge networks for science and economy. Of course knowledge owners can work everywhere in terms of globalization, but this fact again increases competition of cities to gain them as their citizens. Thus society is addressee as well as producer and developer (Nowotny, 2006, pp. 33-34).

Analogous to the meanwhile corrected misunderstanding of informational society discus, knowledge is ubiquitary available and the meaning of spatial and context specific physical or cognitive distances is decreasing or leading to the "death of distance" (Cairncross, 1997), due to availability and usage of new technologies, space is gaining importance and urban accommodations are the baselines for current society. Castells emphasized in 1996 that the relevance of space is increasing especially in cities and moreover in metropolitan areas (Krücken, 2006, p. 60). Therefore the transformation from information to knowledge is a complex and interactive process, which needs local space and face-to-face context of knowledge-innovators. The combination and transfer of diversified knowledge relies on locations where social relationships between knowledge-keepers are necessary for emerging learning and knowledge processes (Dörhöfer, 2010, p. 107). "Although information technology does allow for a greater flexibility in terms of location, particularly for some office functions, it is also resulting in new urban concentrations for face-to-face activity. People need human contact and the city is the place for that, even if technology allows us to do otherwise if we choose" (Ward Thompson, 2002, p. 68). A city, or urban structures and functions in general, provides innovations and networks, knowledge is evolved from (Kunzmann, 2004; Etzkowitz/Klofsten, 2005; Matthiesen, 2009). In context to knowledge society cities are acting as hubs and production locations of knowledge. They provide privileged locations for knowledge transfer, knowledge generation and knowledge exchange. Current urban and regional studies identify these types of locations as "Knowledge-Cities", "Cities of Knowledge" or "knowledge-based cities" (Matthiesen, 2004, p. 11; Matthiesen/Mahnken, 2009, p. 16; Kunzmann, 2004, p. 29). Based on their agglomeration advantages cities have the possibility to enforce a system of spatial and cognitive interaction between different actors and institutions of the knowledge society. Therefore cities force the exchange of tacit knowledge (Amin/Cohendet, 2004; Boschma, 2005; Matthiesen, 2009).

Universities are grave components of cities relating to innovation, regional and global knowledge transfer and in responding social shifts. The innovation effect of universities is undisputed. Within this context universities are a landmark and a central position for demographical and structural development of cities and inner-city accommodations due to their contribution as incubators of a knowledge-based city development. Of special interest is the direct impact of universities on their spatial surroundings and urban fabric as well as on social, economical and cultural sectors. The criteria for integration and linking university sites, the spatial surroundings are the main tasks in this context. It can be assumed that universities are spending a major contribution regarding the development of cities and regions as 'sticky knowledge places' for knowledge-intensive actors and institutions. They are important incubators for the knowledge-based formation, because "in a healthy knowledge society the university becomes the city, and the city becomes the university" (Corneil/Parsons, 2007: 115).

*2.2 The Role of Universities*

Universities today are global acting institutions, but have deep roots to the local layer. The university can be seen as an important building block of the city, especially the European city. Universities and their spatial context have always reflected social, political and economic conditions (Rüegg, 1993, 1996, 2004, 2010).

The expansion of knowledge during the last 4 decades, especially in the area of higher academic education (Martin Trow, 1974, called it the "shift from elite to mass education"), created new tasks and a different comprehension of the institution 'university'. In knowledge society with theoretical knowledge as a strong baseline universities and research institutes are axial institutes – they are schools of knowledge society (Mittelstraß, 2002, p. 67).

Universities keep their status as research locations by generating new knowledge, especially advanced research as well as application oriented knowledge. They are enlarging their position as "think tanks" and the ability of identifying relevant knowledge as well as absorption and distribution the according knowledge to students, scientists and free economy. In summarize, universities act on different levels:

- accumulation of knowledge
- creation of knowledge
- distribution of knowledge
- commercialization of knowledge
- sustainability of knowledge (Schneidewind, 2009, 12)

Besides these tasks universities are faced with other challenges, which not only deal with their core businesses. Since 1999 the Bologna-Process is the most intensive change in teaching and research European universities have to face. On the one hand universities and research institutes should act global and be cross-linked for gaining best output in research and teaching, on the other hand they should act entrepreneurial and compete in international rankings and ratings. Today's universities are "diversified, expanded, globalised, 'marketised', 'technologised', neo-liberalised and potentially privatised" (Morley, 2012, 27). The challenges are very diverse, as figure 1 shows.

To maintain university competences, which were traditionally developed, and to create new competences, new organisational structures must be realized internally but as well according to spatial requirements. Transdisciplinary, project studies, practical use of theories, their transformation into "real life" or life-long learning need new or different spatial conditions (Hubig, 2002, pp. 46-47).

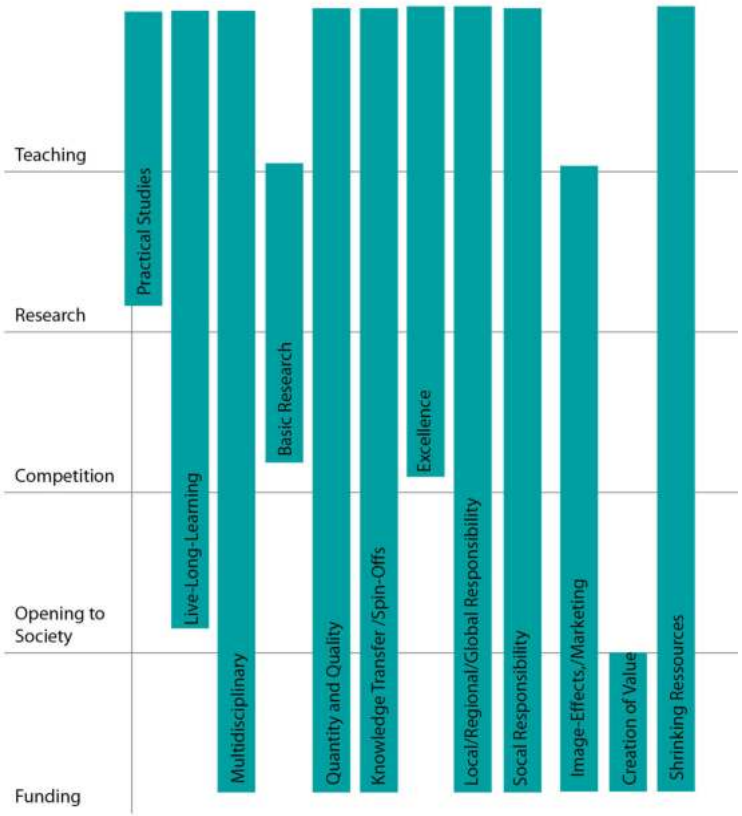

Figure 1: Challenges for Universities

As described before, there is a close cause-effect-relationship between the discussion about the knowledge society and the spatial level of the 'city'. Urban structures with their properties (density, utilisation, cultural and social structures) are particularly suitable for generating and distribution knowledge. It arrives at the conclusion that 'urbanity' in context of knowledge-society is gaining more importance. Urbanity offers a structure, knowledge can be developed from in the most effective way. Knowledge society requires certain urban parameters. Looking at universities as institutionalized knowledge economy for a city, the question of spatial circumstances and how structural and spatial needs can be covered is arising. According to these manifold tasks there is no regional demand for pure knowledge location: Diversity, communication and transfer are the main focus, but without loosing the objective of education and science:

- Functional mixing of university functions and peripheral utilization (spare time, living, working)
- Spatial hierarchies
- Identifying architecture
- Social concentration and interaction
- Access, interface to cities
- Consideration of complex requirements of internal and external users

Assumed that knowledge society has specific demands on space and urban structures (Perry, 2008; Benneworth/Charles/Madanipour, 2010), the assumption is that knowledge society causes spatial demands on university sites. In this context it is the 'Third Role' of universities, which has to be regarded in urban and regional planning. In concepts for developing university sites 'urbanity' has a leading role, not only because of measures regarding the site itself, but to combine the site with its spatial and functional surroundings. These projects and current developments are often associated with terms like knowledge economy, the requirements of the knowledge society and the knowledge-based designing and development of cities and urban structures. These terms constitute the strategies of universities and cities and their marketing. Not only in cities, in which the universities are deep-rooted, but also in small cities, which use colleges or universities – often as new founding or settlements – for establishing a profile in the regional, national or international competition.

The question of structural and spatial development and designing of university sites is getting more important in current urban planning discourses. Urban design concepts, development frameworks or campus plans are evolved, which explain the function, scale, siting and cost of new developments and the improvement of existing facilities to produce an academic setting that is both functional and spatial. From an urban planning point of view different aspects are in the focus of the research, especially regarding questions of urbanisation and linking the sites with the urban fabric. Christiaanse defines, that the discussion about attractiveness of the interdependency of university sites and the urban pattern need a specific design and handling of the spatial conditions, to break up boarders and open the reputed 'gated community' of the campus (Höger/Christiaanse, 2007, p. 29). Similar aspects should be taken into account during the planning phase of company campus areas. As private projects with influence on the image and attractiveness of cities they symbolize a new configuration of private spaces in the public grid of cities.

Current company and management strategies are forecasting future developments of universities with the campus-principle as a major orientation in planning. Open structures, public spaces and a new social architecture are the core elements for interacting in terms of the knowledge society. Beside the physical level it is the social, intellectual and sustainable structures, which have to be taken into consideration. Baseline of the physical development or their guidelines is the public spaces, the buildings and the infrastructure. But in addition to that the strategic approach is important to combine different stakeholders and their development goals.

## Spatial Focus: Universities of the 1960s and 1970s in Germany

The research project considers with a special type of university sites – the large-scaled campus universities, founded between the 1960s and 1980s, the so called 'reform universities' in Germany. Because of the increasing numbers of students in the 'economical boom era', higher educational space was needed and so it was decided from the government not only to extract existing sites, but developing new ones. Those developments accompanied with a reform of education and organization, which was reflected in the construction and spatial guidelines, the structural and physical appearance, the design-guidelines, the hierarchy of public spaces and the composition of buildings. These new university sites of this time were build as campus-universities outside the city centre and – like Jessen (2003) depicts – do not settle the claims of the current society, which are linked with and open to society and the composition of the city.

The new sites were designed as universities with all the typical faculties. But they should also offer public and social space. That meant a big demand for building space. The areas needed to offer more than 100 ha for all the buildings and spaces which were needed. The sites of this modern construction area followed a typical hierarchy and structure:

- Density is reduced from the inside to the outside
- Core with important functions (library, cafeteria, audimax, administration)
- Crossing axis (functional- and open-space-axis)
- Public infrastructure as boarders
- Surrounding landscape

The sites today are approximately 50 years old – build of concrete and steel, they need to be reconstructed in different topics. The interior, especially laboratories and central uses like canteen kitchen or libraries, need refurbishment. The suburban campus-sites need to be improved on different spatial and functional levels to strengthens their role as activators for economical and spatial innovation (knowledge-clusters, research and technology parks), as Christiaanse and Hoeger illustrate by examples like the Science City ETH Zürich or the Hightech-Campus Berlin-Adlershof (Höger/Christiaanse, 2007).

As the foundations of universities in the 1960s/1970s often were instruments of a 'structural change 1.0', which besides the reform and spread of education was boost by industrial location, the aims of the current 'structural change 2.0' are the qualification and advancement of these university sites and settlements as „knowledge scapes" (Matthiesen, 2009). These advancements often are closely connected with urban and/or regional development concepts, strategic processes and urban governance. The universities of the 1960s/1970s made their cities to 'university headquarters'. Todays concepts have additional ambitions: with structural and spatial measures, their physical and functional linking to urban sorroundings and strategical devices for local and regional policy they are purposed to be developed to 'knowledge-based cities'.

## 3. Hypothesis

For detecting the challenges of the university sites of the 1960s and 1970s, their (spatial) basic conditions are faced with the (spatial) demands of the knowledge society (Figure 2). It is obvious, that most of the spatial conditions are divergent to society's demands.

As a result of the comparison of the conditions of the university sites with the demands of the knowledge society, the hypothesis for the empirical studies can be drawn: *The university sites of the 1960s and 1970s in Germany do not correspond to the demands of today's knowledge-society*.

If we think of the requirements of the knowledge society spatial conditions need to be improved or reformed, and of course terms like live-long-learning need specified conditions. In summery, the starting position of the large-scaled sites offers a lot of potential for the needs of the knowledge-society. The challenge is first the existing gap between the city and the campus, on the other hand the retention of the typical modern structure and details. Challenges and measures for advancing the sites rise on different levels and scales: constructional (micro-level), spatial (meso-level), strategic (macro-level).

| LEVEL | | DEMANDS OF THE KNOWLEDGE-SOCIETY | | CONDITIONS OF THE UNIVERSITY SITES |
|---|---|---|---|---|
| | | Density | = | Density |
| | | differentiated by its typology | \|\| | concentrated |
| | | Human Scale | \|\| | Functional Scale |

Figure 2: Comparison of Demands and Spatial Conditions

## 4. Methodology: 3 Case-Studies

The hypothesis and the findings of the theoretical comparison of the conditions and demands are surveyed by the analysis of three case studies. It was asked, which spatial and strategic elements exist at university sites of the 1960s and 1970s. For understanding today's conditions the history and the development of the sites must be analyzed. Besides the finding for each case-study a main question for the empirical work is, if the findings can be compared or generalized, or if each site has individual conditions.

The Ruhr-University of Bochum (1962), the University of Bielefeld (1969) and the University of Siegen (1972) acted as case studies for the empirical work. All universities were founded in the 1960s/1970s in the federal state of North Rhine Westphalia, in the western part of Germany.

For the analysis of the case studies different methods were used, according to the different approaches on spatial and strategic layers and levels identified in the theoretical framework (Figure 3). The *study of historic literature* and documents gives information about the foundation of the sites and the social and political backgrounds in the 1960s and 1970s, by which guidelines of design and architecture were influenced. The *enquiry of current concepts* for the development of the sites gives information about the strategies of a knowledge-based development.

For the empirical research *interviews with stakeholders* were fundamental. The guided interviews with a total of 14 stakeholders gave important information about the history of the sites, their future development and, according to the professions and responsibilities of the stakeholders, interesting and different views on tasks of development and challenges. For every case study at least one stakeholder belongs to the municipality/planning department, to the management/administration of the university and to the "Bau- und Liegenschaftsbetrieb NRW", the agency, which is responsible for management and operating of the university's sites and buildings.

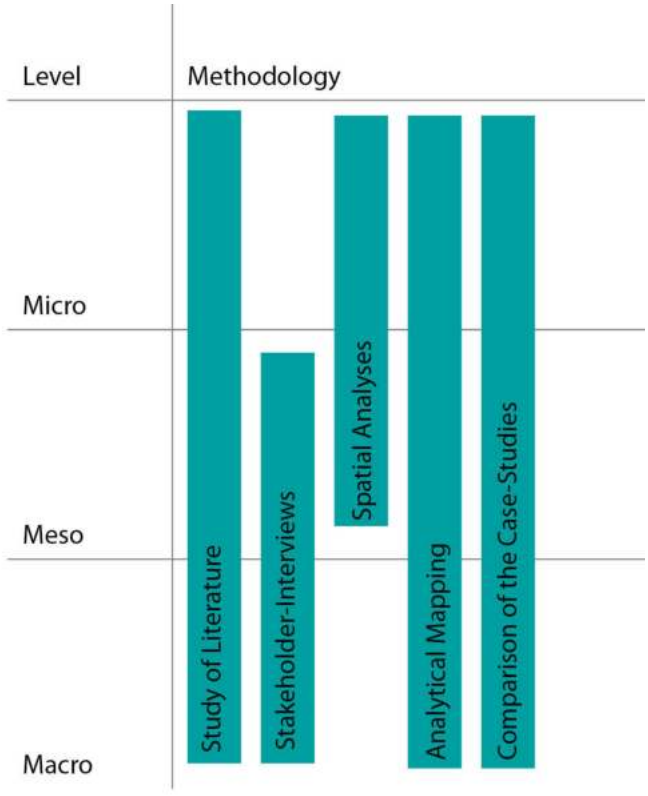

Figure 3: Research Methods

Besides the interviews, *spatial analyses* were the central method for finding out principles on the macro-, meso- and micro-level of the universities. The main characteristics of the spaces were visualized in maps (analytical mapping) of different spatial and thematic layers. The findings of the spatial analyses, combined with the information of the stakeholder-interviews, gave a well-grounded characterization of the different sites, their abilities and challenges on following levels:

- Morphology and Building Characteristics
- Functional Space
- Social Space
- Urban Pattern and Intersections
- Atmosphere
- Strategic Level

Exemplary on the functional level the functions and their interaction were investigated. As the analysing map of the case-study of the Ruhr-University of Bochum shows (Figure 4) the functions are mostly separated in a main part of 'teaching, learning and research', which is supplemented by the main axis with central functions like the library or the Auditorium maximum. Corresponding to the separation of the functions the social spaces of the sites in total are different as well (Figure 5). The character of the social space follows the density and the types of functions. In the central axis there is a high social density. Students and researchers meet here, get in communication and use the space for recreation. The spaces between the buildings do not work as meeting places very well, because people just go here to reach their offices or lecture halls.

In a last analytical step the findings of the three case studies were reflected and compared. The aim was to find out, if the particular findings show commonalities and regularities. This last step sets the ground for the central findings and the conceptual work of the project.

Figure 4: Functional Space, Case-Study Ruhr-University of Bochum

## 5. Findings and Conclusions

As a result of the comparison of the central empirical findings different fields of action can be identified. These fields can be found on mainly four levels:

- Functional Space
- Social Space
- Urban Pattern and Intersections
- Strategic Level

It is not imperative to develop kinds of 'patent remedy' for acting in these levels, but options and restrictions which offer possibilities for improving the sites in terms of the requirements of the knowledge-society. The empirical work has shown, that – besides lot of differences – similarities and spatial principals can be found.

The sites are separated from their surroundings and the urban patterns by their dense and – in some cases – brutal morphology and by their mono-functional character as well. The *functional spaces* concentrate on learning and research, but do not open the sites for other groups than members of the university. The knowledge-society asks for different and urban structures, with mixed uses and spaces for communication. The university sites of the 1960s and 1970s do not offer these needs. Current planning strategies focus on opening the sites by mixing function and making the sites attractive for other users, for example by cultural events or scientific programmes for new audiences.

Figure 5: Social Space, Case-Study Ruhr-University of Bochum

Corresponding to the functional spaces the *social spaces* are characterised. Although it was a requirement in the date of origin to create different spaces for meeting and communication, the spaces today do not correspond with the demand of the knowledge society. First the interdependence with the functional space asks for more public and mixed-uses, secondly the design of the spaces need to be improved. Often the original materials of the 1960s and 1970s today are in a bad condition. Furthermore today's society asks for smaller dimensions of public spaces than the sites do offer.

The social spaces do not invite the public – so it can be summarized that the spaces are not really public spaces. In the consequence they are used primary by students and researches. To connect the public with the university the opening of the sites is necessary – functional, as described, but as well by opening its boarders to the urban fabric. The *urban pattern* often separates the sites from the surrounding, often residential areas. So the functional gap is intensified by a morphological breakout. This problem of different morphologies and intersections cannot only be solved by building smooth transitions, but has to be solved by functional measures as well.

The last level is the *strategic level*, which connects different stakeholders to increase awareness for the importance of universities for the development of the city or/and the region. The 'Leitbild' of the "Knowledge-based Development" describes the process of interaction between municipality, university and society to strengthen common goals. To manage this important aim some municipalities have an own "Knowledge-Manager", who arranges round-tables to bring stakeholders together, or promotes public activities.

Regarding to the hypothesis the empirical findings confirm the statement, that *the university sites of the 1960s and 1970s in Germany do not correspond to the demands of today's knowledge-society*. But – with a closer look to the case-studies the characters of the sites and the different levels – the challenges are not the same in detail. This leads to the conclusion, that for identifying planning strategies and measures for designing, a deep going analysis of the spatial conditions is essential. This analysis has to consider the needs of the users – students, researchers, management – as well as the demands of society to create lively sites and to integrate the peripheral university sites into the urban fabric – where people meet, communicate, research and create new innovations.

Keywords: soundscape design, urban design, urban open space

## Abstract

*How do typological urban factors influence the possibility to experience designed immersive soundscape within the urban landscape? Are there similarities between different projects built during the last 50 years across the world?*

*Soundscapes in situ can be designed by lowering noise levels and adding new sounds. Several urban open spaces (in Paris, Bern, Vienna, Graz, Zadar, Thessaloniki, Sheffield, Cardiff, Dordrecht, Miami Beach, New York City, Phoenix, San Francisco, Chicago, San Louis Potosi, Melbourne, Sydney, Campbelltown, Onohama and Xi'an, for instance) are characterised by designed soundscape elements that have the immersive quality - they offer the 'surround sound' designed experience.*

*This interdisciplinary analysis covers urban (spatial), environmental acoustic (and electroacoustic) and music factors and their mutual influence. Different methods of designing immersive soundscapes within the urban landscape are being analysed using the geospatial data.*

*Methods of achieving designed soundscape span from electroacoustic multichannel soundscape systems to the soundscape articulated through mechanical and acoustic qualities of urban design elements, such as pavement, vegetation or a built structure designed for a specific waterfront promenade, square, plaza or park. Two general spatial principles are recognised: open and enclosed. The former can feature different levels of integration of a soundscape design into an urban design, while the latter tends to isolate certain places from unwanted factors to a certain degree using strong architectural elements.*

*The spaces here analysed were rarely conceived solely to enhance an urban soundscape. Designed immersive soundscapes intertwine contemporary sound art, music and urban design and enrich urban open spaces giving them a new layer of a landmark quality.*

## 1. Introduction

The quality of urban open spaces contributes directly to the quality of city life. Soundscape is a significant factor of the urban ambiance's integral experience and influences the mood and health of the population. However, benefits of the holistic approach to the phenomenon of sound in cities have hitherto not been made distinct enough for such an approach to be widely accepted even though the significance of soundscape has also been recognised in defining the spirit of a place from the aspect of urban planning, landscape architecture and the protection of cultural heritage.

With an aim to contribute to the methodology for the enhancement of soundscape in urban open spaces, this paper explores interdependencies of various urban and acoustic factors influencing the possibility to experience the designed immersive soundscape. Several urban open spaces are being analysed using the geospatial urban data and literary sources. The research is conducted within the framework of the Heritage Urbanism - Urban and Spatial Planning Models for Revival and Enhancement of Cultural Heritage research project, financed by the Croatian Science Foundation.

### 1.1. Designed soundscapes as an enhancement of urban open spaces

With an aim to mitigate the distinctly negative influence of noise on the quality of life, the quantitative approach to soundscape in the form of noise mitigation measures has been included in the systematic planning and design of the built environment. Noise mitigation does not completely encompass the issue of urban open spaces or the attainment of acoustic comfort as a significant requirement for the planning and design of urban open spaces which can be planned solely by including the qualitative approach entailing the consideration of soundscape content. For the aspect of planning and design of the built environment, this entails the following: 1) the suppression of unwanted sounds with landscape and architectural barriers, 2) the valorisation of existing preferable sounds by attentively treating their sources, and 3) the addition of new sources of preferable sounds into the urban open space (Murray Schafer, 1994, p.271). The latter principle, as well as the combined approaches, is in the focus of this research.

This paper therefore aims to contribute to the systematisation of the method of adding new preferable sound sources into urban open spaces from the viewpoint of urban design.

### 1.2. Typology of urban open spaces

The terms *urban open space* and *public space* are not precisely defined and differ from one discourse to another. They overlap in the case of types of squares and streets but tend to differ when it comes to

other spatial-functional types. Urban open spaces are places of social interaction and important factors for creating healthier sociable communities. Urban open space is a term that covers a wide range of public, semi-public and private publicly accessible spatial-functional types (***, 1986, p.2).

Urban open spaces are places accessible to the public, used for collective or individual purposes. They are created using a minimum of two different principles, applicable to the whole built environment - by planned or *ad hoc* interventions (Carr, Francis, Rivlin, Stone, 1992, p.50). This research focuses on holistically designed urban open spaces, where *aural experience* is included in the design.

Their role is ambiguous. Streets, roads and squares have a basic traffic function on which other roles are superposed. Functional social and ritual activities take place in urban open spaces - daily routines and occasional or periodic ceremonies. They are used for private activities such as shopping, recreation, exercise and stay. Sometimes they happen to be the scene of activities that threaten the society on a certain level, such as crimes and protests. There are also distinct types with the principal function of stimulating social life: parks, plazas and children's playgrounds (Carr, Francis, Rivlin, Stone, 1992, pp.11-12). Parks and plazas are among the most frequent types within this research.

According to the synthesis of different authors, the following types of urban open spaces can be distinguished based on the spatial-functional criteria: square, sequence of squares, plaza, pedestrian street, city stairway, portico, urban park, waterfront park, waterfront promenade, public garden, neighbourhood park, memorial, urban forest, forecourt, pocket park, market, children's playground, sports playground and infrastructural spaces.

Within the framework of this research, all of the included urban open spaces are primarily intended for pedestrians. The broadest definition of the term *urban open spaces* was initially used so as to include a large number of examples in the consideration and to reduce the possibility of non-recognition of certain factors.

## 2. Methodological framework

In order to systematise the principles for the enhancement of soundscape in urban open spaces, from the viewpoint of urban design, key urban and acoustic factors must be defined. Key urban and acoustic factors were chosen for this study with an aim to detect the trends in urban soundscape design with implications for the planning practice: the type of urban open space, the type of designed sounds, sound source localisation, the acoustic aspect of elements of urban design and the spatial aspect of elements of soundscape design.

### 2.1. Key urban and acoustic factors

Noise mitigation methods include factors primarily related to legal, economic or city management measures, such as motor traffic speed reduction. On the other hand, this research focuses on factors directly influenced by the urban acoustic design.

Therefore, key urban and acoustic factors refer to the general principle of soundscape enhancement proposed by Bill and Mary Buchen. Their principle of designing a theme sound park includes the use of noise protection and placement of sound sources in the area of acoustic shadow it creates (Buchen, Buchen, 1991, p.8). Its implementation varies regarding the type of urban open space and external factors.

The analysed urban and acoustic factors influence the design of the following principles: 1) adding sound sources (acoustic art installation, electroacoustic system, alarm system, fountain), 2) attenuating

sound sources (engineered acoustical barriers), and 3) achieving acoustic distinctiveness (designed acoustic effect).

For the purpose of this research sound sources are reduced to **the types of positive sound sources** in order to facilitate comparisons by individual sound sources, by which the aural experience of the analysed urban area is generated (similar to those used in the standard questionnaire on the quality of the sound environment - Swedish Soundscape Quality Protocol (Axelsson, Nilsson, Berglund, 2009)): 1) sounds of people (talk, laughter, steps, suitable music, children's plays, bicycles), 2) sounds of nature (wind, rustling of leaves, water, waves, birds), and 3) sounds of designed sources (category added specifically for the needs of this study - musical sounds, art installations, signal sounds). The sound of architecturally designed sources may occur by mechanical, acoustic or electro-acoustic means.

**Sound source localisation** directly influences the immersiveness of the designed soundscape. A soundscape is considered immersive if designed soundscape elements can be experienced simultaneously from two or more directions. Sound sources can be arranged to act as a point, line, field or a complex spatial form. While the first is the most common arrangement of sound sources in urban open spaces, others offer the designed immersive soundscape experience (Oberman, 2015, pp. 130-143). The immersive character of the designed soundscape can positively influence the overall assessment of an urban open space (Oberman, 2015, pp.288-299).

Linear arrangement of sound sources means that, while being in the inner space of the designed soundscape, users are able to experience the added soundscape elements from two different directions. The line may consist of a single physically elongated source or of a number of point sources spatially close enough to be considered a line. Sound propagation from a linear source can be diffused or directed. Orientation is often influenced by the existence of architectural and landscape elements, such as topography or barriers limiting the propagation of sound in one direction and localising its diffusion in the other, or by the possible directivity of speakers (in case of an electro-acoustic system). A linear directional model, for example, is conditioned by the speakers placed alongside the facade of a building (part of the electroacoustic multi-speaker system at the Yarra River Southbank Promenade in Melbourne, for example) or a fountain of an elongated plan which is designed as a waterfall (at the Sheaf Square in Sheffield, for example).

The arrangement of sound sources determining the field within an urban open space means that multiple sound sources are distributed in space in a way that makes the area in which the added soundscape element is being experienced as spatially continuous. The user in the strict space of the designed soundscape can experience the added soundscape elements from at least three different directions.

**Urban design elements** can directly generate different acoustic effects, mitigate noise and define spatial ensembles. Regardless of the level of noise in a particular urban open space, there may or may not exist an architectural barrier designed for noise mitigation.

The optimal space of designed aural experience can be articulated by varying degrees of architectural boundedness relative to the contact area, usually with the goal of a separation from external influences to allow unhindered imaginary aural experience. Designing a pavilion intended for a specific aural experience is the most common way to envelop the inner space of an optimal aural experience.

On the other hand, the inner space of the designed aural experience may not be highlighted by architectural design, but purely acoustically. In that case soundscape becomes the sole means of separation of a certain space by highlighting its part.

Figure 1. (*Left) Sea Organ in Zadar. The space of optimal aural experience is architecturally indicated by steps that descend to the sea, but is not separated from the contact area (Google Street View, photo taken during October 2011)*

Figure 2. *(Right) Echo pavilion in Zagreb. The space of optimal aural experience is defined within the pavilion building (Google Street View, photo taken during August 2011)*

**Pronounced acoustic effect,** significant for experiencing an achieved sonic environment, can be a designed (Echo Pavilion in Zagreb's Maksimir, for example) (Oberman, 2015) or an unintended consequence of architectural and urban interventions (such as Youngstorget in Oslo) (Maag, 2013). This implies an acoustic effect in the strict sense (such as a reverb or a pronounced echo) rather than being understood in the way interpreted by the theory of sound effects whose starting point is that every aural experience can be explained by one or more acoustic effects, i.e. that an aural experience deprived of the acoustic effect is not possible (Augoyard, Torgue, 2011).

## 2.2. Criteria for the selection of analysed urban open spaces

This study includes an overview of urban open spaces from around the world (Regarding the Augoyard's recommendation (Augoyard, 1978) to avoid research on soundscape that does not include the field experience in the first person, this study includes specific urban soundscapes around the world, while referring exclusively to the factors that have been estimated not to be influenced by direct experience). The main criteria for choosing the relevant urban open spaces for the analysis was their acoustical specificity which is documented well enough to allow assessment of key urban and acoustic factors.

The research is based on urban geospatial data provided by the *Google Earth Pro* application which enables an overview of the historical satellite imagery, area measurement, the screening of spatial-functional type of the urban open space, the position of the urban open space in the city, pedestrian accessibility of the urban open space, changes in the urban open space over a certain period of time, the characteristics of the urban structure in the contact area and the recognition of the designed sound sources documented in other literary sources.

## 3. Designed immersive soundscapes within urban open spaces

A total of 25 urban open spaces characterised by the designed immersive soundscape, built in 21 different cities in Europe, the United States of America, Australia, Japan and China, were analysed in relation to key urban and acoustic factors explained in the previous section (Table 1).

The majority of the analysed urban open spaces and/or designed soundscapes implemented within them were built between 1999 and 2011 (the newest public space being the Wilgenwende Dordrecht Park designed by Lola architects in 2009, still unfinished at the time of this research). The oldest analysed designed immersive soundscape within an urban open space was the electroacoustic sound

art installation *Times Square* by sound artist Max Neuhaus, implemented on the Times Square in New York City in 1977. It was built underneath the pedestrian area, with the speakers in the ground plan forming a field (Neuhaus, 2009, p.49).

Table 1. Chronological overview of analysed urban open spaces and key urban and acoustic design factors which influence the immersiveness of the designed soundscape (Oberman, 2015. pp. 322-467)

| **Urban Open Space, Year of the Implemented Soundscape Design** | **Spatial-functional Type** | **Designed Immersive soundscape elements** | **Sound Source Localization Characteristics** | **Boundedness by Urban Design Elements** |
|---|---|---|---|---|
| Times Square, New York City, 1977 | Square | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Open |
| Yacht Road, San Francisco, 1986 | Seafront promenade | Sounds of designed sources (musical sounds - mechanical system) | Lines | Enclosed by pavilion elements |
| Arizona Science Center Plaza, Phoenix, 1986 | Plaza | Sounds of designed sources (musical sounds - mechanical system) | Line | Open |
| *Le Jardin de Bambou* (*Parc de la Villette*), Paris, 1987 | Theme garden within an urban park | Sounds of nature, sounds of designed sources (musical sounds - multi-speaker system) | Lines and Field | Enclosed by garden and pavilion walls |
| Lassallestrasse 1, Vienna, 1992 | Plaza | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Open |
| Yarra River Southbank Promenade, Melbourne, 1992 | Riverside promenade | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Open |
| Forecourts of ANZ Stadium, Sydney, 1999/2000 | Plaza | Sounds of designed sources (musical sounds - multi-speaker system) | Fields | Open |
| Pedestrian bridge *Lorrainestrasse*, Bern, 1999 | Footbridge | Sounds of designed sources (musical sounds - multi-speaker system) | Line | Open |

| | | | | |
|---|---|---|---|---|
| Aquamarine Fukushima, Onahama, 2000 | Seafront promenade | Sounds of nature (amplified by acoustic design) | Line | Open |
| Campbelltown Art Center, Campbelltown, 2001 | Urban park | Sounds of designed sources (musical sounds - mechanical system) | Field | Open |
| Birrarung Marr Park, Melbourne, 2002 | Urban park | Sounds of designed sources (musical sounds) | Field | Open |
| Millenium Stadium River Promenade, Cardiff, 2002 | Riverside promenade | Sounds of designed sources (signal and musical sounds - multi-speaker system) | Line | Partially enclosed by the stadium building |
| Lendkai 1, Graz, 2003 | Plaza | Sounds of designed sources (musical sounds - multi-speaker system) | Line | Partially enclosed by the museum building |
| Millenium Park, Chicago, 2004 | Urban park | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Open |
| *Obala Petra Krešimira IV*, Zadar, 2005 | Seafront promenade | Sounds of nature, sounds of designed sources (musical sounds - mechanical system) | Line | Open |
| Sheaf Square, Sheffield, 2006 | Square | Sounds of nature (designed sound source - water fountain) | Line | Enclosed by the sculptural wall |
| Linz AG Center, Linz, 2006 | Plaza and portico | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Enclosed by the portico |
| William Barak Bridge, Melbourne, 2006 | Footbridge | Sounds of human beings (designed sound source - multi-speaker system) | Field | Open |

| | | | | |
|---|---|---|---|---|
| *Kipos Tou Ichou* (*Nea Paralia*), Thessaloniki, 2008 | Seafront promenade | Sounds of nature | Lines and field | Open |
| *Laberinto de las Cyencias y las Artes*, San Luis Potosi, 2008 | Urban park | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Enclosed by the pavilion walls |
| Forecourt of AAMI Park, Melbourne, 2010 | Plaza | Sounds of human beings (designed sound source - multi-speaker system) | Field | Open |
| Les Erdi Plaza, Melbourne, 2010 | Riverside promenade | Sounds of designed sources (musical sounds - multi-speaker system) | Line | Enclosed by the wall with mounted multi-speaker system |
| Lincoln Park, Miami Beach, 2011 | Urban park | Sounds of designed sources (musical sounds - multi-speaker system) | Field | Open |
| Garden of Labyrinth (Master Gardens Expo 2011), Xi'an, 2011 | Theme garden within a urban park | Sounds of designed sources (musical sounds - mechanical system) | Field | Enclosed by the garden and pavilion walls |
| Wilgenwende Dordrecht Park, Dordrecht, - | Urban park | Sounds of nature (designed sound source - selected treetops) | Field | Enclosed by the artificial topography |

Previous research (Lacey, 2014) on the influence of spatial-functional types on the designed soundscapes pointed out two factors that benefited the public acceptance of the designed soundscape: 1) the transit character of the urban open space, and 2) the non-disruptiveness of the soundscape experience.

The research on multi-speaker electroacoustic systems in Melbourne's urban open spaces, conducted by SIAL Sound Studios (SIAL Sound Studios are a multi-disciplinary research facility at the Royal Melbourne Institute of Technology), indicates that added soundscape elements are better accepted in spaces intended for transit (such as streets, footbridges and underpasses) than in spaces with high social presence (such as squares, plazas or promenades). For instance, the designed immersive soundscape such as the one designed for the Yarra River Southbank Promenade in Melbourne (built in 1992) proved to be an imposition on the existing spatial programs (Lacey, 2014, p.10). On the other hand, the mechanical acoustic installation of the Sea Organ in Zadar (built in 2005), built also in the waterfront (seafront) promenade (*Obala Petra Krešimira IV*), is being highly praised both by the local community and tourists (Jambrošić, Domitrović, Horvat, 2013; Zanki, 2013). The latter is 13 years younger than the former which was decommissioned after some 20 years. This case only speaks for the site specific character of research results within the field of architecture and urbanism.

Urban open spaces offering the non-disruptive advantage are beneficial for the experience of the designed soundscape since it can be experienced as a more traditional piece of art - the passer-by has the opportunity to become the listener of the musical composition (Lacey, 2014, p.11). In that way the urban open space can become an integral part of an art piece. On the other hand, the aforementioned installation *Times Square* was conceived to be experienced within a loud and noisy soundscape and perceived as a work of art mainly by an informed group of individuals (Neuhaus, 2009). Therefore, the boundedness of inner spaces of the designed immersive soundscape is analysed via the enclosed and open principles. The enclosed principle is considered to offer a higher degree of non-disruptiveness on two levels: 1) the urban design element acts as a noise barrier in case of adjacent noise sources, and 2) the urban design element influences the integral perception of the urban open space by emphasising the inner space of the designed soundscape experience in case noise is not an issue.

A small number of analysed projects are urban open spaces dedicated to the experience of the designed soundscape. For example, in *Le jardin de bambou* (designed by Alexander Chemetoff in Parc de la Villette, Paris) water channels were designed along the entrance steps to draw attention to the acoustic experience created by the sound of rippling water with an aim of 'introducing' passers-by to *Le cylindre sonore* pavilion (designed by architect and sound artist Berhard Leitner) dedicated to the acoustic experience. Speakers' locations in the pavilion are highlighted by concrete perforated masks. The whole garden lays *cca.* 3 meters lower than the surrounding surface to acoustically separate passers-by from the soundscape of the rest of the *Parc de la Villette* (Leitner, 1998, p.144-148).

## 4. Conclusion

Without attempting to draw a definite conclusion (due to methodological limitations characteristic for the scientific research within the fields of urbanism and architecture, such as the influence of external factors and specificity of each site) on the influence of typological urban factors on the possibility to experience the designed immersive soundscape, the following trends are visible: 1) the most complex designed soundscapes (which include the principles of adding different types of sound sources and different urban design elements that influence the designed soundscape experience) appear within urban open spaces designed with the goal of experiencing them (typologically it comes to theme parks), 2) all of the analysed sound source patterns can be found in all of the analysed spatial-functional types of urban open spaces, regardless of their inherent shape (which can be linear or field-like), although sound sources forming a field are more common in urban open spaces having the characteristics of a field than in linear ones, and 3) the analysed urban open spaces characterised by the designed soundscape typologically include plazas, squares, urban parks, waterfront promenades and pedestrian routes like footbridges and underpasses.

The most common spatial-functional types of urban open spaces characterised by the designed immersive soundscape are urban parks (32% of the 25 spaces analysed), waterfront promenades (24%) and plazas (20%). Large urban parks are considered to offer the highest degree of non-disruptiveness and are not characterised by high social presence and functional complexity like other analysed urban open spaces. In 3 out of 6 cases, waterfront promenades contain the designed soundscape elements which are inspired and generated by the sea itself. Plazas, being semi-public spaces, are considered to represent the adjacent building as well as the investor, so the designed soundscape has the goal of contributing to their attractiveness.

The spaces here analysed were rarely conceived solely to enhance the urban soundscape. Designed immersive soundscapes intertwine contemporary sound art, music and urban design and enrich the urban open spaces giving them a new layer of a landmark quality.

# BRICOLAGE URBANISM FOR URBAN SOCIAL COHESION

**Alcestis P. Rodi**

Keywords: Bricolage Urbanism, social cohesion, sustainable neighbourhood

## 1. Introduction. The need for urban social cohesion at a 'local' level.

It is expected that 83% of the European population will be living in urban areas by 2050. This prospect brings enormous pressure on European cities that are already facing serious challenges due to financial crisis, globalization, demographic change, increasing flows of migration, disparities among and within cities, inner city decay, urban sprawl, climate change etc. These challenges have a cumulative effect on deepening social exclusion, social polarization and increasing urban violence and spatial segmentation (Urban-Net, 2011; Dhéret, 2015).

For the aforementioned reasons, social cohesion resurfaced in the public sphere and became a foremost need for the contemporary European society, centring on the rights of the individual. Europe has to deal with rapid and radical changes, which upset the mechanisms that have traditionally ensured the maintenance of social bonds. European cities are delegated to play a leading role and tackle the challenge of inclusive growth. They agglomerate all the complexities of social life on a concentrated territory, and they import/export factors of cohesion and fragmentation of their own system on a daily basis. Furthermore, the views of how social fragmentation and cohesion should be addressed vary significantly among groups and people, but also among different types of actors within cities (Urban-Net, 2011). The emergent call for socially cohesive cities is proved by the recent provision that approximately half of the European Regional Development Fund (ERDF) for the period 2014–2020 will be spent in cities, enabling them to design and implement cohesion policies and test new ideas in urban development (European Union, 2014).

In the quest for urban social cohesion macro-structural and local reinforcing processes must interact and "people based" policies need to be complemented by "people and place" ones (Meegan and Mitchell, 2001). For socially cohesive urban futures Urban-Net report (2011) recommends re-orienting current modes (academic and practice) of urban design and planning towards "socio-spatial cohesion" and "environmental sustainability" at multiple scale levels. Developing a common European methodology through an urban social cohesion based approach, the report argues for a shift from the global-metropolitan to the "local" dimension with particular attention to participation and empowerment of inhabitants of neighbourhoods.

The development of urban social cohesion is traditionally perceived as a topic for social-cultural, economical and political experts rather than a consideration requiring multi-scalar spatial design and planning handled by architects, urban designers and planners. As Madanipour (1998) argued, space has a major role in integration or segregation of urban society. It is a manifestation of social relationships and can affect and shape their geometries. Relevant literature already indicates the significance of urban morphology, such as accessible public and private services, availability and quality of infrastructure, physical or ecological barriers, properties condition and environmental quality, etc. (Meegan & Mitchell, 2001; Kleinhaus, 2004; Loukaitou-Sideris 2006; U.N., 2014). Thus, social inclusion or exclusion is a socio-spatial phenomenon.

In this context, we argue that urban morphological aspects related to social cohesion need to be further explored by focusing on the 'local' dimension. Our research explores how urban morphology at the smaller scale, the neighbourhood, contributes to social cohesion policy. With due caution against physical deterministic arguments that social problems can be eliminated by redesigning space, we aim at investigating ways for the promotion of social cohesion within the built environment, on the basis of urban design and planning premises.

Athens' inner city neighbourhood Omonia has been chosen as a case study. Over the past decades the population of the area witnessed large-scale changes and violence due to socio-economic exclusion related mostly to immigration and economic depression. However, its urban fabric cannot adapt in a critical, creative and cohesive manner to these changes due to constraints from preservation, legislation, ownership, FAR reduction/stagnation etc. Through the technique of bricolage, based on relational micro-scale urban interventions, we aim at developing a desirable and sustainable level of urban social cohesion, that would exclude extreme situations such as defensive bonds and fragmenting terror. Subsequently, we propose design actions related to social cohesion criteria, on both public and private space in order for the area to regenerate as a socially cohesive neighbourhood. These actions are intended to be flexible and to enable participation, among others of stakeholders, communities and citizens so that they develop towards a state that is suitable and sustainable.

## 2. Towards socially cohesive inner-city neighbourhoods through urban bricolage.

*2.1. Bricolage Urbanism: A social cohesion approach based on micro-scale urban interventions*

In the pursuit of socially cohesive cities we adopt the concept of Bricolage Urbanism (Rodi, 2015). The notion of bricolage as a way of looking at and producing things was first introduced by Claude Lévi-Strauss in 1962. It offered an alternative vision of creativity to that of Modernism. Rather than a hommage to science, bricolage is described as a creation of meaningful structures out of events. For Rowe and Koetter (1978), the most eloquent expression of bricolage could be found in the city. They rejected "total design," and proposed instead the notion of "collage city" within which a functioning network of pocket utopias can be accommodated.

The unprecedented urbanism of small, spontaneous and collective acts that we nowadays notice in cities, seems to outfox technical expertise and top-down procedures. Public posting of citizens' individual needs and desires on social media becomes a form of public discourse. Current austerity urbanism and social cohesion issues in our cities seem to have contributed towards this phenomenon. Whilst such small-scale interventions are central to the life of cities, yet they remain peripheral in design discourse.

This paper introduces *Bricolage Urbanism* as a process towards socially cohesive urban environments, not just as urban acupuncture. Based on the shared responsibility of all players, *Bricolage Urbanism* focuses on how small-scale neuralgic interventions can have a direct impact on urban morphology and life through a relational, situational and, predominantly, cultural approach. In analogy to Lévi-Strauss's *La Pensée Sauvage*, it intends to propel a discussion about the disciplines of architecture, urban design and urbanism, that will not be sought in citizens' design but in citizens' desires. An objective is to calibrate the nature of small urban acts and to critically appraise the potential trajectories the practice of urban design and urbanism could take in the future. Bricolage urbanism is a planning method and does not replace masterplanning, local planning and other strategic planning tools. But it can enrich, expand, inspire and motivate planning procedures, helping to create a better urban life.

Specific aspects relevant to *Bricolage Urbanism* are (Rodi, 2015):

- Micro vs. Macro interventions. Is the design of urban environment predominately small-scale activity or a bold, large-scale transformative activity? Can small-scale urban changes work in synergy and have a direct impact on urban life? Can they re-adjust easier? Are they less or more vulnerable? How can success of a small intervention be measured?
- Design authorship. Who should design urban interventions? Should they be designed at all? Does urban morphology matter as citizens' participation and empowerment?
- Aesthetics and economics. Do small-scale interventions produce better space than big projects do? In the context of crisis and uncertainty, are small-scale projects more effective and more feasible? Are they more manageable and likely to get done?
- Social cohesion. Can small interventions make a meaningful contribution towards social cohesion? Can small interventions, though ephemeral and low impact, scale up to a broader social return?
- Design Practices. How can design be engaged so as to propose current physical transformations of the built environment? Do small-scale interventions pay less attention to the rulebook and more to the real principles of how we actually do things? Is triggering the design process more important than predetermining its outcome?
- Resilience. How small-scale urban interventions contribute to climate change and other resilience? Are they 'resilient' themselves, that is, easier to fix or undo when they go wrong?

*2.2. Focusing on the 'local' level: neighbourhood social cohesion.*

The research perceives social cohesion as a bottom-up process that focuses on neighbourhood scale. Neighbourhoods provide a useful scale for studying social relations, ties and conflicts in everyday life. One of the reasons why neighbourhoods remain an object of policy interest is the revival of notions, such as 'local community' as means to tackle social exclusion (Forrest & Kearns, 2001). Furthermore, the increasing interest in bottom-up approaches and transition processes as the 'third way' between incrementalism and strict planning, are part of the sustainable development (Grosskurth, 2009).

The quality of social integration at the neighbourhood level is the basis for social cohesion at larger scale, especially in an era when many social relations take place outside neighbourhood communities and virtual social networks seem to be "further eroding the residual bonds of spatial proximity and kinship" (Forrest & Kearns, 2001). According to Moulaert (2010), dynamics of change at the local level, is an integral and vital part of wider urban dynamics and is the pivotal scale through which urban change ought to be understood, although in a multi-scalar way. The local scale can be more "tangible", or a "better" or more "just" and "democratic" level at which to analyse, organize, and imagine change, whilst macro-level solutions are significantly more difficult to find (Moulaert, 2010, Meegan & Mitchell, 2001). The local is a privileged and empirical entry point for understanding the modalities of social cohesion through social innovation, social learning processes, spatial change, new policy initiatives, or collective action (Atkinson, 2007, Rodriguez, 2009, Urban-Net, 2011).

A neighbourhood should not by definition be seen as a "spatially integrated Gemeinschaft", but as a key living space through which people get access to material and social resources. It helps them pass to reach other opportunities and symbolises aspects of the identity of those living there (Meegan & Mitchell, 2001). Thus, four different perspectives on neighbourhoods are identified: neighbourhood as community, as context, as commodity, or as a consumption niche (Forrest & Kearns, 2001).

Socially cohesive but increasingly divided neighbourhoods may coexist in a city. Excessively strong ties within communities or groups in neighbourhoods may cause urban violence related to social, racial or religious conflicts. If there is conflict within or between strongly cohesive neighbourhoods this might impact the macro-cohesion of the city. Thus, social cohesion at the neighbourhood scale is

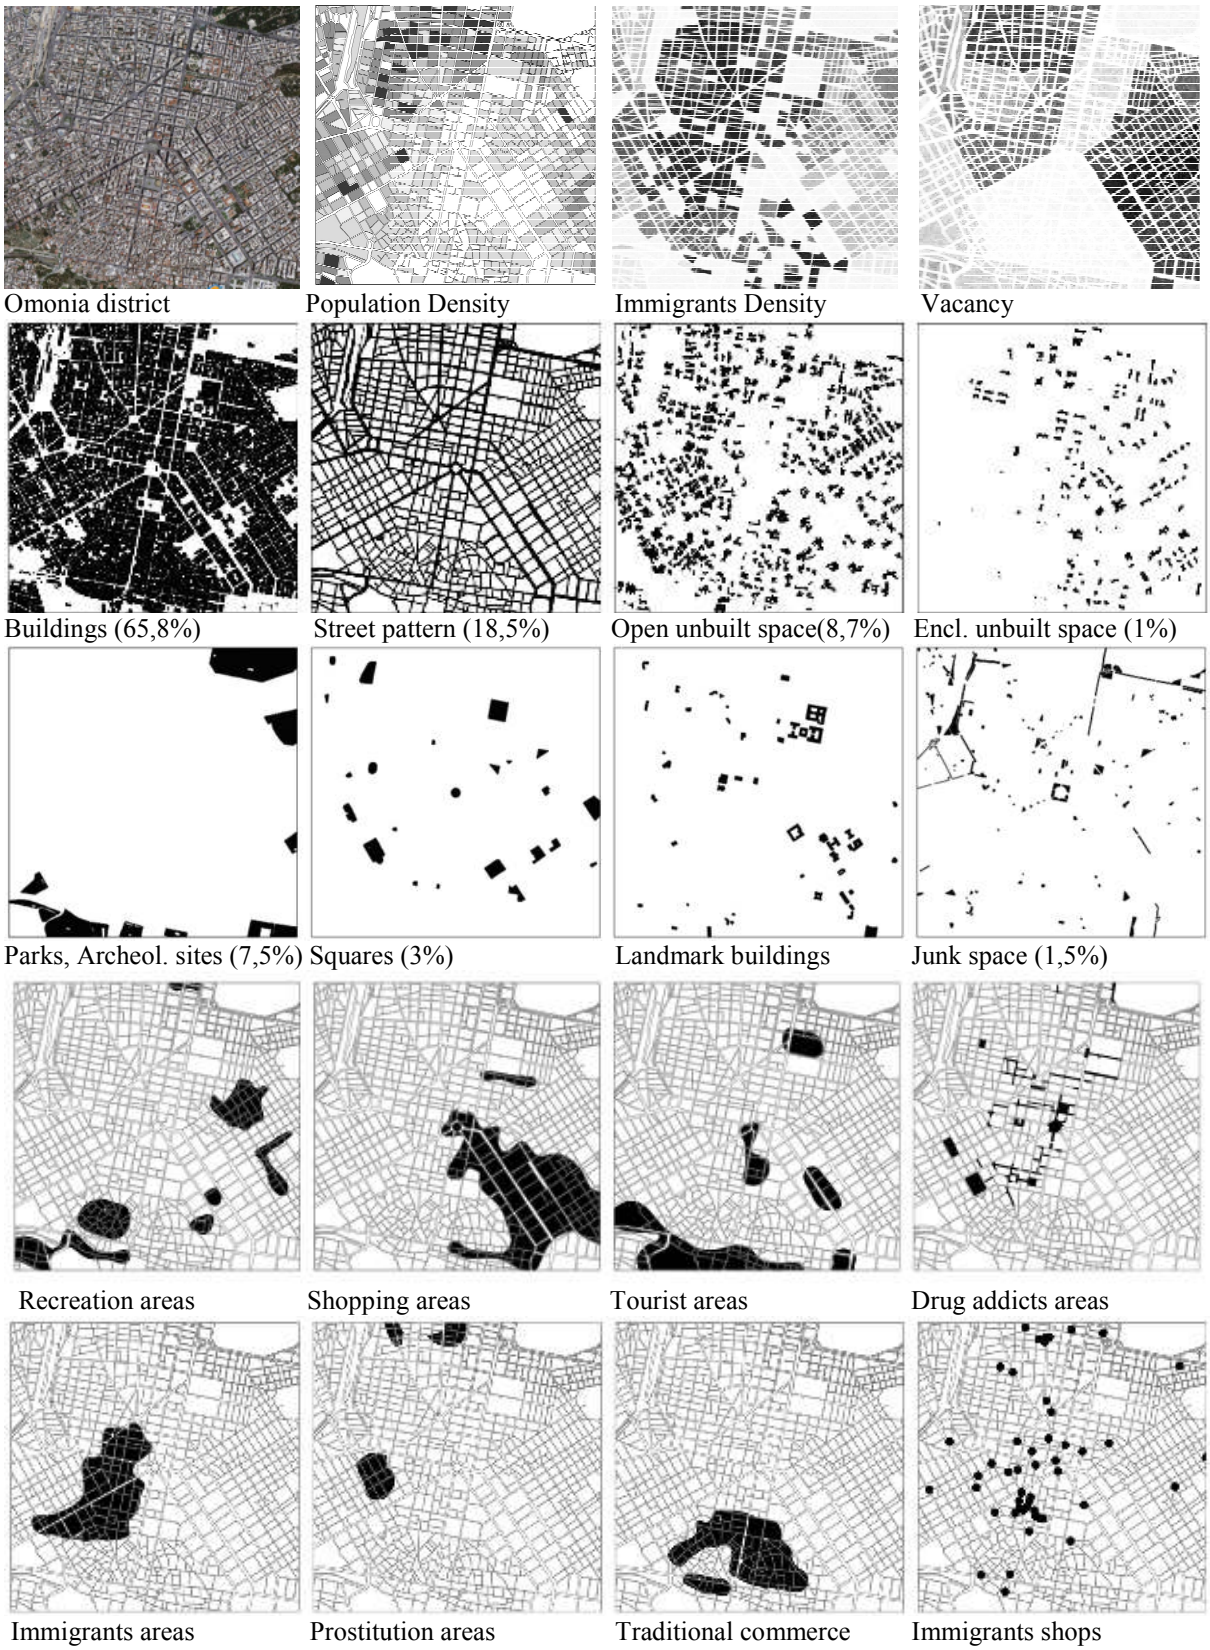

Figure 1. Land uses and activities in Omonia

not unconditionally a good thing and we should aim for a simultaneous, multilevel perspective on it. Forrest and Kearns (2001) state that the less robust and less deep-rooted neighbourhood networks are, the more stable and conflict-free the social order in which they sit may be.

*2.3 Expanding to new grounds and stakeholders of social cohesion.*

**Collective and personal responsibility.** The European model of social cohesion acknowledges the welfare state as the prime guarantor of rights and the public interest. However, urban regeneration and other services formerly provided by public domain have been outsourced. Citizen actions help find solutions and open new horizons in cases where public action is missing. The establishment of new public forums to strengthen those already in place and incorporate concerns for the general interest and for defending the well-being of all, particularly the most disadvantaged, in private action, is essential for asserting the values of social cohesion (Council of Europe, 2005).

Following the aforementioned arguments, the research expands the concept of 'responsibility' for social cohesion from stakeholders as the state and citizen organizations to individual citizens and owners. Doing that new, not publicly owned, spaces in urban fabric, are emerged as a potential social cohesion generators that belong to private and common ownership.

**Public and private space.** Importance of public space as befitting tool for social cohesion has already been established. Our study further expands this quest to the privately owned territory of city blocks. It explores the imperative to further elaborate on the privately owned space of high density urban centres that lack public space in order to achieve social cohesion. We do not withdraw from public realm. We look for opportunities that exist with the private and common ownership instead. Design interventions into the public, semi-public, semi-private and private realm are explored. Emphasis is given on both the fragmented common areas where responsibility is fuzzy letting space underused, as well as built up space, the existing apartment buildings.

*2.4 Social cohesion related criteria*

As Bollens (2006) argues, urban designers and planners should be able to work with areas such as public spaces, neighbourhoods, historic areas, housing, and other urban public facilities to promote good 'inter-group' life. He proposes (a) an urban form that is flexible and porous enough to allow for integration in urban processes (b) city planning that engage marginal groups by encouraging and facilitating participation during the planning process (c) cities that allocate sufficient opportunity for neighbourhoods to present their cultural and historical identity within urban neighbourhood and (d) a sense of 'public-ness' in public space, necessary to respond to all social and ethnic groups.

In the pursuit of socially cohesive urban environments, a high degree of **connectivity** is considered an important cross-cutting strategy. Madanipour (WUF7, 2014) suggests connection 'across' and 'within' space by loosening spatial barriers. Cooper, Fone and Chiaradia (2014) conclude in their research on which factors in the built environment facilitate, or impede, the development of social bonds, that physical connectivity or severance has a significant effect on social cohesion. Street patterns, alternative routes, numbers of intersections and dead-end streets, entrances to the area and route options are some of the urban features that impact connectivity.

A high degree of **accessibility** is also required. Neighbourhood street patterns, networks and open spaces should be designed so as to provide access using various modes of mobility. Accessibility may also refer to a neighbourhood's proximity to services and infrastructures.

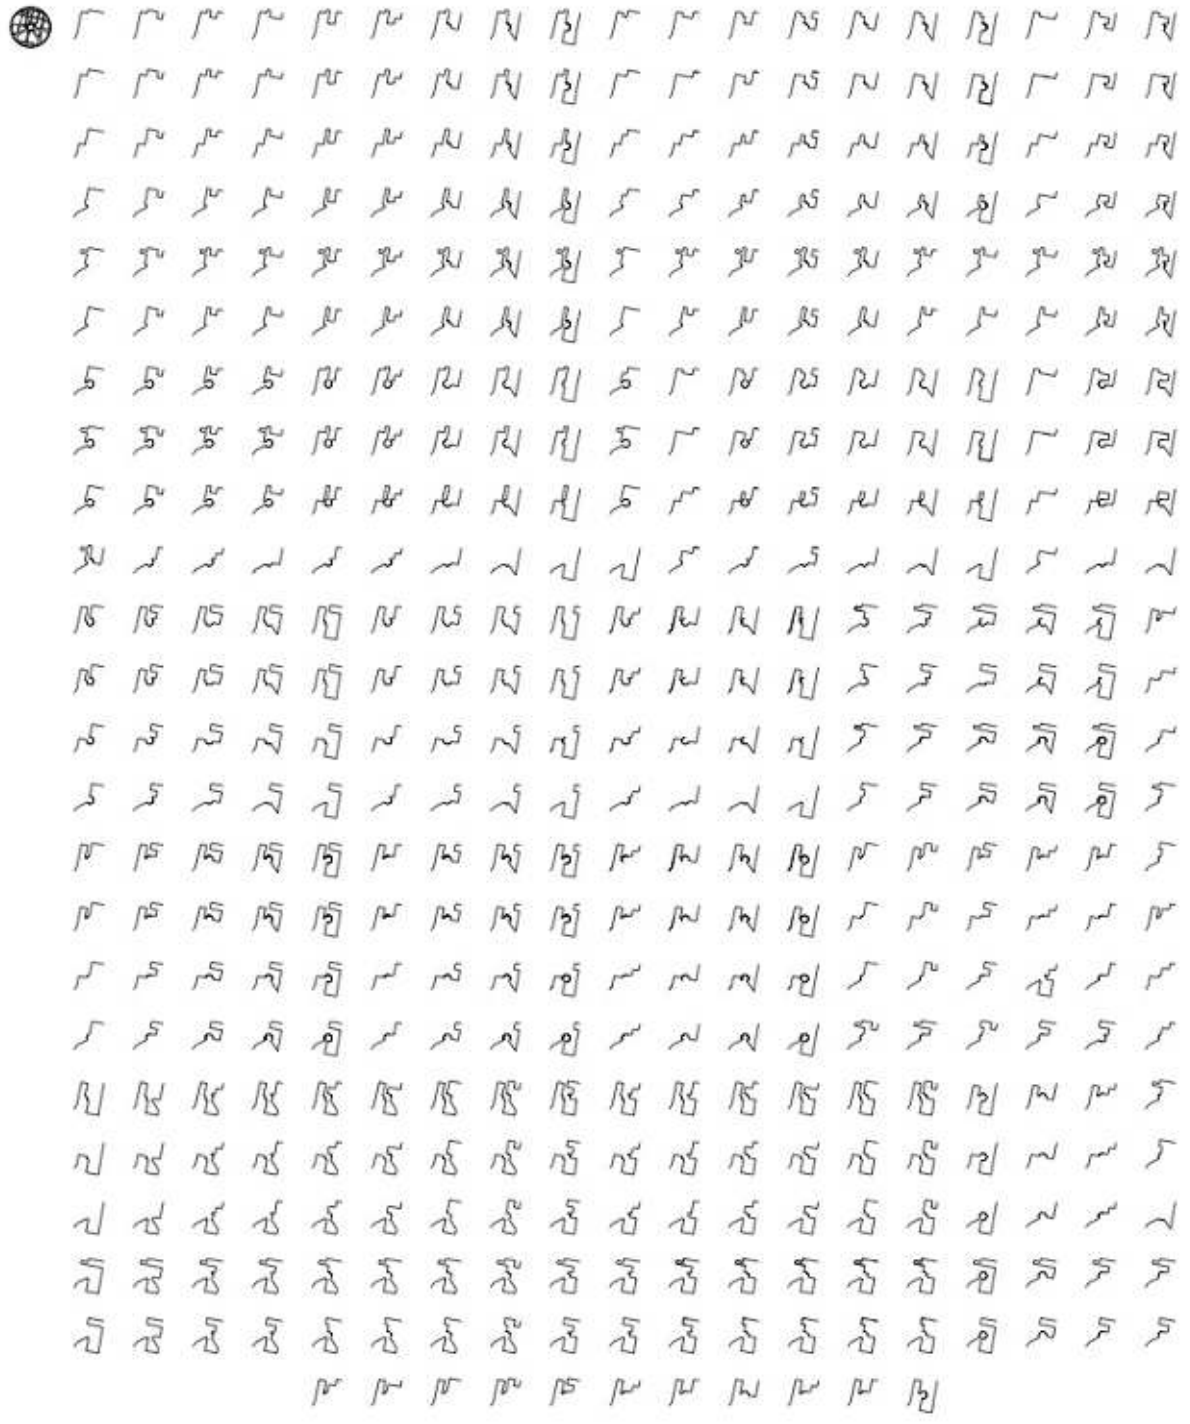

Figure 2. Alternative routes within a conceptual circle of a 200m.-radius connecting two points at a straight distance of 400m

Increasing **walkability** in a neighborhood may promote social cohesion as well. The ability to walk in a neighbourhood indicates not only a type of mobility, but also a type of sociability between neighbours. Architectural and environmental quality, land uses, street patterns, wayfinding ability, human comfort and safety are some of the features that contribute to an individual's decision to walk.

**Flexibility** should characterize master plans. Planners should allow communities and residents to develop a distinctive character of place and shape it in ways meeting local needs and changes in populations, work patterns and social life. Flexibility should include creative use of buildings and open space. Research identifies the importance of flexible and adaptable housing to provide space for families to grow without having to move away from a community where they have become established. (Woodcraft, Hackett and Caistor-Arendar, 2011)

**Social interaction** can contribute to social cohesion. Social relations provide an important source of information and social support that help us get by and cope with everyday problems (expressive social resources), while others are more useful to 'get ahead' in life (instrumental social resources) (Lin, 2001; Wellman, 1992). In order to achieve intimate social interactions the setting and aspects of the built environment should provide individuals with opportunities of contact and interaction within reasonable distance.

Spatial proximity is not a sufficient condition for social interaction (Kleinhans, 2004; Blokland, 2008). Social mixing does not necessarily result in the formation of strong relationships between different groups. However, interaction is more likely to occur between groups when different tenures are placed in close proximity to each other (Lawton, 2013). Therefore, a variety of people and **diversity** of households is considered important for creating an inclusive urban environment. **Integration** in an urban area can be achieved through a mix of housing types in order to accommodate a variety of households, ages and income groups. The role of diversity can vary, and can include the diversity of land uses, an array of architectural styles or the promotion of social and cultural diversity (Fainstein, 2005; Blokland and van Eijk, 2010).

Other authors warn that a high degree of heterogeneity may have unwanted consequences, such as coolness between neighbours (Gans, 1961; Goodchild and Cole, 2001). Even tensions may arise when diverse social and ethnic groups are mixed in close proximity. As Lees (2008) argues "socially mixed neighbourhoods are just as likely to engender social conflict as social harmony, due to the clash of different cultures, classes and socioeconomic groups". Research conducted at the building and block level shows the desire for separation of communal social space within socially-mixed apartment blocks (Uitermark, 2003). Therefore **privacy** should also be provided.

The perceived **safety** of a neighbourhood is a fundamental part of social cohesion. Safety and fear of crime are related to activities that take place in public environments (Loukaitou-Sideris, 2006). Intentional physical risk, such as violence and terrorism, or accidental, such as fall and collisions, can force people to stay indoors, therefore limiting social interaction and cohesion. Some of the claimed associations between safety and the built environment include the benefits of natural surveillance, i.e. windows directly overlooking streets, which is said to increase perceived comfort and safety. Poor condition and maintenance of the built environment are also claimed to have detrimental psychological effects on people's sense of safety.

## 3. The case study of Omonia, Athens

*3.1 Issues of social cohesion in the examined neighbourhood*

As case study a central Athenian neighborhood, Omonia, has been chosen. The selected site has an area of 4.000.000 $m^2$ (2mx2km). Its estimated population is 40.000. A concentration of multiple land uses is observed (retail, housing, offices, recreation, hotels etc.) (Fig. 1). Around 600 building blocks are to be found within the site. Residential have been recorded in 80% of the city blocks (median average number of residents per building block is 85). Green space is only found at the periphery of the site, while public space is lacking.

Omonia was the principal square of the 1834 neo-classical city plan of Athens by Ed. Schaubert and S. Kleanthis and the intended location of the royal palace, the pole of a patte d' oie pattern opening towards the Acropolis (Tzonis and Rodi, 2013). The relocation of the palace led to a continuous transformation of the square and the neighbourhood. High population densities, building heights and FAR without supporting infrastructure led to the neighbourhood's development and subsequent dramatic downgrading. A middle class area during the 1950s and 1960s, it was abandoned by its residents. Several failed regeneration efforts were made so as to reaffirm its identity as the city's heart. The area is currently inhabited by immigrants, prostitutes, drug addicts and dealers living in very confined spaces in dilapidated buildings. The population has become diverse with no single group representing a clear majority. Omonia has become a no-man's land, with a negative and impersonal identity. The square itself is an empty square occasionally hosting waves of immigrants.

Since the early 1990s and due to its geographical position and the broader geo-political change, Athens has received large numbers of economic immigrants who have largely affected the city's socio-economic and socio-spatial structures. Following the 2009 economic crisis, increasing difficulties started when the available niches in the labour market were reduced and the average immigrant's profile changed towards that of a less educated/skilled male. (Maloutas, Souliotis, Alexandri et al, 2013). Nowadays, half of the immigrants in Greece live in broader Athens. Out of this population, 44% of lives in its central sector where inexpensive housing can be found. They count for the 19% of municipality's total population. Immigrant of diverse ethnic background live within proximity of each other and mix with Greeks who remained in the center after the 1980s and 1990s suburbanization and sprawl. This unintended social mix and spatial proximity did not eliminate social difference. Separation in terms of everyday life, consumption patterns and the use of services, along with a mix of cooperative and conflicting coexistence have marked these two and a half last decades of substantially increased ethnic diversity in Athens. Studies dating even back to the 1990s, identified areas excluding immigrants in inner Athens. However, comparative research among European metropolises, showed that there is no area in Athens that could be classified as ghetto (Maloutas, Souliotis, Alexandri et al, 2013; Arapoglou and Maloutas, 2011).

The threat of conflict or disrupted social ties also results from symbolic divisions, as well as ideological and political mediations. Lower-middle class groups feel trapped in a common destiny with immigrant populations in contrast to the upper-middle class who prospers in the fashionable and emerging suburbs. The potential threat for social cohesion is reflected in terms of deprivation and material inequality since the ethnic mix of populations living densely in Omonia, in aging rented accommodation and with deficits in public infrastructure. Too often an apartment building may host households belonging to more than three ethnic groups. The size and level of apartments signify economic and social discrimination even among the residents of a single building (Arapoglou and Maloutas, 2011).

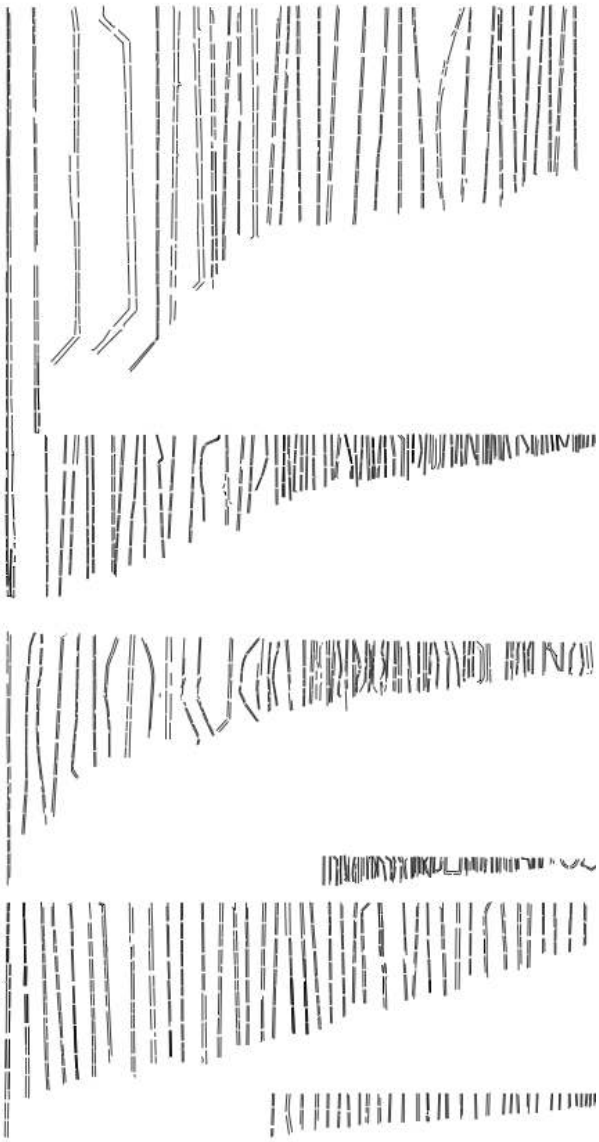

Figure 5. Typologies of streets

Figure 6. Typologies of encl. un-built space, squares, important buildings, junk spaces and green areas

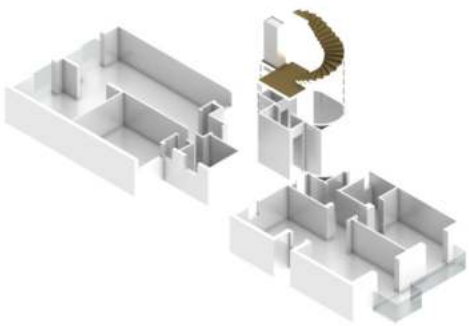

Figure 7. Division of an apartment building into two

*3.2 Dissatisfaction with the city and people.*

In a survey conducted on how citizens perceive quality of life in 79 European cities and 4 surrounding areas, Athens ranked last in most fields (European Commission, 2013). It was the only city where a majority of respondents expressed dissatisfaction with the life they lead (45%) and the place they live in. (56%).

Although safety was not an issue of importance in the majority of the cities surveyed, in Athens was seen as the most important of all. It is the only capital where the majority of respondents do not feel safe in their neighbourhood (63%) and city (81%) with an increase of 32% since 2009. As regards to immigrants, respondents in 7 out of 10 cities agreed that the presence of foreigners is good for the city. In Athens a significant majority disagree with this statement. On the question of whether foreigners are well integrated, 82% of respondents in Athens disagree. This is the highest percentage among all cities in the survey. Athens surroundings follow in rank. Respondents were asked whether they agree that most people in their city can be trusted. In 64 out of 83 cities included in this survey more than 50% of respondents agreed that people in their city can be trusted with Athens ranking last with only 18% of respondents trusting their fellow citizens.

In European cities, level of satisfaction with regards to green spaces is generally high. People in Athens show again the highest level of dissatisfaction (77%). Athens respondents also show the highest dissatisfaction among Europeans with regards to public spaces such as markets, squares and pedestrian areas. Finally, Athens ranks second before last concerning on satisfaction with the state neighbourhood streets and buildings (27%).

*3.3 A spectrum of interventions: Design action to promote social cohesion*

As already mentioned, a critical goal of *Bricolage Urbanism* is to develop new interpretations of public and private space through micro-scale interventions, and also generate new forms of urbanity addressing the integration of the individual with the collective, and the urban with the environmental. The aim is to provide maximum outcome through minimal means, and to establish a network of community partnerships to act as programme generators. *Bricolage Urbanism* moves across scales and develops a series of architectural and urban design elements that are able to satisfy inhabitants's needs.

In Omonia, we explore new and divergent ideas to invert urban decay. We identify a set of design actions for the transformation of the area into a socially cohesive urban neighbourhood. Design actions in the neighbourhood can take place in public space (squares, streets, parks etc.), but can also take place within private or common areas (internal courtyards in city blocks, entrances, roofs, apartments, etc.). Omonia lacks usable open and green spaces. Instead of demolishing parts of the urban tissue to provide new common areas, the strategy activates junk spaces in the public realm and the unused interior of city blocks that can be connected to the street. This "new common ground" functions as a framework for social and physical development, creating a porous urban fabric for the community with environmental benefits. Junk space turned to usable public space will contribute an increase in public space equal to 50 % of the current total area of city squares in the neighbourhood. Access and development of the interior open space of city blocks can contribute further increase, equal to 250% !. These new common areas could provide opportunities for social interaction between residents of different incomes and backgrounds. In this way, they may accumulate extra social capital, which is expected to have a positive impact on social inclusion and cohesion (Fig. 2, 3, 4, 5, 6)

Design actions of *Bricolage Urbanism* operate on private space and transform both city blocks and apartment buildings (Fig. 7, 8). These actions may include insertion of small-scale housing units into

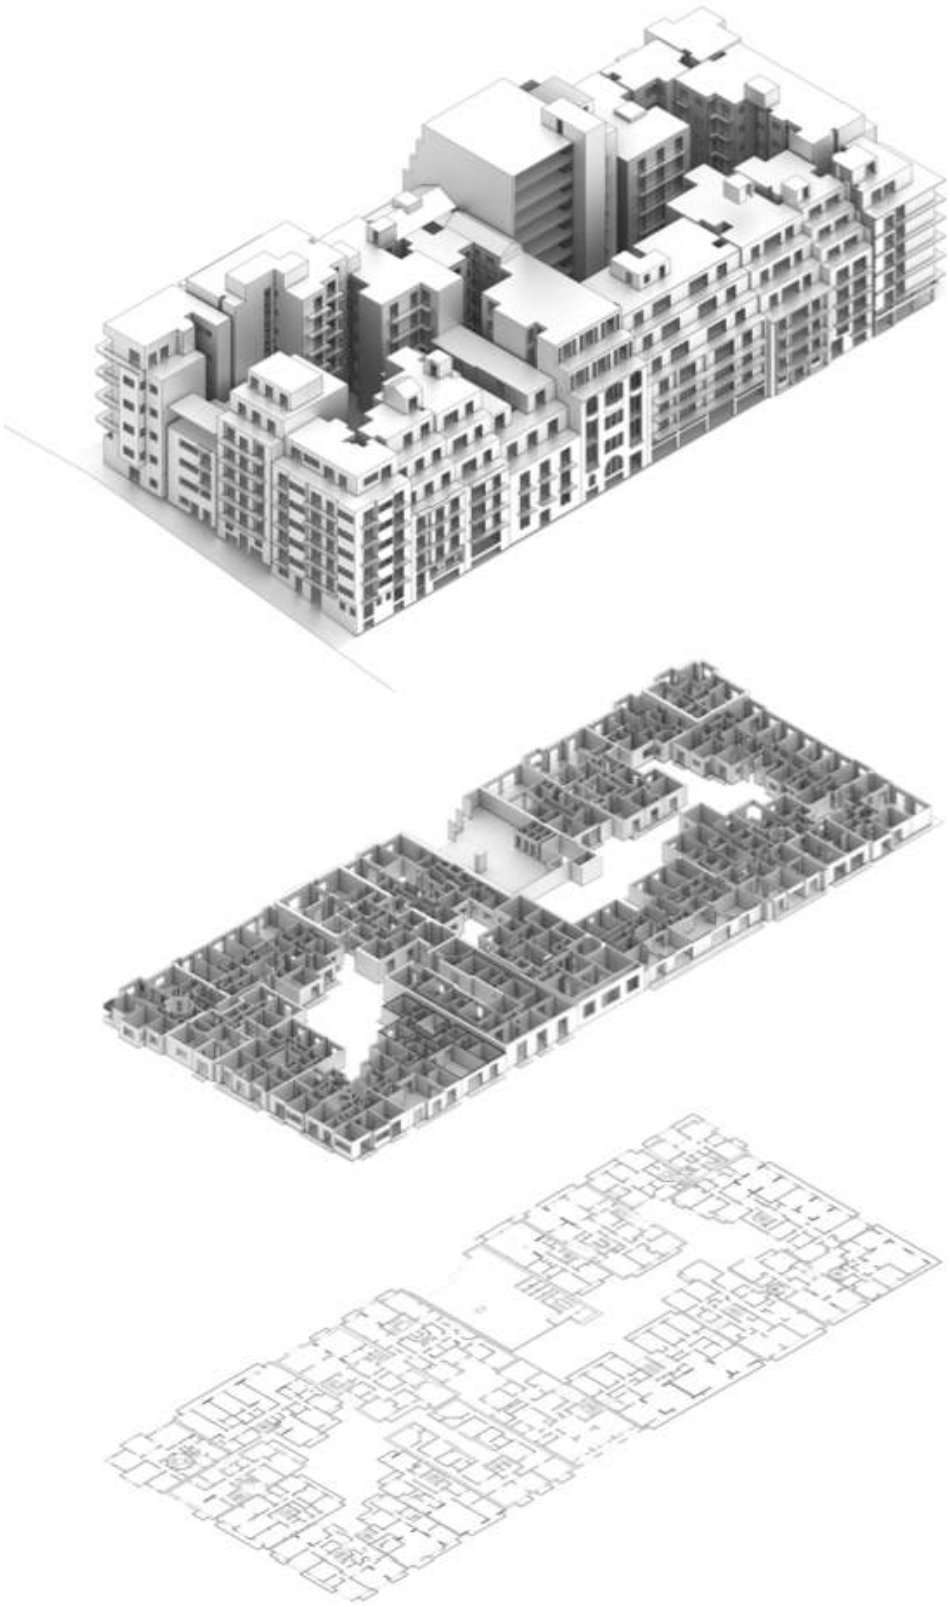

Figure 8. Typical Building Block. Exploded axonometric.showin building volume, un-built space, lightwells, typical floor, staircases

residual spaces of existing blocks, creation of green roofs, integration of planted courtyards and social spaces with cultural, recreational, educational and communal programmes in the interior of city blocks, and invigoration of vacant lots through their linking with adjacent streets and leftover spaces. New pedestrian paths consisting of open air and enclosed accesses and passageways will form networks connecting these new social spaces. As for apartment buildings, we propose transformations towards flexible and varied unit types for households in contrast to the homogeneity and repetitiveness of existing apartments. These changes will offer new facilities and infrastructure addressing a wide range of programmes and catering to a strongly diversified population.

## 4. Conclusions

Promoting and strengthening social cohesion is a principle shared by European societies. In the pursuit of socially cohesive urban neighbourhoods, people-based and place-based policies have to work together. Urban space is perceived as the arena for social cohesion. The densely populated centre of Athens, Omonia, experiences the dramatic impact of immigration and conflict. Public space is lacking and, also, underused. New strategies and patterns of use have to be introduced. Thus, in order to achieve social cohesion, the study expands its scope beyond public urban areas (streets, squares, parks etc) to the private realm (city blocks, apartment buildings, apartments, inner courtyards and roofs). The research established social cohesion related criteria and their correlation to urban form through typo-morphological features. It can inform the thought and work of planners, designers, and decision and policy makers and contribute to the critical analysis and design so as to regenerate high density neighbourhoods. However, we would like to warn against the pitfall of physical determinism that relates morphological features and social cohesion as for example, in the perception that exclusion rates are due to the existence of junk or underused space in the city blocks.

Through Bricolage Urbanism our research aims to contribute to the:

- Development of an appropriate physical setting for a heterogeneous urbanity through small-scale relational and situational urban interventions.
- Urban design process that emphasizes the importance of intervention on both public and private space to meet essential needs of local and migrant communities.
- Perception of the city as a shared space enriched with opportunities for social and cultural activites
- Intensification, reactivation and reinvention of urban space for and with the participation of local people and immigrants through the process of design and implementation of urban interventions.

# WHAT DO CITIES REALLY NEED TO (RE)GENERATE? RE-CONCEPTUALIZING URBAN REGENERATION PRACTICES AS "GRAFTS".

Author: Micaela Scacchi [1]

[1]Affiliation: "Sapienza" University of Rome, Italy - Department of Planning, Design, and Technology of Architecture (PDTA), Ph.D. Student in Territorial and Urban Planning
micaela.scacchi@uniroma1.it

**Abstract**

*Extensive and complex dynamics are affecting urban contexts, radically altering the physical form, social relations and the use of space of the European city as we knew it. Often, both formal dis-organization and fragmentary social relationships change the perception of the "urban", particularly in the peripheries. The concept of "contemporary suburb" has different meanings; today it refers to different realities, including empty spaces, incomplete and/or unfinished places lacking identity.*
*In my view, however, these "fuzzy" spaces can lead to a return to the City, or better to a renewed concept of the urban, based on the neighbourhood as a "minimum unit" of urbanity.*
*I will start here from two considerations: 1) the lack of urban quality and of those elements able to construct identity in the city formation process; 2) a diffuse sense of "rootlessness and alienation" which is perceived much often in the new peripheries. This is part of my PhD research, dedicated to understanding which are the most important design elements able to build new urbanity, quality and identity, in contexts increasingly more fragmented and inhomogeneous.*
*In this perspective, I proposed the concept of urban "grafts" - borrowed by agronomy, to re conceptualize development in contemporary cities. "Urban grafts" include both tangible and intangible elements as source of compatible and sustainable (re)generation, able to integrate the new within a living organism, influencing the morphogenesis of the urban space, as well as the chances to improve social interactions.*

**Keywords:** Contemporary Urban Transformation and Peripheries, Neighbourhood, "Urban Grafts".

## 1. Introduction

This paper would like to propose part of my Ph.D. research about the development of the contemporary City and especially on the reconceptualization of the spatial and social dimension in the neighbourhoods. The sudden changes in the European urban context, and also the economic, social and technological transformations have led to a reconfiguration of space and time lived in cities. The contemporary urban space is increasingly characterized by complexities, changes and specialized aspects. The intensity of these changes leads to review two fundamental components of urban living: the space and the social relations.
It's necessary to find a renewed concept of the urban quality and a "sense of belonging" and local identity. What features and projects or processes can be taken to renew this?
My PhD research has been working on three keywords: the "urban grafts"; the peripheries of the contemporary city; the neighbourhood. These topics are considered key elements for a process of urban regeneration. I have introduced the concept of "urban grafts", borrowed by agronomy, to re-conceptualize development in neighbourhood and contemporary peripheries.
I submitted this paper in the track about "urban design quality and its social dimension", because I believe that it's necessary to review a model of urban development, from the size and morphology of the neighbourhood as a "minimum unit" of urbanity.

## 2. The components / elements of the contemporary city that we need to work on.

This essay examines the concept of an urban (re)generation, recovering the "concept of neighbourhood" and improving the relationship between morphology, quality and local identity.
Below I would like to express some considerations about the relationship between the lack of urban quality and a diffuse sense of "rootlessness and alienation" which is perceived much often in the new peripheries of European contemporary cities.
The research question is whether it's possible to (re)configure unfinished urban spaces and suburbs in liveable and recognizable neighbourhoods.

I want to consider the practice of "urban regeneration" as both a process and an outcome, a response to decline or degeneration. Urban regeneration is defined as << the transformation of a place showing signs of morphological, environmental, social and economic decline or, rather, as the infusion of new vitality to communities and places in decline, through long-term and sustainable improvements to the quality of local life >> (Evans, Shaw, 2004).
In this perspective, I am proposing the concept of "urban grafts" to revitalize, to renewal, as well as in agronomy, an urban place/neighbourhood and also a community.
This paper confirms, also, the concept of urban design as << an art of making places for people…it concerns the connections between people and places, processes and urban form…>>.
Moreover the features of urban design reflects the values of society, the perceptions and aesthetics of the urban environment. Thinking about quality and identity during the whole development planning process, it's the best way to promote successful and sustainable (re)generation and "place-making". If the contemporary City is considered as a "complex and self-produced" organism, it's necessary to look at all local dynamics which can condition the morphogenesis of the urban space.

### 2.1 "Urban Grafts": join together to (re)generate and to improve neighbourhoods.

Today, in the contemporary European cities, many urban transformations are oriented toward "micro" (Indovina, 2008, pp.8-9).
Local programs and regeneration projects neighbourhoods are numerous and there are careful studies of new urban transformations, but most contemporary European city have a standardized development, without recognizable features, a globalized urban context that often creates monotony or even an alienating effect for citizens.
It's, therefore, necessary to identify possible components, by me defined "urban grafts", that are able to "join" to the context for activate and improve the processes of physical and training identity, especially in the suburbs where they have never formed or were interrupted.
The use of "urban grafts" can address the urban planning, influencing the place morphology and also people interactions in the intermediate size of the neighbourhood.
In the contemporary urban space, so increasingly fragmented and chaotic, many people are looking for a "sense of identification" with the environment in which they live. Then you must also working on the concept of "community planning" for a social cohesion and vision of the City as a common resource.

The research has developed through a "qualitative" and experimental methodology. I chose to use a "place-based approach", based on the characteristics of the territory and, in contexts already consistent, you can choose an "area based approach", to recognize the local strengths or weaknesses. I also decided to use an approach "people based", referring to people who live or use the neighbourhood and addressed the active participation of citizens.

The proposed methodology is to describe, analyse and compare a series of incomplete and/or unfinished places lacking identity from the perspective of their deficiencies through the identification of grafting functions.
I have developed a matrix, a graphic representation of the relations between the different urban contexts and some characters and functions of the proposed "urban grafts".
The evaluation of certain planning practices, in Europe in recent years, as case-studies develops a number of examples that can be as models for the understanding of my research of "grafts".
The functions of the "grafts" may be multiple ( to reactivate, to correct, to organize, to regulate the development, to regenerate, to give identity…), improving the condition unsuitable.

I believe that these "grafts" have three main issues on which we can work:
- Physical Space (related to morphological characters, the structural elements and criteria of the urban)
- Socio-Economic (linked to the social, cultural, economic, and participation of local identities)
- Intangible (the expression of "a sense of community", the promotions and activations of citizenship)

The research aims to explore the main components and dynamics of the contemporary city, especially about both physical structure than identity of neighbourhood.
I'm interested to understand the capability of this "urban grafts" as an opportunity for urban transformation and to propose some conclusions with implications for planning.

## 3. Conclusion

In conclusion, in this paper, I would like to express that the contemporary European urban peripheral areas, only through "compatible and sustainable urban grafts", can go back to being quality spaces joining the ability to "city developing" and a good "community planning/building".
So the search could be continued on the analyse of the database and of some particular case of need and practices as examples, to find not an ideal model and the perfect neighbourhood or the "lost community", rather of identifying those components, can improve the grafted context and better address the urban transformation.

# "PUBLICNESS" OF THE SEAFRONT WITHIN RECENT URBAN INEQUALITIES IN IZMIR (TURKEY)

Fatma Senol[1]

[1]Izmir Institute of Technology (Dept.of Urban and Regional Planning), fatmasenol@iyte.edu.tr

Keywords (maximum 3): public open space, urban inequalities, Izmir (Turkey)

## Abstract

*Based on my user survey, this research discusses how users of a main promenade/seafront in Izmir (a metropolitan city, Turkey) negotiate for this promenade's "publicness." It attempts to relate such negotiations to polarized discussions about urban public life and inequalities in Turkey, at which imaginations of Izmir play a significant role since 2000s. Izmir has a high rate of immigration since the 1990s especially with Kurdish people and other groups from Turkey's urban and rural areas. Given Izmir's Mediterranean climate, this promenade is widely used, although the activity areas are limited to a walkway. Interestingly, this promenade is attached to relatively better-off central and coastal neighbourhoods with long time dwellers but also has easy access for those neighbourhoods on the hills with middle and low income residents, including recent migrants. Yet survey results tell that this seafront is primarily used by those living in coastal and nearby neighbourhoods and has evolved mostly as "a kind of communal" public space of a "decent district"—Goztepe, which is known as representing the "modern" life style. Surveys are analysed to see whether and to what degree the users negotiate the "publicness" of this seafront, given the users' socio-economic and demographic characteristics, habits of using urban public spaces, the quality of their neighbourhood life and the physical conditions of users' dwelling. The results suggest that especially the site design favours middle-age working people over older people, children, women, teenagers and those who want to socialize.*

## 1. Introduction

Economic shifts taking place in the late 20th Century have changed and accelerated the discussions about public space as part of political sphere and of built space. Although most of these discussions of public sphere and urban public spaces have evolved as isolated from each other, we must consider them together (Blomley, 2001; Schmidt & Nemeth, 2010). An examination of "publicness" with a consideration of access, agent/control, and interest (Benn & Gaus, 1983), for instance, cannot be separated from the examination of conditions for political participation. Compartmentalizing such examinations leaves urban designers, planners and others dealing with the improvement of built environment in an apolitical position with limited tools of implementation.

This paper is driven from two arguments: First, any analysis and design implementation of urban public spaces should relate to the issues of urban justice and equity. Here *ideally* public spaces are taken as "open" or "accessible" parts of the built environment for all people with different socio-economic and demographic characteristics. They are necessary for providing communication and socializing opportunities for their users and thus, for improving social ties and sense of comfort and safety in the society (Burgess et al., 1988; Boone et al., 2009; Howard et al., 2002; Madanipour, 1999). Also, such opportunities for meeting with those different from the "self" and for representing of identities with differences within community and society can give the individuals and groups a ground for claiming to be a part of "the publics." Thus, for the continuity of public life and public sphere, public spaces as actual built environment are necessary (Mitchell, 1995; Mitchell & Staeheli 2005). Besides, those spaces containing and/or relating to natural environment and advantageous climatic conditions also add to the users' health.

Given these benefits, especially public open spaces should be considered as a part of "*environmental amenities"* (Boone et al., 2009**)**. Similar to the distance from "environmental disamenities," being/living in close proximity to environmental amenities are necessary for individuals' health and life quality. Similarly, public open spaces should be taken as public service areas (usually) developed by public resources. Thus, the distribution of public spaces in the city and their design should be considered as the distribution of opportunities for getting access to public services and resources (Byrne & Wolch 2009; Talen & Anselin 2001; Talen 2001; Wolch et al., 2005).

However, access to the environmental amenities and public service areas is not "equitably" available for all neighbourhoods and city dwellers, which is a serious planning and design problem (Boone et al., 2009; Sister et al., 2010; Heynen, 2006; Swyngedouw & Heynen 2003). Similarly, access to and design of some public spaces might favour certain advantaged social groups over others or disfavour the disadvantaged groups further, and thus, cause or perpetuate urban inequalities (Harvey 1973; Sister et al. 2010; Wolch et al. 2005). Consequently, analysis, planning and designing of public spaces must be part of the discussions about urban and environmental justice, especially within the neoliberal context of urban policies that encourage the development of public spaces as consumption spaces and even discourage their uses as spaces for public representation (Low & Smith, 2013; Mitchell, 1995; 2003).

The second argument tells that any analysis of urban public space should take these built spaces as part of multiple spatial relations. Here, plan and design and use of public spaces are mediated by the interplays of multiple contexts of individuals, communities, places and cities—that is, by users' position in the webs of socio-economic, political and spatial relations and also by these built spaces' macro contexts defined by the state, civil society and the market. Everyday practices in and for public spaces should be taken as the spatialized power relations reified and unfolded through the local practices in these built spaces.

## 2. Study Context and Site

Izmir is the third biggest metropolitan city of Turkey with 4 million people within its provincial boundaries (Figure 1 & 2). To understand the "publicness" of a public open space in Izmir, it is necessary to outline how public discourses and public life in Izmir have been shaped by the economic changes and political context of the country including the urbanization trends based on immigration and polarized and defensive camps between "modern versus Islamic" "dominant-way-of-life."

In the 1980s, Turkey shifted towards liberal economic policies relying on international market forces, following a military *coup*. The gross national product (GNP) per capita doubled between 1980 & 1998 and then continued to increase with a smaller rate, facing with economic crises in 2001 and in 2008 (TUIK, 2014). However, the disproportionate share of the national income between different income groups and urban inequalities has got worse. Besides the redistribution and agricultural policies of its neoliberal government, Turkey has its own conditions that have worsened such inequalities. Turkey has always an urbanization trend supported mostly by immigration to cities, especially with the first peak in 1960s-1970s along with the mechanization of agriculture and labour-intensive industrial production. The state then had relative tolerance of the illegal housing areas mostly by rural migrants, which provided the migrants with upward mobility and ability to escape poverty and exclusion. This tolerance and migrants' coping mechanisms disappeared after the mid-1980s, because urban land has become a primary source of rent for the private sector and the number of "urban transformation projects" and of laws and regulations supporting such projects has increased tremendously (Ataöv & Eraydın, 2011). In the 1990s, the rate of immigration especially from the east regions to western metropolitan cities (primarily, Istanbul, Ankara and Izmir) was the highest, along with new agricultural policies and the armed conflict between PKK (Kurdistan Workers Party) and Turkish State forces on the east and southeast of the country.

Meanwhile, after the 1980s, there was a considerable growth of civic associations including Islamic ones[1]. Next to global forces and influences, the Islamist groups' increasing power in party politics and civil society since the 1990s has made the discussions about multiple identities more intense and even polarized and defensive. Especially in the 2000s, the debates about "the Turkish national identity" got intense. The Turkish national identity was established during the early Republican Era of Turkey (1923-1945) along with various westernized "modernization" and "nation building" projects, which was realized by suppressing various identities based on ethnicity, religion and other characteristics (Keyman, 200?). Questioning of this ideology has been supported by the government held by the Justice and Development Party (AKP) that has an origin on the Islamic right and now "a representative of the new liberal-conservative trend in politics" (Tosun &Tosun, 2008) and has won the national elections since the 2000s, following the Islamist parties winning of municipal elections for metropolitan cities of Istanbul and Ankara and others (except Izmir) in the 1990s. Turkey has had on-going tensioned discussions and practices about secularism and "modernization versus Islam" as "the dominant-way" of life and of the state-operating.

Figure 1 & 2: Turkey and Izmir.

Interestingly, within this political context, certain metropolitan cities in Turkey (namely, Istanbul, Ankara, Izmir and Diyarbakır) got certain symbolic but also politicized images. *Istanbul* and *Ankara* had rivalry and conflicting symbols when building the modern Turkish national identity. Istanbul was the old capital and the most affluent city of Ottoman Empire with a multicultural but traditional (non-western) life to be left behind by the establishment of Turkish Republic. Ankara was the capital of new and young Republic built upon a "modern" and "national" identity (Tekeli 2000, cited by Erkip 2006). This conflict is softened (even disappeared ) since the 2000s with the increasing economic investments of both central and local governments held by AKP to Istanbul as the main city open to international economic links and to Ankara as the capital city with major governmental institutions. Within this context, however, *Diyarbakır* and *Izmir* have emerged with strong symbolized and politicized positions. Izmir has been the representative and protective of the Turkish national identity and "the dominant-way" of life and of the state operating, whereas Diyarbakır has been the "fortress" of Kurdish identity. Such images have been supported mostly through the media and politicians at both right and left-wing, although the municipalities in Izmir have been held by the leftist/ social democrat parties only since the late-1990s.

[1] Some has accepted this growth as a sign for the "emergence' of civil society and "new citizenship" in Turkey with the history of the dominant patrimonial state and "de-politicization" by the military coup of 1980 (Wedel, 1997) or as part of the 1970s' associative movement (Hersant & Toumarkine, 2005:7) that influenced by new international agreements in the post-1990s including the European Union for which Turkey has as a long-standing candidacy for membership.

Now two contrasting views about Izmir, a "fortress" of the Republican ideas with its "modern" dominant-way-of-life *versus* Izmir as the racist-fascist city, has been circulated especially by media and politicians. On the one hand, given that Izmir is also known with its *past* cosmopolitan identity (with its "enlightened," "civilized," "democratic" and "modern" urban life style and "educated" or "civic minded" locals) mostly for being a trade port between 18th-20th century and that Izmir had street protests against AKP-government's policies, it is fair to say that most people of Izmir (Izmirli) are proud of their city's identity as a fortress of "modern" life style defined usually according to urban middle class notions and to "the Turkish State as a secular social welfare state shaped by loyalty to Atatürk and his secularism" (Ataöv & Eraydın, 2011, pp.99). On the other hand, Izmir and the cities in West Anatolia (the hinterland of Izmir then) have had reactions to the threats to the Early Republican ideas about Turkish National identity (*mostly by Islamic trends*) and rising reactions against the Kurdish nationalism.

However, such polarized discourses in Turkey and about Izmir are shaped mainly by the declining economic and political power of Izmir with its hinterland after 1980s, in contrast to other metropolitan cities. Similarly, the local reactions might relate to nostalgia for those days with the economic power of Izmir (Yıldırım & Haspolat, 2010). Izmir has been a port city organizing its hinterland based on agriculture and mining since the 18th Century and also a banking centre of the Ottoman Empire until the early 20th century. During the late-20th Century, given its economic power with tourism sector and mild Mediterranean climate, Izmir attracted high rates of immigration originated in other parts of Turkey and also abroad, but also has lost its economic importance as port city similar to other port cities in the neoliberal era. Its share of GNP has decreased 10% since the early-2000s and also political power in Turkey's governance, in contrast to Istanbul and its nearby cities and also Ankara with its region with higher share of public investments and GNP (*add numbers*). Known with its rates of education level higher than national averages (26% and 14%), the city has an increasing unemployment rate after the economic crisis in 2008 especially by those with higher education level over the national averages (respectively, 44% and 39%) (TUIK, 2014). Its hinterland had loss of property in agriculture, whereas it also attracted immigrants from other rural parts of Turkey especially with Kurdish descents.

## 2.1. Study Site

Within the city of Izmir, there are spatialized differences shaped by various socio-economic and historical factors. At the end of the 19th Century, the city had two main settlements—Karsıyaka and Izmir (today's Goztepe district, where our study site is located). After 1950s with rapid urbanization rate supported by immigration rate, the city grew up along the bay area where these two settlements became central and coastal districts. Today a high percentage of city population live around Izmir Bay Area that is surrounded by hills beginning to rise suddenly after the seashore. Major urban public spaces (i.e., public squares and seafront with concrete promenades built on filled areas after 1980s, and also some major shopping malls) are located generally in coastal districts (Figure 3—to be added later).

Including Goztepe district, central and coastal neighbourhoods in Izmir are known as better-off districts where also social democrat parties got the majority of votes—regardless of whether people are there with social democrat ideology or the liberal, educated, middle-class, centre-right vision. In contrast, in 2002 and 2007 elections, AKP was strongest at the neighbourhoods away from the coast and at the outskirts of the city (Tosun & Tosun, 2008). The promenade, the study site along the seafront, is located in one of these old city district—Goztepe district, known with its middle- and upper-class locals born-and-raised here or with long residency and also place-ties with property ownership. Locals of Goztepe and Karsiyaka have claims that their district has been the major site for emergence and continuity of the public life style that "has made this city the City of Izmir" and people there "*Izmirli*s"—here the **"***urbanites*," rather than necessarily local dwellers, of Izmir (Senol, 2015; work-in-progress).

The section of the seafront chosen for this study is highly used especially in the evening hours during hot summer days of Izmir. Overall, the seafront extends for around 5 km. from a ferryboat pier to the city centre along (see Image 1). The study site is the part with the only pier until the city centre. As the seafront is separated from residential areas by a major road, the main entrance to the study site is through a pedestrian bridge. From the vehicular road to the sea, the seafront has a green surface (ca. 2 m.), a bicycle road (ca. 1.5 m.), a walkway (ca. 4m.) and concrete wall/sitting areas (Figure 4 & 5).

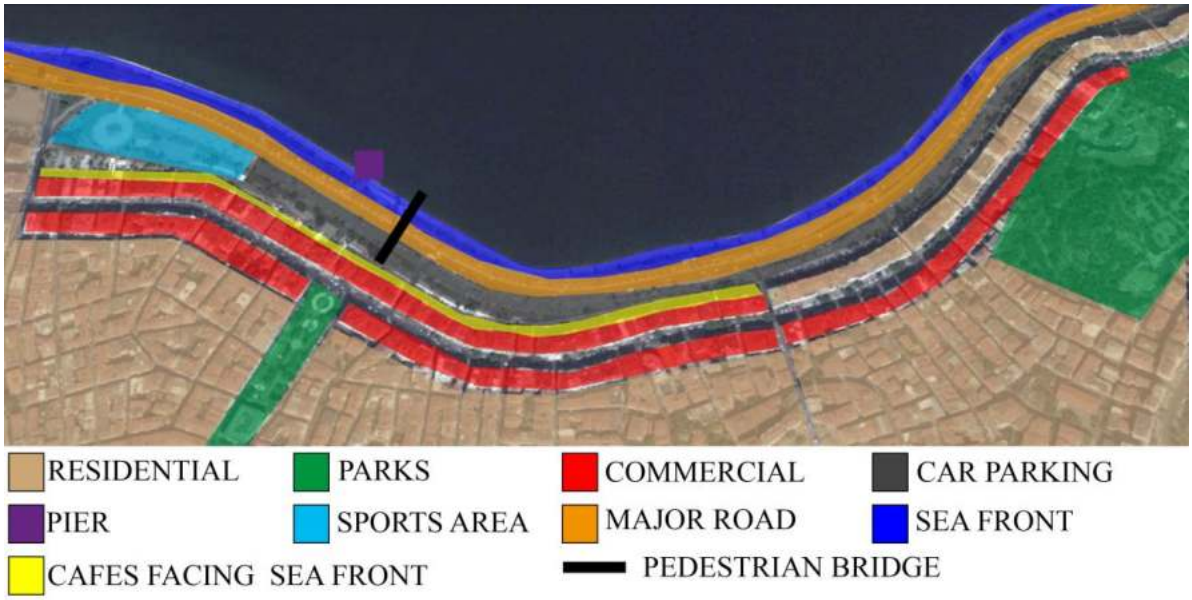

Figure 4: The study site (seafront) and its nearby surrounding.

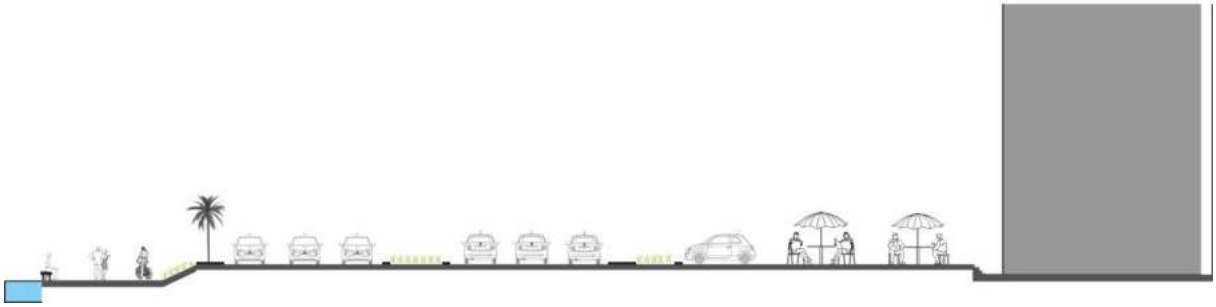

Figure 5: Cross-section of the seafront and its nearby surrounding (from left to right: sea, seafront, major road, car parking and cafes, buildings)

## 3. Study Methods, Analysis and Findings

To gather the main data for this study, I conducted a user survey (251 respondents) on the study site between 7.30—10.00pm on 3 days per week (including Saturday or Sunday) from mid-June to mid-September and. The themes of survey questions were about the respondent's **1)** use (frequency, density and kinds) of the seafront and nearby areas, **2)** socio-economic and demographic characteristics, **3)** perception of comfort and safety on the site, **4)** perception and habits of using public spaces in Izmir and also in their neighbourhood, and **5)** characteristics of their dwelling and household. To analyse the survey data, besides the descriptive analysis, we deployed regression model using the Ordinary Least Squares technique. The number of observations (N) is 251 respondents. The data gathered under Theme 1 above was the dependent variable (Y), whereas the Themes 2, 3, 4 and 5 constituted the independent variables (X).

In order to understand the determinant of Y, we refer to the following regression model: $Yi = \alpha + \beta 1\, X1\, i + \beta 2\, X2\, i + \beta 3\, X3\, i + ei$

> *i*: 1, 2….., 251 (the index notation for the individuals participated in the survey) and *e*: error terms which are assumed to follow a normally, identically and independently distributed residuals.

When evaluating the results of the regression analysis, this study underlines the variables (X) that has a positive/negative and significant coefficient at 5% significance level which actually means that for the respondents that have higher X1, we observe higher Y.

### 3.1. Profiles of the Respondents

Overall, according to their socio-economic characteristics, there appear two main groups. Of total 251 respondents, the first group is early-middle-age, working and married people. The second group is either young usually university students or upper-middle age and non-working people. Of all respondents, the majority holds or pursues university degrees (60.5% compared to 26% of Izmir) and is Izmir's "locals" who are born-and-raised or living here for more than 25 years, whereas a third has been in Izmir since the 1990s. Also, the majority lives in households with a medium[2] or upper income level and usually 2-3 breadwinners, except nearly one third with below-medium-level and with one or none breadwinner.

These characteristics can be detailed among female and male respondents, which would suggest various user profiles on the site (see Table 1). Accordingly, the majority of both male and female respondents are in the age groups of 26-45 (respectively, 76 out of 132 and 65 out of 119), usually with a paid-job, a university degree and a household with upper income level with at least 2 breadwinners. Yet the percentage with university degrees is higher for women. Relatively older men here are married with kids and the younger ones live in households usually with 3 breadwinners—*probably* with parents. Women in these age groups have different marital status but usually no kids. The largest share of women here (43 out of 65) is younger (25-35 years old), of which two third is single. Of the men in this group, nearly a half is born & raised here and a quarter is relatively newcomer to city with a residency of 5-15 years. In contrast, nearly half of these women have been here between 5-15 years.

Among female respondents, those with upper-middle ages (here, 45+) compose the second largest group (37 out of 119). They are usually housewives some of whom have university degrees and are married or widows older than 55. As the age among them increases, their household income generally decreases from upper- to below-levels. Interestingly, the majority of male respondents with the age of 46 and over (31 out of 132), usually with secondary school degrees, have no paid-job (probably retired and/or have income as landlords). They have *usually* one breadwinner in their households with a medium income level, except a quarter with upper-income level. Both groups have been in Izmir more than 25 years.

Those between the age of 18-25 of both female (17 out of 119) and male (25 out of 132) respondents have or pursue university degrees and are not working, single and living in households with three breadwinners and medium or upper income levels. More than half of this group have been in Izmir between 15-25 years, thus, come to Izmir as a child after 1990s.

### 3.2. How They Use the Seafront

Most of the respondents (57% of all) are the frequent users of the seafront with the visits daily or for a couple of times weekly, whereas a quarter visits a couple of times per month. At the seafront, the

[2] This study considered the household income level between 2501-3500 Turkish Lira as "medium".

majority of respondents stay for 1-2 hours (48%) or 4-5 hours (35%) majorly in the evening and early-night hours. They mainly exercise and walk/stroll and then rest/sit. Given the site's physical elements, the mostly used parts of seafront are walkways, and then seashore with sitting and less so the green surfaces and benches.

The results of the regression analysis suggest certain socio-economic characteristics, general habits of using urban public spaces and also neighbourhood characteristics have a statistically significant coefficient. Accordingly, it is no surprise that mostly the **frequent-users of urban public spaces** (i.e., open spaces or malls) come to the seafront often and also stay here longer (i.e., from 4-5 hrs to 1-2 hrs) than those less frequent users of public spaces. Interestingly, more **working people** use the seafront more often. Also, they use the seafront mostly for walking, strolling and exercising. The less frequent users are those without any paid-job (retirees, housewives and students); they usually sit and rest and meet somebody on the seafront.

There appear also **gender differences** in the use of this site. Mostly those with child care responsibilities at home use majorly green areas and also the walkway. 22% of respondents have childcare responsibilities. Mostly this group of respondents come to the site with a company. Yet other results make this gendered difference of site use interesting: More **women** tend to not-use green areas but use mostly walkways. In contrast, **men** mostly use the sitting areas including the green areas. Also, women stay here for shorter period (from 20-30 min. to 1-2 hrs), whereas men stay for longer period from 1-2 hours to 4-5 hours.

Given the physical setting of the seafront designed majorly with continuing stripes of green surface, bicycle paths and walkway and then concrete wall with sitting areas next to the sea, it is easy to understand how mainly active uses are performed here. This might also explain why the age groups of respondents concentrated at the age groups of 26-45—the group with a high percentage of working people—is highly represented among the respondents.

***

Another significant finding relates to the respondents' use and perception of **public spaces in their neighbourhood**. Overall, in their neighbourhood, only less than a half of respondents have either a park, cafes, access to seafront or most of these places "*that they can use*." Of all respondents, most consider the quality of these places "average" (44%) or "good" (40%), but only 12% thinks that number of such places in their neighbourhood is enough. Similarly, more than a half (63.7 %) have neighbourhood parks in walking distance to their home, but only 26.3 % of all respondents use these parks. Asked about the reasons for not using these parks, non-users (37.5%) majorly underlined uncomfortable physical (e.g., park design only for kids) (12.1%) and social conditions (e.g, teenagers bothering them) (4.9%) or their dislike (7.7%) of these parks and/or their preference of using the seafront with wider horizon and size.

Interestingly, the regression analysis suggests that mostly the respondents with public places or cafes in their neighbourhood visit the seafront more often. Also, when choosing the activity areas on the site, understandably more respondents without any public places "that they can use" in their neighbourhood and also interestingly, more of those with a neighbourhood park nearby their home **use the green areas** at the seafront. These findings suggest that the presence of public areas in their neighbourhood does not guarantee the respondents' use or like of these places or none-use of other public spaces. Also, the purposes of using neighbourhood spaces might be different from using this relatively larger space next to sea with chances of meeting people other than their neighbours.

### 3.3. Sense of Comfort and Safety on the Site

Respondents' perception of comfort and safety of the seafront constitute other set of findings here. Overall, more than a half has been living in Izmir more than 25 years (65.4%), whereas 20% is here for less than 15 years. Nearly all respondents think that Izmir is a comfortable and safe city and has urban public spaces with a quality at average (41%) or above average (47%). More than a half of respondents (59%) goes primarily to open public spaces for relaxing in quiet and fresh air and for

exercising. The rest visits mainly shopping malls for shopping, entertainment and socialization with friends. Of all, a high percentage (73.7%) visit public spaces with a company—usually with a friend, then a family member or both.

*Sense of Comfort*: Of this seafront, most respondents (except a third) think as comfortable. A common emphasis is especially about positive aspects of the site location next to the sea and its size with wide space that gives the sense of relaxation and comfort. However, when asked specifically about the design, uses/activities and users of the seafront, slightly more than a half of them complained about mainly **the physical conditions** and less so **social conditions** there. Nearly all the negative aspects of physical conditions are related to practices of design (including the uses and activities) and the lack of climate-sensitive design of the seafront as a public space. These include mainly keeping the uses for bicycling, jogging and fishing on the same (narrow) site with relatively few sitting areas and without any protection from sun and the wind, and disturbance of traffic on the major road.

Complaints about the social environment of the site appeared much less than its appreciation, respectively 3% and 10%. Majority of complaints here relate to the users' attitudes (rather than socio-economic and demographic characters*)*—such as not keeping the area clean, dog fouling, those fishing on the site with long fishing rod,"some men" public drinking "next to the families/kids"). However, interestingly, the appreciation of social environment/ users talks mostly about how "people here are decent" and/or the "district is decent" and the site has people "like a family," pointing out Goztepe District. Also, interestingly when asked about which neighbourhood they live, the majority of respondents give the name of neighbourhoods attached to the seafront (Figure 6—to be added later). Majority lives in the neighbourhoods at the edge of the seafront, followed by those in walking distance around 15-20 minutes. Of the respondents, 90% come to the seafront on foot. Most of them (50%) walk here for 5-10 minute, and others (35%) for 10-20 minutes or for 20-30 minutes (10%).

***

The regression analysis shows who (un)comfortable is with the conditions of the site. As such details might have more explaining power for urban design and planning, here we emphasize mostly characteristics of those respondents **uncomfortable** with certain aspects of the site. Primarily, the **older age groups** think of the seafront uncomfortable with its physical design. As mentioned earlier, the percentage of non-working population is higher for the age groups above 45, whereas mostly non-working respondents use the area for sitting, resting and meeting people.

Meanwhile, respondents' habits of using urban public spaces in general impact significantly the perception of comfort level on this site. The **frequent users of** urban public spaces and those who use urban public spaces for socialization take this site uncomfortable due to its urban design. Similarly, using urban public spaces with or without a company seems to affect the perception of comfort here. Overall, a third of the respondents visit other urban public spaces and also this seafront usually alone, while the rest come here mainly with a friend or then a family member. Regression analysis suggests that those visiting urban public spaces **with friends** consider the uses/ activities on this seafront uncomfortable. Also, those coming here **with family members** (kids…??) are not happy about the site design due to its lack of protection against climatic factors (e.g., wind, sun, rain and waves). Those who use urban public spaces **alone** are not comfortable about the site design and especially about the user profile here. When we examine to see who comes here alone, we can see that as the respondents' education and also age level increases, their tendency to come to the site alone increases.

***

Nearly all respondents come to the seafront on foot, where most of them live in the neighbourhoods attached to the seafront or nearby neighbourhoods relatively with longer walking distance, detailed above (Figure 6). Thus, for most, this seafront might be imagined as part of their district/ neighbourhood. When examining the relationship between respondents' perception of comfort level of the site and of their neighbourhood characteristics, such close geographical and social proximities should be kept in mind.

According to the regression analysis, mostly the respondents living in neighbourhoods attached to the seafront (i.e., 5-10 min. walking distance) (4? %) are not happy about the uncomfortable design and

lack of protection from climatic factors at the seafront. However, more of those coming to the seafront on foot (90%) find the site's climatic comfort well. How to explain this? An explanation might relate simply to the relatively big differences among the senses of climate factors at neighbourhoods. Those living relatively far from the site (and thus, from open and wide space with sea breeze) might be comfortable at the seafront as that might be providing with climatic factors different from their neighbourhood spaces. Meanwhile, mostly the perception that their neighbourhood provides "good" living quality seem to impact the respondents' perception of the seafront as comfortable with its design and climate conditions but uncomfortable with its uses and activities.

*Sense of Safety:* More than a half of all respondents think that the site overall does not have safety concerns. When asked details, 131 out of 251 respondents detailed where and why are (un)safe along the seafront. Given the size of the area, the majority detailed that the crowded and well illuminated areas (usually concentrated around the cafes, elevated pedestrian bridge and the pier) are much safer (Image 3). Of respondents, 10% emphasized that the site is safe because people here are and the district/ neighbourhoods here are "good"/"decent." Similarly, for the unsafe areas on the site, 39% of 131 respondents pointed out the isolated areas with a few people and dark/without enough illumination, which extends at the both ends of the crowded area with pedestrian bridge and the pier. Also, nearly a half of respondents pointed two districts (Üçkuyular and KonaK-city centre) located at the both end of this promenade as too crowded with too many "different unknown" characters as unsafe areas.

The regression analysis tells that the habits of using other public spaces in the city affect significantly the respondents' sense of safety in this seafront but along with differences in the kind of habits and also in their emphasis of physical or social conditions of the site. Most of those going majorly to the malls especially for the purpose of socialization have a strong sense of safety in crowded areas (such as cafes) of the seafront. Yet for those visiting mostly open spaces and all public spaces for relaxation, the open areas at seafront are safer. Meanwhile, mostly those visiting urban public spaces with a company tend to find this seafront "safe because the district is decent," "people are nice/safe here" or "here is crowded," but unsafe due to the lack of design elements such as illumination and lack of activities that lead to isolated places especially at night time. In contrast, those enjoying urban public spaces in general alone find the site safe because of "its quietness" and "well-illuminated places" and unsafe because of user—characteristics -attitudes and certain places with a crowd of "too mixed of characters." Meanwhile, as the education level and also the age of respondents goes up, so does their tendency to come to the site alone.

***

The survey also checked the respondents' sense of safety in this site by asking the question of "*whether it is safe for a man (or woman) to use the site alone*", a few said "unsafe" with a higher percentage for a woman alone than man (10,8% vs. 4,7%). Overall, their reasoning focused on the arguments—such as "nobody would bother anybody here" and "nothing bad happen, as it is crowded/well-illuminated"—which had a higher percentage for the question about woman's than man's safety (63,4 % vs. 59,5%) . Interestingly, also the presence of police power is given as a major response (17.3 %) but only for the woman's safety.

The results of the regression analysis tells that mostly those using public spaces for socialization say that "man alone" can use this space safely. Yet interestingly, with a lower significance, mostly those with a habit of using urban public spaces alone find this site for a woman alone, but not those who visit public spaces with a company. When giving reasons for why this site is safe, the responses change for the cases of "a woman or man alone." Mostly those visiting public spaces with a company and (with a lower significance) mostly female respondents say that the site is safe for a man alone mostly because "*man can defend himself*," "*there is police*" and "*because he is a man*." Male respondents mostly give reasons such as "*nobody would bother him*" and "*it is crowded and well-illuminated*." To explain why woman alone on the site is safe, mostly the respondents with higher household income level and also (with a lower significance) male respondents say that "*nobody would bother a woman"* and *"it is crowded here"* or *"she would defend herself*."

Similarly, those with lower income and also the frequent users of urban public spaces and (with a lower significance) and female respondents explain their reasons for why the area might be unsafe for a woman alone by saying that because *"she is woman"* and *"there might be some 'unsafe' people around,*" rather than "*nobody would bother him"* and *"it is crowded and well-illuminated.*"

***

When asked about how to increase comfort and safety on the site, overall, more than a half of the respondents (61.2%) emphasized the need for design and planning implementations—such as well illumination, more and comfortable sitting areas with protected from wind and sun, separated bicycle-motorcycle roads and exercise areas from pedestrian walkways, places for children, measures for traffic calming on the major road next to the site. Of all, 10% emphasizes that people there need to care about the site and its uses, whereas a significant percentage (19.2%) ask for police surveillance.

The results of regression analysis suggest that most of those with longer stay in Izmir (born-and-raised or for more than 25 years) and of those who lived in another city more than 5 years believe that the site is already safe and if needed, users should solve the problems there, rather than any police or design control. Similarly, the probability of this answer emphasizing the social control to increase comfort and safety on the site is also high among those respondents whose neighbourhood has public spaces and also who live next to the site. Those with relatively shorter (less than 15 years) stay in Izmir and also most of working people argue for the need of police control, camera surveillance or urban design solutions on the site.

## 4. Evaluation and Conclusion

To be added later

***Acknowledgement***: This study is funded by Izmir Institute of Technology (P.no: 2013_IYTE_34). I am also grateful for the assistance of my colleague Assist.Prof.Dr. Engin Duran in using the regression analysis for this study.

**PAPER TITLE**

**Urban Porosity Patterns for Exchange in the City: the case of Europan**

**Author: Socrates Stratis**

**Affiliation:** Department of Architecture, University of Cyprus, stratiss@ucy.ac.cy

**Abstract**

The author of this article develops an Urban Porosity Pattern Matrix through which he studies how urban design projects relate Public Agents (catalysts for public flows) with Urban Interfaces (multiscalar perimeters-edges of urban patches and enclaves), through an urban actors' filter, to envision a porous connective urban environment. In fact, the analysis focuses on the passage from the Europan ideas competition stage to that of implementation. (European Urban Design/Architecture Competition for young professionals). More precisely, the Urban Porosity Pattern Matrix establishes a reading of Europan winning projects under implementation and demonstrates through their mutation, the tolerance of the projects' actors to urban porosity. The author participated in several Europan activities regarding the concept of urban porosity: working on the actual sub-theme of the competition (member of Europan Scientific Committee), writing an article for the catalogue of Europan implementations, ("Welcome back in my back yard: an exploration of urban porosity", 2012) and animating a debate in the Europan 11 Forum of Results in May 2012 in Vienna, ("Creating Urban Fluidity through a porous urban fabric"). Through this article, he links the Europan urban design processes with the problematics in regards to Urban Design Quality and its Social Dimension, mainly how urban design could overcome the fragmentary social pressures and the withdrawal from public space.

Key words: Europan, Urban porosity, Project Actors

## 1. Introduction

In this article the author argues for the collective character of urban design practices that establish urban porosity "friendliness" among the project actors, resisting the fragmentary social pressures such as privatization and withdrawal from public spaces. Urban porosity emerges through an exchange between public flows (Public Agents) and urban patches or enclaves (bound by Urban Interfaces) (Shane, 2005). Urban porosities may have spatial manifestation however, they emerge through an "actorial" filter created by diverse actors' agendas during the formulation of urban design projects.

The author demonstrates how the Europan platform (European architectural competition for the city of young professionals), is a pertinent research area since part of its activities evolve around implicit and explicit processes of acculturation of urban actors with urban porosity agendas.

The author has developed an Urban Porosity Pattern Matrix through which he studies how urban design projects relate Public Agents (catalysateurs for public flows) with Urban Interfaces (multiscalar edges of urban patches and enclaves), through an urban actors' filter, to envision a porous connective urban environment. In fact, the analysis focuses on the passage from the Europan ideas competition stage to that of implementation.

As a matter of fact, the Urban Porosity Pattern Matrix emerged gradually through the involvement of the author in Europan activities (Stratis 2005). More precisely, he studied the process of implementation of some Europan projects to write an article on urban porosities for the Europan Implementations publication (Stratis, 2012). Plus, he co-animated a debate based on the same theme, with Pascal Amphoux (the author and Amphoux are both members of the Europan Europe Scientific Committee), in the Forum of Europan Results in Vienna, 2012.

Firstly, the author introduces, through three stories, the tension between enclaving dynamics and urban porosity practices demonstrating the challenges of urban design towards a less fragmented urban environment.

Then, the author refers to the tensions between Public Agents and Urban Interfaces that take place in the stories, yielding to either practices of enclaving or to those of "knitting" urban patchworks. By doing so, he gradually formulates the Urban Porosity Pattern Matrix.

Further on, the author justifies the relevance of the Europan context to urban porosity challenges especially, that of the transformation of public agents and interfaces during the passage from an ideas stage competition to that of implementation.

Then, the author employs the Urban Porosity Pattern Matrix to unfold some of the findings through the study of a selection of Europan winning projects during the rite from the ideas competition stage to that of implementation.

Finally, he concludes with the implications on processes of collective urban design practices and their relation to the Urban Porosity Pattern Matrix. In fact, the author addresses how the Urban

Porosity Pattern matrix could be both analytical and conceptual tool to support the urban porosity friendly nature of urban design practices.

## 2. Urban design challenges in fragmented urban environments

### 2.1 Urban design as hybrid patchwork making

Urban design lies in fact, in a crack between architecture and planning (Shane, 2005 & 2011, Sorkin, 2001). Urban Design which emerged in the 1940s and is actually gaining popularity (Mandipour, 2006) is a field which by definition has a fragmented character vis-à-vis overall planning development plans. It emerged with the realization of the impossibility to have control over entire cities because of a shift in the social, political and economic contexts. Urban design has become a legitimate tool to city authorities which have gained importance over national planning. In the case of Europe the cities have an important say in their urban transformation, (Stratis, 2012, 2014). The public sector still plays a decisive role in North European cities, contrary to the most of South European and North American ones. Even so, we are witnessing a decreasing influence of the European welfare state on city making, which may increase urban fragmentation. Opposing to the fragmented logic of projects coming out of urban design practices, Sorkin reintroduces the concept of Master Plan stressing its importance for its unifying characteristics.

Shane approaches the urban environment as *"a variety of patches, or enclaves that are interconnected by an ecology of armatures – transportation and communication networks – set in landscape and crucially complicated by a wide variety of embedded heterotopias"* (Shane, 2005, pp 14,15).

His approach aims to strengthen urban design as an emerging field of inquiry for new strategies and tactics to deal with a hybrid patchwork, (Shane, 2005, p.11). In addition, he emphasizes the urban actors' role, in activating a transformative recombinant system of urban elements. Such activation takes place by a sort of urban splicing analogous to genetic recombination, involving sorting, layering, overlapping, and combining (Shane 2005, p. 6). In fact, Shane revisits Urban Design as an agent to help the urban actors operate in a complex and recombinant world with nobody in charge of the overall system. In other words, no actor dominates.

The importance of actors in urban design has been put forward by a recombinant urbanism approach (Shane 2005), where the city is considered to be made of actions taken place by a perpetual re-alliance of all sorts of actors, (Vlay, Stratis, 2010). Shane reminds us of Kevin Lynch's theories but also those of the recombinant approach of Kriers' brothers and of the Urban Design Agency (UDA) kit-of-parts aiming to make accessible design decisions to the broader public. However, such approaches have led to the New Urbanism movement with problematic

modes of participation (Sorkin, 2001). Madanipour brings forward the multi-actor environment of urban design through his approach with three kinds of actors those of regulators, producers and users (Madanipour, 2006).

The actual challenge is to reintroduce unifying characteristics through urban design practices beyond the master plan itself. A sort of acupuncture approach seems to be more appropriate, aiming gradually in a nonlinear manner to a coherent whole by readjusting initial common visions.

### 2.2 Three stories of challenging urban design

Each of the three stories mentioned below, brings forward a different challenge for urban design regarding its posture vis-a-vis fragmentary social pressures and segregation tendencies. The stories build on the relevant urban design references, setting the grounds for the article's problematics.

The first story is about a rather isolated gated community, such as an elderly village in Orlando USA and its political influence for the new US president back in 2012. The second story is about the opening up of a ghetto area in Hooglviet, Netherlands through redefined State urban politics called WIMBY (Provoost, 2008). The third story comes from Europan itself and is about the urban dimension of new housing in Vienna, Austria. Urban connectivities are established between the housing site and the city by a complex alliance of urban actors who participate in the transgression of an ideas competition winning project to its implementation.

***Story One: beware of the intolerance incubated in isolated enclaves:*** An article in the French newspaper Le Monde back in May 15$^{th}$ 2012, was commenting on the likely decisive influence of the USA presidential elections outcome by the elderly community of the "Villages" in Orlando, USA. As a matter of fact, the Obama's policies on national health care were against the exclusive character of such gated communities, endangering the established balance of their protected lives and healthcare services. The article went on interrogating on the possibility of a third age populated enclave in Orlando to influence the whole world by tipping on one US presidential candidate over the other, blocking Obama to run for his second presidential period. We all know the outcome of this debate; however, we are aware of the increasing segregating practices supported by the neoliberal globalized economies guessing that such overturn may take place in the near future.

The spatial organization logic of the "Villages" in Orlando is based on the "New Urbanism" ideals which promote the quality of the proximity scale, human scale and mixed uses. However, the homogeneity of the "Villages" inhabitants in regards to age group and income class, transforms such urban patches into introverted enclaves, intolerant to any social changes that may affect their serenity. The neoliberal market forces zealously, promote such enclaving processes and their spatial products (Easterling, 2005) that thrive in the globalized economy. The art of

enclaving eloquently described by Banham (1971), regarding Los Angeles is upscaled to a globalized context.

The point of this story is the increasing intolerance of such enclaves' populations that eminently could affect the rest of the world with their priorities in keeping their status quo. We are witnessing a generalized NIMBY phenomenon where, what counts is not any more what goes to their back yard, but how the outside world should be changed so that their back yard stays intact.

**Story Two: Use WIMBY politics for rebranding segregated urban areas:** Hoogvliet is the name of a failed modernist housing project in the Netherlands. A spatial product of the Dutch modernist Welfare State policies, that failed to adjust to the contemporary Dutch residents' demands thus, gradually abandoned, becoming a stigmatized urban area. A State initiative promoted the urban porosity as the vehicle to reverse the stigmatized identity of Hoogvliet. WIMBY is the name of the project, in other words a "Welcome In My Back Yard" project, (Provoost, 2008). Through an acupuncture approach, an explicit welcoming of the rest of the city into the housing project site takes place, with new mobility networks, public program both for the residents and for all city inhabitants, with the ground getting reshaped to filter such flows. The engagement of the architects' community as well as that of the housing project allowed another level of connection to take place in regards to the actors involved. However, the crisis of the welfare state has hit even the Dutch door, forcing the cities' actors to rethink their actual urban design practices, such as that of master planning that generated between other things, a considerable amount of vacant housing (Rietveld R. & Rietveld E., 2014).

We keep in mind the role of the State in WIMBY politics and we should start wondering what could be alternative actors' alliances to keep up such politics in the context of a weakening State across Europe.

**Story three: Give an urban strategy to a housing project: "**Oasis 22" is the name of a recently built housing project in Vienna. It is in fact, the result of a Europan 9 competition winning project by the studio UEK. The articles in the monograph publication entitled "An urban strategy for a housing project", explicitly address the cross-scale challenge for any debate on urban connectivity. "From the very beginning the team focused on interdisciplinary methods which brought new focus of cooperation to the project". The team explicitly mentions that "by involving new actors into the project, extra ideas, like the participative activation process could pursue" (from Europan Austria website)

In fact, this project's implementation process mobilized at least fifteen different actors to assist the passage from the ideas competition to the implementation phase. The Europan collective urban design platform, a generative ideas device, has gone hand-in-hand with the Viennese welfare culture of city making, to produce a porous, well connected housing project.

The Vienna Europan project is one of many winning projects in the Europan sessions that undergo the passage from the ideas to the implementation stage. Some of them are more

successful than others. A few get built and others become master plans for future development. Most of them struggle with urban porosity challenges. The winning project teams state initially their images of the possible on porosity matters. Their projects become vehicles for re-allying urban actors around challenges of connectivity.

The question raised in regards to the third story, is as a matter of fact, the main problematic of the article: What alternative urban design practices to support such actors' alliances beyond private driven NIMBY politics and State driven WIMBY ones?

### 2.3 Cross-bordering practices for urban porosity

Considering the urban environment as a "patchwork", could the art of urban "knitting" oppose.to that of enclaving? Building on this metaphor, we could refer to Sennett who introduces two kinds of limits of the patches, where the knitting may need to take place. In his short article in the Venice Biennale of Architecture Catalogue 2006, he distinguishes the borders from the boundaries. He sees borders, on the one hand, as devices which allow infiltrations that generate all sorts of urban dynamics between parts of the contemporary city, enhancing the possibilities of coexistence. Boundaries, on the other hand, are impenetrable urban features that segregate entire areas within the city.

The porous nature of borders attributes them a paradoxical interface character since borders could both channel and block urban flows. The cross-bordering practice may have a multiscalar dimension involving a multiplicity of public agents.

We will focus on three public agents such as mobility networks, public program and that of public ground. We will examine the multiscalar dimension of cross-bordering practice at the urban interfaces of the Urban Design project perimeter, that of the urban block, that of the building perimeter and that of the housing unit, (fig 01)

The aim is to go beyond simplistic assumptions of a generalized need of physical connectivity to resist segregation and to introduce a complex association of urban porosities in physical, temporal and pragmatic contexts (Stratis 2001), demonstrating the need for collective urban design practices.

We will see further on, the pertinence of Europan to the urban porosity debate. How the objectives of this article profit from the Europan context and from the author's engagement into such European Urban Design platform from an architectural approach.

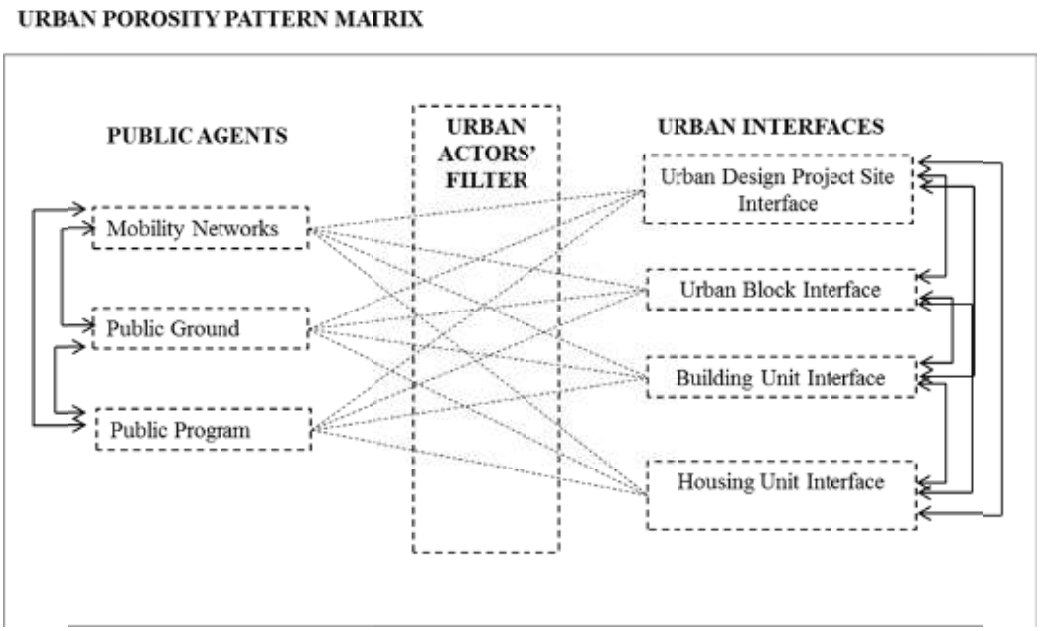

Fig 01

**3. Europan's relevance to the urban porosity debate.**

In this part, we will address the relevance of Europan to a broader aspect of urban porosity, emphasizing its passage through "actorial" filters. We will firstly introduce the reader to Europan and its activities. We will then refer to the literature produced by Europan in regards to urban porosity. Further on, we will allude to two kinds of fuzziness that make Europan even more relevant to the article's problematics.

**3.1**. **About Europan**

Europan is actually a European network of urban design competitions open to young professionals (architects, landscape architects, planners), under 40 years old. It takes place every two years approximately with 45-60 European cities participating in each session.

Looking back to the 25 years of Europan activities, we could see a diversity of agents and interfaces through which an exchange between urban actors takes place in regards to the role of architecture in the city. As a matter of fact, issues of urban porosity have been in the heart of the

Europan project both on physical and temporal contexts as well as on pragmatic ones (Stratis 2001).

It's true that the challenges for urban design have changed considerably since the 1980s when Europan emerged from the French PAN (Progressive Architectures Nouvelles). Following the winning projects over the various sessions we could as a matter of fact, witness the shift on both the definition of porosity by the teams as well as by the Europan literature itself. We could sense in fact, a similar shift like the one taking place in the architectural discourse outside Europan, that from the object oriented proposals where the built form was offered by the architects for all urban problems, to process oriented projects, where multidisciplinary teams enriched with landscape architects and planners, acknowledge the limitations of the built form vis-à-vis urban porosity challenges by employing much more sophisticated tools to address challenges of connectivity in much larger competition sites.

### 3.2. Europan's practice as part of urban porosity strategies

The practice of Europan reveals all sorts of strategies relating to patterns of urban porosity, not only with regard to the physical space of the city, but also in relation to "cross-bordering" practices amongst the actors involved. Such strategies are reflected in the winning projects and extensively described in the Europan Results and Implementation catalogues. For example, the 1999 Catalogue, "From Ideas to Realization", introduced the notion of the open block (schotsen in Dutch) in a discussion between Didier Rebois and the S333 team for the Groningen project. Further on, Chris Younès referred to the crucial role of nature in the in-between spaces of the built environment in the 2004 Catalogue "Europan 1-6 Negotiated Projects". In the Europan 10 Catalogue of Results alone, there are three articles by Bonzani, Franco and Amphoux about agents of urban porosity, such as ground treatment, building morphologies or walking practice. In addition, there is an article on actors' "cross-bordering" practices by Vlay and the author, (Vlay, Stratis, 2010).

### 3.3. Mobilizing ideas for porosity: a hybrid urban design practice between network and centralized Europan's character.

The paradoxal aspects of the pan-european urban design practice platform create a diversity of additional porosities in regards to the processes of formulation of the urban design projects.

Firstly, we are talking about its fuzziness between ideas and implementation competition. Ideas are devices that mobilize urban politics. Consequently, the innovative approaches of the winning projects reassemble the projects actors by facilitating collective visions. Their processes of implementation become platforms for negotiating potential urban connectivities, and they attribute value to the public dimension of Urban Design practice. Both, target to increase the habitat alternatives for inhabitants who may be willing to abandon the comfort of neoliberal enclaving habitats.

The second paradox lies in the simultaneous networked and centralized nature of Europan organization. Thematic concepts are introduced thanks to the Europan's centralized nature supported by a Scientific Committee. Then, those concepts are challenged through the organization's feedback network consisting of urban actors across Europe. The three forums of each session (forum of sites, of cities & juries and that of results) assure physical contact between the network members, both old ones and newcomers. Consequently, the participating urban actors find themselves quite often in unlikely associations across Europe, with cities, sites and projects inscribed in similar conditions as their project site.

We will focus on the recent Europan sessions, profiting from the Europan Forum of Results of May 2012 in Vienna where some of the sessions were devoted to the processes of the Europan winning projects' implementations. One of the sessions explicitly addressed the challenge of "creating urban fluidity through a porous urban fabric". The author wrote a relevant article for the Europan Implementations Publication (Stratis, 2012), used as food for thought for a debate he co-animated with Pascal Amphoux. The session consisted of two circles of participants. The first one included the clients and architectural teams of the Europan projects under implementation in Gembloux, Belgium and Saintes, France. The second circle consisted of sites representatives, winning teams from the following session, that of Europan 11. The winners who came to the Forum of Results to celebrate their victory, found themselves in working sessions, getting insights from colleagues of former Europan practices. In this case, the theme itself of porous urban connectivities operated as a common concern of the project actors coming from 17 cities from 10 European countries. As a matter of fact, the participants' contribution to the theme enriched the debate on the role of collective urban design practices in regards to urban porosity.

## 4. Methodological Approach

The author studies the transition from competition to implementation of 12 winning projects, located on 10 Europan sites from Europan 7 to Europan 10 in 7 countries. The study in fact, explores the tolerance of project actors involved in this transition, to urban porosity. The existing sites are mostly urban voids either enclosed between urban development and transport infrastructures (Vienna (AT), Villeurbanne (FR), Montreux (CH), Halle (DE), Dietikon (CH) or situated mostly at urban peripheries between urban land and agricultural or common land (Córdoba (ES), Isle d'Abeaux (FR), Carouge-Bachet (CH). In the case of Gembloux (BE) and Augustenborg (DK), the sites are potential interfaces between existing urban fabric and public spaces.

The author has combined several qualitative methods to study the urban porosity aspect of the selected Europan projects: a careful study of drawings, images and texts of the projects, a series of questionnaires filled-in by the winning teams and the Europan national secretariats, and participation in a debate with some of the Europan actors discussing about the same issues. The

combination of these methods reduces the risk of false observations. However, we have to admit that the very small number of sampling does not allow us to make any generalizations. Nevertheless, some important specific remarks emerged regarding the "urban porosity friendliness" of the projects' actors under study.

### 4.1 Mapping the filtering performance of urban interfaces

The first part of the study refers to the paradoxical performance of urban porosity: that of simultaneously opening-up and closing-down in regards to public flows (Public Agents). The author studied the drawings, images and texts of the 12 selected projects in terms of four performative elements: a. The opening-up agent that connects the project site to the rest of the city, b. the closing-down agent that promotes privacy for the site's inhabitants, c. the smallest urban unit whose interface manages urban porosity, d. the mode of multiplication of such unit into the project's site.

### 4.2 Questionnaires about the change of the projects' actors' "urban porosity friendliness" during the implementation process

The questionnaires were divided in two parts. In the first one, the project teams were invited to name the actors involved in their projects and their "urban porosity friendliness" in regards to regulations, priorities and mentalities. Then, they had to explain how their "urban porosity friendliness" changed between the ideas competition stage and that of implementation. Which urban actors had disappeared and who had appeared during the implementation process.

The second part of the questionnaire consists of three questions. The first one is about the specific kinds of urban porosity in their projects. The second one is about the change of such urban porosities during the implementation process. Finally, the third question was about the kinds of negotiation employed to sustain the projects' urban porosities into the implementation stage.

The author processed the findings into a "cloud" of urban porosities arranging them in a spectrum ranging from translocal interfaces (regional) to very local ones (collective). In fact, the urban porosities were produced by the three Public Agents of mobility networks, of public program and of public ground. The next step was to overlay on the "cloud", some implementation factors such as safety, market feasibility, financial priorities that challenged as a matter of fact, the degree of urban porosity.

## 5. Findings regarding the Europan's Urban Porosity Patterns and their transformation through the projects' implementation stage

The findings are divided in two parts. The first one relates to the specific examples of Urban Porosity Patterns emerging from the studied projects. The second one is about the change of such patterns through the implementation stage.

### 5.1. Selected Europan projects' Urban Porosity Patterns

We mentioned already the emergence of urban porosity patterns through an interrelationship of Public Agents and Urban Interfaces through an "actorial" filter. The public agents that manage public flows are: the mobility networks, the public ground, and the public program. The Urban Interfaces where the Public Agents are manipulated consist of: the urban design competition project site interface, the urban block interface, the building unit and that of the individual housing unit. The "actorial" filter is formulated by the urban actors with their specific policy making and the embedded urban culture of the city in which the urban design project is proposed for, (see figure 01). We will firstly present the findings regarding the Public Agents and then those regarding the Urban Interfaces.

**-Public Agents.**

**Mobility Networks:** they create translocal porosities and their WIMBY opportunities depend on their type. Secondary car roads selectively infiltrate most of the project sites, creating access to the building blocks or buildings. In other cases they serve the project peripherally (Isle d'Abeau, E10; Vienna, E9, Montreux, E10). Pedestrian and bike networks are more welcome where high-speed transport such as rail and highways are distanced by parks (Córdoba, E8; Dietikon, E10) or topographic interventions (Carouge-Bachet, E9).

**Public Ground:** it infiltrates the project's site in the form of parks with set geometries (Villeurbanne, Isle d'Abeau) or in the form of landscaped fields (CarougeBachet, Montreux, Dietikon, Halle). Its 24hr accessibility is a challenge during the implementation process.

**Public Programme:** ground floor public services in fact, activate in-between open spaces. They attract the rest of the city into the project site via networks. In most of the projects, such programmes either shrink during the implementation phase because of market restrictions (Montreaux, E10; Vienna, E9) or they are displaced to the project site's periphery (Córdoba, E8; Carouge-Bachet, E9). Sometimes the attractiveness of the proposed public programme creates additional centralities in the project's site (e.g. a new municipal hall in Gembloux, E10; an urban centre in Augustenborg, E10).

**-Urban Interfaces**

Borders/interfaces have qualities of both infiltration and resistance. In order to establish urban-porosity acceptable for site developers, the project teams embody strategies for opening up the site to public flows and simultaneously strategies for enclosing it to protect the privacy of residents. Most of the projects become a matrix of multiscalar processes for filtering urban flows, using as their interfaces the perimeter of the project site or those of the urban or the building blocks or even that of the housing unit, but usually most of them. Each project chooses the interface to "fight" for the most. Creating a thick threshold between public and private, becomes the challenge of the projects' teams. They in fact, keep a critical spread between public and collective spaces to allow fuzziness in the use of open spaces.

Fig 2

Fig 3

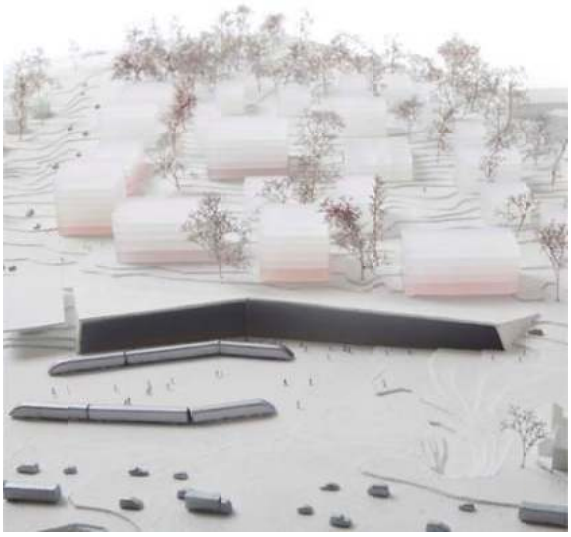

Fig 4

Fig 5

**Project Site Interface.** Since many of the sites are close to transport infrastructures such as highways and railways, the first thing to do is to block the noise. This is sometimes done with buffer vegetation (Córdoba, E8, fig. 2) combined with building features such as window gardens (Dietikon E10, fig. 3). In other cases, a noise barrier is created with topographic formations occupied by a public programme (shops and offices – Geneva, Carouge-Bachet E9, fig. 4).

Situating a public programme on the edge of the project site, encourages connections with the adjacent neighborhoods. Nevertheless, the tendency at the implementation phase is to displace any kind of public programme to the periphery, creating homogeneous residential areas in the rest of the site (Córdoba, E8; Geneva, Carouge Bachet, E9).

**Urban Block Interface.** Choosing the urban block as the main urban porosity interface, allows for connections with the adjacent context. The three projects at the implementation phase in Villeurbanne, E7 show how, on the one hand, public networks and grounds infiltrate the project site within the framework of a joint masterplan. On the other hand, the treatment of the urban block interface varies in each case. The Muoto team project (fig. 5) achieves the most openness by establishing the relevant urban porosity interface at the level of the building unit and at the same time elevating the collective open spaces. The Nakache-Orihuela team's urban blocks (fig. 6) complement the existing fabric, introducing a sort of a 3D striation of public passages, private and open built collective spaces. The W14 team's urban blocks (fig. 7) are more introverted, relying on the diversity of residential and collective spaces. In the case of Córdoba, E8 (fig. 2), the interface of the superblocks, made of 6 smaller residential blocks, resists the intrusion of the main car network, allowing public spaces for pedestrians and plantings to thrive. In the case of Dietikon E10 (fig. 3), the loose definition and mosaic like character of the heterogeneous urban blocks, accentuates the qualities of urban porosity in the in-between spaces and the ground in the form of a publicly activated field. A "multicheck" strategy sets the long-term framework for staged operations. In the case of Vienna, E9 (fig. 8), a loose block opens up to the rest of the city by creating public spaces at its perimeter with part of the block set back. In addition, the introduction of public services at ground level by elevating the residential programme, allows for connections with the neighboring sites. At the same time, the block operates as an agent to protect communal life within it. During the implementation process, the public programme on the ground was reduced. However, a legal framework was created for "cross-border" use of shared spaces.

Fig 6

Fig 7

Fig 8

Fig 9

**Building Unit Interface.** Pushing the interface for generating urban porosity down to the level of the building unit creates all sorts of complex building types that incorporate both the private enclosed and the collective open space. In Gembloux, E10 (fig. 9), a fragmented municipal programme allowed public passages in the competition phase, but for functional reasons accepted only porosity of a visual kind at implementation. As regards programmes, the "Uhouse" explicitly mentioned by the Muoto team in Villeurbanne, E7 (fig. 5) is one example. As already mentioned, the "U-house" (U-section) becomes an agent that protects communal life by means of elevation.

Fig 10

Fig 11

Fig 12

Fig 13

The Isle d'Abeau, E10 (fig. 10) project takes a similar approach, but in this case there is more blurring between collective and public space along the planted open backyard spaces. In Augustenborg, E10 (fig. 11), the elevated residential collective spaces form the roof of a 3D programmatic base, allowing public flows to dominate the city level. In the case of the Montreux project, E10 (fig. 12), it is the grouping of three-armed buildings in a shared landscaped space that filters urban porosity. The shrinking of the public programme at ground level during the implementation phase will probably reduce the project's "urban porosity friendliness". This also seems to be the case for the project at Carouge-Bachet, E9 (fig.4). However, the proximity to the new multimodal train station creates a translocal programmatic porosity for this project site, since the catchment area for potential residents will increase significantly. In the project in Halle, E7 (fig.13), it is the ground as sort of a park that infiltrates between the individual houses, with the hedges providing the only interface between public and private. The question by the authors, who seem to have no control over how the project involves, of how public these planting areas really are, is legitimate.

## 5.2 From ideas to implementation: a rite of passage to re-ally project actors

The implementation stage has a sort of a liminal character, a rite of passage from one condition to another. The initial condition, the competition phase, is the construction of "images of the possible", a sort of imaginative enrichment of perceptions of urban living amongst the stakeholders concerned. The final condition, the post-rite stage, is the transformation of the built environment, here in 10 sites across Europe. What we have from the 12 teams are "blueprints" for such a transformation. Both the above conditions actually operate as devices for reshuffling the project actors, adjusting their relations, shifting them a little and for a while from their everyday routine. Such liminal rituals require support, and in this case it is the existing urban institutions behind city making that play this role. There is undoubtedly an extensive mobilization of actors arising from the project-for-implementation. As we know, European cities are Europan's most important clients and make the implementation of the winning Europan projects part of their modus operandi (municipal urban and planning agencies that are in contact with higher scale territorial administrations). At the scale of the developing site, it is the property developers and building promoters, municipal and/or private. When a residential programme is involved, you get subsidized housing agencies and cooperatives, as well as neighborhood associations.

The case of the Vienna, E9 project (fig.8) is an example, with at least 15 urban agencies involved in the implementation of the UEK studio project (Europan jury, City Real Estate Management, NGO-social services provider). It is quite evident that there is a whole embedded landscape of urban porosity policies are associated with people involved in projects for the Europan cities we are talking about. It seems that "urban porosity friendliness" decreases as the territorial scale from which the project actors come gets smaller.

### 5.3 Manipulate the tolerance of project actors to open up the project site to the city

Establishing urban porosities means increasing the degree of coexistence in open spaces and the degree of sharing of infrastructures such as mobility networks, parks, public services. So how tolerant are site developers and future users /inhabitants of such an opening up process? "The constitution and sustainment of a community and its network relations to a larger territory demand a critical mass of future users that enjoy the diverse possibilities the project offers to them…"(studio UEK, Vienna, E9). In some interviews, it emerges that the majority of the project actors on these 12 projects were public bodies with a commercial interest in selling their project. Here are some sample views by project actors cited by Bernd Vlay (Europan Austria).

"… if porosity helps to sell the site, fine; if we need to shut it in – that's fine too"; "Porosity as a politically correct quality, but depending on what conflicts actually happen "

"… accepts porosity which does not affect the privacy of the living units. Depending on typological intelligence: if the type offers porosity without annoying the residents: FINE"

In other words the urban players, protagonists in the implementation of winning Europan projects, are "urban porosity friendly" provided that it increases the market value of the projects. And provided that incoming translocal flows do not negatively affect the living conditions of the residents. Otherwise, they are ready to shut off any undesirable connections with the surrounding city… This suggests that space has active agent characteristics. So the teams behind the winning Europan projects are very valuable in that they keep proving that such "urban porosity-value-for-money" is possible and the built environment can handle it because of the way it is designed. In addition, such practices bring us to examine the design of the fine grain of the contemporary city, as Thomas Sieverts mentions in his book "Cities without cities: an interpretation of Zwischenstadt" (2001). If we look at all the projects under consideration, the proposed ideas are indeed based on the multiplication of a sort of a fine-grained urban environment, rather than the choice of a one-off mega gesture to make their mark.

## 6. Conclusion: from intolerant enclaves to porosity friendly urban patches

The concluding remarks are divided in three parts. The first one is in regards to urban design references that may produce alternatives to intolerant urban enclaves. The second part is about the Urban Porosity Pattern Matrix from Europan practices and the third part is about using such matrix to resist to the dominance of intolerant enclaves onto the contemporary urban environment

### 6.1 An "actorial" dimension of urban design to establish urban porosity

The art of urban enclaving seems to be gaining over other kinds of arts for urban active coexistence, due to its backing up by the globalized neoliberal economies. We should keep in mind the increasing intolerance of such enclaves' populations that eminently could affect our everydayness. The author referred to specific "actorial" urban design approaches that may engender new actors' alliances to support sharing in a complex urban environment, in other words to adhere into "urban porosity friendly" postures when the welfare State is weakening across Europe. The challenge would be to sustain such actors' alliances within the actual globalized neoliberal context by challenging the disciplinary limits of urban design.

Issues of urban connectivity as a reflection of social cohesion are as diverse as the contexts in which the Europan urban design projects are embedded. Privatized forces backed up by the neoliberal global economy may be on the doorstep of all European countries. However, the peripheral countries with weaker heritage of a welfare state urban culture (southern Mediterranean countries), or in state of denial of their State past, (former eastern European countries), seem to be much more exposed to social segregation, thus urban fragmentation.

### 6.2 From envisioned Urban Porosity Patterns to implemented ones

Europan still operates within a western welfare state heritage. The porous urban practice of the French PAN and in continuation that of EuroPAN has enabled a considerable number of young talented groups, usually architects, to become part of the best European practices. This is true of course, where Europan goes hand-in-hand with other urban apparatus inherited from the welfare state, usually in the Northern Western European countries. This is not true in countries such as the UK, or Eastern and South European countries.

The "cloud" of urban porosities produced by the author, through the study of the selected Europan projects, showed an arrangement of urban porosities in a spectrum ranging from translocal interfaces (regional) and very local ones (collective). In fact, the urban porosities were instigated by the Public Agents (those of mobility networks, of public program and of public ground) and were managed by the Urban Interfaces. The overlay on the "cloud" with the implementation factors that challenge the degree of the urban porosities, showed how the actors' urban porosity friendliness changed due to safety, market feasibility, financial priorities etc.

We may conclude that in spite of the decreasing degree of urban porosity from the competition to the implementation phase, urban porosity is still clearly present and multifaceted. Such process may increase the critical mass of users who would prefer to live in such urban conditions rather than in "safe", gated environments. It is true that post-occupancy evaluation of the completed projects will show whether such objectives are met.

### 6.3 Europan as a fertile ground for research on Urban Porosity practices

The author has developed an Urban Porosity Pattern Matrix through which he studied how urban design projects relate Public Agents (catalysateurs for public flows) with Urban Interfaces (multiscalar edges of urban patches and enclaves), through an urban actors' filter, to envision a porous connective urban environment. In fact, the analysis has focused on the passage from the Europan ideas competition stage to that of implementation and it showed the transformation of the project actors' degree of tolerance.

Further on, the author proposes to use the Urban Porosity Pattern matrix as facilitator in reframing the relationship of collective urban design practice to urban politics. It could become in other words, a negotiating framework as an alternative to the art of enclaving that is backed up by the overwhelming capacities of the neoliberal global economy through its spatial products (Easterling, 2005).

The Europan platform could be very useful for such endeavor, by reconnecting practiced based theory with the practice itself. Despite the fact that the research on Europan as a collective urban design network platform has remained limited within national boundaries, there is a substantial archive of best practices of collective urban design that could help us to establish an international research on "urban porosity friendliness".

Keywords: Public spaces, urban space, identity

## Abstract

*Appertain to the place has several dimensions – identification with the state, region, area, city (town), village, district, neighbourhood. Character of the place defines the urban fabric, the urban space, its importance, location, history, economical prosperity and, naturally, people, their memory, manners, experiences, actions and nature.*
*The basic elements of identification with a place can be stable, either with long period fixed character, or they can be changing with the dynamic evolution. Also our sensibility is changing according to the character of the place, its elements during the evolution. There are periods, when we are less sensitive to the value of the environment; even arrogant. Sometimes we are calculative when the commercial effect from otherness is more important for us than human or spiritual aspect.*
*Urban resident and occupant identifies himself with the city and urban environment via arrangement of spaces. Identification with urban space and its characteristic elements is linked to good orientation, accessibility, functions, activities, people... Also details of public spaces create memorable places.*
*The paper is focused on evaluation of public spaces in Bratislava with the emphasis on squares in the central city area. The study is aimed at problems and potential of the squares. Based on the complex research, a strategy and concept of squares development and transformation in the scale of the whole area is presented. The concept is consists of prioritization and differentiation of spaces, which should support their identity and good legibility.*
*Study presents applied research supported by city council of Bratislava.*

## 1. Introduction

Spatial structure of places on has gone through significant changes in last 70 years, caused by modernistic approach towards urban design. This approach has brought retraction from traditional spatial form and has started introducing free form design of urban spaces since the 1960´s. Tighter urban structure has started to be applied since the 1980´s, but in a less significant way than in other developed european countries, as a result of starting mass-housing period. However modernistic approach legacy is quite heavily maintained and present in our cities. Single-use commercal areas and family-house "landscapes" located mostly on the outside of city border represent the mentioned system. In those structures, a man usually identifies himself with his own house or appartment rather than with space that commonly surrounds him. Therefor the role of spaces, their image perceived by men and their character is more and more important. Supporting the distinctive individual character of a city and its places and the identification with districts is fundamental.

Bratislava is becoming recognized as a city without properties. This nickname was given by Tijs van den Boon in his publication Bratislava - city of peace. Moravčíkova sees this name as *"provoking, but according to the fact of permanent change as appropriate"* [Moravčíková, H., 2010, p.34]. The reason is that Bratislava has gone through a set of modifications in last hundred years and *"is open to transition yet too much, mostly the urban fabric"* [Vitková, Ľ., 2013, p. 20]. Architectonic tracks are erased after each fundamental political change. Bratislava is carelessly getting rid of its typical buildings, even whole complexes. Mostly those industrial ones; Podhradie (area under the medieval castle), typical rural settlements... Nowadays modern 20th century architecture is endangered. This approach is reflected into the image of public spaces of Bratislava. By losing areas, public spaces with unique identity are getting lost as well.

Cultural and social meaning of public spaces has been underestimated in Slovakia for a long time. Their role has changed from a stage for public life into a role of traffic corridors or crossroads. Traffic swallows the public space and so degrades the perception and identification with place. This is another problem of public spaces in Bratislava.

The report is focused on characteristic parts, elements and places in Bratislava. In the first phase the emphases is given on squares of central district of Bratislava.

Research objective is to analyze individualities and utility of nodal public spaces in Bratislava.
Spatial structure of acity was focused on evaluation of acharacter:

- System of nodal public spaces in the city strcture (location, hierarchy, significance, distance, use...) and their mutual relations and connections.
- System of nodal public spaces in the city district structure (location, hierarchy, significance, distance, use...)
- City spatial structure analysis within the frame of historical development, development of site use, location of main nodal spaces and development axis.
- Arrangement of nodal public spaces within city structure in linkage with important public buildings, city entrances - railway stations, bus stations, high-rise buildings.
- Arrangement of nodal public spaces within city structure in linkage with development axis (boulevards, city streets, pedestrian areas...)
- Character and way of defining the selected public spaces, intensity of connections and building entrances.
- Use of public spaces and their surrounding structure (character of parterre, buildings entry strength)
- Type of nodal and linear public spaces use.
- Size parameters of nodal public spaces.

Research was focused on the quality of public life in public spaces from these aspects:

- Quality and intensity of public life (degree in use of public space) compared to the evalutaion level of quality of public space (by residents, professionals) by exact methods.
- Quality and intensity of public life compared to the use of surrounding structure of public spaces

The objective of the research was to review the qualitative level of public spaces in Bratislava as a whole and its single districts with accent put on their individuality and utility.

Public spaces of Bratislava are the research subject studied as a whole since there is no such complex material about the issue of public spaces and still the capital of Slovakia misses this kind of document. Considering the difficulty of a problem and a need for a somplex solution, the research is studying mainly the nodal public spaces of central city area. Individual types of spaces were characterized and classified on the base of formerly defined criteria. Character and structure of spatial raster, quality of spaces, their type and intensity of use were evaluated.

Special attention was given to the analysis of readability of main public spaces from the aspect of outer image of a city and to the analysis of readability of public spaces within the urban city structure - readability of their individuality and singularity.

Essential part of the research has taken a look at a review of relation between spatial quality of a public space, use of enclosing structure and parterre, use of the area of place and quality, character and intensity of use.

There was an assume that a place claerly spatially defined, used in different ways, operationally well organized would be more attractive and more intensely used and more lively.

## 2. Definitions of urban space

Traditional basic spatial elements of a city - streets and squares have been forming the growing city framework and gave the city an image. Hierarchy of elements forming cities is fundamental for the city development, for contemporary growth and transformation. In his theory of an image of a city, Kevin Lynch considers nodes and lines, borders, areas and orientation spots being the most essential.

### 2.1. Definitions of public space

Spatial urban structure can be characterized from several aspects, e.g. spatial definition. Carmona defines two basic types of urban space: *"first where space is defined by buildings, second where the buildings are objects in space"* [Carmona, M., 2010, p. 77]. Others simplify the definition even more, for example Jan Gehl uses the term *"space between buildings*" [Gehl, J., 2010, p.15].
According to the accessibility, the public space can be divided to public, semi-public and private. The relation between owner right principles and the degree of its communal use is getting less and less unambiguous. Several authors pay higher attention to this question. [Madanipour, A., 2003]. Manuel Delgado characterizes a public space as: *"A space, that public has rights to use."* [Gausa, M., 2003, p. 563] Frederico Soriano points out that: *"private spaces are used by public (shopping malls, airports) and vice versa, a public space is taken by private use."* [Gausa, M., 2003, p. 563]
However, the urban fabric is associated with other features; economy, owner-rights, intensity of public use. Thus public space is a space intensely used by public, citizens. This part as a social and cultural layer is inevitable for living city. *"Public spaces are kind of a mirror to the city culture, to the city life... undoubtedly it is a medium influencing and completing the cultural profile of a man and society."* [Melková, P., 2014, p.4]

### 2.1. Definitions of squares

A square definition from Edward White highlights the social and cultural meaning of these places: *"Squares are a place for sharing, living and befit." ..."While the streets encourage us to go, portals to pass through, squares invite us to stay, sit down and take part in public life."* [White, E., 2007]
Jan Gehl underlines the difference between a street and a square in the same sense: *"Streets reflect the linear move formula, a square matches the field of view." ..."While streets symbolize the movement: ""go on please"", squares encourage to stay. If a place says: ""go, go, go"", the square means: ""stop and look at what is happening""*. [White, E., 2012, p.38] Pavla Melková and her collective highlight the social dimension: *"A square is a place of an identification and a permanent community confirmation, a place for national, urban, local and communal representation, a place for meeting, a city saloon." ..."it is an orientation spot in the mental city map."* [Melková, P., 2014]

## 3. Identification through public spaces

### 3.1. Identification with space via form, system of unique places

The study of public spaces in an analytical phase is focused on data collection and evaluation. The type of data collected is led by already realized studies from Copenhagen [Gehl, J., 2004] and Prague [Melková, P., 2014] and partly affected by the environment already known. In the chapter *Identification with place via form* basic volumetric elements sensed in space will be discussed. We chose schemes of several characteristics in site plans to describe the city - dominating, present, absent. Partial conclusions bearing the information about a place, locality, area are to be made; conclusions about the identity, even about the unfinished /unspoken identity, a violated identity.

### 3.1.1 Characteristics

For the needs of this study, **constriction** is taken for a degree of secretiveness of space. All the publicly accessible spaces will be processed: streets, squares, other corridors. These will be stylized and simplified, capturing the estimated height of surrounding buildings and the "floor" bordered. Bearing in minds the basic compositional principles [Sitte, 1995] [Krier,1975] only corridors where the "walls" exceed half the width of the horizontal surface will be rendered (Figure 1). In the already analyzed part of a city we can see places where the streets are getting lost somehow. For example places hit by vast reconstructions in past decades (solitary construction, traffic linear structures). Although a different region can be identified by wide open spaces, it should be well considered whether this is a case of a city getting lost and whether it should be further completed and subdivided. We cannot assume any close identity support from current development plans, speaking of zones, localities.
meaning: understanding the city structure and its inner subdivision to smaller segments.

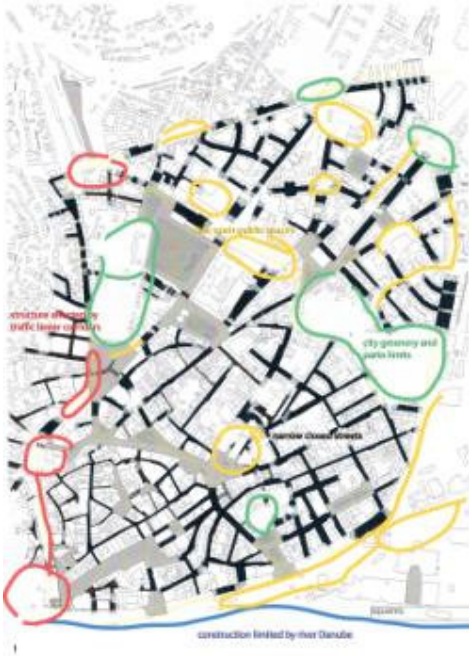

Figure 1. Street constriction in city centre plan

**Connectivity** describes a frequency of nodes in the city structure where the pedestrian can decide what route to take next, it bears the information of how intense is the freedom to choose. The frequency can be higher or lower when the nodes are closer or more distant. Interestingly, this characteristic bears information about how is the built structure used by residents and visitors actually.
Node and line is the basic pair of analytic elements. The node or point is place where three or more routes meet. A line is a real connection between any two points that can be taken by a man. (Figure 2) Bold black lines are highlighting those short connections, creating the blue zones where it is quite a frequent situation for a user to stop on his way and choose how to go on. The pink bold lines mark those long paths that can often be boring.
We found out that passages meliorate the connectivity of a city. On the picture we can see a mesh of bold black lines within squares. It is caused by a solitair put in the middle (as a result of socialist and mass-housing construction period). This phenomenon should be called connectivity of lower level because the moment of option is multiplied by solitairs and by fact that nodes put in a map does not join streets or defined corridors, but pavings, roads, areas and stripes defined superficially by material only.

In the Figure 2. we can see four named blue zones. A zone is historical area with narrow houses forming short streets with passages leading to another short streets. In the B zone, there is an emerging east-west longitudinal system of longer and shorter streets. Those shorter lead from north to south. However, there are many spots where it is violated by irregularities. The C and D zone (famiy houses and city villas; appartment houses and section panel houses) could by described as a bit twisted gridiron structure of a modified square shape where the irregularities are found, too. Even though, we consider the presence of the above mentioned irregularities as elements orienting the person inside the place.

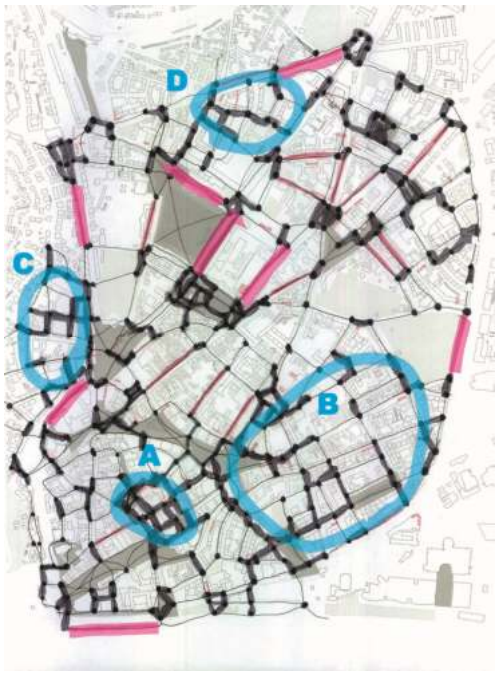

Figure 2. Connectivity of pedestrain routes in urban structure as a factor of identity

**Volume interaction** describes the act of space entering the mass vice versa (walkway, cantilever, arcade). This accent is most often found on individual objects. However, few localities with passages or overcast arcades, colonnades are emerging. These places are favourite to pass through and sit in, they are analyzed from the sociological aspect, also.
meaning: shortcut, curiosity /interest, hideaway from sun, rain, from views.

**Perceived roof shape**, excluding extremely narrow spaces, can be basically divided into flat and sloping; or other shapes, arcs, combinations. Once again, it must be reminded that this is not a pure qualitative feature where one category is always taken for the positive or negative. Anyway, the phenomenon of one kind prevailing over the other enhances the identity of a place will be important for the study. The historical expression of the building facade could be studied further, this is what we consider for quite detailed features, more planar than volumetric; it is even bearing the information on the origin.
meaning: prevailing type supports the identity; from the visual aspect, the saddleback mellows the view and its flow through the space

**Greenery** in the corridor and in front of facades will be mapped because of the uniqueness and related consequences inflicted by its presence. Whereas the greenery in the corridor stands for accessible and touchable trees and lawns from around and the greenery in front of facades, understood as the front gardens usually without direct access serving as a visual sensation.
meaning: (corridor greenery) orienting and guiding, subdividing, covering and hiding, completing and adjusting the character of a place (in the sense of a typology)
meaning: (front garden) isolate, protect

The aim of this analysis is to point out a way how the greenery is placed in city, how does it complete the identity if a locality and how does the identity exceed the place boundary (for example crossing the square´s border to streets). Moreover, there are some other features associated with greenery, but less concerned with the issue of identity, the image of a city and with the urban psychology.
Facade and corridor greenery were studied in their posistion when some basic qualitities were met. Facade greenery is meant to be a stripe of a lawn wider than 1,5 meter with trees in a row (explained below). This strip makes up a kind of buffer zone for the building offering a visual contact. Greenery in acorridor is accessible and touchable row of trees that can be combined with lawn of different widths. The trees in row have to be in fourths at least and the distance between them has to be less than 6 meters. These trees create "a ceiling", "a hideaway" for the users, for pedestrians; they divide the space also. Lawns with short bushes but without trees in a row were not mapped.

*Results*

Applying this approach, several facts were found. The greenery is usually placed without concept and order; the system of organizing into alleys, green streets, boulevards has typically got weak parts that threaten the readability and simplicity of a corridor. Smaller groups of trees and bushes remind rather a spot element. Pairs, triplets and solitairs were found most often; they float in a non-structured space, without clear composition and therefor understanding of a man. These solitairs are placed individually, by chance, additionally. Furthermore, they are not of typical solitair features - of an accent: colour, specie, meaning).
To sum up, few localities with prevailing identity associated with the greenery were identified. Areas where the lawn, bushes and trees flank the building, a kind of garden neighbourhoods are circled in the figure below. (Figure 3) There are also areas with absolutely no green element in the corridor, they are circled in the dark blue shapes. The yellow lines represent emerging green streets, linear urban greenery functioning as a ceiling from the top and a partition on the sides. Grey areas are squaares in the central district of Bratislava.

Figure 3. Urban greenery forms creating typical areas.

### 3.1.2 Characteristics exceeding the issue of volume

**Typical materials** are other basic features of a place perceived by a user /passer-by easing the orientation (Lynch: The Image of the City). Repeated facade material, smaller or bigger cobblestones

with tall or low cross-section, comfortable walk through street segments, facade cladding pleasant to look at and to touch, varied historical stucco, stem large-scale plates, vegetation walls.

**Communicating parterre** is more and more taken for a great asset to city life. Although sometimes a little less in a reality, including the idea of a city effectiveness on different scale. If we still want to talk about volumetric features, the material, shape and service provided make us understand the types of activity in public /private spaces in the floor at the ground level. This characteristic stands on the borderline of the volume, flat and function.

**Accessibility** of the building favours pedestrians to move slower move and stay, consecrating the place to walk without threats. Buildings and residents should not be cut apart. Pedestrian localities are spots with calm transport or traffic excluded, within the 5-meter offset from the building. The aim is to identify areas with potential to bring the life back, which can be easy or difficult to do. Interesting but at the same time dangerous spaces are expected to be found as well as places with good accessibility but no activities taken.

*Results*

The study aims at the relation figure-background (square-area). The question is: Is it a A-B relation while talking of some characteristics or is it a A-AB-B relation? Within the A-B we talk about a contextual greenery (Figure 4) (Jakubovo námestie with front garden continuing as a part of the square into the street), about a contextual constriction (Main square, Komenského námestie with enclosed corridor with proportions over 1:1) or about the contrast constriction (Kamenné náemstie, Námestie SNP, Kollárovo náemstie with constricted street corridors leading to wide and open space of a square). The A-AB-B relation gives an opportunity to describe the double contrast. For example the great openness of a place is accentuated by narrow street walkways entering the open volumes (Námestie slobody and surrounding area). It is not our goal to decide which paradigm is appropriate, but to highlight the importance of relativity of scale when analyzing the city; to work with the scale of a zone, area, city part; identities and their structure.

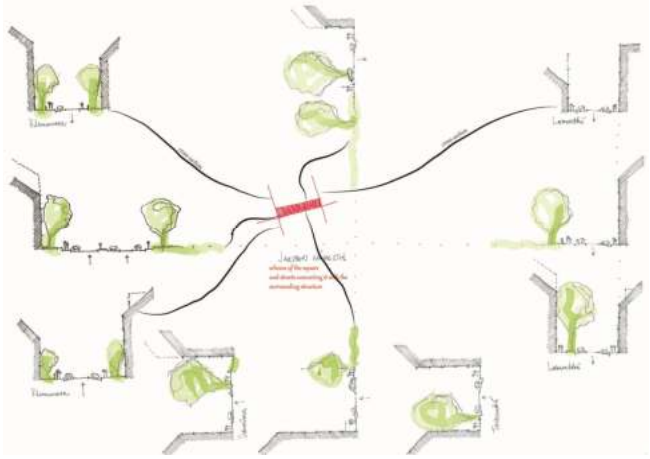

Figure 4. Contextual greenery

### 3.2 Identifications with space via dominants, important objects (monuments)

Significant buildings are important for the readability of public spaces. Not only with the role of orientation points, landmarks. They are a message of a period, remind significant historical events, prosperous times, importance and role of a place.

Thanks to the natural features, terrain configuration support natural dominants that highlight the position and importance of public spaces, the central areas most of all. Bratislava castle reef, Slavín (war memorial and cemetery), Bôrik... hanging over the city, places in contact with the river Danube, spots raising their importance. Natural features enhance the uniqueness.

Dominants, historical or contemporary, are the city symbols easy to identify in the urban fabric creating the solid orientation spots in public spaces. Some of them are symbols of the city overcoming its borders. Once again, this affects the identity of a town. It was partly realized by foreign architects. For example the Riverpark project (Erick van Egeraat´s concept), a set of dominants Panorama City under the construction from Ricardo Bofill and the complex of dominants from architectural studio Zaha Hadid Architects in starting point of the realization process. Like many other big cities, Bratislava is trying to get known thanks to the big names and iconic architecture.

Figure 5 Dominants and hierarchy of public spaces according to their importance
Authors: Ľubica Vitková, Katarína Boháčová

### 3.3 Identification with space via use

Activity - life is the basic feature of a place - a square we realize in a public space. What is happening in the square? What attracts pepole to come to a square? Use of surrounding structure, active and pleasing parterre and activities taking place in the sqaure area. Finally, it is also people occupying the place who attract the others to come.
Atmoshpere of a square consists of a character and a form of architectonic space as well as activities and energy, symbolism... a church, a museum, town hall, a theatre, pleasant caffees...
A way of organizing the services is essential for utility of a square. What is the relation between the traffic and the pedestrians? What is the ratio of them? To what amount is the dynamic and static traffic and the pedestrian move divided? A square surface adjustment plays a great role: is it a lawn or paving with solid subsurface? Is the square surface walkable enough? These are the aspects influencing the atmosphere and ease in the sqaure as well as relations to the place.

For the system of evaluation, the use of space was considered as one of main criteria; including the use of surrounding buildings, use of parterre and the square surface itself (Table 1). During history, some squares have kept and developed gradually some particular functions: commercial, traffic,

representative, cultural... Although the use of buildings and square area changes in time, there still is a maintenance of a character based on the locality, importance and character of structures. Regular and irregular events and activities taking place in here are negligible.

Table 1. Use and potential evaluation of selected squares of Bratislava

| Square | Use | Parterre | Current use. (Potential) |
|---|---|---|---|
| Namestie A. Dubceka | Parliament, government buildings | Passive | Greenery, public space, traffic, **Representative**, public |
| Namestie F. Liszta | Railway station | Passive | Greenery, public space, traffic **Traffic, shopping, public** |
| Namestie E. Suchona | Cultural buildings, hotel | Active | Greenery, public space, traffic **Cultural, public, relax** |
| Namestie L. Štúra | Cultural buildings, government buildings | Active, passive | Public space, traffic **Cultural** |
| Námestie M. Benku | Mixed use fabric | Active, passive | Greenery **Public, relax** |
| Námestie slobody | Government buildings, university buildings | Passive, partly active | Greenery, public space, traffic, **Representative, public, relax use** |
| Námestie SNP | Mixed use fabric, churches, hospital, bank, department house | Active | Greenery, public space, traffic **Public, shopping, relax** |
| Primaciálne námestie | Municipality buildings | Passive | Pedestrian zone **Representative, public, cultural** |
| Rudnayovo námestie | Mixed use fabric, cathedral | Active, passive | Pedestrian **Public, cultural, relax** |
| Rybné námestie | Mixed use fabric, disrupted | Active, passive | **Public, relax** |
| Šafárikovo námestie | Mixed use fabric, university | Passive, partly active | Traffic, greenery **Public, relax** |
| Odborarske námestie | Mixed use fabric, university building | Active, passive | Traffic, greenery **Traffic** |

Evaluation of selected squares from the aspect of social and cultural use is following:

8 squares are part of a pedestrian area, social character with varied intensity of use
2 squares social - commercial
2 squares social - rest
2 squares traffic - walk
5 squares traffic
3 squares traffic - "vegetation" with low degree of stay /rest character
4 squares "vegetation" with lower degree of stay /rest character

Surprisingly, while considering the use and the character of surrounding structure, historical context and location, the potential of analyzed square is far greater. Whether from the qualitative or quantitative aspect, squares of Bratislava are nowhere as used and lively as they could be. Different prevailing use of these spaces could be considered in the future - not in the way of single use but in the sense of supporting particular identity and readability as well.

### 3.4 Identifications with space via importance and history

Historical meaning of a public space in not sensible superficially, but acts like an important factor affecting the atmosphere. Historical forming of a square, development process along the events, important personalities, groups. We have tracked the following:

- what was the role od a place in the history of a city?
- how has the use of a place changed during the development?
- what important pesronalities lived in the square?
- what important events took place in the square?
- what historically important events happened in the square?

History strongly enhances the value of a place. White points out this in his works. [White, E. W., 2007] It can be associated with a building, a balcony, a tree, with the sqaure area itself... A symbol, an importance of a plce is present, it acts as its part.

In our research we took a look into the history of analyzed squares. Some of them are presented in the study.

**Hviezdoslavovo námestie** (bearing its name since 1879)
*"Spacious square with beautifull alley and representative buildings"* [Ortvay, T., 2005, p.22] this is a characterstic by Tivadar Ortvay proceeding with: *"It is one of the most beautiful publi open space in the city. Surrounded by macadamia roadway with granite cube paving."* In past, there was a water ditch and river Danube branch. This was a popular place to walk and it was a main city promenade. It bore name of important personalities of Austria-Hungary, it was called Radeckého námestie, Kossuthovo námestie, today it bears name of a distinguished slovak poet. Placing significant urban activities was always typical in here. After filling up the river ditch and the river Danube branch, famous noble and bourgeois families started to build their residences in the western and southern side of the square. The old theatre is standing there from year 1776 and the city theatre since 1886. Both have played important role in the cultural life of Bratislava. Medical and naturalistic guilds were based in Ján Palffy´s residence. There were two hotels in the square - the National and Palugyay´s Green tree. The latter have become recognized far beyond the city borders. Ľudovit Kossuth has declared the Hungarian renaissance from the balcony of a Green tree hotel in 1848. In the square, there were caffees, renowned bakery with famous "Bratislava rolls", there were statues: a bust of Hummel, Petöfi... [Ortvay, T., 2005, p.22-43]

**Námestie Ľudovíta Štúra**
Also called The Coronoation square after a coronation hill placed in the square for 96 years. Later a statue of Maria Theresawas placed here to remind of a coronation. The Coronation square was defined by palaces, "granary" - later Reduta (building for cultural performances and meetings), eastern wing of Water barracks. There were also horse railways tracks leading through the square. After constructing the stable bridge over the river Danube, a propeler to Petržalka (city district on the opposite side of the Danube) dock was constructed. [Ortvay, T., 2005, p.58]

**Šafárikovo námestie**
It had significant position - acting as a city entrance from the side of Petržalka after constructing the Old bridge over the river Danube in the end of year 1890. There were important buildings - barracks of František Jozef, exposition palaces, office building for military command in the southern part. In the beggining of the 20th century it was transformed into a park. [Ortvay, T., 2005, p.100]

**Jakubovo námestie**
The square was named in the honor of two former reeves of Bratislava - Jakub (Jacob), a city reeve in years 1279-1286 and Jakub, a reeve in years 1326-1327 and 1338-1373. *"Prešporok has named a public open space as an eternal memory of their name."* [Ortvay, T., 2005, p.110]

**Kamenné námestie**
Townspeople were building their houses here. The title comes from mason company and stone warehouse standing in the square. [Ortvay, T., 2005]
In our research, we saw it necessary to evaluate the current importance of squares in centre of Bratislava. The squares were hierarchized according to the importance and location in the city, placement of important objects, historical events and the intensity of social activities. (Table 2) Based on the mentioned evaluation system, squares´ potential seems to be quite bigger.

The squares in central area can be divided according to the importance as follows:

- 13 squares of international and national importance
- 9 squares of regional /citywide importance
- 2 squares of city /local importance
- 2 squares of local importance

Table 2. Evaluation according to the importance and potential of selected squares of Bratislava

| **Square** | **Importance of a square /** Potential | **Location** | **Important buildings** Dominants Selected monuments | **Activities** Historical events |
|---|---|---|---|---|
| Namestie A. Dubceka | International, national /local | Inner city<br>Edge location | **SNR, Bratislava castle**<br>Monument for the politicians | Political representation<br>Public activities |
| Namestie F. Liszta | International, national | Inner city | **Main station (railway)** | |
| Namestie E. Suchona | International, national | Historical core | Reduta | Political representation |
| Namestie L. Štúra | International, national | Historical core<br>Entry to historical core | SNG, ministry<br>Monuments for activists | **Coronations** |

| Odborarske namestie | Regional/national | Inner city<br>On the main axis | | |

## Conclusion

This paper presents results of a research focused on evaluation of current state of squares in Bratislava central area. The research includes character and the quality of spatial and structural definition, use, affection and quality of services, location and intensity of usage and public life. Degree of identification of residents with public spaces in Bratislava. Analyzed features have important role in this process and for keeping the genius loci.

A more detailed analysis has been focused on reviewing all nodal spaces in central city district. The research was conducted in the following sites: Americké námestie, Floriánske námestie, Františkánske námestie, Hlavné námestie, Hodžovo námestie, Hurbanovo námestie, Hviezdoslavovo námestie, Jakubovo námestie, Kamenné námestie, Kmeťovo námestie, Kollárovo námestie, Komenského námestie, Námestie 1. mája, Námestie Alexandra Dubčeka, Námestie Eugena Suchoňa, Námestie Ľudovíta Štúra, Námestie Martina Benku, Námestie slobody, Námestie SNP, Primaciálne námestie, Rudnayovo námestie, Rybné námestie, Šafárikove námestie, Franza Liszta, Odboráske námestie, Župné námestie.

Based on the research, the following can be stated:
A hypothesis saying that spatially clearly defined public spaces, their functional complexity and appropriate services and aesthetical expression is fundamental presumption to more intense use and identification of residents with mentioned place was proven.

Places missing (or nearly missing) any of these features have turned out to be problematic.
Even places with strong historical message or associated with significant historical events or with residences of important governmental or cutlural institutions and monuments were found in this category of public spaces.

Particularly Námestie SNP which used to be a market square, place of cornation selebrations, "Velvet revolution" venue. It is clearly defined and creates main historical centre round. Factors decreasing its importance and degree of use are the following:

- bad service oranization (area subdivision into dynamic and static transport, allocating unused green area) - generating operational barriers.
- decline of surrounding building use
- great amount of "deaf" facades
- missing areas for spreading the activities
- very low quality of architecture

Analyzed nodal public spaces of Bratisalva can be divided according to the study to following:

- Squares in the need of complex solution - spatial definition (only bearing the title square), appropriate use and architectonic-urban design
- Squares with inappropriate use (that moved to the outer city)
- Squares where the operational and spatial barriers have to be removed
- Squares missing only an impulse in a form of activities (events, week markets, quality mobiliary and street furniture)

Users and residents themselves can play abig role in the process of identification with mentioned place. Usually local residents and activists bring new life and new meanings here.

There are good examples of the mentioned phenomenon. Several squares in the historical centre have been reconstructed to achieve aesthetical and qualitative goals, although the use of surrounding structures and the social dimension of the parterre is left behind. This level does not support the quality of public spaces, even though they are of national and international character and of great potential.

Keywords: gated communities, social impact, spatial exclusion,

## Abstract

Nowadays modern cities experience emergence of new urban forms. One of those forms are gated communities. The aim of the paper is to discuss the phenomenon of gated communities through the lenses of the city of Wrocław (Poland), the fourth biggest city in Poland.

The phenomenon of gated communities, guarded and inaccessible for "mere mortals" developed in Poland on an unprecedented scale. Although gated communities in Europe are rather rarely, in Warsaw there are few hundreds of such settlements. People choose to live in a gated community due to the need for security and cut-off from “lower class”. However, psychologists suggest that people who feel threatened and decide to live in secured housing estates, tend to isolate themselves even more from the rest of society, so that their fears and insecurity may even deepen (the so-called “circle of fear" ).

The purpose of the paper is to discuss the issue of gated communities in the city of Wroclaw. Starting from the theoretical discussion on definitions, the paper will move towards the selected cases located in Wrocław in order to analyse profile of their residents. Results of surveys on the perception of gated-communities will be presented. Additionally, influence on the society and urban space as well as legal aspect of those settlements will be discussed. The paper should contribute both to the theoretical and practical knowledge on gated communities and their impact on social and urban life.

## 1. Introduction

Gated communities are socio-spatial phenomenon, which developed in Poland on an unprecedented scale never found in Europe before. Proponents of this solution mention the sense of security which is present for citizens living in such type of residential. Opponents, on the contrary, criticize them for isolation increase and distrust toward other members of the society. It would be truism to claim that equivocal evaluation of this type of housing is difficult. In this article, the authors takes the opportunity to explore the idea of gated communities by the citizens opinions recognition.

The aim of this work is to find the answer for the question “Who lives in gated communities in Wroclaw ?” The answer will let us to create the profile of a person who decided to live in such a kind of housing. This way we extend the knowledge in the area of modern settlement processes and sociology of the city.

There are four hypotheses stated and verified in this article:

1. People living in gated communities are in working age and have higher education.
2. The household of these people is characterized by the income, which is higher than average household income in dolnośląskie voivodeship.
3. Their choice of living in gated communities was based on sense of security and prestige.
4. The occupiers are satisfied of living in this type of housing.

The article was divided into two main parts. The first, theoretical, concentrates characteristics of gated community. Describes also current state of research on this subject. In the second part, there is methodology proposed and the results of questionnaire. Finally in summary there is a conclusion of performed research.

## 2. Gated community in theoretical approach

Urban space is continuously changing, more or less dynamically (Spyra, 2011). These changes are caused by exo- and endogenous factor series, which determine the urban area development. Examples of such factors are socio-economical conditions, spatial planning and architecture trends or political influence. This transformation refers also to housing development, where gated community is one of possible form of evolution. It is worthy to mention that the idea of separating the houses but also whole cities with high walls and deep moat is very old and comes from ancient and medieval times. In this approach, the gated communities are the step back in settlement evolution. There are some kind of retrospection in housing complex planning. Judd (1995) and Morris (1994) describe it as "return of ancient forms of urbanization". In previous epochs, such urban isolated enclaves had usually military reasons and let the citizens to feel safe from external dangers. What are the causes of supply and demand trend of gated communities observed today, which has started in the last decades of 20th century in USA (Blakely, Snyder, 1997)? It is caused by two significant reasons: improvement of security and prestige (Brodowski, 2013), which are correlated with living in gated housing complex.

According to Grant and Mittelstead (2004), gated housing is remedy against the fear of "enemies" who could theoretically disturb the order and harmony. The problem seems to be more complex. In the cities, criminal behaviors and pathology reach such extremes that ordinary people can not feel safe walking on the streets or sending children to the kindergartens. Is it only false belief? Does high wall, bodyguard, CCTV cameras improve security? One may take the risk and claim that there is no such guarantee. Well prepared and trained burglar is able to break all forms of protection. According to Blakely and Snyder (1998) research results, analyzed form of housing doesn't improve safety and the crime level in these places is similar to open communities. Moreover, various systems of protection may even trigger criminal behaviors, following the stereotype: "Where there are sophisticated methods of protection, there are sensible reasons to break into".

Living in gated community may be commonly treated by the occupiers as the manifestation of wealth and high social status (Grant, Mittelsteadt, 2004). There is popular conviction, that having luxury products such as a house in gated estate, raise the respect in surrounding. The wall, apart from defensive function, has also symbolic meaning and expresses the message about the uniqueness and inaccessibility. Cesarski (2010) takes the attention on the other aspect of prestige. The decision of buying the property in such a place can be caused by the urgent need to live with "better" companion. It means that separated houses concentrate groups of the same status, education, etc.

Gądecki (2007) noticed that explanation of gated housing complexes by safety and prestige arguments is not sufficient and require to raise issues of neoliberalism influence on the city. Grant and Mittelstead (2004) explain that creating such a kind of urban space is the response for privacy, highly demanded by citizens.

Probably, there are much more factors responsible for this modern phenomenon. However, equally important are the consequences of its existence. Jałowiecki and Łukowski (2007) noticed the most significant problem, which is society segregation. It happens when rich areas such as gated communities are created while other areas become gradually the place of poverty. The authors call this process "ghettoisation of urban space". This metaphor doesn't seem to be exact description due to the historical context. Ghettos were usually places where people were forced to live. Such areas isolated specific ethnic groups regarding race, nationality or religion. The similarity between ghettos and gated areas are only in the fact that both are usually surrounded by the walls. The gated houses occupants decide to live in there freely. Additionally, occupants of poor areas also don't describe the places where they live as ghettos. It seems that the illness of modern cities is not actually ghettoisation. It rather should be named "socio-spacial fragmentation".

There is a significant difference in dynamics of gated houses development between east, middle and west Europe. Such solutions are very rare in west Europe cities on the contrary to post

socialist countries where this model of urban space is currently very popular (Polańska 2010, Csizmady, 2011). Initial symptoms of gated communities appeared in Poland on the beginning of '90s (Brodawski, 2013). First such a housing complex was built in Warsaw just after regime transformation. On the beginning of second decade of 21st century its number exceeded 300. For comparison, there is one left in Berlin. Gąsior-Niemiec and other (2007) explain this phenomenon as reproduction of voluntary isolation patterns, significant for communist and socialist nomenclature. Polański (2010) mentioned more prosaic evidence, responsible for isolated housing complexes success in middle-east part of Europe. He noticed the reasons in vast range developers offers in situation of lack municipal flats and defective legal system, creation of new social structure and fear of high criminality. Additionally, Szczepańska (2011) found them in the need to have own property ("stand on own feet") which was not fulfilled in communism times. Although these reasons, gated communities expansion in the urban space of post communist countries is ongoing. It also influence the space of Wrocław with population of 600 000 people, the main city of dolnośląskie voivodeship.

Unfortunately, there was no scientific literature, which would identify the subject of isolated housing complexes in urban space of this city. Even though it is not possible to omit their existence in the municipal space. They are created in various parts from the city center to suburbs. They have different forms of protection - from complexes surrounded only by short fence to castle shaped buildings with high walls, CCTV and guards. According to Brzeziński's (2010) typology of gated communities, there are two types of them in Wroclaw: "islands" (one isolated complex inside open architecture) and "archipelagos" (many isolated settlements in neighborhood).

## 3. Methodology

There were occupants from three gated communities in Wroclaw considered in the research: "Zielona Wyspa" (Strońska St), "Atrium-Geo" (Raclawicka St) and "Zielona Etriuda" (Turniejowa St). The choice of the settlements was based on a number of reasons. Firstly, all of them were located in the same district of Wroclaw - Krzyki, close to each other, which means that occupiers can utilize the same social infrastructure. Secondly, chosen settlements were erected in comparable time and are in the similar distance and travel time to the city center (Table 1). Three housing estates are in diverse size, concerning the number of flats: from 72 („Zielona Etiuda") to 248 („Zielona Wyspa"). Moreover, all of them were created in the same urbanization process. They were integrated in existing municipal body instead of city development in urban sprawling process.

Table 1. Characteristic of settlements in context of location, the time of erection and number of occupants.

| | Zielona Wyspa | Atrium-Geo | Zielona Etiuda |
|---|---|---|---|
| Travel time (min) at 13:00 | 11 | 10 | 12 |
| Travel time (min) without traffic jam | 8 | 8 | 10 |
| Distance from city center (km) | 4,4 | 4,9 | 4,9 |
| Year of erection | 2008 | 2009 | 2008 |
| Number of flats | 248 | 96 | 72 |

*source: data based on Google Maps TM.*

Described group of common features makes possible to hypothesize that occupiers of selected settlements could have similar reasons and personal values when decided to join to gated communities that makes possible to treat all of them as one, uniform statistical population.

There are a few definitions of research methods in available literature. Kaminski (1974) claims that the method is “a group of theoretically justified conceptual and instrumental actions, generally covering the entire researchers proceedings, aiming to solve specific scientific problem”. Okoń (1975) describes the method as "systematically applied procedure, leading to defined result. Conducted operations are mental and physical activities, properly selected and implemented in a fixed order.” In submitted research, authors decided to utilize diagnostic opinion poll, because in exact and precise way describes behaviors, preferences and personal values - specific for gated communities members. T. Pilch and T. Bauman (2001) write about opinion poll as „it is the way of collecting knowledge about structural and functional attributes, social phenomenon dynamics, opinions, views, intensification and directions of phenomenon development, which have educational value, based on a specially selected group, representing the general population, in which examined phenomenon occurs". Therefore, one can say that opinion poll is useful during social phenomenon research and lets get the insight into opinion, behavior and respondents motives. In effect, it makes possible to widen view of gated settlement society.

The term “research technique” can be understood as “the way of data collecting, based on a carefully elaborated directives (exact, clear, scientific), verified in studies of various sciences and thus having interdisciplinary values (Kaminski, 1974). In diagnostic poll, the most popular techniques are questionnaire, interview and observation. In described research the questionnaire was applied. This is a method of data collecting, which is based on filling in especially prepared form, personally by respondents, with the high level of standardization, in pollster presence or absence (Pilch, 1977).

Research tool, used to perform the poll is a questionnaire form. T. Pilch and T. Wujek (1974) define the research tool as „the object used to accomplish chosen research technique”. While the research technique means all activities, such as observation or conducting the interview, it is a research tool which is technical instrument for data collection. In this sense, a research tool is a questionnaire, observation sheet, and even pencil" (Pilch and Wujek 1974). Authors define the questionnaire as "a set of questions, built according to special rules". For research purpose, created questionnaire consists of 16 questions of multiple and single choice as well as free response type queries. There are seven general questions on the beginning, referring to sex, age, education, occupation, salary, time of living in gated community, and the number and relations to people living in the same household. The rest of questions are more specific. Six of them ask about preferences and personal values of occupiers (reasons for choosing gated estates as the place to live - positive and negative sides, neighborhood relations, wish to moving out, spending the leisure time inside the housing estate. Another two questions refer to satisfaction of living in gated community comparing to the previous place of living. Finally the last query refer to general satisfaction of living in this type of urban space. The questionnaire was anonymous, respondents were asked to fill in the form personally, The results are presented in the following chapter. The questionnaire form is attached to the article in appendix.

## 4. Results of the survey

The study was conducted on 20-24 April 2015, between 4-8 p.m. Interviewers were standing next to entrances (wickets) to the selected gated communities. 180 people were asked to fill the questionnaire of which 86 agreed to do so. The rest refused due to lack of time and / or rush (68 persons), tiredness (12 people); 14 persons did not give a reason. The authors were unable to carry out the research with residents of the housing estate "Zielona Etiuda" (Turniejowa St) due to lack of contact. The interviewers noticed that the inhabitants of the “Zielona Etiuda” estate enter its area with cars through underground parking and they do not use pedestrian entrances (gates). The estate

manager was asked to inform the residents about the research during a settlement council meeting and to obtain (on behalf of the authors) a permission to send questionnaires via mail or e-mail. Unfortunately, no positive response was obtained and the authors were unable to conduct the survey with the inhabitants of the "Zielona Etiuda" settlement. Therefore, only inhabitants of two gated communities "Zielona Wyspa" and "Atrium-Geo" participated in the research. The overall number of inhabitants of three selected areas was estimated on the basis of the available number of flats in them and the average number of persons per household (in Lower Silesia in 2013 it is 2.5 people per household by the Central Statistical Office (CSO) and 2.3 persons according to calculations made on the basis of this research, as it is discussed later in the paper). This means that the selected three gated communities are inhabited by about 1,000 people (957 people with an average of 2.3 persons/household, and 1040 with an average of 2.5 persons by CSO). The group of respondents (86 people) accounts for 8.6% of the population of these three settlements.

The study involved slightly more men (44 persons) than women (42 persons). In terms of age the research group could be named "young people", since 87% of respondents are under 35 years of age. No one declared age higher than 55 years (Figure 1)

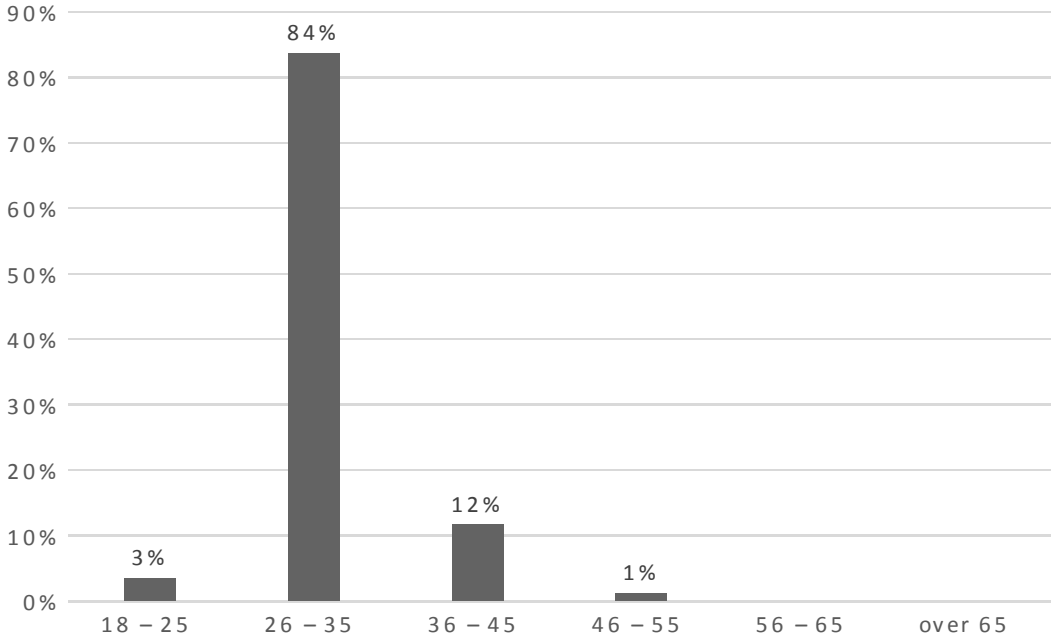

Figure 1. Respondents age profile
source: self-reported

Noteworthy is the education of the respondents, as 95% of them declared higher education, and the remaining 5% declared secondary education.

Taking into account occupation of the respondents, the research group can be divided into four subgroups. Nearly half of respondents (48%) are corporate employees, mostly associated with the IT, finances, etc. The second largest group (23%) are employees of the public sector: teachers, civil servants, doctors, etc. Businesses/firms are carried by 16% of respondents, while 13% of people declared to be so-called freelancers (artists, designers, etc.) (Figure 2).

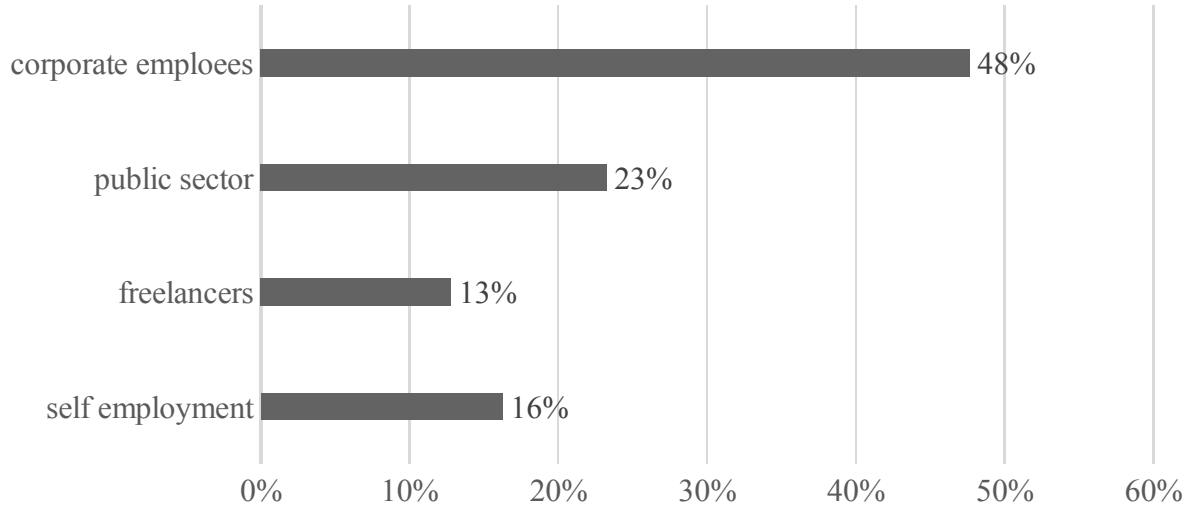

Figure 2. Respondents employment profile
source: self-reported

The research group has also been analyzed in terms of declared incomes. As a basis for the analysis, the following data taken from the Local Data Bank CSO:

- the average number of persons per household in Lower Silesia in 2013 is 2.5 persons/household;
- average monthly disposable income per 1 person in a household in Lower Silesia in 2013 is 1,344.79 PLN.

Given these data, it is possible to calculate the average monthly disposable income of a household of 2.5 peoples which is 3,361.98 PLN. Due to the research hypothesis: "residents of gated communities have higher incomes than the average households by CSO, the first income threshold was set at 3,500 PLN. It turned out that 87% of respondents exceed this level, while 56% percent of people say that their household disposable income is between 3,500 – 6000 PLN. Another 16% of people declare income of 6,000 – 10,000 PLN and 15% of respondents say that they have a monthly income of more than 10,000 PLN. Household disposable income below 3500 PLN is declared only by 13% of the respondents (Figure 3).

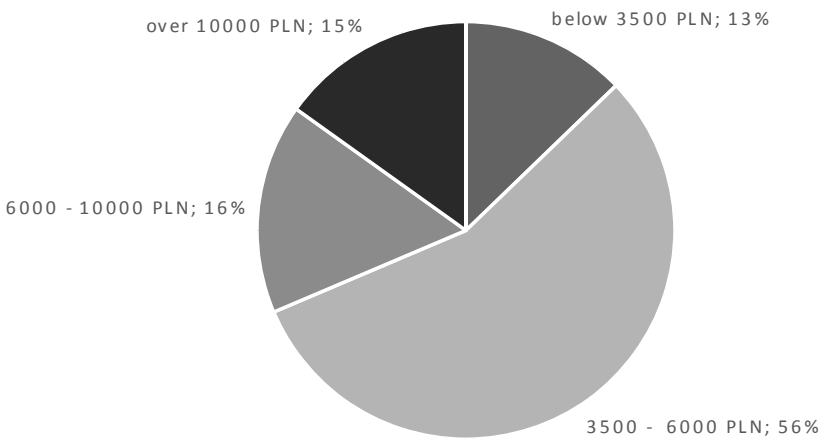

Figure 3. Income profile
source: self-reported

Next question asked about members of households and each respondent was allowed to give more than one answer. 10% of respondents answered "I live alone", while 85% of respondents live with a partner or a husband/wife. 3% of respondents declared that they live with other people (grandparents, roommates, etc.). 43% of respondents live with children and this means that 2% of respondents are single parents (Figure 4). These data also allow for the calculation of the average number of persons per household, which is 2.3 persons / household, so only slightly less than the data provided by the Central Statistical Office (2.5 persons).

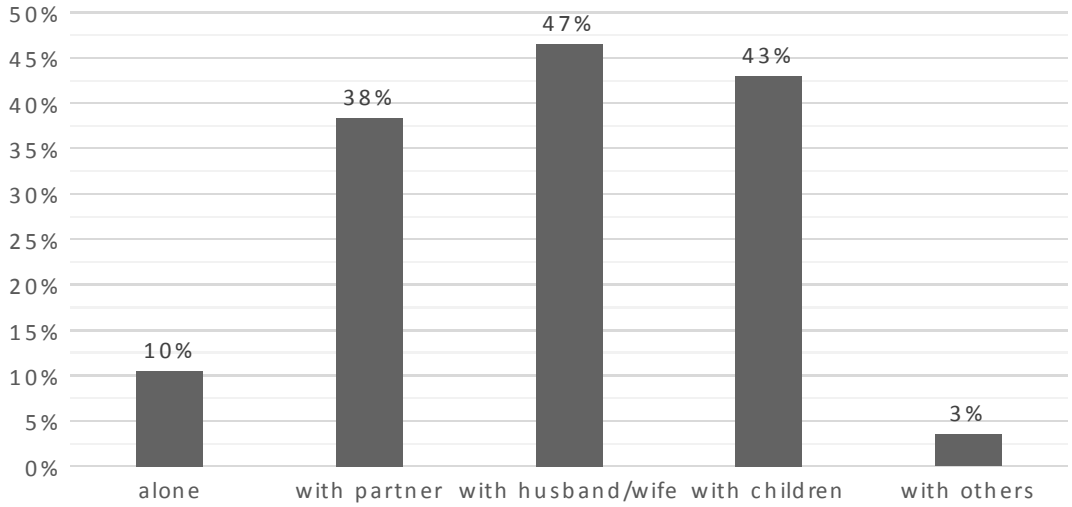

Fig. 4. Members of the household
source: self-reported

Next question was checking how long people live in the selected gated communities (Figure 5) The largest group are people living in a fenced housing estate from 4 to 6 years (41%). The second largest group are people who live there more than 6 years (27%), which probably means that they live there since the construction of settlements, which took place in 2008/09. 14% of respondents live in the gated community for less than 1 year. 9% of respondents replied "1 year – 2 years" and also 9% replied "2 years – 4 years".

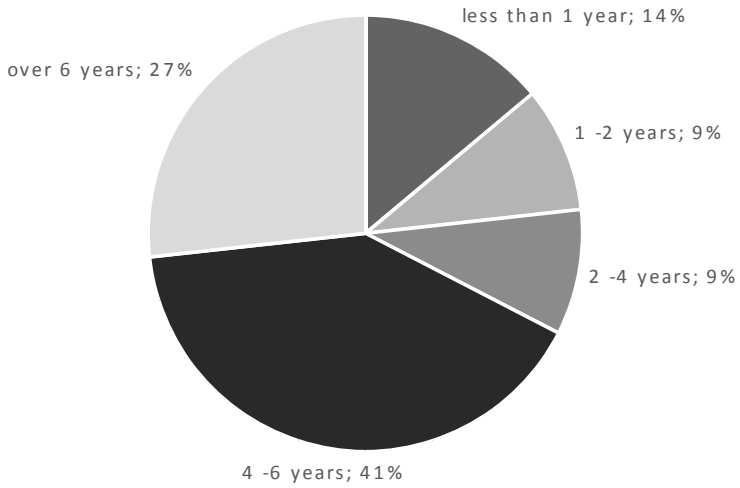

Figure 5. The length of occupation time
source: self-reported

Question no. 8 investigated reasons for moving into a gated community. Respondents could give up to four answers. Most people (66%) pointed to peaceful surroundings. Next causes are: nice architecture (56%), security concerns (55%), and lots of green areas (44%). Less than 30% of people gave following answers: high standard of buildings (27%), recreation facilities (22%), closed form of settlement (20%). 10% of respondents pointed to the favorable price and 5% of respondents reported other causes (i.e. availability on the market). Nobody pointed to the prestige as the reason for selecting the gated community for a place to live (Figure 6).

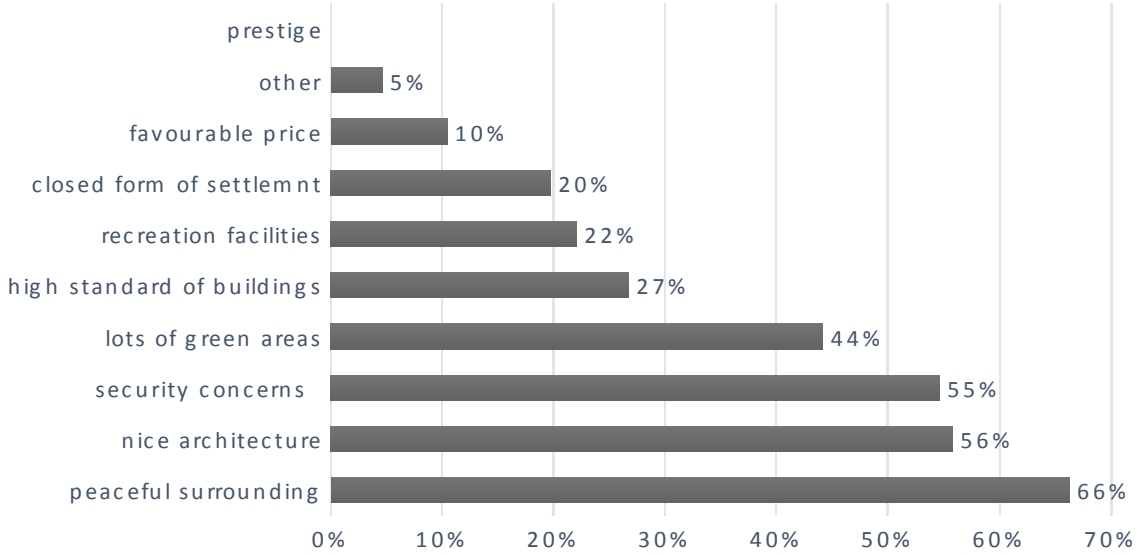

Figure 6. The reasons for moving into a gated community
source: self-reported

The research group was also asked to identify advantages and disadvantages of living in a gated community. Respondents could also give up to four answers. Most frequently mentioned positive aspects were: suitable/convenient location in the city (72%), safety (53%), lots of greener areas (52%), peaceful surroundings (49%), and monitoring and/or the presence of the security guards (42% ). Less respondents indicated such factors as: high standard of buildings (31%), recreation facilities (20%), closed form of settlement (16%), good relations with neighbors (14%), nice

architecture (10%). Only 3% of respondents appreciated isolation and anonymity (Figure 7).

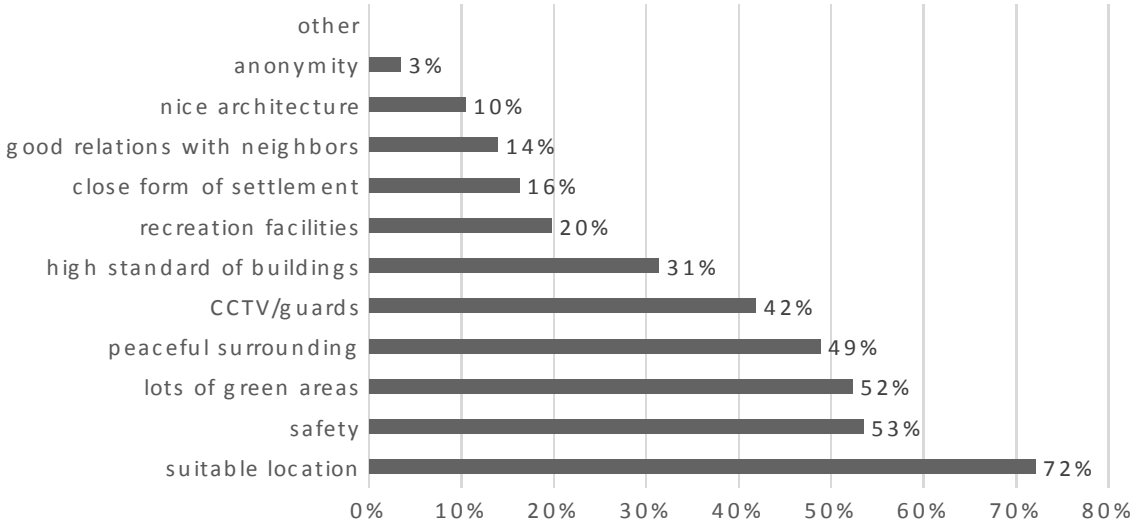

Figure 7. Advantages of living in a gated community
source: self-reported

Among negative aspects of living in a gated community the most important factor is lack of parking spaces (66%). The respondents complained also about: high development intensity (43%), isolation and anonymity (34%) and limited access to services (29%). Further positions were occupied by answers: no/bad relations with neighbors (22%), unsafe area (15%), lack/poor condition of green areas (12%) and recreation places/facilities (8%). Only 1% of respondents rated location in the city as unfavorable, but no one recognized the fenced form of the settlement as an disadvantage (Figure 8).

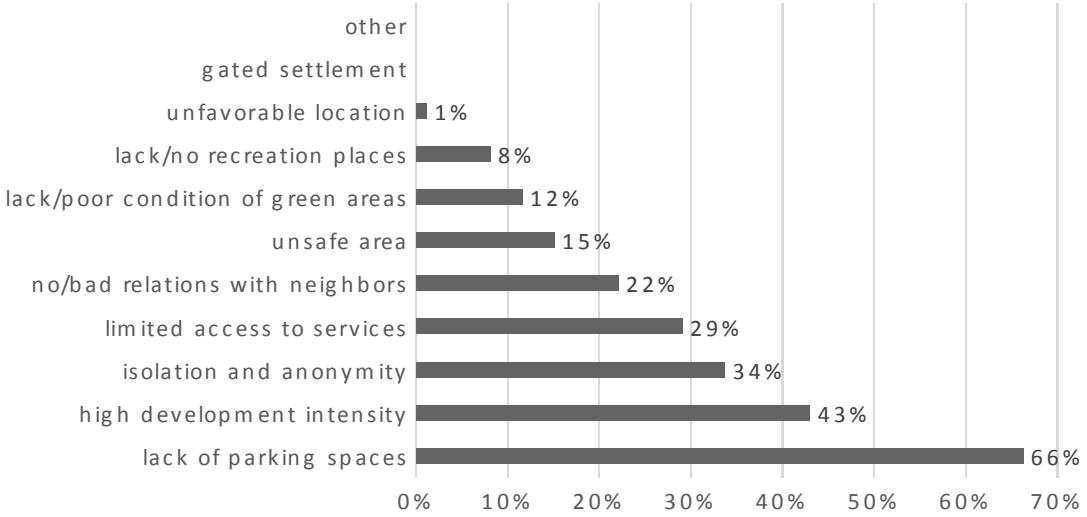

Figure 8. Disadvantages of living in a gated community
source: self-reported

Social relations between residents can be described according to the classification provided by Kryczka (1981), who takes into account a degree of involvement of inhabitants:

1. limiting neighbourhood (neighbours avoid behaviours that could be considered inappropriate, e.g. noise, littering, etc.);
2. conventional neighbourhood (neighbours exchange greetings);
3. informed neighbourhood (neighbours have some knowledge about each other, e.g. where they work, whether they have children, etc.);
4. providing neighbourhood (neighbours exchange small favours);
5. solidarity neighbourhood (neighbours have sense of unity and they conduct joint actions as a community);
6. friendly neighbourhood (neighbours visit each other and spend time together; they establish peer relationships or even friendships).

Most of the respondents (51%) can be classified as "conventional neighbours", i.e. they exchange pleasantries. The second largest group (31%) are respondents creating "informed neighbourhood". 15% of respondents are "friendly neighbours", and the remaining 2% of people are building "providing neighbourhood". No one chose responses indicating affiliation to "solidarity neighbourhood" or "limiting neighbourhood" (Figure 9).

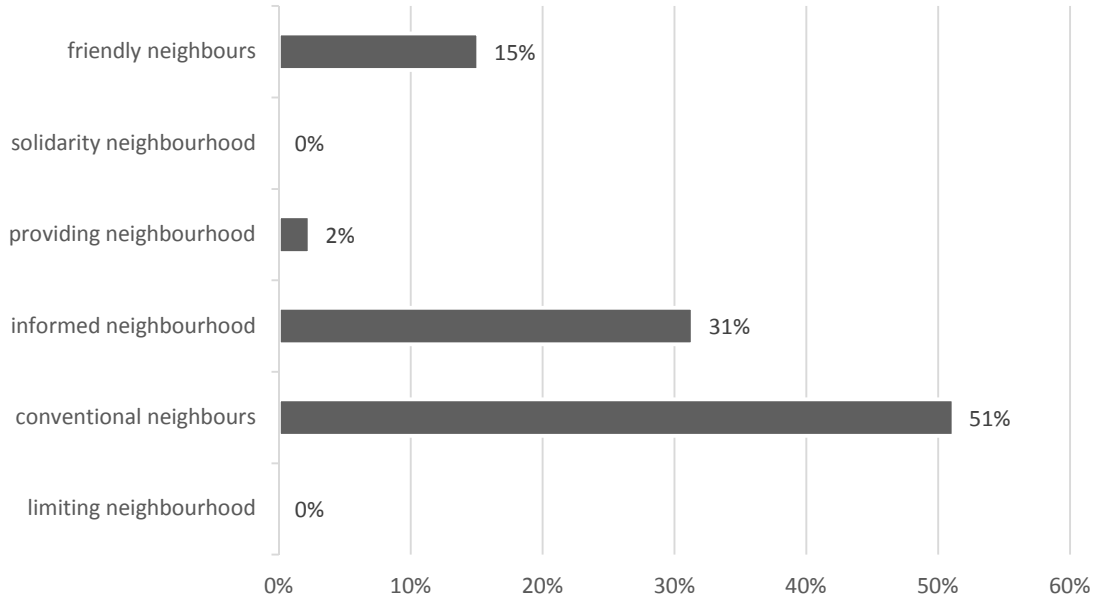

Figure 9. Social relations between residents in a gated community
source: self-reported

The research group was asked if they are willing to move out from the gated community. Positive answer was given by 36% of respondents, giving such reasons as: a larger size of an apartment (16%) or building a house (20%). 64% of respondents are willing to stay in the settlement. Another issue examined in the study was spending time inside within a gated community area. Positive answer was given by 22% of respondents, listing activities such as sitting on the benches (8%) or playing with children (14%). The vast majority of respondents (78%) does not spend free time within their gated communities

The research group of residents was also asked to evaluate their gated communities and compare them with their previous places of residence. The vast majority evaluated gated community

"much better" or "better" (45% and 30%) than the previous place. 22% of respondents said that those places are “similar” and just 2% of respondents gave answer "worse". Nobody has evaluated their gated community as "much worse" than the previous place of residence.

While examining respondents’ previous places of residence, it can be noticed that the vast majority (89%) moved to gated communities from multifamily housing estates: so-called Paneláks (panel buildings constructed of pre-fabricated, pre-stressed concrete) (30%), townhouses (30%) or modern settlements (29%). From single-family building (semi-detached/terraced and cottage) moved out 8% of respondents; 2% of the respondents previously lived in a dorm.

Next question was dealing with “openness” of previous place of residence. It can be noted that the majority of respondents (86%) moved from the open estates. 13% of respondents previously lived in a gated community, and 1% of the respondents lived in an open settlement with monitoring/security guards.

It also turned out that for 65% of respondents gated community is the next step of their "wandering" in the city of Wroclaw, and 30% of respondents chose a gated community as a place for living while moving to Wroclaw from other cities. Just 5% of respondents moved into a gated community from a village/rural area.

The last question in the questionnaire referred to the general satisfaction with living in the gated communities. It turned out that 88% of people are satisfied with their settlements and 12% is not satisfied with living there.

## 5. Conclusion

The results of conducted survey verify the hypotheses posed in the work. Residents of gated communities in Wroclaw, as alleged, turned out to be people of working age and with higher education. The assumption that household incomes of the residents are higher than the average household income in the province of Lower Silesia was also correct. The presumption that residents are in general satisfied with living in the gated communities is right. The hypothesis saying that main reasons for moving into a gated community are security and prestige is just partially true. While the survey confirmed security and safety were ones of the most important reasons for choosing a gated community, prestige was a less significant cause. As it was already discussed in the work, prestige is considered to be one of the main factors contributing to the spread of gated communities in the cities. However, the conducted survey has not confirmed this statement, on the contrary, it was denied. Nevertheless, it should be taken into account that respondents could have avoided giving the answer “prestige” on purpose, as they may be aware of the fact that gated communities are often perceived as a manifestation of snobbery.

The study provided data that allows for sketching a profile of a gated community resident in Wroclaw. This seems to be a person 26-36 years old, with higher education, living with a partner or a wife / husband and children, employed in a corporation, or in the public sector. The resident does not establish close social relationships with their neighbours, but exchanges greetings only. However, it should be taken into account that examined settlements were built ca. 7-8 year ago, therefore, the residents have not been given a chance to establish strong and long-lasting connections. Nevertheless, observations and impressions from the survey conduction allows for an assumption that these relations will probably not change with time. The question remains whether the connections between residents of gated communities differ from the bonds established by people living in unfenced housing estates. Of course, giving an answer to this question requires additional research, but literature reveals that these relations in both cases are rather similar.

Moreover, a resident of a gated community in Wroclaw is satisfied with the housing estate and rarely mentions any disadvantages. He/she does not plan to move out in the nearest future. A key factor for living in a gated community is safety. Most of the respondents moved into gated communities from open (not fenced) settlements located in Wroclaw. This may lead to a conclusions

that people move into gated communities as soon as they have financial capabilities to do so. A question arises whether improvement of safety among unfenced settlements would prevent the spread of gated communities in Wroclaw. It seems fair to say, that greater safety in open housing estates would reduce the number of such investments. Improving security (among other factors affecting the quality of life) in the open settlements may protect Wroclaw from transformation into a giant zoo, where you can watch people behind a fence instead of animals.

# TRACK 07

# Dealing with Urban and Rural Decline: Interplay of Actors and Responsibilities

## Track description

Co-chairs: **Martina Schretzenmayr**, **Wim van der Knaap**

Planning as profession and institution was established as a means how to manage growth. Now the dwindling population growth and stagnating economies in many of urban and rural regions make planning to cope with decline. To manage and, possibly, to reverse the decline, a collective action of various public and private actors is recommended. Which actors should be involved in dealing with urban and rural decline, which roles they should play and which competences and responsibilities they should regain and what should be their good response?

# Planning and Democratic Structure in Oil Related Development Areas on Norway's West Coast

Professor Jørgen Amdam,
University College Volda, Volda 6103, Norway. ja@hivolda.no

## Abstract:

This paper describes how changes in civil society, economic development, communication systems and related changes in the localisation of economic activities and jobs can influence regional structures and integration. The development processes increases the differences between the urban core and the rural periphery, which appears to be changing into three major regional structures with different planning challenges:

1. The large-town belt in the South West, from Stavanger to Bergen that has almost 700.000 inhabitants and 2/3 of all jobs in Western Norway.
2. The small-town belt in the North West, dominant clusters are marine industries related to fisheries, shipbuilding and support services to oil and gas activities.
3. The marginal rural area, comprising fjords, mountains and islands with ¾ of the land, but with less than 1/5 of jobs and population. This area is divided into a lot of small job markets due to the geographical structure.

There is no clear "best" alternative for regional political and administrative organisation in Western Norway that can build on an existing "total" integration, mainly due to a lack of infrastructure, networks and intra-regional flows. The region has a lot of conflict lines and differences of interests between coast and inland, urban and rural areas, south and north and maybe only a strong common enemy (the capital Oslo) can unite the area. I have tried to illustrate structures that are possible in the future; the challenge is that they do not exist today but they can be developed by heavy investments and involvement. Instead of establishing political/administrative structures that "fit" existing social and economic patterns, political/administrative reorganisation would be an "instrument" and part of the strategies for the creation of new intra-connected regions, regions that will be relational and geographically dynamic. If so, new models of geographical political and administrative organisation are needed.

## 1. Introduction

In Norway a political process is currently taking place in respect of how to reform sub-national political and administrative structures. At present Norway, with a population of 5 million, holds direct elections to 426 municipalities, in Norwegian termed *kommune,* and 19 counties (in Norwegian *fylkeskommune*). The last major reform of the local political structure was made in the 1960's which saw a 30% reduction in the number of municipalities from, approximately, 700 to 450. The county structure has however remained unchanged for over 100 years (Selstad 2003), though directly elected councils were first initiated in 1974.

From the 1960s onwards, urbanisation, better communications, internationalisation, the construction of the welfare state, and the emergence of new politico-administrative approaches such as New Public Management etc., began to fundamentally alter the political and territorial landscape to such an extent that government (KMD 2014 a, b) now sees a discrepancy between functional and political regions. While most municipalities in the 1960s contained a common job- and housing market, new roads, more cars, urbanisation and the acceptance of longer travel distances from home to work have helped produce a new structure of approximately 160 residential and labour market regions, 60 of which have such a difficult or constrained geographical make up that they exist as single remote municipalities,

most often with a population below 5000 inhabitants and with a low population density (Juvkam 2002, Gundersen & Juvkam 2013). Similarly Norway's few metropolitan regions should be seen as being special cases as regards their urban structure. Excluding these metropolitan and peripheral regions, there are about 90 residential and labour market regions in Norway with an average population of 30 000 inhabitants divided between 2 to 10 municipalities. These are the municipalities that represent the biggest structural challenge to the success of the reform process. Typical arguments from politicians and/or researchers who favour a reduction in the number of municipalities include the following (Amdam *et al* 2004):

- Small municipalities (below 5000 inhabitants) are simply not capable of efficient welfare production and able to solve responsibilities transferred from state to municipality level. A state expert committee concluded that a municipality needs 15.000 inhabitants (KMD 2014 a, b) to take care of advanced responsibilities. A lot of public partnerships have evolved and have developed challenges regarding political control.
- It is not possible to develop sustainable and self-developing residential and labour market regions because of the lack of political empowerment at this level.

The same types of arguments have also emerged at the county level. The challenge here is that the functional boundaries of the metropolitan and other larger urban regions do not correspond well with the old county structure (Amdam et al 2014). There is also a growing need to coordinate activities on a level below that of the state but above the existing counties. As such, and in line with this observation, responsibility for hospitals was transferred from the counties to five state owned regional health companies in 2002. A similar approach to territorial reorganisation has now, moreover, been developed by more than 30 other state authorities (Amdam et al 2014).

While the strategy in the 1980 and -90s was to utilise county and municipality borders to provide the basis for the allocation and provision of all kinds of public activities, the last 20 years has seen a process of territorial reorganisation and state centralisation, in relation to a number of activities, both 'up' and 'down' the administrative scale to new levels between state and county and county and municipality. The need for greater coordination at the labour and residential region level and on the K-region level (communication and knowledge, university regions) can, for instance, be seen as the driving force behind such a change in approach. The problem remains however that each state sector has its own borders and territories and faces inter-sector coordination challenges. In effect we have public activities and administrations on five separate levels below that of the state.

Municipalities and counties are according to planning law supposed to coordinate all kinds of public activities in their territory, which is very difficult in this situation. A further challenge moreover is that the counties in particular have lost legitimacy as political authorities, while two of Norway's major political parties have stated in their programme's their desire to eliminate the county-municipal level along with its directly elected county councils.

The focus here is on both local and regional politics, development and planning - the role of the municipalities and counties as 'leading partners' and responsible planners and the role that municipalities and counties have as important welfare producers in Norway. Structural changes will certainly have an influence and on the role of local and regional politicians and administrators. What then are the alternatives, and what are the likely consequences of such a change for local and regional development and planning, as well as for welfare production? Such questions are typically representative of those we often receive from local and regional politicians and administrators and are discussed in part 1. Western Norway is used in part 2 and 3 as an example on how model structural alternatives can be problematic when applied in specific regions..

In this article the challenges and alternatives we can see emerging in respect of these questions will be discussed, as well as the types of important consequences likely to emerge in the context of this type of planning process with possible political conflicts between the state, regional and local levels (Amdam *et al* 2003, 2005 a, b, Amdam et al 2014).

## 2. Part 1. Challenges on the local and regional level

Any local or regional community exists within a specific context and situation and faces challenges both from other parts of the world, and from within, which inevitably vary from community to community. How inhabitants, companies, organizations etc., react to such challenges – how they cooperate and compete - to a large extent influences the capacity such actors have to develop efficient responses to these challenges (Amdam 2000, Amdam and Veggeland 2011, Bennet and McCoshan 1993, Healey *et. al.* 1999, Putnam 1993, Stöhr 1990, Vigar *et al* 2000). For practical reasons the notion of community has been divided into three areas; public activity (both political and administrative), private industries and the civil society. The focus of this paper is on public activity at the local and regional levels in addition to cooperation with the private sector and on public activity at the national level.

If we look at the current list of municipal (and county) responsibilities of both as a community and as a political and administrative organization they can be divided into three areas as in figure 1 (Amdam and Veggeland 2011):

- **Public administration and the allocation of rights**. The municipality issues building permits etc., to inhabitants and companies in accordance with national laws and local and regional plans, while also providing economic support to inhabitants and families who fall outside the national welfare scheme or other labour insurance systems – 'help for self help' - which was one of the first responsibilities the new political municipalities adopted in the 1840s (Teigen 1999, 2000, Amdam et al 2014). Usually there is little participation from inhabitants in respect of such activities, illustrated as a one way arrow in figure 1.
- **Public production of services** such as education, kindergartens, hospitals and the care of the elderly and infirm etc. The modern Norwegian welfare state is more of a 'welfare municipality' than a 'state' since most of these activities are organised and produced by the municipality, within the context of economic support from the state and where services are provided in accordance with state regulations. Some activities in this area compete with private sector providers while in monopoly situations some 'user participation' exists, illustrated here by weak back arrows in figure 1.
- **Development of the 'good society'.** Politically this has been the most important activity on the local and regional level since the emergence of a local political system in the 1840s until, approximately, 1960 when most of the rebuilding after the war was over and the construction of the welfare state began in earnest. A municipality or a county cannot however develop a society by itself, participation and partnership with the private sector as well as with civil society and nongovernmental organisations (the municipality as a community) more generally is also required as illustrated by arrows from both sides in figure 1.

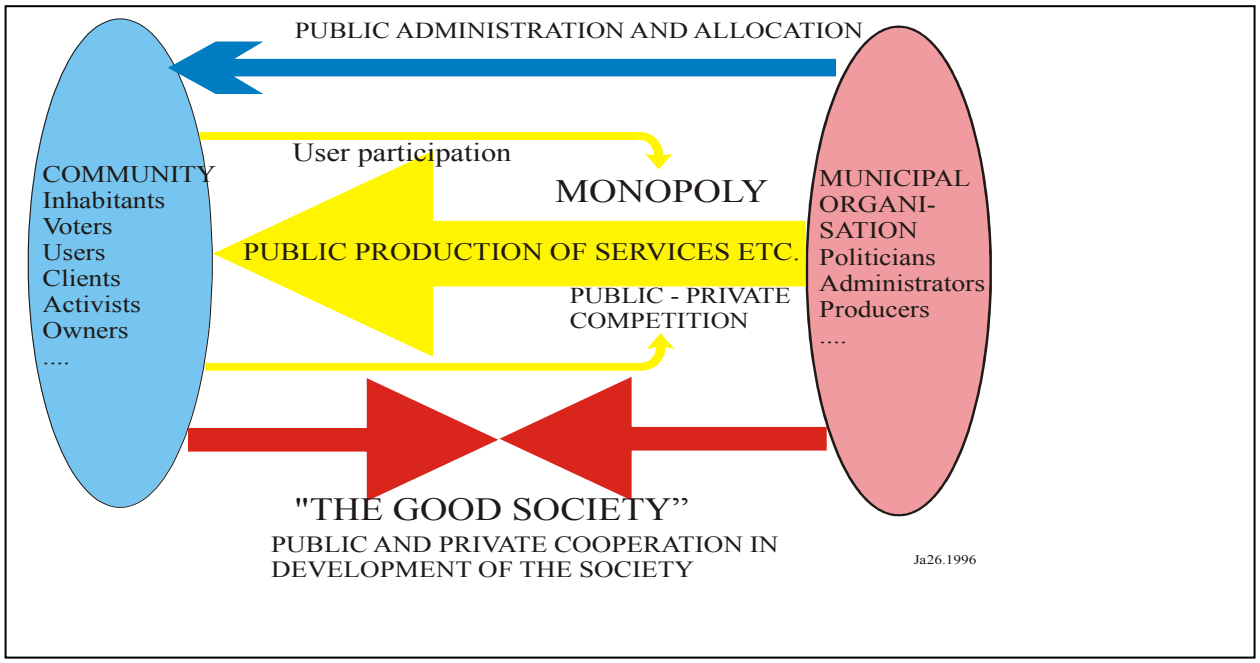
To lead and coordinate these activities a **democratic authority** is needed and in Norway we have direct elections to municipal and county parliaments. A change of municipal structure could have some, though probably small, consequences for the administration of rights and welfare state activities. In most municipalities the prevalence of such activities is small as compared to welfare and service activities or production, or to the nature and scale of the challenges related to the further development of the specific society in question. As such then this paper focuses on production and development activities as well as democratic planning activity.

### *2.1 Welfare production*

The production of welfare services mainly relates to public activity and to civil society as outlined above. Individuals and families are the main recipients of this production and thus any proposed changes will directly influence both the recipients themselves and 'voters' more generally as many are employed by the municipality to produce services (over 10% of inhabitants are full or part time employees in this production and approximately 50% are recipients, mainly children and the old and infirm). We have then to focus on the impact on these groups if we are to understand the consequences of any proposed change.

As shown by Myrvold and Thorsen (2003) and others (KS 2003, KMD 2014 a, b) there are few, if any, economies of scale to be had for kindergartens and primary schools in municipalities larger than 3000 inhabitants. For home-based care and homes for the elderly there are almost no economies of scale at all, and the same is true for health-care facilities for the elderly with more than 30 to 40 patients. In small, rural municipalities with an aging population this is often the number of people who need such attention in a general population of 3 – 4 000 inhabitants. These activities can be termed basic welfare production activities and typically take 75 to 80 % of the municipal budget. Thus the question emerges why should municipalities that are already larger than this merge when it is clear that no economies of scale will result?

Figure 1. Different kinds of 'cooperation' between public organizations and communities.



One reason often forwarded for this is that small municipalities often do not have what central politicians and administrators believe is an 'optimal and efficient' production structure. Instead of one school, one kindergarten, one hospital for old people etc., there are many spread over different local communities that fight politically to preserve themselves while in some places, for instance, private schools are established when public schools are forced to close. These institutions are important to local inhabitants, particularly for their identity, where it is often perceived that there is benefit in having common institutions and activities in a small remote community.

Local politicians, moreover, usually accept this even if it implies greater costs than a more centralized structure. So to reduce costs the municipality has to be merged so that the larger and stronger unit can fight more efficiently against local interests. What is interesting here is that alternative solutions are seldom forwarded. Why not accept the idea of having local kindergartens and schools if local inhabitants themselves are willing to cover the extra costs and organize the activity? Why not let parents take control of local schools in partnership with the municipality where they, by contract, are bound to national standards and curricula? This approach is likely to be as least as cost efficient as any general centralization process and may even increase local activities and promote a positive local identity.

A further reason for the desire for mergers is the savings they can deliver in respect of the centralization of activities that automatically produce economies of scale, such as administration, culture and sport facilities, health care, technical infrastructure and activities that need specialization (KS 2003, KMD 2014 a, b), ie are on the regional level as illustrated on table 1.

The Norwegian concept here is that of the 'general municipality' i.e., that all municipalities have the same responsibilities and activities regardless of scale. Small and remote municipalities however continue to experience difficulties in recruiting specialists such as doctors, planners, technicians, and administrators. Some cooperation with neighboring municipalities is possible and is undertaken (Sanda 2000, KMD 2014 a, b), but often only on a single project or functional basis. Since research has shown that large 'merged' municipalities produce such services more efficiently and often to a higher standard then small municipalities, this is deployed as the main argument for merging municipalities in spite of the fact that this usually concerns only 20% of budget thus producing a cost reduction that is often is no more than 10 to 20% (2 – 4 % of total budget, Amdam *et al* 2004, 2014).

Table 1 Responsibilities of welfare production and development and planning at the municipal and regional level

| Territory | Welfare production | Development and planning |
|---|---|---|
| Regional level – job and housing markets<br>> 5000 inhabitants | Administrative systems<br>Secondary education<br>Health care<br>Homes and hospitals for inhabitants with significant handicaps<br>Technical infrastructure<br>Culture and sporting activities and facilities<br>Education and retraining of employees | Regional development and planning of the region as an integrated entity<br>Activities for, and support to, industries and entrepreneurs<br>Nature and environment preservation and use<br>Influence on national politics concerning the region<br>Regional partnerships and projects for development |
| Local level – basic living space<br>< 5000 inhabitants | Kindergartens<br>Primary schools<br>Home care and homes for the elderly<br>Hospitals for the elderly<br>Other local public services such as libraries, information access etc. | Development of the local community – identity and relation- building activities in respect of culture, sport, hobbies, the environment etc.<br>Partnerships for local projects and activities |

*2.2 Development and planning*

Local and regional development and planning focuses on all activities in a municipality or region, as well as on individual inhabitants, private companies and NGO's. Typically, before 1960, local politics was tasked with organizing and implementing improvements in an area's infrastructure, organizations and institutions, while autonomous and stakeholder-owned organizations were made responsible for continuous activities such as the running of the cooperative bank, diary, shop etc. – the development of which we would today term as 'partnerships' or 'collaborations' based on social networks and territorial 'belonging' (Friedmann 1992, Healey 1997, 1999, Storper 1997). The municipality and county were arenas for the development of common visions and initiatives – 'meaning-making-processes' based on negotiation and cooperation – which today we try to 'reproduce' in strategic and mobilizing communicative planning processes (Amdam and Amdam 2000, Amdam R. 2005).

This part of local political activity has however been neglected in Norway because of the challenges local and regional politicians face in respect of the way in which welfare production is allocated 'on contract from the state'. Instead of being entrepreneurial and problem-solving, most of that which passes for local political activity has degenerated into conflict prevention since such allocation conflicts, where resources are too small to produce 'win – win' situations, are never solved.

*2.3 Possible municipal and regional structures*

We have made a study for the *Norwegian ministry for municipalities and modernization* regarding possible municipal and regional political-administrative structures in Norway, see table 2 (Amdam et al 2014). A voluntary amalgamation process among municipalities started in 2014 and is supposed to end in 2020 and we have identified four possible outcomes. Without commando from state level we think that the number of municipalities will be refused from 426 to approximately 300 in 2020 and with a structure not unlike the situation today, over 100 of these will have under 5000 inhabitant compared to over 200 today.

Expert advice, like Rattsø (2014) and the Expert group (KMD 2014 a, b), is to organize municipalities according to regional daily life regions (focusing on tasks in the upper group on table 1). Two alternatives will reduce the number of municipalities to: a) approximately 150, accepting 70 regions/municipalities with less than 15.000 inhabitants or b) demanding that all must municipalities must have over 15.000 inhabitants and approximately 80 local/regional political-administrative units, over 30 of these very big in land, long distances and low population. A forth alternative with a flexible organization of responsibilities between municipal and county level is also discussed (Selstad et al 2012, Amdam et al 2014), but is not politically acceptable today. On national level political support for using national commanding power to change municipal structure is not present, but can be possible after the coming election to parliament.

Counties are also invited to participate in the restructuring process ending in 2020, but not with the same enthusiastic government support as on local level. One reason is that our blue-blue government would like to abolish the county level and have a two layer political system, but have not support for this strategy in parliament. Another reason is the view that a change on municipal level will promote change also of the county structure.

Norway has 19 counties, one of these the capital Oslo is both a county and a municipal. Regarding county responsibilities like college level education, public communications etc. expert groups have advised that counties should have more than 200.000 inhabitants. Today 5 counties have fewer inhabitants and voluntary amalgamation processes have been tried without success. One county Finnmark has only 70.000 inhabitants but localized next to the North Pole and with a tremendous land area and long distances this is a special situation, see map 1.

On county level we (Amdam 2014 a, b) have described five possible alternatives including the 0-alternative, see table 2. The county structure is and will be dependent of the changes of municipal structure and we have identified 5 combinations what is more or less possible or acceptable. I will use these alternatives in my discussion regarding the restructuring of Western Norway in part three of this paper.

**0-alternative** – the existing county structure is combined with 300 municipalities. As shown in table 3 this alternative is possible but also problematic due to small population counties will have problems regarding cooperation and responsibilities with bigger and fewer municipalities.

**Alternative 1. Amalgamation.** The number of counties is reduced to 10-15 by voluntary processes so that all of them have more than 200.000 inhabitants maybe except Finnmark/Troms. Responsibilities as today but increased population and land area can increase possibilities for transfer of responsibilities from national level and increased political power. If the number of municipalities is reduced to maybe 300 we would advice this change and have evaluated it in our analysis.

**Alternative 2. Big regions.** Regional structure is decided on national level base don moderen communications and geographic structure and not bound by county borders. Seven new regions are established with increased responsibilities compared to counties like hospitals, universities, communications, regional development and planning etc. This change have low possibility on the short term but if introduced we believe it will be in a combination with 80 – 100 municipalities.

**Alternative 3. Big city** and flexible regional organization. Like Selstad et al (2012) propose municipalities are divided into four groups according to size and the (4 – 6) biggest are given responsibilities like Oslo, they are both municipality and county. Outside cities municipalities cooperates and develop partnerships also with counties in a structure where responsibilities are related to the number of inhabitants, the principle that all municipalities have the same responsibilities is abolished. This alternative has been proposed by Rattsø (2014) but have little political support outside the bigger cities. We have evaluated this alternative with 150 – 170 municipalities.

**Alternative 4. Flexible political organization.** As in alternative 3 the general principle is abolished but municipalities have responsibilities according to their expertise and recourses in near cooperation with neighbors and the county. The county and its municipalities are together responsible for tasks given by the welfare state and local/regional challenges, in fact have an almost total responsibility for planning, development and welfare production according to local and regional needs and challenges. This idea was proposed by Selstad et al (2012). We analyses this alternative with 150 – 170 municipalities and 10 to 15 regions, but we recognize that this is a challenging alternative regarding political-administrative traditions in Norway.

On table 2 our summative evaluation of these alternatives is presented, see Amdam et al (2014). The criteria used are built on the proposal from the municipal amalgamation expert group (KMD 2014 a, b) and the discussion above.

Table 2. Alternatives and consequenses (Amdam et al 2014)

| Alternative<br><br><br><br>Criterion | 0-alternative<br>19 counties<br>ca. 300<br>municipals | Alt. 1.<br>Amalgamasjon<br>10 - 15 regions<br>ca. 300<br>municipasl | Alt. 2<br>Big regions<br>7 regions and<br>ca. 80<br>municipasl | Alt. 3.<br>Big city<br>Flexible<br>organization<br>ca. 150<br>municipals | Alt. 4.<br>Flexible<br>organization<br>10 – 15<br>regions and<br>150 – 170<br>municipals |
|---|---|---|---|---|---|
| Democracy | Unchanged | Positive | Positive | Negative | Strong positive |
| Production of welfare | Negative | Positive | Positive | Negative | Positive |
| Public administration | Unchanged | Positive | Strong positive | Strong negative | Positive |
| Planning and development | Unchanged | Positive | Positive | Negative | Positive |
| Total | Negative | Positive | Positive | Negative | Positive |

## 3. Part 2. Regional structure and innovation

The term region can have many meanings. In our context here, it primarily refers to a geographical area between state and municipal level that appears as a homogeneous economic area in which business, industry, civil society and public sector activities are facing more or less the same challenges. The capability of a region to meet challenges is particularly dependent on how the various actors manage to produce and exploit competitive knowledge (Diez 2000). At the same time, challenges must be answered with strategies and measures in which the whole community involves itself and which are adapted to suit the situation and meet the challenges in the region in question (Stöhr 1990). The establishment and development of regional innovation systems requires certain conditions to be met (Nilsson & Uhlin 2002). There needs to be an active business and industry with a high degree of co-location and co-operation, plus active co-operation between various actors and organisations with competence in the field of developing and dispersing knowledge (Lagendijk & Cornford 2000, Storper 1997).

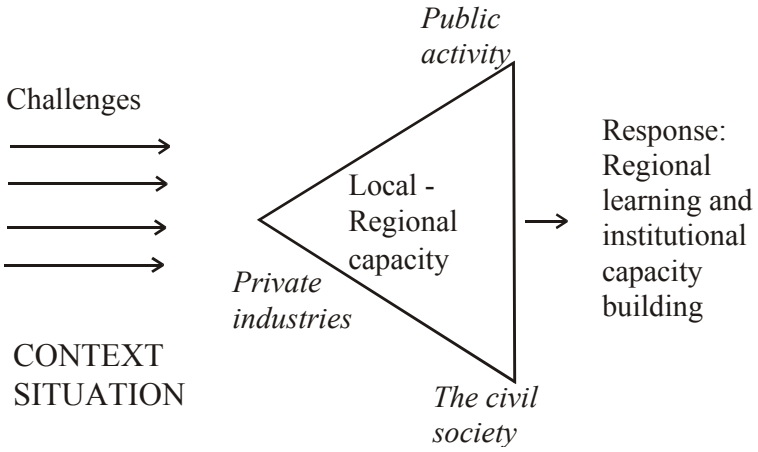


Figure 2. Regional capacity building (Amdam 2003).

In this article where the interconnection between economic and political-administrative structure is focus, the starting-point is that the ability of a region's business and industry for innovation and change is dependent on the conditions and changes in civil *society*, in public activity *(the public sector)* and in *business and industry* (see figure 2). If one transfers this perspective to competence and capacity development – to develop "learning regions" (Asheim 1996) or "clusters" (Porter 1990) - the challenges to the system can be illustrated as in figure 2. At regional level, there are three sub-systems which have to be made to function as well as possible as a collective unit: business and industry itself, public sector activity aimed at competence and capacity building, and the civil community. Each of these sub-systems is linked together with both larger (national and international) and smaller (local suppliers, etc.) systems that form the framework of conditions, challenges and changes (Stöhr 1990). In this perspective a region is a set of dynamic relations with a geographical concentration and the development capacity of a region can be changed by changing sub-systems. The basic question will be how to change the sub-system public activity by political and administrative reorganisation so that the regional capacity increases. How will the alternatives described in part one her function on the West Coast of Norway regarding this objective.

Co-operation, joint development work, the building of networks, interactive learning etc. seem today to be the main strategies in use to get such systems to function together and to further regional development (Asheim 1996, Asheim & Isaksen 1997, Healey *et al.* 1999, Koschatzky & Sternberg 2000). But basic to the whole process is the fact that it is human beings who develop, communicate, use and are bearers of knowledge and competence. Knowledge gathered in libraries, on the Internet, etc. is passive and does nothing to further regional development unless it is activated and integrated in social processes (Amdam 2000, 2003a, 2014), i.e. the development of human resources and competence. Even though it is possible for individuals to develop new knowledge, the recognition, further development, dissemination and use of such knowledge is linked to co-operation and networks

between people and organisations - to social processes that require nearness (Törnquist 1997). This is another perspective for the understanding of figure 2; the spatial integration of the three sub-systems will provide better opportunities for social processes and a higher intensity of intra-regional flows that will increase the abilities to cope with challenges. A political-administrative structure that is as identical as possible with the economic and social spatial structure can be an advantage with regard to development and competition. This perspective can be called "total integration" (Cornett in Bengs 2002). It can be necessary to use strong economic, social and political power to influence all three subsystems to "create" such a region and also to maintain it.

My focus is regional planning and development from a communicative viewpoint: whether it is possible politically and by using tools like political and administrative reorganisation to change structures and institutions and to get systems to produce other and better results for society than has been the case? According to both the perspectives presented above; what are the major changes and challenges in Western Norway and how can and should these influence the decisions on new administrative regions? The focus is Western Norway, which from the north comprises the four counties of Møre and Romsdal with Ålesund as the biggest town, Sogn and Fjordane, Hordaland (Bergen) and Rogaland (Stavanger). Based on figure 2 I will first present and discuss the structure and changes of the three sub-systems before discussing possibilities for geographical integration and change that can stimulate future development.

### *3.1 An overview of structural change in Western Norway*

Looking at details regarding population and employment structure and change in Western Norway after the Second World War, some general characteristics are dominant (Amdam 2005):

- the South is growing while the North is stable or declining.
- the Coast is growing while the fjord and mountain areas are declining
- urban areas are growing and rural areas are declining

In post-industrial urban society there is a large difference between communities that are or can be integrated into these urban structures and communities on the outside. Almost all job and population growth is now taking place in these urban zones, while the rural communities on the outside show stagnation or decline. Selstad (2004) also reveals a strong geographical correlation between level of urbanity and population growth.

The process that increases the differences between the urban core and the rural periphery also influences Western Norway, which in my opinion is changing into three major structures, see figure 3:

a. The large-town belt from Stavanger to Bergen that has over 700.000 inhabitants and 2/3 of all jobs in Western Norway. The area is still not well integrated due to fjord crossings, but in the near future it will be possible to travel by car from Stavanger to Bergen in approximately 2 hours. Oil and related industries is the dominant cluster.
b. The small-town belt in the North West that includes Kristiansund, Molde and Ålesund and due to a new undersea car tunnel opened in 2008 also Ulsteinvik and Ørsta/Volda as the fourth region with more than 10.000 jobs. This area organise approximately 1/5 of the jobs in Western Norway, some of them related to oil supply and fishing abroad, and a population of approximately 200.000. It is less dynamic than the south and dominant clusters are marine industries related to fisheries, shipbuilding and support services to oil and gas activities.
c. The marginal rural area, comprising fjords, mountains and islands, inland of and between the urban structures with ¾ of the land, but with less than 1/5 of jobs and population. This area is divided into a lot of small job markets due to the geographical structure, and faces the same kind of challenges as the eastern mountain areas of Norway, see figure 3. Welfare production as well as primary production and tourism are the dominant industries.

In 1942 Inge Krokann (1982) gave the name "Det store hamskiftet" (literally, "the great shedding of skin") to Norway's industrial revolution, the change from traditional agriculture into modern industrial

production that started around 1860 in most rural areas in Norway. A corresponding change has been ongoing after the Second World War, from the modern to the post-modern society. In Western Norway this change is somehow different than in other parts of Norway. While primary production has been reduced on the same scale as the rest of Norway, secondary production (manufacturing industries) is still important and even small peripheral job regions are less dependent on public funding than corresponding regions in other parts of Norway (NOU 2004:2, Onsager & Selstad 2004).

## CIVIL SOCIETY

An important task in local and regional capacity building is to increase social capital. Healey *et al.* (1999) define this task as influencing the three dimensions of institutional capital; knowledge resources, relational resources and mobilisation capability. A region with a high local openness combined with strong local capacity usually copes better than regions with strong local capacity but a local closure strategy or a region with high local openness but weak local capacity. Traditional rural regions typically have a combination of local closure (strategic focus on traditional activities) and weak local capacity due to class struggles and internal conflicts, while flexible rural regions are both open and have high local capacity – a common strategy for development that includes all important local shareholders. Important factors are nearness and identity. As illustrated by the authors of the history of Western Norway (Helle ed. 2006) the area has a strong common identity due to its common history, the combination of agriculture and fisheries, high equality, a sea-based system of transport and communications etc., but also strong local identities due to the difficult communications.

Maybe the major change in modern times is the shift in transport and communications from sea to land, from boat to car, which is still going on and will certainly have a strong influence on identity and social proximity. A strong indicator is the change in geographical labour markets. These changes are illustrated in figure 3, which shows labour market regions (municipalities where the centre is within commuting distance of the centre of the region) with more than 10.000 jobs in 2001 and compares these with (approximately) the corresponding commuting area in 1960 (Sandal 1977). Comparable changes are taking place in smaller labour markets.

Before the Second World War the sea and fjords were the dominant systems of transport and communications in Western Norway. Only Bergen, Stavanger and Åndalsnes (Møre and Romsdal) had railroads to Oslo and no north-south connection due to the high cost of fjord and mountain crossing. Also proper roads were rare and found mostly near the bigger towns. Ferries for fjord crossings were extremely scarce before 1960 (Nerheim 2006).

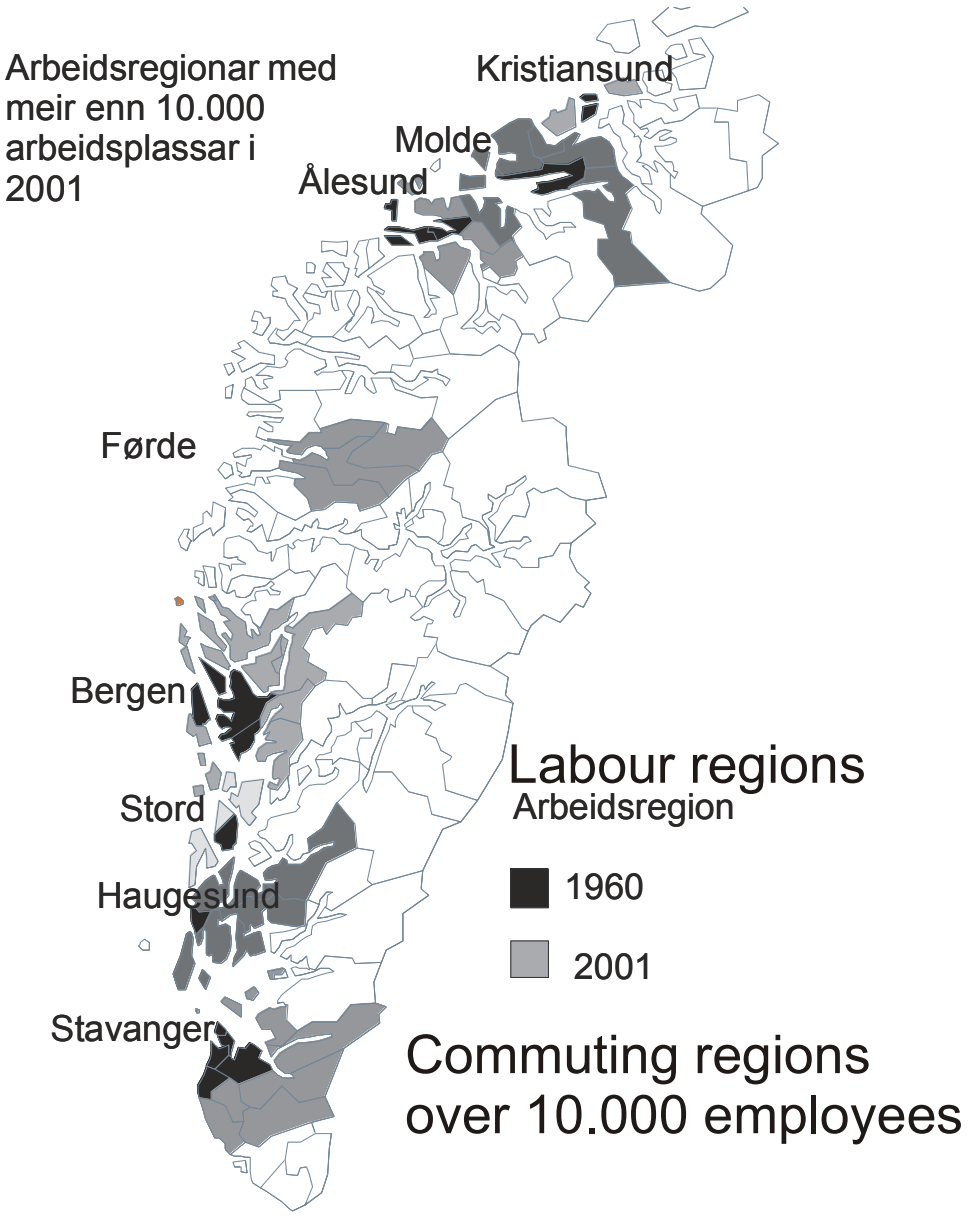

Figure 2. Labour market regions, over 10.000 employees in 2001 (Amdam 2005).

From 1960 onwards there has been a continuous political effort to change the transport system from boats to roads and cars, but Western Norway is still lagging well behind the eastern and central part of Norway. To go by car from Stavanger to Kristiansund using the road system in the four counties will take approximately 12 hours and involve 6 fjord crossings using ferries. Nevertheless, this still represents a tremendous change from the situation before 1960, when only boat transport was possible. Some regions implemented the shift from sea to land transport earlier than others, particularly the urban regions. But still the commuting regions were small in 1960 due to the lack of proper road systems and the fact that cars were scarce, even around cities (at least in the Norwegian context) like Bergen and Stavanger (see figure 3). In fact Sandal (1977) has shown that in 1960 the commuting areas in practice were a lot smaller than the theoretical area.

The most profound structural change in Western Norway after 1960 is the tremendous geographical growth of the commuting areas. But as shown by Gammelsæter *et al.* (2004) and Amdam *et al.* (2000), fjords and mountains still act as borders and result in labour regions that are a lot smaller than the direct distance as the crow flies. Especially in the fjord and island areas the change from boat/ferry to car is still a thing of the distant future due to a lack of proper investments and political priority.

Some integration processes are ongoing due to changes in transport and communication patterns. The most dominant one is the Main Coast Road project from Stavanger to Kristiansund (south-north). The plan is to make this road "ferry free" (6 ferries today) and have two-lane standard (only 40% today), a process that can take 20 to 30 years dependent on national priorities of infrastructure investment. But if plans are fulfilled the road between Bergen and Stavanger can be ferry-free in 10 years' time, reducing the travel time by car from over 4 to close on 2 hours. This process will strengthen the coast and the south even more and can create a very strong urban belt from Bergen to Stavanger. This will also increase the need for common strategies for development and planning and an administrative integration to meet such challenges. A corresponding integration process in the north is more difficult, due to lower population and higher costs.

The other process is better communications along the fjords – east-west, to integrate the fjords into the more dynamic coastal areas and to integrate small town labour markets, like Kristiansund/Molde, Førde/Florø and Ulstein/Volda. But these changes will mainly have local effects. The challenge is that over 70% of the land areas of Western Norway have less than 20% of the population. These rural areas are so distant from major towns and town belts that major commuting integration is very unlikely in the near and distant future because the political power is now predominantly in the urban areas illustrated in figure 3.

In 2002 Western Norway had 40 labour market regions, 14 of these were single peripheral municipalities and 18 consisted of less than 4 municipalities. New infrastructure as well as population change will certainly reduce the number of real labour market regions and the expansion of the dominant urban regions will continue as illustrated in figure 3. But this will mainly lead to a better opportunity for integration in the urban areas in the south and north, while the rural areas "in between" can be left behind.

Local and regional newspaper structure is another indicator of the integration of civil society. Both Bergen and Stavanger have strong regional newspapers that dominate their corresponding counties and also the southern part of Sogn and Fjordane (Bergens Tidende). In the northern part three regional newspapers share the market, each based in a small town (Kristiansund, Molde and Ålesund), the biggest Sunnmørsposten in Ålesund is also dominant in the northern part of Sogn and Fjordane. The north-eastern part of Møre and Romsdal is dominated by the regional newspaper in Trondheim. At the local level there are a tremendous number of small newspapers covering one to a couple of municipalities, especially in the North West. This is a strong indicator of the lack of social integration in Western Norway and also of counties like Møre and Romsdal and Sogn and Fjordane.

On the other hand the regional structure of the state broadcasting company NRK adheres strictly to county borders and acts as a strong integrator in a county like Sogn and Fjordane. Looking at the media as an indicator of integration, Western Norway has no common structure that links information flows spatially. In reality Western Norway can be divided into 6 regional newspaper regions, two large and one small in the south and three small in the north corresponding to the urban structure (see figure 3), and maybe an emerging small region in the middle with Førde as the core. A lot of private services are also structured in this way since they use these newspapers as important parts of their marketing.

## 4. Part 3. Future structure and integration

Real spatial integration of economic, political and civil regions is a major challenge. As shown in figure 2, a possible integration that can increase the capacity for regional development must also include a social integration (common identity etc.) and a political/administrative integration into a region where all actors work together to meet challenges and respond to opportunities. A spatial "political" integration is not enough; for example, according to Cornett (in Bengs 2002) a "total" integration is characterised by:

- The development of specific geographically defined systems of production such as industrial districts, clusters of industries, or systems of innovation.
- A system of urban networks defined according to specific functional links.
- The availability of a relevant regional infrastructure linking the analysed areas together.
- Last but not least, the intensity of intra-regional flows relative to outside flows can be considered the "conditio sine qua non" when we talk of a spatially integrated area.

In short and according to Healey *et al.* (1999) the internal knowledge structure, relations and mobilisation activities must be stronger in the region than between the region and the outside, and the region must not include sub-regions that are stronger on their own than as a part of the whole. A common commuting area that has functioned over a long period is typically one such integrated region, but can these characteristics also include a band of partly overlapping commuting regions, since there will be demands both in the south and north to create real "town belt regions"? Can territorially distant areas like the north and south of Western Norway be integrated in the future by better communications etc. in spite of the dominance of Oslo as the capital and communication node? And can such an economic integration lead to a common understanding of the situation and the challenges faced by all involved and in that way lead to social, political and administrative change that can empower the area?

Based on the arguments above and the pattern shown in figure 3 I will analytically divide Western Norway into three zones regarding situation and challenges and also discuss whether and how it can be possible to meet the characteristics of a "total integration" as described by Cornett. The three zones are a) the south-west; the urban belt from Stavanger to Bergen, b) the north-west; the small town belt from Kristiansund to Ørsta/Volda and c) the "rural remainder".

### *4.1 From small-scale manufacturing to a diversified "metropolitan" region – the South-West?*

One type of region and a regional development that maybe is historically characteristic for Western Norway as a whole is "Small-scale manufacturing" (Nilsson 1997), also called "Flexible rural areas". Typical is production on a small scale, flexibility, labour intensive production, small cooperating companies, etc. – often "Third Italy" is used as a model for areas like Sunnmøre (north) and Jæren (south) in Western Norway (Asheim & Isaksen 1997). With regard to manufacturing, the difference between the factory and the workshop is often used as an illustration of the difference between "English" and "French" industrialisation. Except for the metal and textile factories, most of the industries in Western Norway have grown out of workshops and in tight cooperation with demanding customers (fishermen etc.) (Wicken 1997). The "clusters" (Porter 1990) we have today are the result of such processes (Reve *et al.* 1992). But some regions are more "dynamic" than others and maybe also more lucky regarding specialisations, which also explains some of the dynamics of regional concentration (Selstad 2004).

Jæren (South-west) is an example of demands for new equipment from agriculture that leads to new industries and national dominance in the production of such equipment (Asheim & Isaksen 1997). But it is also the history of "English" localisation of oil industries and a flexibility regarding new markets and challenges that has created an impressive cluster of maritime oil activities. In the region around Stavanger there are today 600 large and small companies with approximately 33.000 jobs in the petroleum cluster. In a Norwegian context the Stavanger region is a large-scale manufacturing region

with a high proportion of foreign ownership, but still with a lot of the characteristics of a flexible and dynamic rural region.

Above I have shown that changes in transport and communications in the near future will integrate the commuting areas from Stavanger to Bergen. It will be difficult to live in Stavanger and commute daily to Bergen, but by living in the middle of the area it can marginally be possible to commute both to Bergen and Stavanger and not spend more time than in many metropolitan areas. But not only must the ferry-free road system be built, road taxes must also be reduced to an acceptable level.

One important demand regarding integration is the intensity of intra-regional flows, networks and infrastructure and this kind of integration has not been achieved today. For example, air transport is a lot more intensive between Bergen and Oslo or Stavanger and Oslo than between Bergen and Stavanger and this is not compensated by land or sea transport. What are common to both Bergen and Stavanger are of course services but also oil related and marine activities (Selstad 2004). Stavanger dominates the oil cluster, but on the coast companies in Bergen, Sunnhordaland, Haugesund and Stavanger are cooperating and competing when it comes to production and services to both the oil industry and other North Sea activities. Shipbuilding has to some extent changed into oil rig building. Fish farming is integrated into large international companies etc. The universities and other knowledge and research organisations in the area compete internally but to a lesser extent than with Oslo and Trondheim and internationally. To increase economic growth a stronger regional cooperation and integration as well as specialisation in activities that have a strong regional environment, such as oil and maritime activities, should be promoted.

Western Norway has no diversified metropolitan core like Boston that can function as a growth centre (Nilsson 1998), but is that possible in the future? Bergen may have ambitions, has a good university environment, but to a great extent functions as a campus for youth from Western Norway before getting work in the Oslo area.

What are the possibilities that Western Norway can meet the challenges of the post-industrial society and change into a knowledge-based diversified metropolitan region? In fact the term metropolitan will be an exaggeration, since the total population of Western Norway is only 1.1 million and as mentioned above, only South-Western Norway with its approximately 700.000 inhabitants can be integrated into a region that possibly can function as a diversified urban region. To do so, two strategies must be implemented, a) regional enlargement with the development of an integrated polycentric core, and b) knowledge growth. This means tremendous investments in communications, especially road and tunnel building, and universities; education and research. The area already has a high knowledge base when it comes to both petroleum activities and marine and maritime activities.

Since economic integration is possible in the future, can a political/administrative change promote this development? In reality the major challenge to the area comes from the capital Oslo and overseas regions; an integrated South-West region may be the only region nationally that can compete with Oslo. But to do so the region must develop a common strategy and also have common means to achieve goals and tasks and this can most easily be organised by a joint political/administrative structure. But a common “enemy” is maybe not enough in an area with strong local and regional identity that from days of old has been “organised” around the fjord systems and where Bergen and Stavanger from time immemorial have competed economically and politically. Still the area is split into two by regional newspapers, based in Bergen and Stavanger, which very much create their own political agendas and “internal” conflicts. An amalgamation “from above” before the area has been integrated with regard to transport systems, economic activity as well as socially can easily increase the level of conflict between the different identity regions, between the two large towns and between urban and rural areas.

*4.2 Growing self –developing urbanised rural areas in the North-West?*

So what about the North-West? Is this a stagnating, formerly flexible, rural area with little dynamics in the small towns? While the South-West has scale and is already growing, the North West's lack of scale and growth is a profound challenge. The geography also makes it difficult and very expensive to expand labour markets and to integrate the urban areas. While the South-West is still growing when it comes to advanced services, Oslo functions as the service provider for the North-West and with small local growth in advanced services and jobs. The North-West is even among the most difficult regions in Norway with regard to communications (Selstad 2004). The change in the pattern of communications from sea to land is still going on and will do so for a long time. The area is also very fragmented with regard to identity, dialects, newspapers, commuting areas etc. (Gammelsæter *et al.* 2004).

Fisheries, maritime and oil related activities integrate the small town band from Kristiansund to Ørsta/Volda and also most of the coast in Sogn and Fjordane. The Kristiansund region is enjoying a "fresh start" related to oil and gas activities, the Ålesund and Ulstein regions are dominant in fisheries as well as in the building, equipping and use of supply boats for the oil industry. Ownership is a challenge in the area since a lot of the dominant companies have been taken over by international companies like Rolls Royce (who have their maritime headquarters in Ulsteinvik), Aker Group etc. The region is an important international cluster when it comes to specialised boats and equipment for fisheries and oil activities in climatically challenging areas. The major challenges for this cluster/area are to achieve an increase in competence, knowledge, research, economic support etc. so as to be dynamic on the international market in the future and in that way create conditions for stability and growth in the region – to become a flexible and dynamic "rural" area in the future. The demands and challenges are greater than in the South-West, as is the need for the support of regional and national policies.

With proper investments in communications it should be possible to better integrate the area from Kristiansund, Molde, Ålesund, Ulstein to Volda (see figure 3). By road building and tunnels under fjords to get rid of ferries it can be possible to reduce travel time to maybe less than 3 hours compared to over 4 today. The required investment is possibly 30.000 mill NOK and the population that can be integrated into this zone only numbers 200.000. It is not possible to finance this kind of investment without heavy national investments. And the integration of transport in itself gives no guarantee for growth and dynamics. Interestingly the North-West town belt is already politically integrated as a County, but has a lot of political conflicts between the three fjord and town systems. Economically one could argue that the coastline of Sogn and Fjordane also is integrated into such a unit. On the other hand the fjord- and mountainous eastern part of Møre and Romsdal has a lot in common with the small regions in Sogn and Fjordane and the inner part of the South-West.

Gammelsæter *et al.* (2004) argue for an amalgamation of the North-West into one region due to the many common challenges that especially are different from those facing the large urban area in the south. Such a region will be dominated by rural small and medium-size municipalities and commuting regions. Of a total population of approximately 360.000 inhabitants, only approximately 150.000 live in the commuting areas of the three towns (see figure 3). If one focuses on common interests, the small town belt on the coast may have other interests in the future than the rural periphery, especially in a possible future where globalisation and economic development is more dependent on what is happening in the commuting area than in the marginal rural surroundings.

*4.3 What about the traditional rural areas in Western Norway?*

The areas outside the South and North town belts, what do they have in common apart from challenges involving stagnation and decline? The area consists of two economic (commuting) regions in the north, Sunndalsøra and Surnadal, that in the future can be integrated into the Trondheim region due to changes in transport and communications (see figure 3). In the middle are 7 economic regions from Odda in the south to Nordfjord in the north, or the County of Sogn and Fjordane together with two

economic regions in Hordaland, with a total population of approximately 150.000 inhabitants. This area has from days of old been dominated by Bergen as the service and administrative town and connections are still strong. Each of these 7 economic regions even has areas that are outside commuting distance from "local region centre", the lack of an integrated transport network is profound.

Employment structure and challenges also vary and one can point to the fact that the only feature they have in common is that they are all outside commuting distance of a town with at least 10.000 inhabitants in the urban area! But this characteristic is something these regions have in common with most of the mountain area of South Norway. Compared to remote regions in the east of Norway the marginal regions in Western Norway have a strong tradition of manufacturing industries. As shown above and exemplified by Sogn and Fjordane County the primary industries have been reduced as in the rest of Norway, but even in these small regions manufacturing industries are still important.
While the opportunities for integration that can stimulate growth are high for the urban South-West, and maybe for the urban-rural North West, the marginal rural areas of the South Coast face even greater challenges. The area is very fragmented with regard to dialects, identities, local newspapers etc., has a lot of commuting regions with few possibilities for integration into bigger urban regions, large in land and sea area and small in population. Some of these regions like Årdal, Sunndal, Odda are dominated by large-scale metal production that is going through downscaling processes. Other regions are very dependent on agriculture and/or fisheries. Since the population is small, even minor changes in employment can lead to significant growth or decline.

Further decline in primary industries will continue; also a decline in the established "English" pattern of manufacturing industries will certainly happen and with few possibilities for new manufacturing jobs as compensation. But small scale and a tradition of social equality and flexibility, the will to live in a certain region, are maybe the most important means for development. The national change from a rather young population focused on manufacturing to an older population focused on welfare and dependent on oil incomes, combined with growing social conflicts in the rest of the world, maybe offers new opportunities for small "safe" rural communities.

Rural communities in Western Norway have historically few of the social differences of the typical big farmer – land worker communities of most of inland Scandinavia. Farms were small, all inhabitants equally poor, but also open to the wider community since the sea transport system was perfect for jobs as seamen, fishermen etc. (Gammelsæter *et al.* 2004, Kolle & Haaland 2006). Healey *et al.* (1999) characterise such communities as having strong local social capacity combined with local openness. This is an advantage also with regard to the integration of "differences", as we see few challenges involving foreign workers in industry etc. As the number of old people will double in the coming 30 years, social unrest maybe will increase in the typical "old town areas" in the south – perhaps the very socially secure fjord and island communities in Western Norway can be places to escape from a turbulent world? Can care, tourism etc. become growth industries for at least some rural regions?

What is clear is that a "total" integration of this area according to Cornett's demands is not possible, but some of these areas can possibly be integrated into the more dynamic urban areas in the south and the north.

## 5. Conclusion. Possible regional organisation in the future

Due to the spatial structure of Western Norway the area can be divided into three zones with different situations and challenges now and in the future. A political structure that corresponds fully to this structure is not realistic or even advisable, mainly due to the geographical structure of the "rural remainder", see figure 3. But the spatial structure shown above can be used to discuss pros and cons regarding proposals for a new political-administrative structure see part 1. The 0-alternative is also a possibility if the ongoing voluntary municipal restructuring process ends by small changes in 2020.

**Western Norway as one region**. This alternative is called "Big regions" in part 1 and is based on proposals in Selstad (2004) and his alternative with 7 regions in Norway, and an integration of all of the 4 counties on the West Coast. This political structure will be dominated by the south west town belt that will have more than 2/3 of the population. It is very uncertain that the northern part of Møre and Romsdal will join such a construction due to its proximity to Trondheim. The large western region will be a strong region nationally with over 1 mill inhabitants, but if no proper understanding is developed between south and north, coast and inland, town and country, there can be a lot of conflicts that will reduce the external and internal political power of the region. The major challenge is a lack of integration south-north, for a lot of areas Oslo is closer in travel time than Bergen or Stavanger. The potential power struggle between Bergen and Stavanger can easily reduce the necessary political focus on the rural area and the north-west. Using Cornett's criteria the region fulfils the requirement of a geographically defined system of production, but the three other demands are not fulfilled now, nor can they be in the near future. Looking at the demands for a coordinated economic development a political region for most of Western Norway should be positive; the challenges will be the lack of intra-regional flows, of integrated urban networks and of a linking infrastructure.

**Two regions; South and North**. This alternative correspond to alternative 1 (Amalgamation) in part one, but with flexible change of borders. The south will consist of Rogaland and Hordaland and parts or all of Sogn and Fjordane. The population will be approximately 800.000 inhabitants. The two cities of Bergen and Stavanger will dominate the region and if they can cooperate and integrate activities as well as plans into a functional polycentric structure, this can be a rich and dynamic region that can even stimulate the marginal areas and integrate them more fully than today. A full integration of the most distant areas north, east and south will need at lot of investments in infrastructure and also a policy concerning decentralisation, cooperation and the expansion of urban networks that will be very demanding.

The north will include the rest of Sogn and Fjordane and Møre and Romsdal, maybe apart from the Sunndal and Surnadal regions – and have a population of 250.000 to 350.000 inhabitants. The small towns of the northern region do not have the dynamics today to stimulate the area and an integrated transport network will be difficult to establish. The area has more in common as a political empowerment structure with regard to national and maybe international policy than with economic and social integration. While Sunnmøre and Ålesund traditionally have been "on their own" (Gammelsæter at al 2004), the northern part of the area is closely linked to Trondheim, while the southern part has close links with Bergen and most of the area has stronger flows to Oslo than to these two cities. The region can be full of internal conflicts that can result in passivity and a lack of political focus on economic and social development. Only by heavy investment in infrastructure and coordinated polycentric development can it be possible to establish an urban core that can stimulate regional integration and development.

**Three regions**; This alternative correspond to alternative 1 (Amalgamation) in part one. Møre and Romsdal and Rogaland as they are now, and an amalgamation of Hordaland and Sogn and Fjordane – maybe with some border corrections. This alternative will separate Bergen and Stavanger and can reduce the synergic effects of a polycentric integration as shown above. Both Møre and Romsdal and the new "mid-region" will have internal conflicts between town and country, coast and fjord and in the north also between the small towns. The positive effects of this structure can be a clearer structure regarding town and hinterland and can stimulate that integration.

Also other alternatives like a two-layer system with large municipalities that correspond to economic regions as well as division between cities and rural areas (alternative Big cities in part 1) have been discussed (Amdam *et al.* 2000), but these are today politically unrealistic. The challenge is of course that while economic integration is a continuous and ongoing process in an area like Western Norway, where major changes in transport and communications are still taking place, where international competition results in activities being clustered geographically and strengthens urban areas, the social integration in particular is lagging behind. Due to the continuous economic and social changes, any political integration into stable spatial governing units is difficult. This is also apparent in the

fragmented state sectors' own spatial organisation processes. Using Cornett's criteria the possible alternatives for integrated political-administrative regions are not fulfilled now, nor can they be in the near future.

There is no clear "best" alternative for regional political and administrative organisation in Western Norway that can build on an existing "total" integration, mainly due to a lack of infrastructure, networks and intra-regional flows. The region has a lot of conflict lines and differences of interests between coast and inland, urban and rural areas, south and north and maybe only a strong common enemy (the capital Oslo) can unite the area. I have tried to illustrate structures that are possible in the future; the challenge is that they do not exist today but they can be developed by heavy investments and involvement. Instead of establishing political/administrative structures that "fit" existing social and economic patterns, political/administrative reorganisation would be an "instrument" and part of the strategies for the creation of new intra-connected regions, regions that will be relational and geographically dynamic. If so, new models of geographical political and administrative organisation are needed (Farsund *et al.* 2002). Particularly the possibilities for polycentric cooperation and organisation as promoted by the EU system (Bengs 2002, Selstad 2004), can provide new opportunities but will also inevitably create new challenges.

# Using quality indicators to assess urban regeneration in residential areas

Lida Aminian [1], Harry Timmermans [2]

*1 Eindhoven University of Technology, l.aminian@tue.nl*

*2 Eindhoven University of Technology, H.J.P.Timmermans@tue.nl*

## Abstract:

*Urban regeneration programs play a dominant role in improving declined areas and inject new life into cities, neighborhoods and urban centers. They can be long term and costly projects and therefore evaluating them is a key issue for both urban policy makers and academic scholars. Although urban regeneration efforts have many similarities, they differ significantly in terms of their outcomes and the level of success across neighborhoods and regions. Detecting a successful regeneration depends on the set of factors such as the development potential of the location, the socio- economic context of the area and the commitment of all involved actors and authorities. Hence, to measure the success of such a complicated process it is necessary to consider all these factors and also the consequences of the implementation on residents' life.*

*In this article, the chief argument is to explore the main approaches in evaluating urban regeneration programs and then to propose a model to assess the implemented interventions in residential areas. The model contains a method, which quantifies different aspects of a regeneration program through sets of measurable indicators. It also addresses a survey from the residents, asking them to compare and evaluate their quality of life before and after the regeneration. In this method, measurable indicators are translated into survey questions and connected to physical aspects of the environment*
.

**Keywords:** Urban regeneration, planning, evaluation method

## 1. Introduction

Urban spaces are diverse and dynamic places where different activities and events take place. The diversities and changing characteristic of urban places have always been influenced by macro developments, such as globalization and economic situations and, as a consequence, new visions and methods are needed to manage these multi – scale issues in the existing urban environments. Urban regeneration programs are the tools to face diversities, inequalities and major challenges in urban areas across the world. In the last two decades, many towns and regions have been involved with regeneration programs to eliminate deprivation and improve the individual spaces as well as the collective ones (Roberts & Sykes, 2000). The primary goal of these programs has been mostly economic, but in recent years it has shifted toward concepts such as vitality and human development.

Urban regeneration processes have been regarded as a key element of urban policy to promoting land values and environmental qualities (Adams & Hastings, 2001). It contains various approaches to tackle economic, social and physical issues of urban centers and therefore involves different planning

actions and stakeholders (Couch, Sykes & Boerstinghaus, 2011).

In recent decades, many of implemented actions regarding regeneration program emphasize on human development rather than economic growth of the regions. Thus, the reflections of the link between regeneration and these aspects bring out new questions whether the components of regeneration activities have been characterized with respect to human development indicators (Wei *et al.*, 2015). It is therefore crucial for planners to develop an evaluative tool to monitor the effectiveness of regeneration programs. This tool contains indicators, which demonstrate the regeneration initiatives for resident's interests.

Urban regeneration requires time consuming approach, dealing with various urban problems related to the built environment, such as urban decline, unbalanced urban growth etc. Therefore, its intervention in urban space is through sets of physical, social, economic and environmental domains. In this regard, this study aims to develop a model to evaluate the outcome of urban regeneration and empirically test whether those projects were successful in terms of enhancing indicators of resident's life quality. These indicators will be measured using objective and subjective methods in the context of neighbourhood. The findings will allow us to have a better understanding of urban development projects and the real impacts of physical interventions on residents. This can lead to improved design guidelines for the practitioners and will bring insights to both theory and practice of urban regeneration.

## 2. Background

From the earliest human settlements to modern globalized cities, urban regeneration has played a vital role in the world history. The concept of urban regeneration has gained a lot of attention especially after the Second World War due to the large damages and became part of urban policies. Cities have been rebuilt in response to the problems of economic decline, environmental demolition and social dereliction (e.g. Hulsbergen & Stouten, 2001; Stouten, 2010). It is possible to classify different strategies under the flag of urban regeneration depending on the implementation scale, time interval and location of the project. These strategies are known as urban revitalization, urban renewal and urban development (Dempsey *et al.,* 2011). All of these strategies make a direct link to the communities living in the areas where regeneration is planned. As a consequence community and its demands are an integral part of any urban regeneration program. Urban regeneration is multi-dimensional action, which contains different aspects of human life, and it should help the cities to become viable, vibrant and sustainable communities.

Although urban regeneration efforts have many similarities but they differ significantly in terms of their outcomes and the level of success across neighbourhoods in response to unique historical, social and economic realities of the area (Evans & Jones, 2011) Detecting a successful regeneration depends on the set of factors such as the development potential of the location, the attitude of the local authorities and the commitment of all involved actors. Hence, to measure the success of such a complicated process it is necessary to pay attention to all those factors and also the fact that urban regeneration involves in injection of new life into cities, neighbourhoods and urban centres. Since urban regeneration is multi - conditional and context related process, evaluation of urban regeneration projects should place emphasise on both the outcomes and the planning process. In summary, Roberts & Sykes (2000) explain urban regeneration in the Handbook of urban regeneration as: "Comprehensive an integrated vision and action which leads to the resolution of urban problems and which seeks to bring about lasting improvements in the economic, physical, social and environmental condition of an area that has been subject to change".

As figure 1 represents, urban regeneration performance at different scales from macro to micro aims to improve different indicators of social, environmental and physical aspects of urban system.

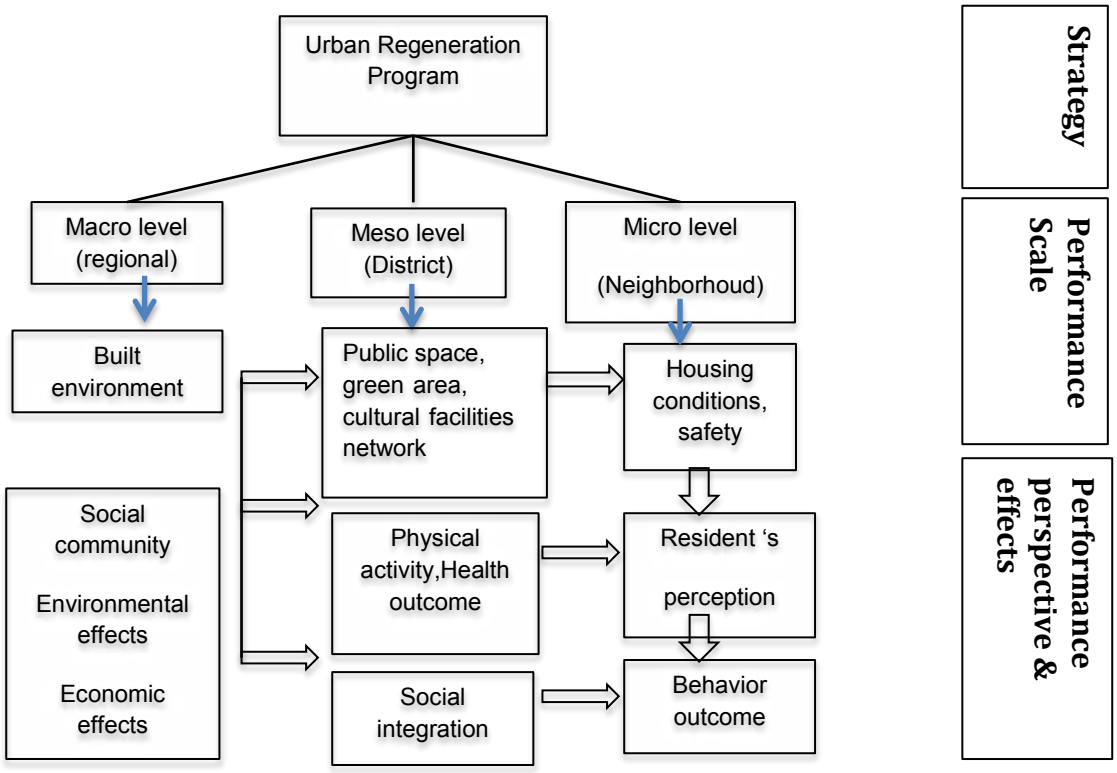

Figure 1. Regeneration performance scale

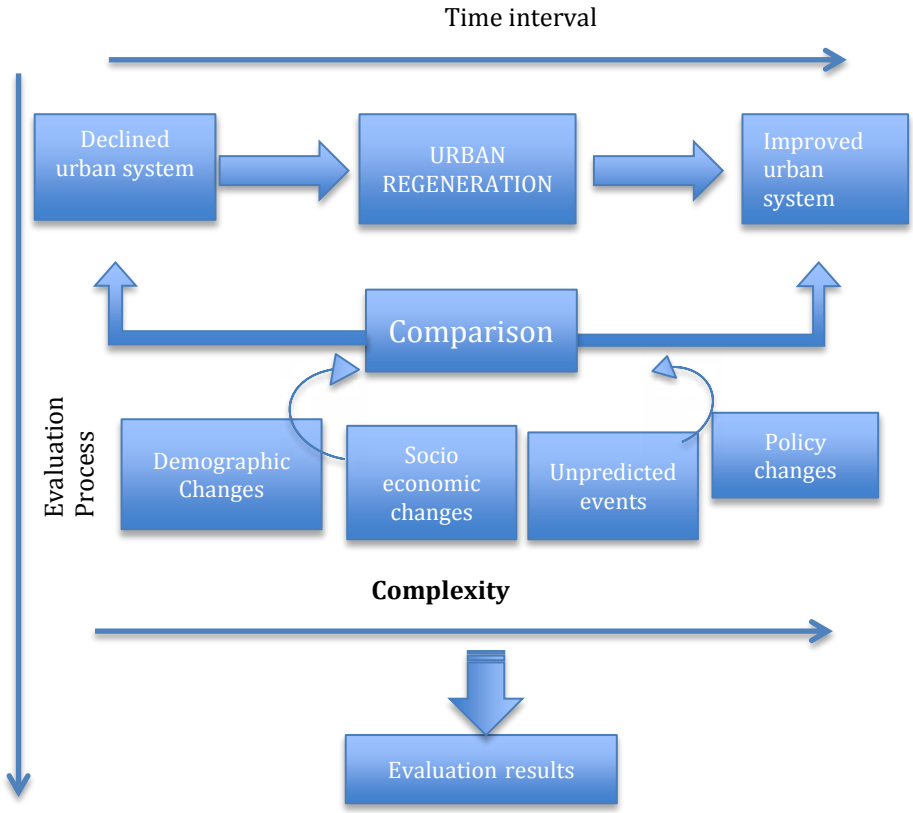
## 3. Evaluation of urban regeneration

There is consensus among authors and urban scholars that evaluating urban regeneration is necessary and enables planners and designers to see the areas of weakness and strength, thereby preventing them to repeat the same mistakes in future plans (Boyko *et al*., 2012; Cahantimur *et al*., 2010; Cheng & Lin, 2011). Assessment of urban regeneration is complex and according to Tyler (2001) there is no accepted method among researchers to evaluate and monitor the outcome of urban regeneration operations since they contains both short terms and long terms effects (figure 2). Due to temporal effects on the interventions, what appears successful at the beginning can lead to ineffective long-term results. In addition, changes in socio economic situation and demographic composition of area can also increase the complexity of assessment during and after the implementation. To tackle these issues, researchers propose different methods and approaches namely, Hemphill et al. (2004) developed an indicator-based approach for assessment of urban regeneration, although the use of indicators is not new and dates back to mid-1960s (Wong, 1995), they proposed indicators and weighting system as evaluative tools for regeneration activities and interventions. This method can employ different sets of indicators or frameworks, and includes both qualitative discussion and quantitative assessment of urban regeneration. The application of this approach is mostly on the

district levels where different indicators of land use, transportation and buildings are interrelated and measurable.

Figure 2. Complexity of urban regeneration evaluation

However, there is still ambiguity about what indicators should be used, Coombes *et al*. (1992) mentioned that indicators selection is not an easy job while the economy that provides the resources



for regeneration usually rooted far beyond the designated areas. This consequently makes indicators sensitive to locations and contextual factors. Taig (2002) suggests using of experts and people opinions as means of identifying the list of main criteria and their significance. Coombes & Wong (1994) suggest a four-step method for determination of indicators: conceptual consolidation, analytical structuring, identification of indicators and creation of an index.

Moreover, to evaluate the actual operation of urban regeneration, it's important to determine the physical changes in the area which ranges from housing renovation, public and green space development to urban fabric improvement. Each of these interventions can affect urban system and residential quality of life in different ways and to different degrees. Therefore, it is essential to identify the exact changes implemented through urban regeneration process in the neighbourhood in order to choose, collect, analysis and interpret indicators for the study. This will ensure that the most relevant indicators would be used during the study. A good Indicator must be relevant, valid, meaningful, measurable and sensitive to changes in the urban environment. Hollander (2002) also adds consistency, cost effectiveness and comparability to the criteria of indicator selection.

Although it is difficult to define and measure urban regeneration effectiveness, it is possible to conceptualize it through sets of key performance indicators such as length and cost of the program.

Example of measurable indicators for evaluating urban regeneration:

- The length of the program
- The cost of the program
- Number of buildings renovated
- Number of streets redesigned
- The amount of public spaces created
- Ratio of green space
- The number of new jobs created
- The number of bus, metro, tram added
- The number of retail business
- The value of properties

In addition to indicator-based approach, recognizing the underlying causes of regeneration process can help to monitor the outcomes and evaluate the effects of the process based on the problem-oriented approach. Figure 3 briefly shows the process of urban regeneration, from identifying the challenge to evaluating the success. It demonstrates the numerous reasons for regenerating an area, which covers physical, social, economic and environmental issues.

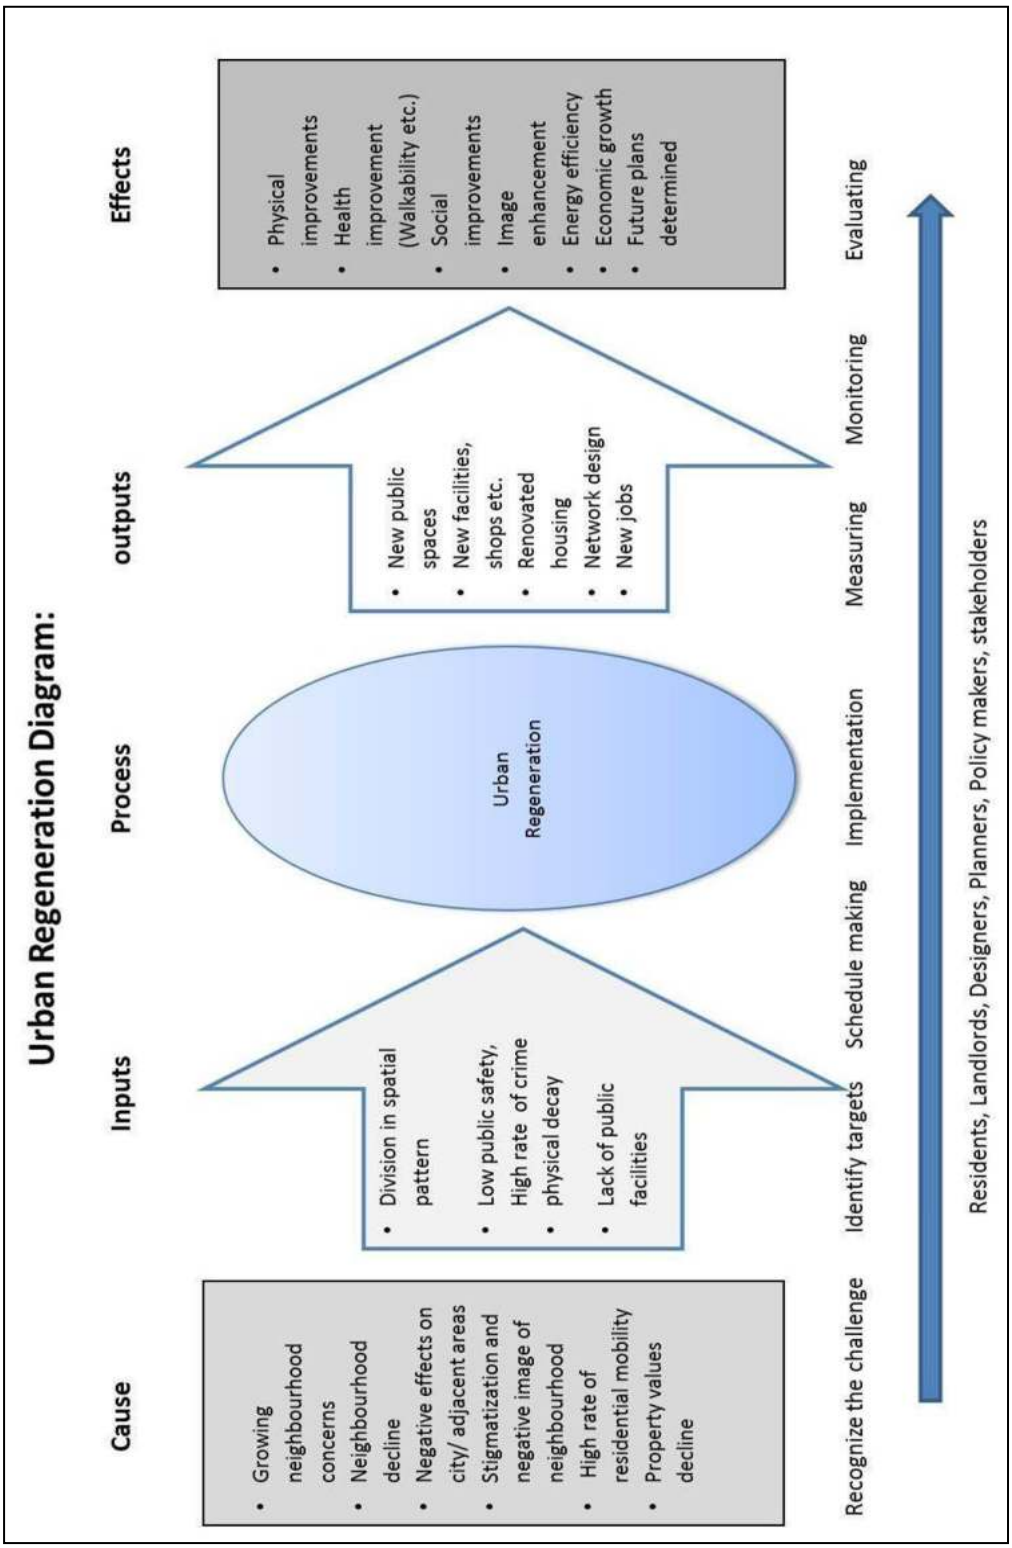


Figure 3. Urban regeneration diagram

## 4. Survey approach

Urban regeneration is a multi-faceted process that affects residential liveability of space and therefore survey and exploratory interviews should be an integrated part of the evaluation. Interviews with residents and stakeholders should contains:

(1) Comparison of the situation with similar size projects in the city

(2) Changes over time

(3) Future perspective and capacity of project to deal with coming issues

(4) Evaluation of projects in terms of defined sets of indicators

Collecting information for subjective assessments of residents' quality of life (QOL) has been usually conducted through social survey methods. In such survey, it has been common to ask residents to evaluate different aspects of their QOL (McCrea *et al.*, 2011). In this type of research, similar type of the questions can be asked from the residents who has seen the urban regeneration process and/or used to live in the intervention area before urban regeneration implementation. Therefore, they can compare the quality of their lives and whether it has been improved or not. The survey samples also should be spread out in a way that respondents are representative of the cultural diversity within the organization. Furthermore, statistical method will be used on the results of subjective QOL for further analysis and interpretations. These questionnaires and questions aimed to measure indicators designed in the previous step. Table 1 illustrates different indicators that might affects resident's satisfaction after regeneration implementation and can be translated into questions in survey-based approach.

| **Physical condition** | **Social condition, Civic behaviour** | **Economical Satisfaction** |
|---|---|---|
| • Landscape quality<br>• Housing quality<br>• Street design<br>• Network and accessibility<br>• Traffic-noise-pollution<br>• Air and water quality<br>• Public facilities<br>• Cultural amenities | • Satisfaction with people who live in the area<br>• Social interactions<br>• Safety/crime<br>• Privacy<br>• Ties with people in the community | • Living cost<br>• Housing price<br>• Socioeconomic status of neighbourhood (Unemployment rate, etc. )<br>• Neighbourhood improvement |

Table 1. Key performance Indicators

## 5. Integrative method

In recent years, assessing the effectiveness of regeneration practice has been gained a lot of attention among policy makers. Following this path, both "good" and "bad" practices need to be evaluated and deeply studied. The current financial situation and unemployment rate affect safety, housing quality and bring poor environmental conditions, which highlight the major challenges to improve quality of life through both top-down and bottom-up approaches. Increasingly, key performance indicators enable a range of measures to evaluate the achievement of regeneration through four main categories

of physical, environmental, social and economic. Figure 4 presents number of key factors to evaluate regeneration policy and practice.

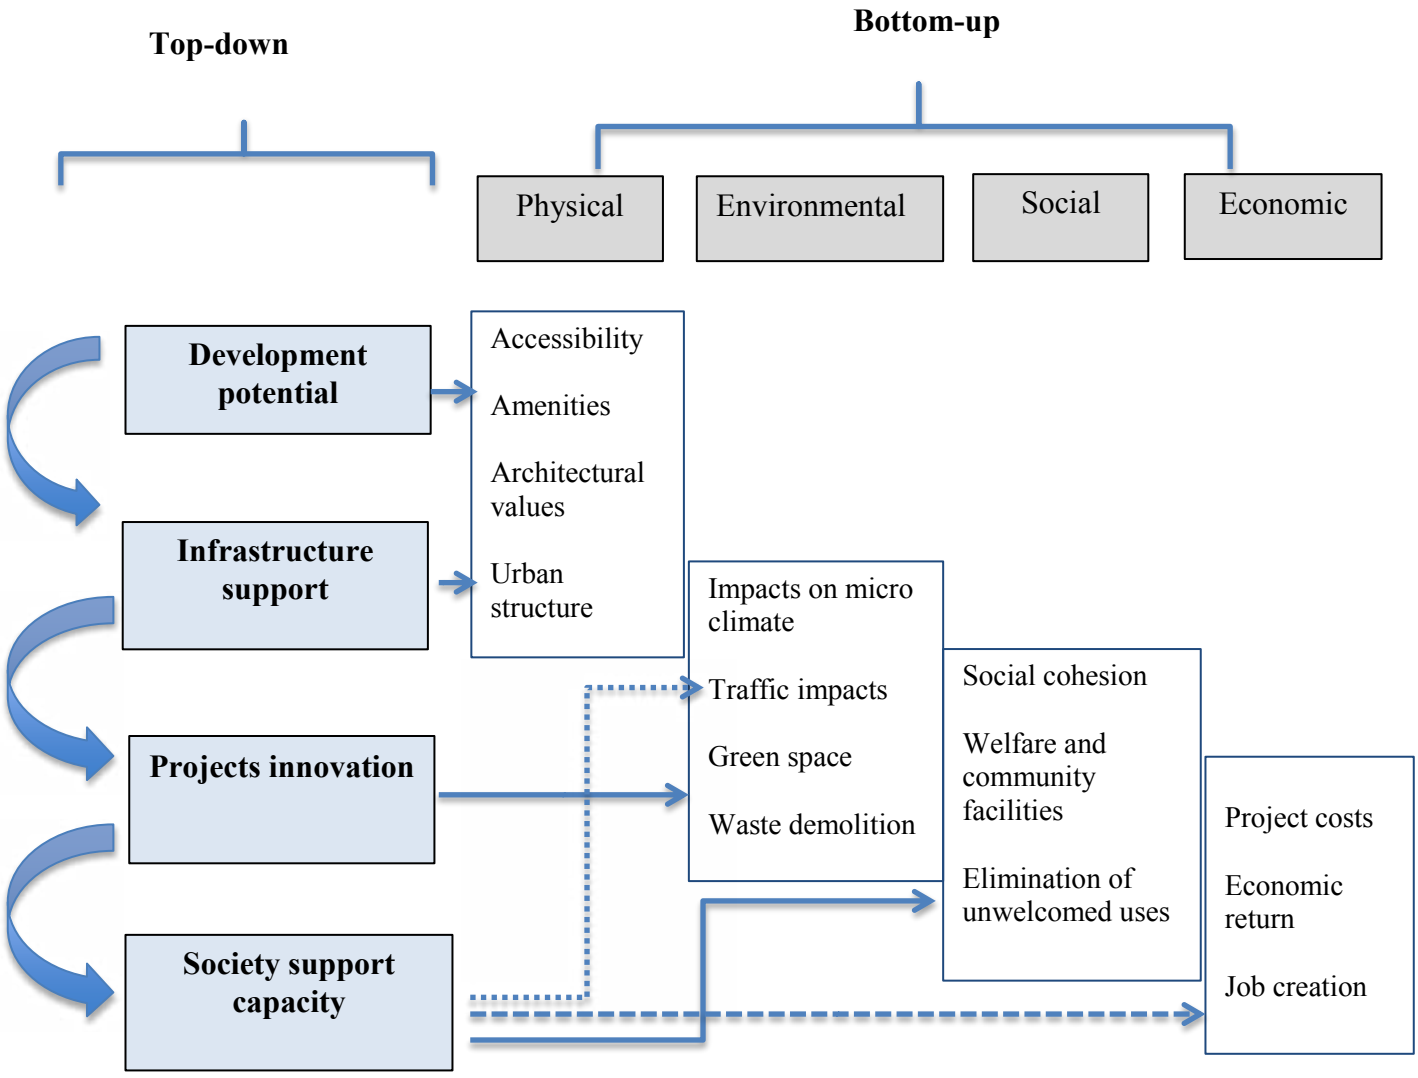

Figure 4. Key factors to evaluate regeneration process

## 6. Discussion

The above study provides insights into the complexity of urban regeneration process and discusses different approaches to assess regeneration policy and practice. In general, it is to say that four main factors play dominant role in the success of regeneration program; the development potential of the area, infrastructure support, projects innovation and society support capacity.

Despite the great emphasize on evaluating regeneration projects among researchers, there is still a huge gap in this field. Considering regeneration process as a long term and costly program highlights the necessity to deeply study the role of various planning factors and reach to an agreement on what to measure, why and how to measure it.

Evaluation of urban regeneration programs contains three distinct phases; Monitoring the current performance capabilities, assessing the future potentials and proposing corresponding solutions. Therefore, future-based approaches are also applicable to assess these programs and enrich their functionality in remarkable ways. Future scenarios can bring in depth insights for decision makers and protect the investments on existing and potential plans. In summary, to gain a better understanding of the urban regeneration mechanism, it is necessary to study every single element that contributes to the process and also interrelated to other elements.

Keywords: Land use/cover change, Master plan, Planning enforcement

## Abstract

*Planning enforcement is "probably…the weakest link" in the planning system (Dobry 1975 in Mckay & Ellis, 2005). Detection of breaches of planning control can profit from analysis of aerial photography or aerial imagery (Harris, 2011). Despite its limitations systematic monitoring of land use changes provides an important valuation in planning compliance.*

*This paper analyses the land use/cover data dynamics in three municipalities of Lezíria do Tejo region (Almeirim, Benavente and Santarém) and aims to support a reflection on the effectiveness of the main development restrictions foreseen in the Portuguese planning system: the National Agricultural Reserve and the National Environmental Reserve. A quantitative analysis of the recently-converted areas will be given, based on the comparison of land-use cartography, COS-1990 and COS-2007.*

*Official data on unauthorized development (and information on the characteristics and motivation of private actors) is nonexistent. Therefore, the paper provides an important diagnosis and an overall perspective of the built-up increase during two important decades in which the planning system was implemented. Numbers indicate that farmland and environmentally sensitive areas are being reduced, due to land use changes in areas where guidelines and specific rules have been drawn up to guarantee their preservation. These outline the links of compliance and the very rationale of planning law which can aid planners, scholars and administration officers.*

## 1. Introduction

Planning enforcement is "probably…the weakest link" in the planning system (Dobry 1975 in Mckay & Ellis, 2005). The chance of breaches of control being detected is one of the key aspects of effective enforcement (Mckay and Ellis, 2005). Traditional monitoring tasks are based on the labour of enforcement officers 'on the ground', either (1) screening the built environment for detection of unauthorized development, (2) visiting sites to certify compliance with conditions of planning permissions or (3) investigating complaints made by third parties. Such tasks encounter several limitations, one of which relates the legal powers to enter private premises. Evidences of unauthorized development may not be visible from public roads and additional problems arise when entering private property becomes necessary.

Lack of staff and resources is often pointed out as a reason for the absence of active monitoring by public bodies. This is one of the reasons why various municipalities in Portugal (especially small ones) tend to adopt a 'reactionary" enforcement system, in which actions are initiated primarily by reports or complaints made by private citizens (Harris, 2011). Among the three traditional enforcement tasks, screening the built environment for detection of unauthorized development is the one that requires most resources and brings fewer results, as location is uncertain, detections are based on circumstances and offenders usually do not cooperate. Despite its limitations, systematic monitoring of land use changes using Geographic Information System (GIS) to compare land-use imagery offers an important valuation of planning compliance. Although information provided by a "view from above" does not allow

identification of some type of hidden development, it can assist the most difficult of enforcement tasks. The use of such technology does not displace traditional methods but complements "ground" enforcement (Lai, 1998 in Harris, 2011).

Portugal, like other South European countries (where public administration and trust in government are not as high as in northern European countries) has a "tradition" of unauthorized development in privately owned property. On this topic, international literature can be found in Italy (Zoppi, 200; Zanfi, 2013), Greece (Potsiou & Ioannidis, 2006; Potsiou, 2010), and Turkey (Unsal, 2009; Balamir, 2002). Surprisingly, in Portugal, official data on unauthorized development is nonexistent and academic literature is meagre (focusing almost exclusively on illegal settlements in the Lisbon region). Little is known about this phenomenon and even less about the socio-demographic characteristics of those disobeying the law. Individual actions of private actors, either acting intentionally or unaware of regulation, promote deep changes in the territory. Pre-existent urban sprawl, permission to build on agro-forest zones, and exceptions to development restrictions makes it difficult to identify breaches of control to the naked eye. Nevertheless, current leniency of planning and enforcement bodies (both on local and national level) carries shared responsibilities in the malfunction of the planning system. As our research shows, in the previous two decades, extensive development has occurred in rural zones and in areas where guidelines and specific rules have been drawn up to guarantee their preservation. Due to the impact of successive breaches of control, important questions arise for planners and enforcement bodies. What kind of breaches of control are most frequent? What are the characteristics in terms of severity and location? How extensive is noncompliance with development restrictions?

The object of this paper is to estimate location and the extent of built-up areas in National Reserves during the initial period of municipal master plans. Conclusions are supported on quantitative data of transition from agricultural and forest areas to built-up areas in three municipalities of the Lezíria do Tejo territorial sub-unit: Almeirim, Benavente and Santarém. Information was extracted using GIS to compare land-use cartography from the years 1990 and 2007, analyzing national-wide development in restricted areas: National Agricultural Reserve (RAN) and in the National Environmental Reserve (REN).

The paper assesses mostly the responsibilities of planning agencies on plan design, building permits and enforcement (or lack of it). The next section introduces observations on land-use cover-cartography in Portugal, and explores definitions necessary in understanding results, e.g. of development in built-up areas. In section 3, we explain the methodology regarding selection of case-studies, technical specifications to obtain quantitative data, limitations and expected results. Section 4 introduces the main features of the Portuguese planning system, starting with brief notes on administrative organization, characteristics of municipal master plans, development requiring a permit, and diagnosis of unauthorized development. Section 5 presents data on case-study municipalities and results of comparative land-use cartography, which show the incidence of built-up areas according to National Reserves zoning.

## 2. Monitoring planning compliance

### 2.1 The use of land use/cover cartography for plan monitoring

Extensive photographic survey requires appropriate data, technology and expert staff, which may be an impediment for wide implementation. At a local level, none of the municipalities in Lezíria do Tejo uses COS or even aerial photography to monitor breaches of control. Reasons are probably related to aerial imagery cost (still high and beyond small municipalities' budgets), lack of geographic information system staff, and enforcement leniency.

Systematic monitoring through aerial imagery can probably be found in more developed countries. However, in Portugal there is little tradition in using aerial imagery to monitor planning compliance. The sole (and probably isolated) example we encountered was a project undertaken by the Geographic

Portuguese Institute (today Territory General Direction), that created an interactive information system directed "to support the planning and management of the coast, allowing a global vision and locally supported by geographic information, which promotes integration of bodies and users, and promotes continuous updating of knowledge on coastal dynamics" (CCDR-LVT, 2014, pp. 120). This project, initially called "Support system to restore compliance" (Sistema de Apoio à Reposição da Legalidade) had its name changed in 2012 for a designation with less enforcement tone: "Support system of administration of coastal resources" (Sistema de Administração do Recurso Litoral). One of the initial aims of this project was to report on the methodology used to identify alleged breaches of control in coastal areas, by the analysis of aerial imagery and master plans zoning Barbeiro (2011). Despite several cases identified, no direct consequences were published. However, information may have been used by government bodies to support the future demolition of noncompliant development in the coast, announced on the media (see section 4.4.).

Cartography analysis for land-use changes monitoring is used today more intensively in academic environments. As such, the methodology and results presented in this paper is an outcome from a combination of different academic researches.

### 2.2 Definitions

"Unauthorized development" definition is diverse, and international readers should be aware that planning control may be different in different countries. We have adopted the expression "unauthorized development" (not "illegal development") as it is more commonly used in planning enforcement literature in Europe (Mackay and Ellis, 2005) and America (Burby *et al*. 1998). The term "illegal" may also be found in planning texts, but usually referring to "illegal settlements", which are either named "squatter settlements" (when built with no landowner permission on private or public land) or "semi-unauthorized settlements" (when they had their origin in the division of agricultural/non-urban plots). We also make a distinction between "noncompliant" and "unauthorized" development to differentiate situations that fail to meet planning compliance (and therefore cannot be legalized through retrospective applications) from general breaches of control, undertaken without a permit or not in accordance with a building permit (that may or may not be legalized in the future).

As for development, the British planning system operates on the basis of a definition of development that includes series of activities, including "building, engineering, mining and other operations, as well as material changes of use" (Harris, 2011). Similarly, Hong Kong Planning Department (2015) interprets development as "carrying out building, engineering, mining or other operations in, on, over or under land, or making a material change in the use of land or buildings". The Portuguese Building Control Law[1] defines the corresponding "operação urbanistica" as a "material urbanization, building, use of buildings or land, as long as, in the latter case, not exclusively for agricultural, livestock farming, forestry, mining or public water supply purposes". Additionally, "building", it is regarded as "the activity or the result of the construction, reconstruction, extension, alteration or maintenance of a building for human use as well as any other construction that incorporates ground on a continuing character".

In Britain certain activities that can be excluded from building control are hard to define, such as the one captured in the illustrative phrase of "use incidental to the enjoyment of a dwelling house" (Harris, 2011). In the same way, in Portugal the expression "construction that incorporate ground on a continuing character" feeds debate on how long and which characteristics are acceptable for a construction to be considered of "no continuing character". The discussion reveals the complexity of day-to-day planning enforcement.

"Built-up areas" considered in our research is less extensive than "development" definition. Buildings use changes, increase of height or floors to existing buildings, under land development and isolated

[1] Decree-Law no. 555/99 OJ (PT) December 16 [legal framework for urban development and construction works] with amendments.

detached buildings were not monitored in the GIS comparison of land-use cartography. With a minimal cartographic unit of 1 hectare, "built-up areas" should be regarded as "large areas of buildings, pavements and any other construction works that cause a visible transformation of the soil (i.e. highways and railway infrastructures)".

## 3. Methodology

### 3.1 Selection of the case-study municipalities

Selection of the case-study municipalities was based on several factors, such as: geographic association, master plans date, incidence of development restrictions and availability of information. Almeirim, Benavente and Santarém are municipalities connected by the Tagus River and belong to one of the most productive agricultural administrative sub-territorial units in Portugal, Lezíria do Tejo. Away from the coast, in the third ring of the Lisbon metropolitan area, municipalities comprise a large area of rural land, scattered with small-to-medium urban areas. Agriculture is strongly connected to the large floodable areas in the Tagus Valley, and urban areas development is influenced by the main transportation connections to Lisbon.

Due to its agricultural potential and environmental sensitivity, this sub-territorial unit is largely covered by the main Portuguese planning development restrictions: the National Environmental Reserve and the National Agricultural Reserve. As such, it provides an interesting field of observation on location of land-use changes.

The Municipal Master Plans of the case-study municipalities came in force either in 1993 (Almeirim) or 1995 (Benavente and Santarém), which provides that results are close in the matter of years of implementation. In these three municipalities, master plan information is already incorporated in Geographic Information Systems, and was made available by the administrative body of the Inter-municipal Community of Lezíria do Tejo with the academic projects AGRIMET-MOD (PTDC/ATP-EUR/4910/2012) and DAUME (ANR-10-STRA-0007) in view.

### 3.2 Land-use database specifications

We use the official Portuguese maps of land use/cover for 1990 and 2007 (called COS1990 and COS2007) at the scale of 1:25,000 and with a minimal cartographic unit of 1 hectare. No official COS is available between these dates, but the time-frame suits the purpose of this research as it allows an assessment of the land situation in 1990 (before any Municipal Master Plan was approved) and later, 12/14 years after its implementation.

The maps were produced by the Territory General Direction based on orthophotomaps with four spectral bands (blue, green red and near red). These datasets were photo-interpreted with an average interpretative accuracy of 95%. The Land-Use Cover was divided in hierarchical levels, from level one containing five primary types (artificial areas; agricultural areas and agroforestry; forests and natural and semi-natural areas; wetland; waterbodies) to level five containing up to 190 classes. For the purpose of this study we use level one, extracting three major Land-Use Cover classes: artificial, agricultural and forest and semi-natural areas. The master plan zoning was produced at the same spatial scale of the Land-Use Cover maps, e.g. 1:25,000, thus allowing overlay and comparative analysis.

RAN and REN zoning works as independent "layers", from soil classification zoning and from each other. This means National Reserves zoning overlap soil classes and also overlaps each other. Other "public utility restrictions" were not considered in the analysis because they have local specifications and we were looking for a transversal methodology that could be duplicated in other municipalities. So that results are clear, we defined the total area in the RAN, the total area in REN, and the overlap quantity (that should be deducted for assessment of area exclusively in either RAN or REN).

### 3.3 Methodology limitations and expected results

Land-use cartography has limitations that should be considered in monitoring and planning enforcement. On the one hand it depends on the correct interpretation of the images and/or reliability of automatic remote detection methods. On the other, one cannot assume directly that these are breaches of planning control, because plan implementation and restrictions have a time gap (previous-to-plan approved development may take a few years to show on aerial imagery) and, also, planning restrictions have exemptions and thus may not be an impediment for specific land use changes.

In this research, both these considerations are relevant. Time gap effect exists because between the first land-use database (1990) and Municipal Master Plans approval (1993 and 1995), increase of built-up area has certainly occurred. Second, as explained in the next section, RAN and REN regulation law allows certain type of land use changes, under specific conditions. So, land use changes identified in RAN and REN areas should be considered as alleged illegalities (that merit further analysis on more detailed aerial imagery and on the "ground") but are not necessarily unauthorized. Furthermore, the research does not make a distinction between private development and public construction (i.e. roads, railways and other public amenities). Closer analysis shows that the number concerning public roads is not very relevant, except in the case of Benavente municipality, where a highway was constructed during the time-frame of this research.

Nevertheless, the paper provides an important diagnosis and an overall perspective on the location of the built-up increase during two important decades, in which the planning system was implemented in the case-study municipalities (as in the rest of Portugal). Results allow a quantitative analysis that can support an assessment of the efficiency of the main development restrictions in Portugal. Numbers reflect the extensive increase of built-up areas between 1990 and 2007, in urban but also in rural and development-restricted areas, evidencing the decline of environmental, agriculture and forest uses. Besides providing support for the conclusions of this research, this data outlines the links of compliance and the very rationale of planning law which can aid planners, scholars and administration officers.

## 4. Overview of the Portuguese planning system

### 4.1 Administrative organization

The 1976 Portuguese Constitution establishes a three-tier structure of sub-national government: regional, municipal and civil parishes. Each of the 308 municipalities is responsible for plan design, planning control, enforcement and post-enforcement administrative legal tasks. Certain government bodies also have enforcement powers, i.e. in coastal areas, national parks and heritage sites. There are no regionally elected administrations on the mainland, although regional planning governmental structures do exist. Regional Coordination and Development Commissions (CCDR) are composed of regional representatives of the Central Administration, and overall revision of zone changes in master plans are subject to theirs opinions. Geographically, they correspond to the five EU's nomenclature of territorial units.

### 4.2 Characteristics of municipal master plans

Municipal master plans cover the entire municipal area and were enacted all over the country, mostly in the decade of the 1990's. They carry legal-regulatory powers - this means building permits must accord with these planning instruments and authorities are usually obliged to issue the permit if the plans allow. Permits may be issued directly from them as lower-level detailed plans are not mandatory, neither frequent. Accordingly to Campos (2007), during the previous decade there was an annual rate of 7 Urbanization Plans, and 24 Detail Plans in 224 municipalities.
"Soil classification" zoning provides general rules for building permits, such as indexes and height limits. Setbacks and other specific location determinations are not common. Small settlements may have only a couple of soil classifications; medium cities, several classes and sub-classes. Zoning may relate to roads and other geographic boundaries (not always clear) but are detached from plot configuration.

As such, a small plot may be covered with two or three different classes and building rights may be ambiguous.

Municipal master plans also integrate several "public utility restrictions", related, for example, to water resources, heritage conservation, infrastructures protection (i.e. roads and railways), preservation of forest, environmentally sensitive and agricultural land. These last two matters correspond to the legal figure of National Environmental Reserve (REN) and National Agriculture Reserve (RAN), being the two most extensive public utility restrictions in Portugal, and covering major areas of its land. Environmentally sensitive areas are always covered by REN and may have a double "protection", which means additional restrictions, i.e. in those integrated in *Rede Natura*, Natural Parks and the Coastal Zone. Public utility restriction oblige owners or municipalities to request an external opinion on permit applications. Despite a general interdiction on development for National Reserves, exceptions are defined in specific laws[2] and certain land-use changes can be allowed under a positive external opinion of the corresponding administrative body[3]. Greenhouses, warehouses, infrastructures tourism facilities (under specific conditions) and "projects of national interest" are examples. In general, conditions for positive external opinion for land-use changes in RAN tend to be "softer" that in REN. In rural areas with no public utility restriction, building permits depend exclusively on compliance with master plans and municipality powers.

Case-study municipalities had their municipal master plan approved either in 1993 or 1995, and have made several amendments (five in Almeirim, seven in Benavente and 13 in Santarém) but no overall revision. Initially, in agricultural or agro-forest classes (corresponding to rural areas) construction of new buildings, including dwellings, was allowed with a minimum plot-size of 3.000m2 or 5.000m2. After 2010, the situation changed. To prevent further urban sprawl, the Regional Plan for the West and Tejo Valley Region "forced" municipalities to increase the minimum plot-size to 40.000m2 for new dwellings. However, the previous minimum plot size still stands for other uses, such as tourism, warehouses, farming and industry facilities.

Despite a 10-year updating requirement, more than 2/3 of Portuguese municipal master plans have not yet accomplished their overall revision (Campos, 2011). Many of the 1990's master plans and reserves zoning in force today seem "out of place" when compared to aerial imagery.

### 4.3 Building control and exemptions

Building control was initiated in Lisbon and Porto in 1864[4], and was unevenly implemented in the rest of the country between 1951 and the 1970's[5]. Since then building and occupancy permits are required for every use. Currently, the Legal Framework for Urban Development and Construction Works[6] defines which development requires permission. After 1999 (when it was first enacted) several of its 13 amendments introduced, changes the scope of development control. The most relevant was the 2007 one[7], which introduced a building-certificate procedure to simplify and accelerate the building permit procedure and amplified construction works exemptions from building control (for details on building procedures see Pedro *et al*., 2009). Today, permanent structures of less than 10m2, greenhouses up to 20m2, changes inside existing buildings (unless it affects structure), exterior paving inside a plot, fences up to 1,80m away from public roads and other simple construction works, do not require a permit or certificate. On the other hand, changes to a roof, painting a façade on a heritage site and other use-

[2] Exceptions for development in National Agriculture Reserve are established in Ordinance no. 162/2011 OJ (PT) April 18 and for National Environmental Reserve in Ordinance no. 419/2012 OJ (PT) December 20.
[3] Regional Body of Agricultural Reserve for RAN and Regional Coordination and Development Commissions for REN.
[4] Royal Decree OJ (PT) December 31.
[5] Decree-Law no. 38382 OJ (PT) August 7, 1951 made building permits mandatory for the main urban areas and later each municipal council decided building control commencement outside the main urban areas.
[6] Decree-Law no. 555/99 OJ (PT) December 16 with amendments.
[7] Decree-Law no. 555/99 OJ (PT) December 16 amended by Law no. 60/2007, OJ (PT) September 4.

changes, do require permission. Any construction work (even a major one) undertaken by public bodies is also exempt from building permits.

All these forms of development must comply with existing plans and restrictions, regardless of the need to obtain a building permit. This means that even the above mentioned greenhouses, fences or small structures, when located in national reserves, still require positive external opinion of the corresponding administration body.

**4.4 Diagnosis of unauthorized development**

As mentioned before, official data on unauthorized development is nonexistent. Nonetheless, some sense of the scale can be provided by literature and other items from the authors' research. Among all forms of different unauthorized development, semi-unauthorized settlements in the Lisbon metropolitan area have had the most interest from scholars. During the 1960s and 70s – the years of quick urban expansion – illegal settlements (both squatter and semi-unauthorized) appeared on the fringes of a few Portuguese cities. The appearance of semi-unauthorized settlements was most rampant in the Lisbon area, where farmland was subdivided into small plots and sold thorough the dubious systems of "avos" and jointly-owned property (Cardoso, 1983; Rolo, 2006). Although this phenomenon has ceased and special laws[8] were enacted to deal with the complex urban situation, authorities are still challenged with how to deal with extensive unauthorized development in the past. However, in most municipalities across the country, as in our case-study municipalities, these kind of settlements are not common.

Squatter settlements on public land are also rare in Portugal but, besides Lisbon, they also exist in the Lezíria do Tejo sub-region. In the 1950's, a few settlements appeared in Tejo river margins/banks, where Avieiros (fishermen) started building their wooden stilted houses on public and floodable land (Gaspar and Palla, 2009). Some of these have become permanent houses, and grown into small villages, such as Caneiras in Santarém, Palhota in Cartaxo and Escaroupim in Salvaterra de Magos. Due to their small size and lack of any administrative solutions, they remain disregarded by local and national authorities.

Building and land-use changes on privately-owned property are the most frequent pattern of unauthorized development in the majority of Portuguese municipalities, as it occurs in our case-studies. However, very little has been written about. Around the city of Porto and the center of the country, "property was already quite divided (rural plots with smaller areas) and therefore subdivision of plots was not as significant [as in Lisbon], existing mainly detached unauthorized buildings on plots already registered properly" (Matos, 1990: 195). Back in 1986, the article on the Municipality of Évora (1986), presented in the "New Conference on Illegal Settlements", revealed that in the historic center of Évora and the rest of the municipality, 32% of the total development had no permit. Regarding new buildings it would correspond to 23%, and additions and other changes to existing buildings more than 50%.

From the beginning of the 1990s the literature on unauthorized development is even scarcer. Nonetheless, some numbers of non-compliant development can be found on the media. In 2005, the Institute for the Conservation of Nature reported 3241, unauthorized buildings in protected areas (Diário de Notícias, 23/02/2005). One year later, the Director of the North Coast Natural Park announced the demolition of more than 200 noncompliant buildings in the town of Apulia, in Esposende municipality, "including 97 storage rooms, 78 houses, (56 of which were second residence) and seven commercial buildings, including restaurants" (Diário de Notícias, 22/06/2006). Recently, in 2014, the "Government promises to demolish 835 unauthorized buildings on the coast this year" (Público e Lusa, 12/03/2014). Despite non-compliance with planning standards, many of these buildings were erected in the 1970-1990's and are "old problems" of enforcement.

Today, while cases where entire new buildings are raised without a permit are not frequent, smaller infringements are common, in the form of construction not in full accordance with a building permit,

[8] Decree law no. 804/76 OJ (PT) November 6 and later, Law no. 91/95, OJ (PT) September 2 with the amendments introduced by the Law no. 10/2008, OJ (PT) February 20.

unauthorized additions to existing buildings, or unauthorized conversion of an otherwise legal building. An insight of the use of noncompliant development can be provided by partial results of an (unpublished) survey of one of the authors, on the attributes of noncompliant buildings for which a retrospective application has been submitted (and denied) by Santarém municipality. According to the survey undertaken in 2013, 89 retrospective applications were denied by the Santarém land management department between 1995 and 2012. Since an application may be for more than one construction (i.e. house, swimming pool or warehouse), they regard 122 construction activities. The survey reveals that single houses' building activities were the most frequent, corresponding to 68% of the total number (84 cases). Of this, the construction of entire houses in vacant plots show the lowest number (16 houses) and house extensions and "outbuildings" (i.e. sheds, barns, or garages) were more frequent (respectively 30 and 38). Fences - most of them related to housing - are also common and represent 12% of the total activity (15 cases). Industry, warehouses and commerce were not as frequent: each show results of between 6 and 7 cases. Rare are noncompliant development activity such as quarries' support facilities, swimming pools and farm buildings (1 to 2 cases). The absence of noncompliant multi-family dwellings should be noticed. This survey provides an example of developments activity in a "sample" Portuguese municipality that encompasses both urban and large rural areas.

## 5. Case-study municipalities

### 5.1 Socio-economic and geographic characteristics

Image 1 – Leziría do Tejo location and administrative organization
Source : Abrantes, P., from CAOP, 2010

Almeirim, Benavente and Santarém are municipalities in the third ring of "Greater Lisbon" and belong to the same sub-territorial unit entitled Lezíria do Tejo (Figure 1). It extends over 4,275 km², comprises 11 municipalities and about 250,000 inhabitants. Santarém is the main city, where 25% of the Lezíria do Tejo population is concentrated (as well as commerce, services and public amenities). It plays a major role in the organisation of the territory, together with the municipalities of Almeirim (23,403 inhabitants) and Cartaxo (24,574 inhabitants). Benavente (29,388 inhabitants) is part of another urban axis, together with Salvaterra de Magos (22,053 inhabitants) and Coruche (19,931 inhabitants), which, due to expansion of highways, are now integrated in the logistical and business structure of Lisbon.

Table 1. Data on population in 1991 and 2007 in Almeirim, Benavente and Santarém.

| Municipality | Surface ($km^2$) | Population 1991 | Population 2007 | Population increase |
|---|---|---|---|---|
| Almeirim | 222 | 21 505 | 22 998 | 1493 |
| Benavente | 521 | 18 871 | 27 376 | 8505 |
| Santarém | 557 | 62 980 | 63 023 | 43 |
| **Total** | 1300 | 103356 | 113397 | 10041 |

Source: Nacional Statistic Institute

The axis Santarém-Rio Maior is an important link to the West coast. Extensive commuting dynamics with Lisbon metropolitan areas is indicative of current urban development (Sá Marques and Alves, 2010). According to the Census data regarding daily trips, in 1991, five to 15% of students / work force of the municipalities of Cartaxo, Salvaterra de Magos and Benavente, commuted to Lisbon. In 2001, Santarém and Almeirim joined the preceding municipalities. They all recorded daily commuting of about 15 to 25% (Abrantes, 2013). According to Portuguese Census the region gained 25,000 new residents between 1960 and 2011, and from 1991 to 2001 the region recorded a population growth of 14,500 people. Population dynamic is reflected in an increasing soil sealing.

Among case-studies, Benavente and Santarém municipalities have approximately the same area (521 and 557Km2[9]), and Almeirim about half that (222km). Table 1 shows population variation for the years for which statistics are available, and closer to the land-use cartography dates used in our comparison: 1991 and 2007. Santarém remains the municipality with more people (more than 62 000 inhabitants) but Almeirim and Benavente changed positions: in 1991 population was higher in Almeirim and lower in Benavente (21,505 and 18,871 inhabitants), but in 2007 it was the other way around (22,998 and 27,376). Population increase was more significant in Benavente (8505 inhabitants), low in Almeirim (1493 inhabitants) and minimal in Santarém (only 43 inhabitants).

The axis Santarém-Rio Maior is an important link to the West coast. Extensive commuting dynamics with Lisbon metropolitan areas is indicative of current urban development (Sá Marques and Alves, 2010). According to the Census data regarding daily trips, in 1991, five to 15% of students / work force of the municipalities of Cartaxo, Salvaterra de Magos and Benavente, commuted to Lisbon. In 2001, Santarém and Almeirim joined the preceding municipalities. They all recorded daily commuting of about 15 to 25% (Abrantes, 2013). According to Portuguese Census the region gained 25,000 new residents between 1960 and 2011, and from 1991 to 2001 the region recorded a population growth of 14,500 people. Population dynamic is reflected in an increasing soil sealing.

### 5.2 Municipal Master Plan data

Municipalities land size is 221km2 in Almeirim and about the double in Benavente and Santarém (521 and 556 km2). Concerning soil classification in municipal master plan, each of all three municipalities have about the same proportion of rural zones (87-89%) and non-rural zones (11-13%). However urban

[9] Municipality surface in 2007, previously to administration limit changes in 2013.

and developable zones are distributed differently: Santarém has a large urban zone (9%) but the lowest developable zone (2%) and Benavente the opposite, with 5% of urban zone and 7% of developable zone. Almeirim has the same approximated proportion of urban and developable zones (7 and 6%). This difference reveals differences in plan design and, as a consequence, in strategies of land management.

Table 2. Data on Municipal Master Plan of Almeirim, Benavente and Santarém.

| Municipality | Almeirim | | Benavente | | Santarém | |
|---|---|---|---|---|---|---|
| Year of Master Plan | 1993 | | 1995 | | 1995 | |
| | Area ($Km^2$) | | Area ($Km^2$) | | Area ($Km^2$) | |
| Master Plan Zonning | | | | | | |
| Soil Classification | | | | | | |
| Urban zones | 16,12 | 7% | 28,41 | 5% | 48,46 | 9% |
| Developable zones | 13,62 | 6% | 36,68 | 7% | 9,74 | 2% |
| Agricultural or agro-forest zones | 191,93 | 87% | 456,10 | 88% | 498,64 | 89% |
| National Reserves | | | | | | |
| Areas in the RAN | 105,26 | 48% | 138,09 | 27% | 150,96 | 27% |
| Areas in the REN | 112,04 | 51% | 315,17 | 61% | 208,56 | 38% |
| (Areas in the RAN + REN) | 95,85 | 43% | 132,01 | 25% | 88,89 | 16% |
| Areas with no RAN or REN | 100,21 | 45% | 199,94 | 38% | 286,21 | 51% |
| Total area with National Reserves | 121,45 | 55% | 321,25 | 62% | 270,63 | 49% |
| Total area outside National Reserves | 100,21 | 45% | 199.94 | 38% | 286.21 | 51% |
| Total municipality surface | 221,66 | | 521,19 | | 556,84 | |

Source: Project AGRIMET and CIMLT, 2014

National Reserves cover a large portion of total municipalities land, ranging from 49% in Santarém to 62% in Benavente. Analysing each national reserve total: area in the RAN is higher in Almeirim (47%) and lower in Benavente and Santarém (26% and 27%); and as for area in the REN, restrictions are more stringent in Benavente (60%), Almeirim (51%) than in Santarém (37%). Note that numbers concerning to RAN and REN should not be added, because there is land covered by both national reserves. Overlap of RAN and REN occurs 43% of the total land in Almeirim, 25% in Benavente and 16% in Santarém.

The high incidence of REN in Benavente is explained due to the existence of large protected area of Tajo Estuary, which is additionally protected by NATURA 2000 network. In the Northwest of Santarém municipality there is also a large area of REN interconnected to the Natural Park of Serras de Aires e Candeeiros.

### 5.3 Results of comparative land-use cartography (1990-2007)

Our research findings (Table 3) demonstrate the impact of forest and agriculture transformation, into built-areas in development-restricted areas such as the National Agriculture Reserve (RAN) and National Environmental Reserve (REN). From the total of transitional land-use changes between 1990 and 2007, a large percentage (43%) of Almeirim's built-up areas occurred on land covered by National Reserves. The ratio is lower in Santarém (33%) and in Benavente (27%), however, corresponding to much more built-up land: 5,57km2 and 5,10km2 respectively. These sound "big numbers", even taking into account the time-gap between 1990 and master plans' dates, legal exceptions and highway construction. It should be noticed that in Almeirim and Benavente, numbers in National Reserves are higher than agricultural or agro-forest areas not classified by RAN, where development was allowed with a (rather small) minimum plot-size.

Our survey also demonstrates that built-up areas affect REN more than they do RAN, which is also unanticipated, as positive external opinion on development is more difficult to obtain in REN than in RAN. In Almeirim the difference between the two reserves is not significant (1%), probably because of a larger overlap of both national reserves. Results are more revealing in Benavente and Santarém:

differences between 1990 and 2007 show that the large majority of built-up areas in reserves occurred in REN (25 and 24%) and just a small percentage in RAN (4% and 12%).

Table 3. Built-up areas by National Reserves zoning in Almeirim, Benavente and Santarém

| Municipality | Almeirim Area ($Km^2$) | | Benavente Area ($Km^2$) | | Santarém Area ($Km^2$) | |
|---|---|---|---|---|---|---|
| Built-up areas transitions (COS 2007 - COS 1990) | | | | | | |
| Forest + agriculture areas > Built-up areas in agricultural or agro-forest areas not classified as RAN | 0,19 | 5% | 3,71 | 19% | 6,48 | 38% |
| Forest + agriculture area > Built-up areas in RAN | 1,59 | 40% | 0,83 | 4% | 2,03 | 12% |
| Forest + agriculture areas > Built-up areas in REN | 1,64 | 41% | 4,84 | 25% | 4,18 | 24% |
| Forest + agriculture areas > Built-up areas in RAN+REN | 1,51 | 38% | 0,57 | 3% | 0,63 | 4% |
| Total Forest + agriculture areas > Built-up areas in National Reserves | 1,71 | 43% | 5,10 | 27% | 5,57 | 33% |
| Total Forest + agricultural areas > Built-up areas | 4,01 | | 19,19 | | 17,09 | |

Source: Own elaboration based on project AGRIMET and CIMLT data

These results show that development restrictions in master plans may have either encountered too many breaches of control or exceptions in granting building permits, and that the current planning system may not be effective in the protection of environmental and agricultural land.

## 6. Conclusions

In this research we aim to provide an overall perspective of land-use changes and efficiency of master plans restrictions, based on the comparison of land-use cartography in three Portuguese municipalities: Almeirim, Benavente and Santarém. The adopted methodology may become an important tool to complement traditional enforcement methods for detection of breaches of control, to be used by Portuguese municipalities.

Research demonstrated a high incidence of built-up areas on National Agriculture Reserve (RAN) and National Environmental Reserve (REN). Numbers may disquiet planners, as development seem to have occurred "out of place" – built-up areas in National Reserves corresponds to 27 to 43% of total agricultural and forest land transformed into built-up areas. Between 1990 and 2007 in two of the case-studies, more built-up areas occurred in Natural Reserves than in agro-forest areas with no RAN (where development was allowed with a minimum plot-size). Despite development restrictions, a total of 12,38km2 was transformed into built-area in the three case-study municipalities. Analysis of data also revealed that built-up areas tend to occur more often in REN than in RAN, which is contradictory to the degree of restrictions. Population dynamics in these three municipalities had positive (but moderated) growth which does not justify the high numbers for built-up area increase. Farmland and environmentally sensitive areas are being reduced, due to land use changes in areas where guidelines and specific rules have been drawn up to guarantee their preservation. These results meet the criticism of Pardal (2006:27) of this "sectorial" vision of the planning system. "The body of laws on spatial planning which prevailed the previous four decades fostered easy business in the real estate sector, increased clandestine, rewarded development and construction of poor quality (…)".

Much research on unauthorized development in Portugal has yet to be done. Future research using GIS can provide more detailed information on new built-up areas (according to master plan classes) and types/uses of development (using other hierarchical levels of Land-Use Cover cartography). Methodology can also be sharpened to identify solely unauthorized development in private plots and hence become a more precise tool in the detection of breaches of control.

Urban planning pressures on "Zwischennutzungen"/ "temporary uses" with special reference to Tempelhof airport. AESOP – Prague

Sarah Dubeaux[1]

Emmanuèle Cunningham-Sabot[2]

Keywords: Urban decline, temporary uses, governance

## INTRODUCTION

On the 25th may 2014, a referendum proposed by the organization 100% Tempelhofer Feld stopped the official development plan intended by Berlin's Senat on the former Tempelhof Airport. The huge space of 380 hectares located in the heart of Berlin became a "no building land zone". This situation is a good illustration of pressures, tensions and conflicts about vacant spaces and their uses in a period of transition between shrinking and growth in the new capital of Germany. This presentation seeks to analyse critically the use of ZN made by the local authorities to manage vacant spaces. The first part of the presentation provides a brief discussion about the urban context in Berlin, between shrinkage and growth. The second part will focus on vacant spaces in shrinking cities with the pragmatic tool called *Zwischennutzungen* (ZN), which we will translate as "temporary uses" for the moment. In the final section we will discuss this Tempelhof case study, which illustrates these divergences about vacant spaces and ZN in Berlin. In the conclusion we will propose certain questions for future research about urban planning and vacant space in times of crisis.

## 1. From shrinkage to growth.

After reunification, Berlin experienced a big rise of its population. Expectation was at its peak.

> "The hype around an emerging "new Berlin" raised high expectations about anticipated population growth (up to 5 million over the next ten years), the settlement of headquarters of large international corporations, and the overall opportunities for the investment and economic development. Overoptimistic growth forecasts by many urban and economic research institutes decisively influenced public discourses and urban planning processes. A strategic

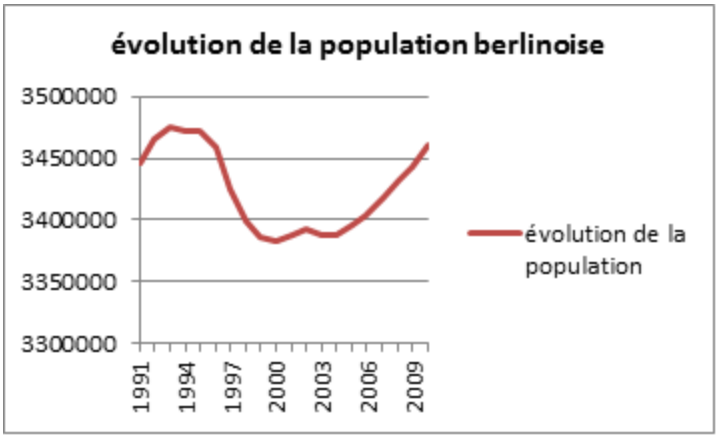
> study "on the way to the commercial capital Berlin," launched by the local government in 1992, predicted that Berlin would soon play in the same league as London, Paris or even New York, and rise to a global city status." (Bernt, Grell, & Holm, 2013, p. 23)

However the population increase was very brief. Since 1993 Berlin has become an obvious example of a shrinking city, "an urban area — a city, part of a city, an entire metropolitan area or a town — that has experienced population loss, economic downturn, employment decline and social problems as symptoms of a structural crisis." (Martinez-Fernandez, Audirac, Fol, & Cunningham-Sabot, 2012). The population began to shrink. Economically , Berlin remained very weak after the Reunification, and suffered from a "de ökonomisierung" (Hannemann, 2003) like GDR as a whole.



This situation was reinforced with the administrative dismantling of GDR and the will to erase the GDR administration within the city. At the same time, with a rising number of ownership-transfers added to a financial crisis of the city…It became difficult for Berlin to put in place a land strategy. At this time vacant spaces proliferated and their duration extended. They took a huge place in Berlin and became part of the daily landscape of the city. A lot of spontaneous and grassroots uses, today very famous, appeared, for eg. the beach bar YAAM on the banks of the river Spree.

By the turn of the 2000s, we can observe a small improvement in the city population. This regrowth of population was a result of an urban policy, which promoted the attractiveness of the city and its underground culture. This growth is essentially based on tourism (Novy, 2013) and the capacity of the city to become a "creative city" through certain Zwischennutzungen / temporary uses. Colomb notes a "gradual integration of temporary uses of space in Berlin's official place marketing discourse and in the economic development policies set up to promote Berlin as "creative city" post-2000"(Colomb, 2012, pp. 146–147). Nevertheless Berlin's situation is still weak: the bank scandal in 2001 ruined the city, and according to Bernt (2013, 16) "Berlin is until today not only the German city with the highest unemployment but is also on a European scale the only capital whose GDP lies below the national average".

**2. Vacant spaces in Shrinking Cities, an opportunity materialised by the pragmatic tool "ZN"?**

As said previously, one of the spatial results of the phenomenon of shrinking cities is the growth of vacant open spaces; this constitutes a common denominator to Shrinking Cities. In a way, "less is more" Bauhaus Dessau (i.e. being a shrinking city means less inhabitants, less economy, and more and more vacant spaces within the city), but this saying "less is more" also means more space for alternatives or informality and a paradigm shift in urban planning, from consumption to production. Nowadays, vacant spaces are no more seen as a disease in the city, but are eventually opportunities (Andres, 2006; Janin & Andres, 2008) in an era where ideas of recycling-land appear with for instance the "second hand space project" (Ziehl, Oßwald, Hasemann, & Schnier, 2012), or "do-it-yourself" urban design (Douglas, 2014), or "urbanism light" (Urban Catalyst, 2003).

In this way, at the turn of the century, scholars (Bürgin & Cabane, 1999; Freitag & Werner, 1999; Mellauner, 1998; Seidemann, 1998) developed research about a pragmatic tool called "*Zwischennutzung"* which allows/permits the management of the vacancy and the time gap between different uses. The concept of ZN did not originate in Berlin, but, rapidly, the German government embraced it as a possible solution for shrinkage (BBSR, 2004). At the same time, with the help of a European fund, a study focused on *Zwischennutzungen* in five European countries; **Germany**, Finland, Denmark, Austria, and Italy and give ZN a European visibility. (Urban Catalyst, 2003). This was followed by a a study by Berlin State which adopted the concept for Berlin and its municipality under the term of "pioneers" (Stadtentwicklung, 2007).

The expression of *Zwischennutzung* is constructed from *Zwischen* which means « between » and *Nutzungen* for « use(s) », it is characterized by informal uses (like mini-golfs, pedagogical areas, community gardens, theatres, bars…) in vacant spaces, by ownership-property which stays in the same hands, by users, who are usually informally organized local inhabitants. However, behind this simple definition lies hidden tensions and conflicts about different conceptual aspects of temporality, informality and spontaneity, and future plans for the area. In relation to this last point, according to Urban Catalyst' study (2003), there are 8 different types of ZN depending on the relationship with the next use: stand in, impulse, consolidation, coexistence, parasite, subversion, pioneer, displacement. This detailed and comprehensive typology is interesting, because we can observe some specific aspects carefully selected in the definition of ZNs by the different authorities. For instance, it is obvious that the Berlin Senate is focusing more on pioneer ones in order that they impulse new uses or strategies. The definition given by the German government is also very focused on temporality and preservation of next use: ZN are "A new means of designing and utilizing blighted urban sites that does not require a change of owner or additional planning permits. This preserves long-term options

for building out the site while permitting temporary uses that improve the quality of urban amenities." (BBSR, 2004)

Colomb (2011) explains this divergence because "From the early 2000s onwards, however, the creative, unplanned, multifaceted, and dynamic diversity of such « temporary uses of space » was gradually harnessed into urban development policies and city marketing campaigns. New images and narratives began to be integrated into Berlin's official promotional discourse – including sites, places, activities, and people which had been left out of the promotional imagery of the 1990s." (Colomb, 2012, p. 132). She links this focus on the Senate with the emergence of theories about the creative class (Florida, 2004). At this time, Berlin developed a political discourse on creativity in the city and promoted ZN to a comparative advantage in the international competition. It is also interesting to note, that the Senate's definition of ZN mentioned them as a new tool, whereas in reality this kind of uses was already existing since the 90s.

At the same time, we can observe a tension in the term itself, and also in the translation usually proposed ; "temporary uses" (Oswalt, Overmeyer, & Misselwitz, 2013). Indeed, translating ZN as temporary use(s) not only dilutes its meaning, it results in the concept losing its meaning. Gstach (2006, p.16) explains that the border between a permanent use and temporary use cannot be the characteristic to define ZN because the time gap can be very different and the border between the two uses can be very unclear. Also, the situation is more complex: according to Haydn and Temel 2006 "Temporary uses are those that planned from the outset to be impermanent. We understand the idea of temporality to be determined not, as its literal meaning would suggest, by the duration of use: temporary uses are those that **seek to derive unique qualities from the idea of temporality. That is why they differ from lasting uses, not because they want to prepare their location for something other that will last longer**." (Haydn & Temel, 2006, p. 17) Following this idea, Till goes one step further and proposes another semantic with the term "interim-use";

> "Rather than focus on temporary *land use* per se (*Zwischennutzung*), a planning concept that designates parcels of property according to zoning codes and development strategies, I argue that a more appropriate concept is *interim spaces*. First, the concept of interim spaces recognizes space as relational rather than seeks to stabilize urban space through boundaries (...). Second, it spaces are understood as relational, then the German term *zwischen* is more accurately translated as "interim" for my purposes than the English "temporary" (land use, in the sense of technical planning). The notion of interim allows for the dynamic and open-ended sense of in-betweeness, interventions, and unexpected possibilities. Interim suggests a fluidity of temporality, rather than an understanding of time measured and designated as insignificant or as located between the "real" times of before development and after development. Urban

> appropriations of "wastelands" enliven public space and offer new possibilities to imagine a neighborhood." (Till, 2011, p. 106)

Inspite of this discordance, one group of scholars and studies about ZN wants to see this tool as a way to manage vacant spaces. For urban catalyst “In the context of the research of Urban Catalyst it becomes crucial to integrate the informal and the formal more effectively. This means on the one hand to formalize the informal: to analyze and understand the unplanned patterns behind self-organized activities, deduct prototypes, models and tools from these investigation, formalize them and make them available to all stakeholders. One the other hand, formal procedures of planning, administration, management etc. have to be critically examined and ways and strategies to be found, how existing practices can be de-formalized, de-institutionalized, adapted and changed.” (Urban Catalyst, 2004, p25) The role of local authorities seems very important at this point. In this context, the closure in 2008 of the Tempelhof Airport located in the heart of the city can be the very first large experimentation of the use of ZN by the Senate to manage transition and promote Berlin as a leading creative city. Tempelhof became the test and the showcase of the creativity in Berlin. The slogan “Tempelhof Freiheit”, Tempelhof Freedom is in this way, also significant.

## 3. The case of Tempelhof; an illustration of divergences and contradictions about vacant spaces and ZN in Berlin.

The airport closed in 2008 because of the creation of a new airport; Berlin Brandenburg international (BBI) in Schönfeld. This closure created de facto a huge vacant area of 380 hectares, located in the heart of Berlin, right in the middle, bordered by several districts: Neukölln, Tempelhof-Schöneberg and Friedrichshain-Kreuzberg which were very marginalized and considered as deprived areas during the Wall period. All these districts were shrinking. This airport was also famous, being used for the vital Berlin Air lift during the 2nd world war.

Considering this historical and challenging urban context in the neighborhood of TP, ZNs seemed at first glance a good way to encourage and organize community participation, and a way to create community capacity building within the surrounding areas.

At the start, the opening of Tempelhof with different ZNs, was based on a big participative program. Within this context, the ZN was a way to encourage the appropriation of urban landscapes, a way to create community capacity building. Indeed, we can read on the official website of Tempelhof: “The spontaneous and unplanned use of open spaces is characteristic of Berlin. Until now, these informal intermediate and pioneer uses were not involved in the formal planning process to any great extent. The State of Berlin is looking to change this status with its new “pioneer process” – an open process

that, if successful, will transform TempelhoferFreiheit into a model location for participative urban development. » http://www.thf-berlin.de/en/get-involved/

In this large space, 3 areas have been specifically dedicated to ZNs.

*Source: www.berlin.de*

All kinds of people can get involved: there is a webpage for the submission of projects and a large variety of uses emerge in the field with the ZNs; an educational garden for children, community gardens, mini golfs…

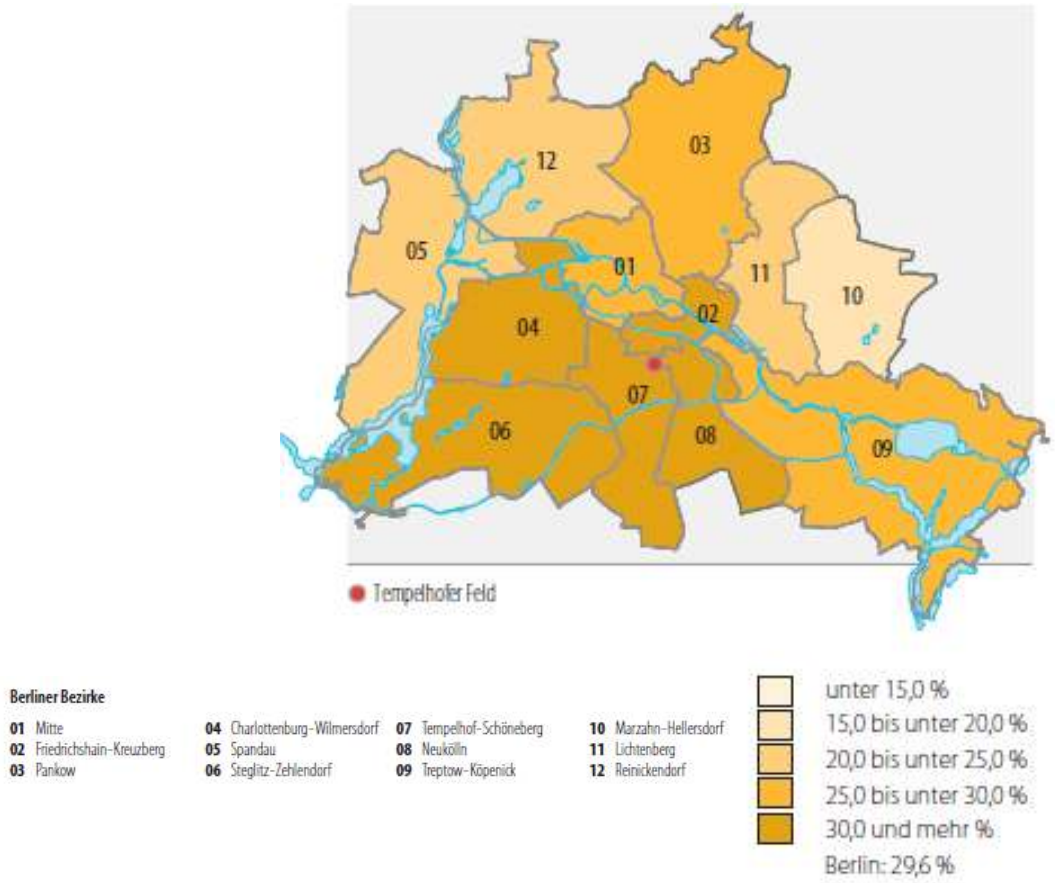
However, in the particular case of TP ZNs, they seem to be a way for the local authority to gain and keep control of the area, while waiting for a major project for investors. Indeed, we can observe that the ZNs are spatially very strictly and tightly bounded with a strict zoning of the field, and each ZN is allocated a specific area. There is also a very strict time restriction imposed on each project. . The different possible uses are also highly regulated and defined.

In fact, the ZNs are entirely determined and regulated by the development plan made by the local authorities. For the local authorities, they are not really a tool for a coproduction with the inhabitants or a way to think about the future of the site, they are just temporary uses. For the local communities these temporary uses are not a stepping board for planning what could be next.

At the end of the day, for the local authorities the ZNs seem more a way to occupy the place during a strictly limited time frame, waiting for a major permanent project. Indeed, Rosskamm (2014) notes that between the closure and the opening of the field « it became obvious that the perception of the

Tempelhofer Feld had changed completely. Suddenly the area no longer possessed a 'huge potential' for Berlin urban development (as it was posted in the debate before the closure of the airport), but a place at risk of getting out of control." (Roskamm, 2014, p. 66) As a result, for the local government, the area is no longer viewed as an opportunity but a source of fear. Fear of a permanent appropriation for good by the local community.

However, the future development plan of the local authority was stopped by an organization of citizens called 100% TPHFeld. With the law system in Berlin and Germany, the organization was able to call for a referendum about the future of this area and put forward a draft law, which would prohibit any construction on this field. After several stages the referendum was organized on 25th May 2014. The draft law of the 100%TPFeld organization won by a huge margin.



*Source ; Amt für Statistik Berlin Brandenburg, 2014*

The red point on the map is the former airport of TP. All of Berlin's districts voted in favor of the law.

In the debate during the setting up of the referendum, the local authority failed to use ZNs as a means to promote the official development plan. On the contrary, there has been a close proximity between the organization 100%TPFeld and ZNs that we can for example observe with the sign on the photo.

*Source : private photo*

CONCLUSION

As we can see in this very particular case, the ZNs were set up by the local authorities while waiting for a big project according to a development plan. However, they encountered some resistance. The local communities found a way to reject the local authorities' plans, which stuck to the very limited definition of the ZN (just a "temporary use"). The inhabitants, with their vote, brought back the ZN to its larger definition. They made it clear that they want to be involved in the decision making process deciding the future of the area, the field. And they want it to stay as an open space, with informal uses, according to the larger definition. They are against the development plan which promotes new commercial and residential buildings.

This case study is a good illustration of the articulation between grassroots empowerment and local governance, and the conflicts that arise from having two different visions of a city. On one side for the local authorities, a growing and compact city minimising vacant and open spaces, to shape the capital city of the country, and ensure its position in Europe; and, on the other side, for its inhabitants, to keep the identity of Berlin as a city with lots of vacant and open spaces with spontaneous uses and informal users. The multifaceted aspects of ZNs and the different acceptations of their definitions studied in this paper reveal these tensions, as well as point out the failure of local governments to engage in the long term with bottom-up planning in a growth paradigm context.

# Dodging decline: the post-industrial landscape of Niagara Falls, Canada

Dr. Ian Ellingham, The School of Restoration Arts at Willowbank, ianellingham@carltd.com
Dr. Helen Mulligan, Cambridge Architectural Research, Helen.Mulligan@carltd.com

**Keywords:** Niagara, cities, post-industrial

*Abstract:*
The two Niagara regions, one in Canada and one in the United States, facing across both a river and an international border, provide a case study of contrasts. Both were developed as energy and industrial centres in the late 19th and early 20th centuries, but over the past fifty years their paths have diverged substantially. Through the period of de-industrialisation, the city of Niagara Falls, New York, since 1960, has lost over half its population. For various reasons, American initiatives to combat decline have been largely unsuccessful.

In contrast, Niagara Falls, Ontario, has experienced ongoing, if modest growth. This can be attributed to a number of factors, some geographical, however each has been subject to very different forms of government involvement, with the differences extending back more than a century.

The paper argues that very specific focused interventions, by the provincial government, have been of major importance in the development of the non-industrial economic activities that have enabled the Canadian Niagara to survive de-industrialisation better than its American neighbour. In particular, these have included the creation of the Niagara Parks Commission, and support for Niagara casino enterprises. There have also been various policies to encourage agri-business - specifically the wine industry; to leverage the historical legacy of the area, and to develop other forms of heritage tourism. The Canadian side has successfully tapped the economic opportunities, while the pro-industrial attitudes on the American side have restricted their ability to adapt to changing circumstances.

==========

## 1.0 INTRODUCTION: THE QUANDARY

The issues associated with de-industrialisation have been frequently observed and documented. In many areas of the developed world, this has been associated with the disappearance of well-paid employment in manufacturing. The study of twins of any sort can be revealing, and worthy of consideration in this respect, are the areas bordering on the Niagara River - one part in Canada, and one in the United States. Over the past five decades these two areas have followed markedly different paths, although in many ways they are similar in geography, transportation, resources, climate and the origins of their populations. Strand (2008) summarised the matter: “Niagara Falls, New York, is by general agreement a mess.”

Why? What happened? What lessons can be learned?

This paper examines Niagara Falls, Ontario, Canada in comparison to the less-successful Niagara Falls, New York, United States, and identifies reasons for their divergence. Reference will be made to the larger areas in which they are situated, being the Canadian Regional Municipality of Niagara, which has a number of centres, the largest being the cities of Niagara Falls, Ontario, and St.Catharines, and Niagara County, in the United States.

## 2.0 HISTORICAL BACKGROUND

The Niagara area has been populated for about 12,000 years. As the area warmed after the last ice-age, successive cultures occupied the area. The first Europeans to visit Niagara Falls were French, in the 1670s, who shortly after built the first military installations, and maintained them until the Seven Years War, with Fort Niagara (now on the American side) falling to the British in 1759.

Settlement of both sides of the Niagara River occurred in the late 1700s, subsequent to the establishment of the international border after the American revolution. Significant settlements included Queenston on the Canadian side, from which an ancient portage route led to the upper river and Lake Erie, around the Falls.

Settlement of the Canadian area was initially by 'Loyalists' who moved into Canada after 1783, after the American Revolution. The first census was undertaken in 1782, and found that there were 84 people living in the Niagara area, "...eleven of which were in the two families who first located in Stamford Township." (*Niagara Falls Review*, 1978), Stamford Township is now part of the City of Niagara Falls, Ontario. A year later, there were ten families in Stamford, and 790 acres cleared. In 1786, the first mills had been built next to the Niagara River, and were using it as a power source.

Government involvement in Niagara lands came with settlement, and the first capital of 'Upper Canada', now Ontario, was at Niagara-on-the-Lake: it was subsequently moved further from the border to Toronto. In 1791 a linear reserve one chain (20 metres) wide along the Canadian side of the river was established by the colonial government for military purposes, linking the border forts. The military role of the region in the defence of Canada became important in the War of 1812-14, and numerous small battles were vigorously fought in Niagara.

After the war, immigration from the United States diminished (Black, 2014, p.195), and the population was augmented by succeeding waves of Scottish and Irish immigrants through the 19th century; ex-slaves; the English in the decades before the First War; and ongoing immigration from various European countries. On both sides of the border, growth was slow until technological innovation allowed full exploitation of the energy potential of the Falls, beginning in the late 19$^{th}$ century.

In both Canada and the US, development was spurred by the construction of canals and railways, beginning with the Erie Canal - completed in 1825 - connecting the Hudson River with Lake Erie at Buffalo. The first transit of the Welland Canal, between Lakes Ontario and Erie, occurred in 1829. These pieces of infrastructure were of great significance in stimulating growth. The Welland Canal has been successively rebuilt, and now allows access by ships of up to 225 metres into the upper lakes. In the 19th century the canals enhanced the growth of the Niagara area, however, increasingly, with larger canals and larger ships "... commerce tended to pass through the Peninsula on its way to the Atlantic or Great Lakes cities rather than creating Canal ports as such" (Young, 1981, p.82). The completion of the St.Lawrence Seaway, an initiative of the Canadian government, in 1959, enabled large ocean-going ships to enter Lake Ontario.

Rail connections to major centres on both sides of the border were developed through the late 1800s, with the first cross-river bridge being completed in 1848. Bridge linkages became an integral part of Canada/United States cross-border trade.

With critical transportation links and abundant waterpower, both sides of Niagara became a centre for industry. Photographs of the American side prior to electrification show numerous factories using

water power directly, diverting it around the Falls through canals and, after use, directing it into the Niagara Gorge below the Falls.

Commercial hydro-power arrived in the Canadian Niagara area in 1896 with installations at Niagara Falls and St.Catharines. Electrification allowed industry to move away from the immediate area of the Falls, and on the American side this led to substantial development along the upper river.

Young (1981, p.81-82) noted "...the 'gateway' mentality' and other geographical factors, tended to structure industry to serve inter-regional rather than regional needs. This caused development to occur primarily on the perimeters..." This meant, on the Canadian side, along the shores of Lake Ontario and along the Niagara River, and on the American side, along Lake Erie and the Niagara River.

The area is crossed by the Niagara Escarpment, a geological feature running through central Canada and the United States. In the Niagara area this manifests itself as a vertical height of up to 100 metres, and is the geological formation over which Niagara Falls flows. This results in a zone of excellent agricultural land, an asset on both sides of the border. In the earliest days this was used for general farming, but through the 20th century it came to be dominated by soft fruit orchards and vineyards – for which the climatic and soil conditions were found to be ideal, with the accompanying canneries and wineries.

Being on a national border was of consequence. Although there was always a considerable amount of cross-border trade, Canada's need for development and economic growth led to a high tariff policy through the late 1800s. The resulting customs duties and regulations encouraged companies, primarily American, to set up branch manufacturing operations on both sides of the border. Hence, the appearance, in Niagara Falls, Ontario, of subsidiary factories of American companies. These companies could thereby exploit both Canadian markets, and, utilising imperial trade preferences, access the rest of the British Empire and Commonwealth.

Transportation routes were developed on an ongoing basis with the 138 km long Queen Elizabeth Way linking Niagara to Toronto. This was built through the 1930s as a make-work provincial initiative and opened in 1939. Based on the design of the German autobahns, it was the first major divided highway in North America.

Tourism has been a part of Niagara since the French era. The Falls have been variously seen as curiosity, and as a sublime natural wonder. Tourism unfolded in conjunction with transportation, as canals and railways in the 19th century, and cars in the 20th, gave better access. Through the 19th century, on both sides of the border, the areas around the Falls filled with the expected Victorian tourist emporiums - including those offering views of freaks and oddities (shrunken heads, miniature violins...). Some of these, in particular the Niagara Falls (Ontario) Museum, survived into the later part of the 20th century. Clifton Hill, on the Canadian side, still offers to the discerning visitor such things as 'Elvis Niagara Falls', dinosaur mini-golf, and wax museums, one being located in a replica of the Empire State Building on its side, with a giant gorilla perched on the end.

## Decline of Manufacturing:

The decline of manufacturing unfolded over a number of decades. Manufacturing employment on the Canadian side decreased from 46.5% of the employed population in 1951 to 38% by 1961, 32% by 1971, and 30% in 1981. In the same period, service sector employment rose from 38% to 60% (Fischer, pp.91-95). On the American side, there has also been a ongoing decline in manufacturing

employment, continuing to the present – in the Buffalo/Niagara Falls areas in 1990 there were 91,900 employed in manufacturing – this had declined to 49,000 by 2010 (Bureau of Labor Statistics).

## NAFTA

A major factor in the decline of the Canadian Niagara-area manufacturing was NAFTA (the North American Free Trade Agreement), which came into effect on 1 January, 1994, establishing a free trade area between Canada, Mexico and the United States. This evolved from earlier agreements between the United States and Canada, including the Canada-U.S. Free Trade Agreement of 1989, and the 'Auto Pact' (Canada-US Automotive Products Agreement) of 1965.

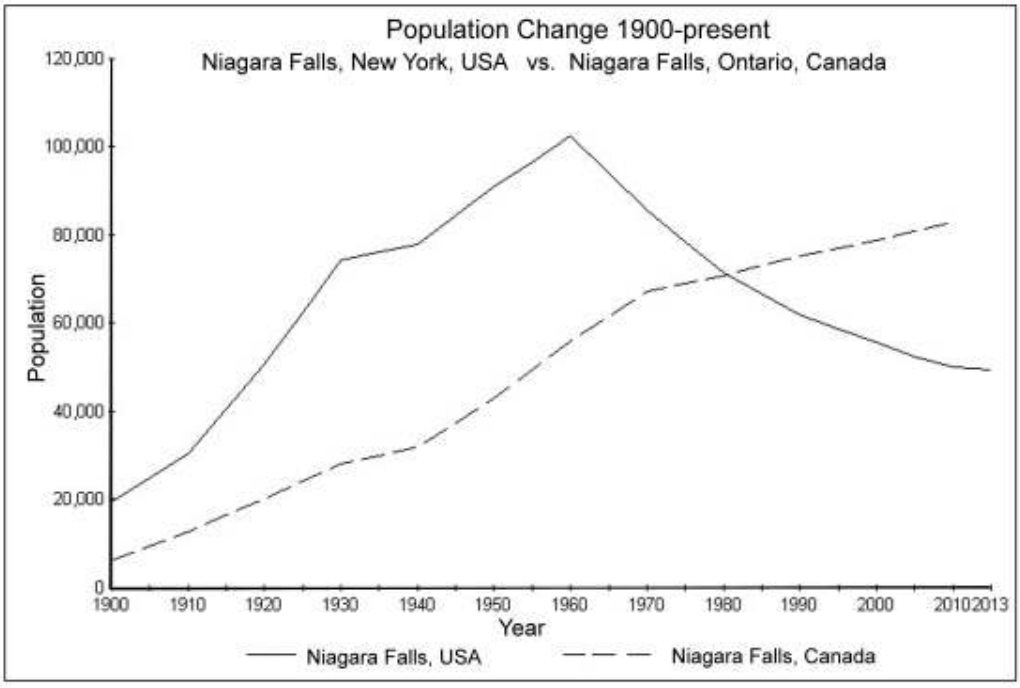
While NAFTA had a generally positive effect on the three countries, the need for American companies to manufacture in Canada ended. This led to the disappearance of many of the American subsidiary production facilities, but not all: for example, the Nabisco (now Post) Shredded Wheat factory in Niagara Falls, New York was closed while that in Canada remained open (Eck, 2014).

In spite of free trade policies, some Canadian Federal and Provincial policies do slow the flow of imports. These include requirements for French language on packaging and instructions, the use of metric measures, and protection of certain agricultural sectors.

## Indicators

Figure 1 compares the populations of the two cities of Niagara Falls. In 1960 Niagara Falls, NY had a population of 102,394, while that of Niagara Falls, Ontario (including the former Township of Stamford) was 56,110 in 1961. Since then the population of Niagara Falls, NY has fallen to less than half its level of fifty years before, while that of Niagara Falls, Ontario has grown to 82,997 (2011 census) - showing ongoing, if not spectacular, growth.

Figure 1 - Population Change (US and Canadian Census data)



On the Ontario side new houses are being constructed, while a drive through Niagara Falls, NY.reveals many streets on which houses have been abandoned or have disappeared entirely.

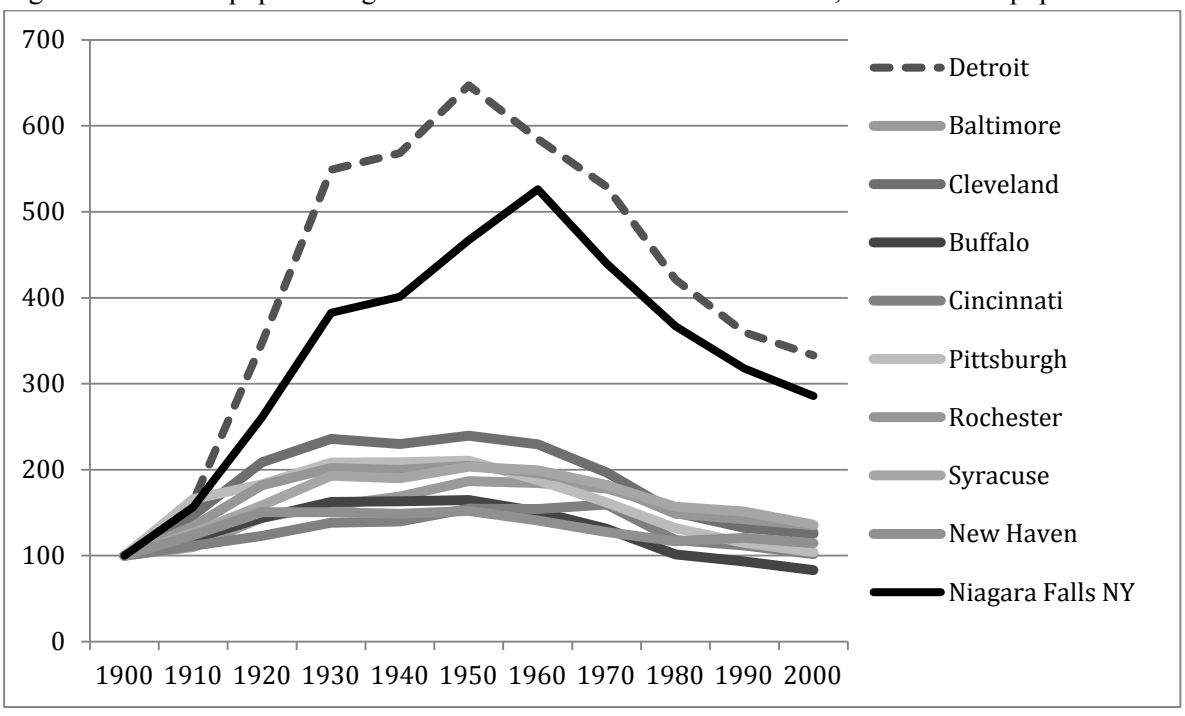
Meanwhile, in the surrounding American area, the population of Niagara County (excluding the City of Niagara Falls, NY) has increased slowly over the decades. The largest communities (after the City of Niagara Falls) being North Tonawanda with a 2013 population of 31,097, itself being a manufacturing centre on the Niagara River, and Lockport, the county seat, with 20,870. Both of these communities have lost 6.5% of their populations since 2000, while the rural areas have grown.

## 3.0 IMPLICATIONS

Shrinking populations are not unusual. There are many communities that were built around resources that were eventually fully extracted or became economically redundant. People quietly pack up and leave, with the community returning to nature - Europe is full of abandoned medieval villages.

However, it appears that this phenomenon is becoming more prevalent throughout the world, and most particularly in industrialized countries (Oswalt and Rieniets 2006). Beauregard (2013) tracked population figures for the 50 largest US cities by decade from 1790-2000. He found the decline greatest in the decades after WWII: two-thirds of the sample cities declined in population during the 1970s. This evolution appears most typical in the manufacturing centres of the Northeast and upper Midwest – the region dubbed the Rustbelt - with population loss apparently moving westward within this region over time.

Figure 2. Chart of population growth and decline of selected US cities, as % of 1900 population.



The prevalence of this pattern within the Rustbelt, for each time period in Beauregard's study, suggests "urban population loss might be as much a regional problem as an industrial one" (Beauregard 2013, p.39).

As Figure 2 shows, this pattern has been particularly acute in Niagara Falls, NY. Its growth in the early 20th century and precipitous decline from the 60s onwards is almost as dramatic, in percentage terms, as that of the much larger (and more infamous) Detroit.

The tourism and renewable energy base of Niagara should provide a sustainable common economic base for both Niagaras. The problem is that Niagara Falls, NY has become generally unattractive, and although numerous attempts have been made to increase tourism they have been largely unsuccessful. One indicator might be that the Evel Knievel Museum (and pawnshop), with its stars-and-stripes logo, is located in Niagara Falls, Canada.

This decline has imposed financial stress on Niagara Falls, NY. This is expressed by the bond rating. On 9 January, 2013, Moody's downgraded its rating on city debt to Baa1 from A2 and placed the rating under review for further downgrade. Their concerns include the ongoing dispute over the city's share of casino revenue, and the diminishing tax base (Moody's Investor Services, 2013). A shrinking city has difficulties in reducing its costs fast enough to match the taxation loss.

The lack of attractiveness of Niagara Falls, NY is indicated by a comparison of crime rates on the two sides of the border. Again, although the data collection is different on the two sides of the border, the message is clear (Figure 3).

Figure 3: Crime in Niagara

| | St.Catharines/ Niagara CMA | Niagara Falls, NY |
|---|---|---|
| Violent Crime: | 1,229 / 100,000 | 5,952 / 100,000 |
| Property Crime | 814 / 100,000 | 3,228 / 100,000 |

Sources:
St.Catharines/Niagara: www4.hrsdc.gc.ca/.3ndic.1t.4r@-eng.gsp?11d=57
Niagara Falls, NY: www.city-data.com/city/Niagara-Falls-New-York.html

Even in comparison with New York State, Niagara Falls, NY comes out badly - with an index of double that of the US as a whole (CityData crime rate factor = 605.7 vs. 299.4 average for US ).

Perhaps even more important than the crime itself, relative to economic growth, is the image of a crime-infested city. Among the comments heard were those that suggested that one had to be very careful where one went in Niagara Falls, NY. Others suggested that the entire local government and much of business had been infiltrated by organised crime, something supported by past history. Indeed, Hartt and Warkentin (2014, p.17) noted "Between 1991 and 2007, no standing mayor had been re-elected due to allegations of corruption (some of which led to federal charges), mismanagement,..."

This is not to say that all is well in Niagara Falls, Ontario. One instance is the old 'main street' - Queen Street, which since the 1960s has experienced massive decline, and is largely vacant. Attempts to revitalise it have met with limited success. This problem is not unique, and is shared by many older 'main streets', where suburban malls have been developed and thrived.

## 4.0 CROSS-BORDER DIFFERENCES:

### 4.1 Fundamental Differences

There are various reasons why Niagara Falls Ontario has survived de-industrialisation and has had ongoing success in exploiting tourism and as a retirement destination. Some are independent of specific government activities. These include:

View of the Falls:

The orientation of the Falls themselves is such that the Canadian side has a better view, which has encouraged development since the tourist industry began in the early 1800s. This gives the Canadian side better access to what Wurst (2011) described as "the world's largest industry" - tourism.

Border Implications:

The border has significant implications to Canadians. Niagara and south-west British Columbia are the locations in Canada with the most benign climate - and access to the government-based Canadian health care system. Between US tax regulations and the health care system, Canadian seniors are limited in their ability to move to warmer places, unlike American seniors. Elderly Canadian 'snowbirds' who spend substantial amounts of time in places such as Florida or Arizona, concern themselves with possible U.S. tax entanglements.

Geographical:

Each relates to a larger city – Niagara Falls, Ontario to Toronto, and Niagara Falls, NY to Buffalo. Toronto has thrived through last part of 20th century, while Buffalo has languished (population peaked in 1950 at 580,132 - then shrinking to 261,310 in 2010). Toronto in contrast has grown: (Toronto: 1951: 1,262,000, 2011: 5,583,064). Niagara Falls, Ontario has benefited from Toronto's massive and ongoing growth, even though, the lack of train connections, makes commuting to Toronto unattractive.

Images of Niagara:

Images are important to Niagara. Schneekloth and Shibley (2005, p.105) note: "Those of us who live in Niagara know that this is a powerful place if only because of the presence of the Falls and the magnitude of fresh water that flows through the region, generating settlement, power, and a legacy of rich livelihood." McGreevey (1994, p.1) called it "a strange place".

Yet this image continually changes. Through the 19th century Niagara was seen as place of power and technological innovation. Through the later part of the 20th century, this image became less inspiring, and faded as factories moved away. Without this particular shade of image, other image factors can dominate.

The development of industry along the American side of the Niagara River blighted the area. The website of the City of Niagara Falls, NY notes "The famous Mill District located one mile downstream of the Falls and two miles upstream of the Falls had become an unsightly blight upon the landscape. Pollution once again was a common sight. Smoke and smog hung in the air causing a foul smelling odor. Tall red chimneys were commonplace, each spewing smoke and soot into the air above the falls. The industries and mills were unkempt for the most part. Trash and waste piles littered the landscape. ...Niagara Falls had become an unpleasant place to visit and live" (NiagaraFallsInfo, 2015). Most of those industries have disappeared - usually leaving vacant sites.

The image of Niagara Falls, NY has also suffered from disasters associated with its industrial past.

- The Love Canal problem was "one of the most appalling environmental tragedies in American history" (Beck, 1979), and has been well documented and publicised. In 1910 a short canal was abandoned before construction. It was turned into a chemical dumpsite in the 1920s, being ultimately covered with earth, and sold by Hooker Chemical to the city in 1953, with houses and a school built on the lands. In the 1970s problems became apparent as chemicals percolated to the surface and into basements, and health problems multiplied. After denial from industry and local government, in 1978 it became an international scandal, the problems recognised, and the schools and closest houses demolished. References continue to appear in the media as an example of the wrong way of disposing of chemicals, and the wrong way to react to environmental disaster.
- In 1976 a chlorine rail tank car exploded at the Hooker Chemical plant, killing four, and injuring 87 more - up to three miles from the explosion (Beitler, 1975).
- In 1956 the Schoellkopf Power Station collapsed. As a result of numerous canals built to supply water to the power stations, and originally to water-powered factories, cracks appeared in the gorge face and two-thirds of the power station dramatically collapsed into the river. As significant generating capacity was lost, it was replaced by 1961 by a new plant at Lewiston. In the five years before the new plant came on stream, many businesses relocated to obtain the power supply they needed, kick-starting population loss.

The image of Niagara in Canada differs from the American: economically and geographically the area is more important to Canada than to the United States. It is a short drive from Toronto, Canada's largest city, so more familiar to a greater proportion of the population. "The region is often referred to as the Gateway to Ontario, Canada." (Jayawardena, 2008, p.364). Again, this is not uniform; older residents will often reminisce about how wonderful things were when factory jobs were plentiful, hence the article 'From Garden City to Garbage City' (Reinhart, 2005) appearing in a national newspaper based on interviews with a few disgruntled people.

Structure of the cities:

Niagara Falls, Ontario has the advantage, not shared by the American city, that its decayed city centre is located well away from the tourist areas. It is possible to visit, or even live in the city, and never need to encounter that area. As of 2015, the area has an unfortunate distressed appearance, with its many empty or under-utilised shops. The wealthier parts of the city are in the north-west: for many people it is more convenient to shop in the major enclosed regional mall in St.Catharines.

## 4.2 Non-Fundamental Differences: Initiatives of Government

In Canada, higher levels of government involvement over more than a century, in particular the Province of Ontario, have made significant successful policy interventions assisting the Niagara economy.

It is worth considering the various actions undertaken by the various levels of government in Canada, and their relative levels of success, especially in contrast to those on the American side, where outcomes have been very mixed.

### 4.2.1. Provincial Initiatives

Niagara Parks Commission (NPC)

A key action by the Province of Ontario has kept industry away from the river. It established the Niagara Parks Commission in 1885, on the recommendations of famous railway engineer Sir Casimir Gzowski (1813-1898). The NPC was mandated to preserve and enhance the lands along the Niagara River and develop it as a public resource. This orientation towards the preservation of natural beauty and the encouragement of tourism has been in distinct contrast to many policies in the United States that encouraged industrial development along the river.

The NPC addresses what Healy (2006, p.525) pointed out as a common problem for the management of 'tourism destination resources': that they are subject "...to both overuse and underinvestment." For example, they illuminate the Falls, something no individual entrepreneur would be likely to undertake.

The Niagara Parks Commission has regulated development in the areas it controls along the river. One example relates to the older power stations near the Falls, built on land the NPC leased to the generating companies. Carr (1981, p.27) noted of the Canadian Niagara Power Company's Rankine Power Station building completed in 1905: "It is a very large building, but its overhanging pitched roof and a terrace running the full length of its front make it appear long and low. It is built of rough-cut limestone with a roof of green-glazed Mediterranean-style clay tiles." The Toronto Power Generating Station, opened in 1906, was designed in a neo-classical Ionic style, by one of Canada's foremost architects. This building, closed since 1973, has been designated as a Canadian National Historic Site. Both buildings have reverted to the Niagara Parks Commission, and are expected to be converted to new uses.

A similar initiative to the NPC did unfold on the American side, termed 'Free Niagara', leading to the formation of the 'Niagara Falls State Park' in 1885, although it took fifteen years of significant effort. However, while New York State gained power to acquire private lands, it was limited to the area immediately around the Falls. Moreover, conflicts of interest were rampant, with industrialists pressuring government to keep the protected area to a minimum (Strand, 2008, pp.148-151). Hartt and Warkentin (2014) note that the structure of the New York parks system leads to chronic underfunding, and that there is a lack of integration between the city and state that also compromises the success or the parks.

Support for wine industry.

The wine industry has offered diversification, attracting more sophisticated tourists than the casinos and wax museums - thereby adding another dimension to the tourist industry, as by 1968, Niagara was seen as having become a "low-brow tourist trap" (Wurst, 2011).

Grapes are indigenous to the Niagara area, and the earlier settlers developed vineyards based on varieties that could withstand cold winters - these were used for juice and wines of dubious quality. Gaylor (2010, p.196) discussed the industry and its no-frills product, "...delivered in metal-capped gallon jugs. For almost 100 years it was an industry going nowhere." Furthermore, the wine industry was handicapped with respect to domestic sales by the policies of the Liquor Control Board of Ontario - a provincial monopoly on the sales of wines and liquors. The policies of the LCBO were to make purchases as unappealing as possible: until the late 1960s the customer selected from a list - and was not able to see the final product. In Ontario between 1920 and 1970 there were only seven wine producers with no new licenses issued until 1975, when Inniskillen

Wines was created. Since then there has been a rapid growth of competitive estate and boutique wineries. This has been aided by significant action on the part of government.

Starting in 1989, the Federal-Provincial Grape Acreage Reduction Program funded grape growers with $CAN 50 million to remove many of the old 'traditional' labrusca vines. Legislation was passed that effectively eliminated the use of labrusca grapes in commercial wines.

Another provincial initiative was the creation of VQA Ontario in 2000, "a regulatory agency responsible for maintaining the integrity of local wine appellations and enforcing winemaking and labelling standards" (VQA, 2015). By establishing frameworks for the designation of VQA wines it promotes better quality Ontario wines.

A significant step in the preservation of Niagara's agricultural resources was in 2005, when the Province, in co-operation with the Regional Municipality of Niagara, created a greenbelt system (Ministry of Public Infrastructure Renewal, 2006). The intent is to preserve Niagara's agricultural lands "from urban development in perpetuity." (Gayler, 2010, p.195). While such protection remains controversial, and not necessary absolute, it is a step in safeguarding agricultural resources.

This development and promotion of the Niagara wine industry extends well beyond the production of grapes and wine - it has become a significant part of the tourism industry. Wineries are allowed to sell wine and associated products on-site, and can sell directly to restaurants. Virtually all other wine retailing still remains in the hands of the LCBO. Many wineries offer tours, tastings, and in some cases, excellent restaurants and conference facilities. Ancillary events are conducted at wineries, including Shakespeare performances, concerts, and car shows. During the summer tourist season and on pleasant week-ends, it is not unusual for the major wineries and their shops to be crammed with tourists - over half a million people visit Niagara's wineries each year (Gayler, 2010, p.207), although this represents only about five percent of the total visitors to Niagara.

Further regional benefits have resulted from this industry. Several programmes have channelled formal recognition and supportive funding through the Ministry of Colleges and Universities of Ontario. Brock University in St.Catharines founded its Cool Climate Oenology and Viticulture Institute in 1996 offering degrees and certificates. The Canadian Food and Wine Institute at Niagara College runs a two-year diploma programme educating Winery and Viticulture Technicians. A federal-provincial initiative re-established the Vineland Research and Innovation Centre in 2007, with a mandate to address agricultural issues and ensure its ongoing viability (Halseth et al, 2010).

In negotiating the North American Free Trade Agreement, the Federal government ensured the wine industry was given protection.

Casino Development:

On both sides of the border, casino development has been pursued, with markedly different outcomes.

Belford (2004) discussed the importance of casino development on the Canadian side: "Then in 1996, the Ontario government came to the rescue. Niagara Falls would get a casino on the site of what had been Maple Leaf Village, an amusement and hotel property overlooking the Rainbow Bridge. Legalized gambling became a hard-driving economic engine, lifting the city from

economic depression. Eight years later, Niagara Falls is coming off the end of a $3-billion development boom." "Hotels sprang up like mushrooms. The city says there have been 40 new projects or expansions of properties since 1998."

In contrast, casino development on the American side failed to create the same positive spiral. Their casino opened in 2002, however it did not become a catalyst for further development Byrnes (2012) commented: "...it tends to exist as an island, with vacant lots and surface parking never far from it. Ten years since its initial opening, the casino has failed to generate spin-off development..." Moreover, ongoing political entanglements between the state government and the Seneca Indian tribe who own the casino, have caused budgetary problems for the city government.

### 4.2.2 Federal Initiatives

#### Immigration Policy

It is perhaps surprising that the second most common mother language in Niagara Falls, Ontario, after the official languages, is Serbian (Statistics Canada). Locals have acknowledged this and pointed to Serbian restaurants and bars of varying qualities and repute. Serbian immigration to Canada goes back over 150 years, but the events through the twentieth century have encouraged more Serbs to come to Niagara - understandably attracted to areas in which members of their ethnic background and language were already living - and could recommend.

This Canadian policy of encouraging immigration, while it can be criticised for denuding troubled countries of their educated, entrepreneurial and professional groups, has benefited many areas, including Niagara. The result is that in 2011, 20.5 percent (Statistics Canada) of the population of Niagara Falls, Ontario was born outside of Canada, with the most common place of birth for the immigrant population being Italy (18.5%) and the U.K. (8.1%). In contrast, 5.3 percent of the population of Niagara Falls, NY were born outside of the United States - the number in New York state as a whole is 22.6%. This suggests that Niagara Falls, NY has been unsuccessful in attracting immigrants.

In contexts of negative fertility rates (both the Province of Ontario and New York State are below replacement, with Ontario at 1.52 (Statistics Canada, 2011) and New York State at 1.814 (2010, National Vital Statistics Reports, 61(1)), it is necessary for a city or region to attract people - or the population will naturally decline.

### 4.2.3 Local Policies

While it is difficult to point to notable successful initiatives of local government in Canada, it can be contrasted with the activities of local government on the American side: "It encompasses just about every mistake a city could make, ... a 1960s mayor's decision to bulldoze his quaint downtown and replace it with a bunch of modernist follies. There was a massive hangar-like convention center designed by Philip Johnson; Cesar Pelli's glassy indoor arboretum, the Wintergarden, which was finally torn down because it cost a fortune to heat through the Lake Erie winter; a shiny office building known locally as the "Flashcube," formerly the headquarters of a chemical company and now home to a trinket market." (Business Week, 2010).

Niagara Falls, New York believed its salvation to be in capital-intensive mega-projects, but the results have been disappointing due to their various failures to thrive or create further development. Niagara Falls, Ontario has flirted with numbers of similar mega-projects: perhaps fortunately most, such as the 'Maharishi Veda Land' first proposed in 1992 by magician Doug

Henning, or the 'Worlds of Jules Verne', or an 'Ancient Chinese City' have not materialised (Ricciuto, 2008).

## 5.0 THE LESSONS

### 5.1 Diversification

Wurst (2011) noted: "At the beginning of the twenty-first century, the United States is a country where many manufacturing jobs have been wrenched abroad, leaving a domestic economy dominated by service industries. Today, tourism is the world's largest industry, and many have predicted the calamities that will result from the reliance on service labor in the West." The Canadian side has, for over a hundred years, cultivated its tourist industry, - thereby reducing its reliance on manufacturing, although typically manufacturing pays more than tourism.

Furthermore, Niagara Falls, Ontario has avoided the risk, pointed out by Wurst, of becoming simply a 'low-brow tourist trap', through ongoing development of a diversity of tourist attractions. Clifton Hill with its outlandish collection of wax museums and shops selling rubber mounties remains popular, but other experiences are offered by the riverside trails, the heritage aspects of Niagara-on-the-Lake, and the wineries. There are many opportunities for golfing and cycling, family tourism includes the Marineland theme park, the Butterfly Conservatory and the Botanical Gardens (both operated by the Niagara Parks Commission), jet boats go up the river as far as the Whirlpool, and the Welland Canal can be an unexpected spectacle for the visitor. This means the local economy and the tourism infrastructure (hotels, restaurants and campgrounds) are not dependent upon any one of them.

This lack of reliance on any one company or industry, means that the sudden shock of a major closure will not occur. If an employer fails, a large portion of the population is not affected, so time is available to adjust to new circumstances.

### 5.2 Maintenance of a Positive Image of Place

The image of a city is important, especially when the natural fertility rate is lower than replacement. People have to be attracted to a city to maintain both its population and its vitality. This implies that the city/area has to be visually, culturally, and socially attractive. Visitors must not be repelled, and people living there can recommend it as a place in which to live and work. In a mobile globalised world, it must appeal to people both within the country and to those in other countries. Industry in Niagara originally grew on the basis of cheap energy and manifold transportation advantages. As these advantages have diminished, making other factors relatively more important. To make effective, central government must enable workforce mobility and offer a supportive immigration policy.

The maintenance of image on the Canadian side has even supported industry. Bagchi-Sen (2001, p.47) of the State University of New York-Buffalo noted: "However, the reversal of fortune in other sectors such as tourism and agriculture continues to encourage manufacturers: most SMEs in this study show efforts in improving their performance such as through product development, export market development, and the recognition of the importance of external service inputs and networks in enhancing business performance. Furthermore, the Niagara region SMEs show better business performance than the SMEs across the border in the Niagara–Buffalo region in the United States".

### 5.3 Balance between Public and Private Interests

The balancing of competing interests is one factor between the success of the Canadian Niagara Parks Commission and the American Niagara Falls State Park. Lord Kelvin, when visiting Niagara, offered the opinion that the primary worth of the Falls was its potential for industrial development - the spectacle was irrelevant (Hulbert, 1908, p.99).

This partially reflects the differences between the individualistic American culture and the greater collectivism found in Canada. The Canadian side was able to accommodate both interests - with the preservation of open space and the recreational use of the lands along the river, while the American side followed the shorter-term interests of commerce and allocated much of the river frontage to noxious industrial development. In Canada, the process pushed such industrial development away from the river.

This cultural difference can be found in the words of Sir James Pliny Whitney, the Premier of Ontario, who created the publicly-owned electric utility generally referred to as 'Ontario Hydro' in 1906: "The water power of Niagara should be as free as the air." (Hampton, 2003, p.35). Today one would regard it as extraordinary that Whitney was the *Conservative* party leader.

The balancing better protected the essential resource of the Falls and river in Canada, thereby preserving options for other types of development.

### 5.4 Preservation of Options

An emerging field that might give insight into the contrasts between the Niagaras is that of 'real options'. Niagara Falls, NY limited its ability to adapt to change, through its wholesale acceptance of noxious industries, which discouraged the development of other activities. The presence of such industries directly on the river undermined the potential utility of a major, and unique, asset, the Falls itself. The repeated discussions of a blighted environment along the river, and the unpleasant smells and toxic waste that found their way into the city will tend to discourage in-migration, and perhaps worse, this image undermines Niagara Falls, NY as a place to live, set up a new business, or even visit as a tourist. Was it a wise decision to follow this rapid growth route through the first part of the 20$^{th}$ century, thereby implicitly negating other forms of development – in particular those that might have been associated with the Falls? Real options analysis may offer insights into the value of retaining the ability to address alternative possibilities relative to more immediate returns.

## 6.0 CONCLUSIONS

Niagara, geographically, historically and economically is an exceedingly complex area, hence governance and management are equally complex. While there are some fundamental differences between the two sides of the Niagara border, the divergence in outcomes does offer a number of insights:

(a) Diversification is important. To improve the probability of long-term success of an area or region it should ensure it is not reliant on any one type of commercial activity.

(b) The visual/social/cultural image of a city or region may be critical in ensuring its ability to retain and attract people and businesses. This is particularly important in areas with negative fertility rates that are relying in an inflow of households to maintain a stable population or to grow.

(c) The success of a region or city may be based on policies created and implemented by different levels of government, who must also be able to balance competing interests.

(d) The relative success or failure of a region or city may be a long-term process, requiring consistent productive action on the part of numerous actors.

(e) Well-considered, key government intervention to support existing and emerging activities can be effective in ensuring the long-term viability of a city or region.

(f) There may be fundamental cultural issues facing institutional or managerial systems that are attempting to direct outcomes.

The two Niagaras offer a natural, if unique, laboratory in which adjacent cities with different cultures and regulatory regimes can be compared and contrasted in order to understand how a complex of different interrelated factors can contribute to their relative success or failure.

Keywords: NGO, Rural Decline, Rural Governance

Abstract:
*Rural decline and rural hollowing has become serious problems in China's rapid urbanization. Since 2000, millions of China's villages have disappeared while the local culture and folk art traditions attached to them faded away. As a representative of civil society organizations dealing with China's rural decline, Non-Governmental Organization (NGO) have launched a series of practices. The paper summarizes and analyses the practices process in China's rural areas conducted by "Beijing Green Cross", a local NGO, comparing the experience of successful and failed projects, to explore the role and responsibilities of NGO in China's rural decline. This paper is divided into four parts. Firstly, we summarizes the characteristics of China's rural declining areas which mainly indicates the deconstruction of local culture and decay of physical space; secondly, we analysis the process of rural communities project conducted by NGO in rural hollowing areas which is based on rural conditions for development and cooperation with local government. The NGOs improve peasants' living environments by enhancing rural infrastructure, guide industrial development through establishing villagers' self-government mechanism, and enrich peasants' spiritual life by creating cultural space. The projects revitalize the rural areas by constructing democracy communities based on peasants' real demands. The third part concludes the limitation of NGO rural communities including improper methods, misunderstanding of peasants and lack of funds. Fourth, we contrast the positive and negative effects of NGO rural communities and propose the role and responsibilities while dealing with china's rural declining issues.*

## 1. Introduction

Rural decline has become a worldwide unavoidable problem in the country's development, especially in the process of rapid urbanization in China. A large number of young people move from countryside to city which have caused great damage in the physical space and cultural space in rural areas. Based on this issue, China's NGOs have launched a series of practice, aiming at the problems of different rural recession and progress have been made in recent years. However, in the process of rural community construction China's NGO also encountered some problems. This article attempts to analyze the role and responsibility of NGOs in the process of dealing with rural decline from the perspective of the practice project and realistic background.

## 2. Research backgrounds of rural decline and NGO practice in china

From the experience of developed countries, local culture structure and physical space decline in the process of urbanization, as the rural population move to cities. The problem is even

severe in China's rapid development. As a civil organization, NGO is also one of the actors aiming to dealing with the rural decline.

*2.1Experience of developed countries: the shift of population from rural areas to the cities make rural decline*

Developed countries' experience has uncovered that following the urbanization, more and more rural population move to cities. As a result, villages shrink gradually.

Take Japan, which also has dense population as China as an example. It has the highest urbanization level in Asia. In 2002, its rural population make only 7.8% of the domestic population. The agriculture labour decrease and aging problem is occurred by megalopolis led by Tokyo megalopolis. Their advantages like high-quality public service, abundant employment opportunity, better life quality has attracted many people, mostly the youth. In 2000, the population of the agriculture labour is 3.89 million, half of which is aged over 65.While many young rural people choose to work in companies without any intention to work on agriculture. As a result, the old people are the main part of the agriculture labour force who have low labour quality contributing not much to the development.

The Japan government estimates that the domestic population will drop from 127 million to 86 million in the future 40 years while the percentage of the people over 65 will increase to 40%. Meanwhile, with the rural decline, the domestic population distribution will lose balance seriously caused by the increasing population in big cities like Tokyo and Osaka, which are crowded by young people.

At present, the average age of the agriculture labour force is close to 67. Throughout the nation, 8% of the farmland have been left uncultivated. Moreover, folk culture has no longer been maintained and some temples have been disused. Furthermore, many forests and islands have also been deserted without care.

As a result, following the urbanization, the rural population decrease and the urban population increase are the main cause of the rural decline.

*2.2 Rural-decline problem in high-developing China: vicious circle of the population loss and rural life- quality decline.*

In China, urbanization is on a rather high pace which make the speed of rural areas' shifting to urban faster than that of developed countries. Although there's a great decrease of rural population, the exploitation of farmland hasn't reduced which on the contrary, has increased. The rural population decrease has also led to other problems. As the people under service decrease, some public service sites combined leading to larger service zone of each site. So people need to bear more time and traffic cost to get service. Moreover, the leaving of young people makes the inheritance of rural culture more difficult.

### 2.2.1 Rural population is decreasing

The date of State Statistics Bureau shows that in the past 20 years, the total reduction of rural population exceeds 0.2 billion (Figure 1). The date of Civil Affairs shows that, in 8 years, the number of village committees has decreased from 623669 to 588547.While the date can't cover the number of the disappeared villages as not every village has village committee(Figure 2).

The rural population decrease mainly caused by rural population shifting to urban. The annual population survey in 2000 uncovers that,13% family have outside workers. For example, in 2001,in Hunan Province, the outside workers working in other provinces is 4.87 million, while in Sichuan Province, the number is 5.6 million. Meanwhile, the possibility of them returning home doing farm work is low which also lead to the rural population decrease.

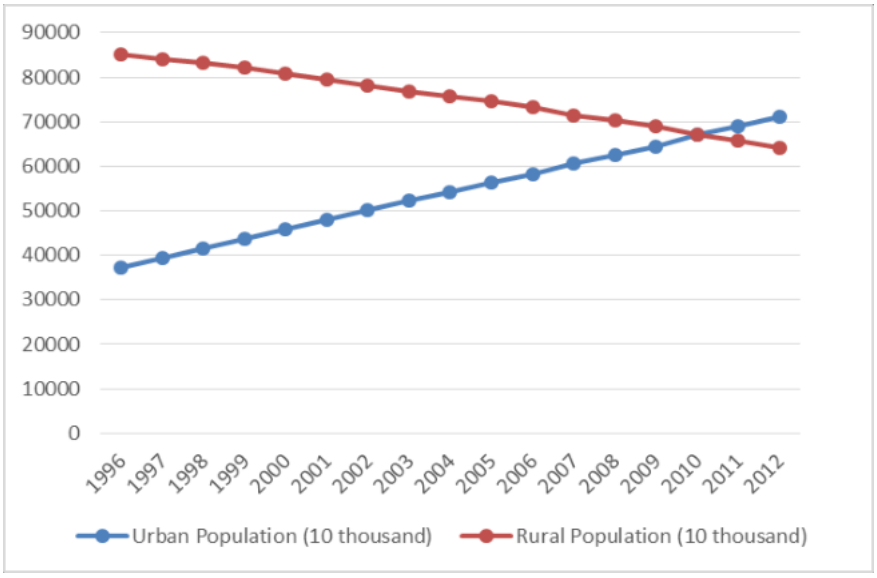

Figure 1. The dynamic variation of urban and rural population
Data sources: The official site of State Statistics Bureau

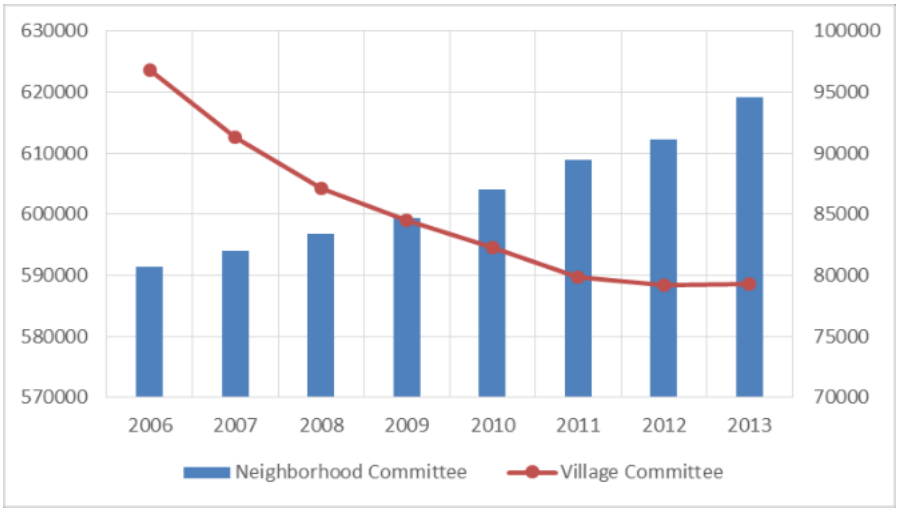

Figure 2. The dynamic variation of neighborhood committee and village committee
Data sources: The official site of Chinese Ministry of Civil Affairs

Following the main rural labour force shifting to urban, rural decline leads to the decline of physical space, the underdevelopment of service facilities, and the quick destruction of folk culture.

### 2.2.2 The quality of rural material space is declining

These years, the exploitation of land has influenced rural areas a lot. The exploitation amount hasn't decreased which in turn tends to increase. The report analysing the relationship of rural construction land and registered population tells that the amount of rural construction land increased yearly from 2007 to 2011, while the registered population per unit area decreased. The land use has presented an extensive look (Figure 3).

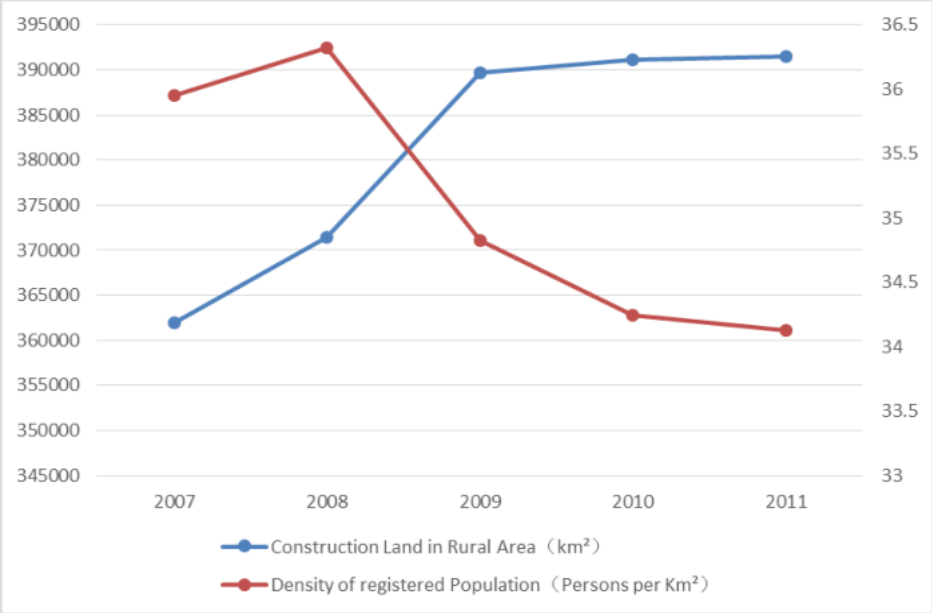

Figure 3. The dynamic variation of population and land use in Jilin Province
Data sources: The national statistical yearbook, 2007-2011

What's more, blind cancel of public service facilities caused by population decrease has also affected rural life quality. The report named "estimation on the rural schools' distribution adjustments" shows, rural primary schools have been reduced 52.1%,which is 229.4 thousand .The teaching centres have been reduced 60%,which is 111 thousand. The survey sampled by 10 provinces shows that the average distance from home to school for pupils is 10.83 miles, for middle school students is 34.93 miles. As a result, the actual and potential dropout rate increase accordingly. Relevant surveys uncover a sharp fall of dropout rate of pupils from 1990 to 2000,which fluctuates from 2001 to 2006 and rise again largely after 2007.The dropout rate raised from 5.99‰ in 2008 to 8.22‰ in 2011.That is, 800-900 thousand students drop out per year.

### 2.2.3 Folk culture is declining

Folk culture decline is inevitable. Chinese rural studies represented by "Liang zhuang village in China" have presented the collapse of the inner structure of villages. Villages are no longer set up by same family name, but set up as economy center. The agricultural transition reduces the demand of agriculture labour, as a result, many young rural people choose to work in big cities. Villages are losing their vitality and vigor while empty villages are common view. Moreover, with the least attachment to hometown, the outside workers can't inherit traditional folk culture which is at stack.

### *2.3 Research on the NGO program and village management*

Non-governmental organizations play a very important role in modern social governance. "The government is the leading role of public administration, but social public affairs management also

needs a number of supporting roles". "One of the enlightenment of the Western administrative reforms in the 1970s is that along with the social progress, especially the rapid development of science and technology, people increasingly profoundly realize that in dealing with relationship between the government and market, between the government and society, between the government and the public, the traditional government's role will change while many non-profit, non-governmental organizations will undertake some function in different forms. These organizations provide not only public products and services, but also undertake the management of social public affairs. Since the 1980s, whether in the developed countries or in developing countries, NGOs are committed to providing public service and solving various social problems as an active part in public management like local autonomy, community service, and public policy formulation and implementation.

Folk organizations rooted in rural areas have developed maturely abroad. Such as the agricultural cooperative organization in the US since 1810 which provides a platform for farmers' mutual reciprocity. And the agricultural cooperative combination in Japan since 1948 not only provides agricultural products-processing, commission sale, storage and transportation, production and living materials and other engagement in insurance, credit, culture, entertainment and so on.

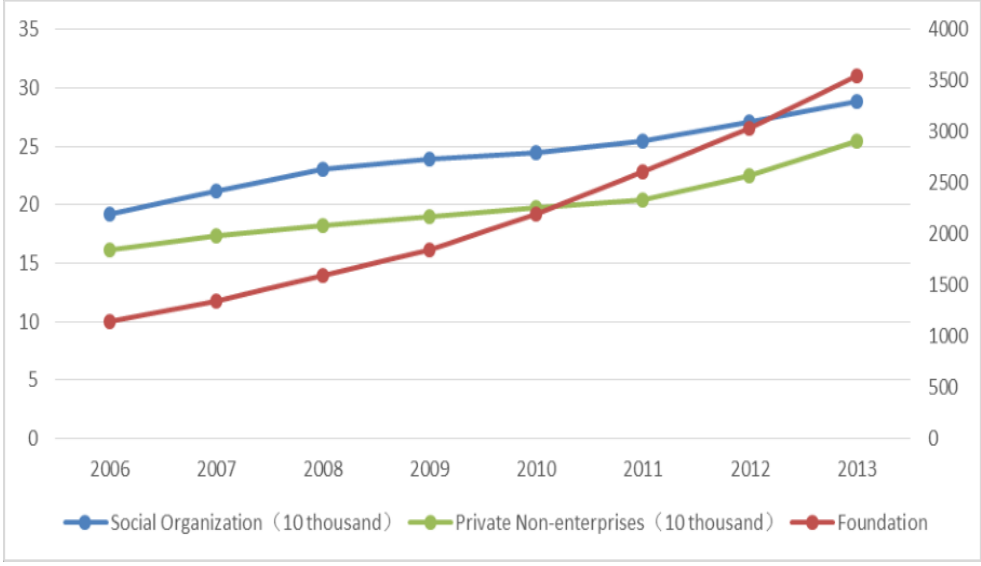

Figure 4. The developing trend of Chinese social organization
Data sources: The official site of Chinese Ministry of Civil Affairs

China's folk organizations develop fast as well. According to the date of the national civil affairs, social organizations become more and more yearly. In 2013, the number of social organizations reached 289000, while the number of foundations reached 3459, the number of the private non-enterprises reached 255000 (Figure 4). These social organizations are involved in science and technology, education, culture, health, labour, civil administration, sports, environmental protection, legal services, social intermediary services, business services, rural and agricultural development and other fields of social life. Despite China is insufficient in the social, legal, and capital conditions to develop NGO, NGO is without doubt becoming an integral new part of Chinese social and economic life.

## 3. Analysis and evaluations of the NGO community construction practice in rural declining areas in china

There exist huge differences in development conditions in Chinese rural areas as China's vast territory. The rural construction conducted by the government is much less than urban areas because of the limited budget. NGOs is making models in rural areas for other similar villages under this situation. The main measure of rural community construction conducted by NGOs is enhancing rural infrastructure, guiding industrial development through establishing villagers' self-government mechanism, and enrich peasants' spiritual life by creating cultural space cooperating with the government. The projects revitalize the rural areas by constructing democracy communities based on peasants' real demands.

### *3.1 Improving the infrastructure to enhance villagers' living quality*

The decline of rural physical space due to the life-style transformation from traditional rural life to modern life. However, the lagging of infrastructure services lead to the worst quality of rural life which mostly reflect in the environmental deterioration in the country life.

There is a long history of environment management in the city and the environment department deal with the environment problems every day. Instead, environment issues in rural areas have been ignored for a long time. Individual farming discharge wastewater and other agricultural waste to the river near peasant's home. Floating dead livestock in the river lack professional management and cause stinking smell. The rural environment issues is becoming increasingly serious.

As one of the representatives of rural NGO, "Beijing Green Cross"(hereinafter referred to as BGC) started their rural community construction with improving rural environment in Wushan Town of Xiangyang City in Hubei Province which locates in the central region of China. They organized the farmers to improve rural basic production conditions and living environment by advancing the quality of village road, drinking water system, drainage, garbage disposal facilities so that the village's image is getting clean and tidy and significant improvement have been made in rural civilization (Figure 5&6).

Transformation, construction and communication are the three keywords in the BGC's projects. They transformed the water system, kitchen, toilet and livestock shed; they constructed homes, gardens, factories and pools; they communicated the village to outside world with roads, electricity, phone and broadcast. As the living conditions, public facilities and other infrastructures greatly improved, BGC motivated the villagers' enthusiasm to build their homes. BGC have done similar projects in Haotang Village of Xinyang City in Henan Province and Wangtai Village of Xiangyang City in Hubei Province. Rural environment improvement refresh the whole village's image. The projects not only improve the quality of villagers' life, and also brought tourism revenue.

Figure 5. Wushan Town

Figure 6. Wushan Town

*3.2 Guiding industrial development through establishing villagers' self-government mechanism*

One of the most important reason of rural decline is the limited capacity of traditional agriculture absorbing rural surplus labour force which led to a huge loss of the rural population. In the process of dealing with rural industry transformation, the industry guidance conducted by government could not focus on each individual country to take appropriate measures. NGO has its own advantage in this area.

Take Wushan Town as an example. In 1980's to1990's, Wushan Town was a poor town in remote mountain area. The township enterprises under The Reform and Opening-up policy failed to make Wushan Town being rich. Relying on industrial development have been proved wrong in this area. In addition, Wushan Town was also facing is pressure of less land and more surplus labour force like other towns.

Local government and the BGC combined the development of characteristic industry with promotion of labour transfer in Wushan Town.

The project cultivated tea industry and made progress in the integration of ecological tourism of developing pastoral scenery tea art performance, tourism, leisure and entertainment based on the characteristics of mountain town. This strategy is closely rely on the location and resources condition, and it is also the current new rural construction way in Hubei Province. Rural labour

force transfer is not only made it possible to agricultural industrialization, intensification, and modernization, and bring powerful financial support to the rural economic and social construction, as well as modern civilization to rural areas.

Due to the project implementation improved the ability and independency of the villagers, when the project ends, the village made the development sustainable according to the aim of the new countryside. In 2012,there are 25 farmhouse in Yanhe village of Wushan Town making profit more than 30 million yuan; 1200 mu organic tea garden have been planted with an annual output value more than 10 million yuan; they registered trademark "Yanhe Xiang" for the production of mushrooms, cured hooves, dried chicken and other local products which led to an annual output value of nearly ten million yuan. In addition to breeding, planting medicinal herbs and other industry, a rough estimate of the village industrial and agricultural output value is nearly 100 million yuan. In 2012, the per capita net income reached 9850 yuan, which is 4.8 times comparing to 2003 before the implementation BGC project.

The transfer of rural surplus labour force not only makes it possible to develop modern agriculture, but also bring financial support to agricultural industrialization and changes in management concept. By 2009, the whole town has long-term transformation of surplus labour 6, 870, short-term transfer of surplus labour is 2, 300. Total income of labour force transformation is more than 1 billion.

*3.3Enriching peasants' spiritual life by creating cultural space*

The lack of public service facilities hinder the quality promotion of villagers, lower the quality of the rural life, and baffle the healthy rural development.

Rural public service facility construction dominated by the government more based on the population and the facilities more located in town for the whole service of countryside. Such services mostly are basic service, such as health care and education. However, due to the spatial distribution of rural fragmented, the accessibility of individual to basic services affected. In addition, the villagers' spiritual needs, such as the construction of villagers' folk cultural space and cultural entertainment space are being ignored.

In order to solve this problem, BGC established rural library and rural e-information center in Wushan Town. They formed small groups to host monthly cultural activities of laws and regulations knowledge, rural practical technology, and environmental protection knowledge to villagers who could learn the latest information from the BGC and participate in the activities. The BGC took "Tea culture" as the breakthrough point and established Yanhe Teahouse, designing and constructing the symbolic altar of "tea". The BGC built the major industry in Wushan Town and promoted the cultural taste and quality of the villagers.

According to the relevant laws and policies, the BGC made the rural regulations under the realistic situation in Wushan Town which reflected the most villagers' will and being a kind of common public rules forming the atmosphere of villagers' self-management and self-education.

## 4. Reflection of the limits in NGO rural community construction

At present, most NGOs are mainly involved in the works in traditional villages and towns, focusing on developmental cases including poverty alleviation, charity, education and entertainment, etc. In

spite of the urbanization, modernization, polarization and transition of these rural areas, many NGOs are still following the old developmental concept, staying in the stage of simple resources & information importation and Self-Assumption. Because of these points, these brought negative impacts into the development in rural areas and took disadvantages of the reputations, development and growth ability of the NGOs themselves as well.

The difficulties of governance in rural areas could be seen of which NGOs involved in. Nevertheless, BGC is suffering from the same predicament as well, that could be seen from its development by the latest decade ( Figure 7).

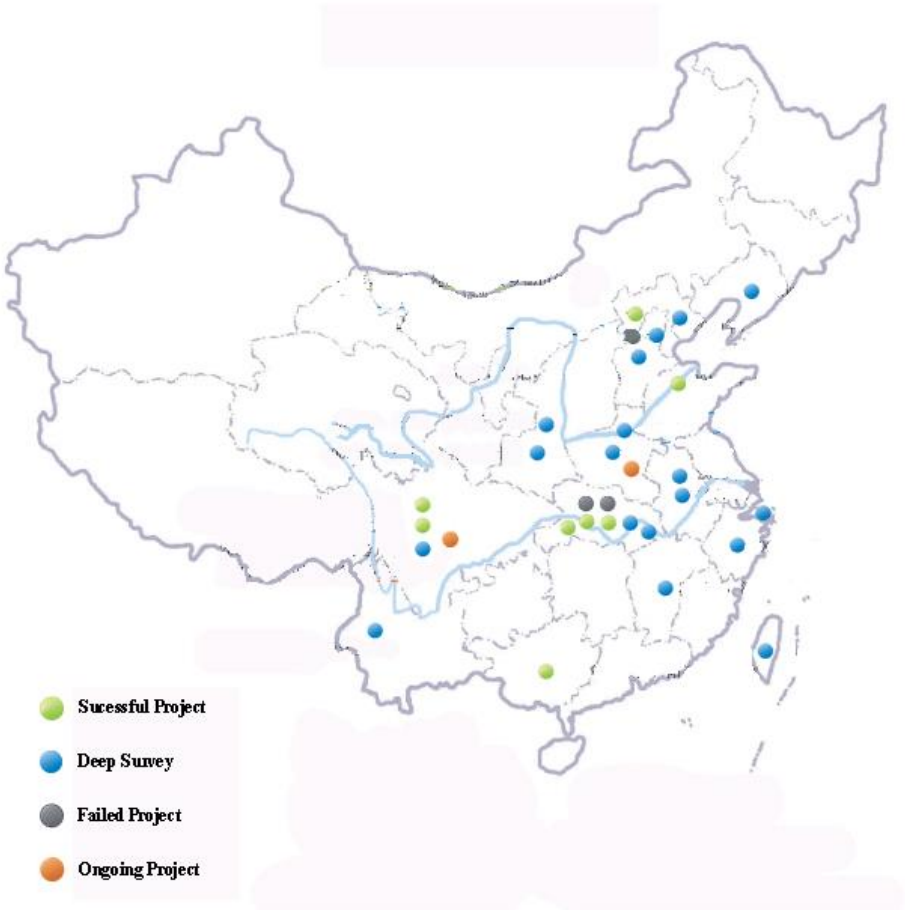

Figure 7. The BGC projects in Chinese rural areas
Data sources: The official site of BGC
http://www.bjlsz.org.cn/

According to the development of BGC and the project experiences of relevant NGOs', there are some major predicaments in the process of NGO's rural community construction (Figure 7).

*4.1Top-down authoritarian system become a burden of charity*

In the government-leading mechanism, villagers are used to accept the arrangement of the government. "waiting, relying and demanding" have become their normalcy. Thus, in this situation, the unsustainable governance inevitably causes population loss and recession. However,

NGOs brought in another options, farmers could build “new village” by their own hand and advanced concept.

However, in some extents, if it is only simply relying on the resources & information importation by administrative or authoritative measures, there would be additional burden imposed on villagers, even though it was well-meant by the NGOs. If the subjectivity of villagers wasn’t launched by NGOs, there should be meaningless of the implications that NGOs could bring in.

There are failures in the projects that BGC involved in, which were caused by excessive interventions. In 1999, in Baishi Village of Yanqing county, BGC mastermind a series of measures for the village’s environmental management and economic development. During the process of the project, the NGO kept well relationship with local villagers, who were passively following the management. Just because of BGC’s responsibility and enthusiasm, the role of local administrators were took place. Thus, when NGO left, local administrators were confused and did not know how to continue, then it was slowly turned back to the previous terrible situation. The problems were still exist.

*4.2The inconformity of the development concept and peasants’ realistic development demands*

Depending on the powerful resources, backgrounds and relationship network, NGO take part in the development of rural community, but NGO couldn’t truly integrate into it. The powerful self-confidence should response for the problem. With too much concept and technology, when facing the real rural decline, NGO couldn’t analyse problems dialectically. NGO just use the experience of other region unquestioningly, thus leading to the unfitness to the development of the local rural community, and lost the confidence in development with the consume of spiritual strength and energy.

In China, the rural management model is closely related to the rural society. The moral restriction in acquaintance society is the core part of Chinese rural management. When facing the self-contained rural society, the NGO’s practices using external experience have proved this.

Because of the regardless of basic communication, the project has difficulty to carry out. In 2007，a rural project lead by BGC in Niushou Town of Xiangyang City in Hubei Province was failed. The main reason of the failure was that NGO was not well prepared for the rural cooperation. They just made agreement with the third and fourth tiers of government, thus leading to the non-compliance of the executives.

Democratic Governance is not the master key of rural management. In 2009，after the ″5.12″ Wenchuan Earthquake, "Beijing Green Cross" won the support of foundation to set up rural cooperatives. NGO used the western democratic experience to lead economic development in rural village. The fund bypassed village committee, went directly to village group. And this caused a lot of trouble. Many issues couldn’t resolved just because of the disagreement of a single person. On account of the noncooperation of village committee, the results came out terribly, and NGO was driven out of the village. Stranger society forced legal system, and acquaintance society created morality. The rural village group is some kind of acquaintance society, a family, so it is very inappropriate to use the western democratic governance to manage Chinese rural area.

*4.3The lack of fund hinders the progress*

Compared to the Western countries, China's NGOs are weaker in raising fund while the fund structure is not totally reasonable. The US has 1.6 million NGOs whose total asset is 2 trillion dollar. And their income is 1 trillion dollar per year, on average, 625 thousand dollar for each NGO per year. Till the end of 2002, the number of charity organizations registered in the UK charity commission reach 186 thousand, and their asset is about 70 billion pound. We can judge from NGO's expenditure scale that most NGOs in China haven't an optimistic fund-raising condition. Some researchers have studied that almost 90% of NGOs spend less than 500 thousand yuan per year while the ones spend more than 1 million yuan per year are less than 2%.

In China, the main source of NGOs' fund is the financial allocation and subsidies from the government, which makes up 49.97% of all. While 21.18% of the fund is from membership fee,6% is operating income,5.63% is sponsorship and project budget from enterprises and less than 5% is from other sources. Meanwhile, the personal donation make up only 2.18% of all (Figure 8).

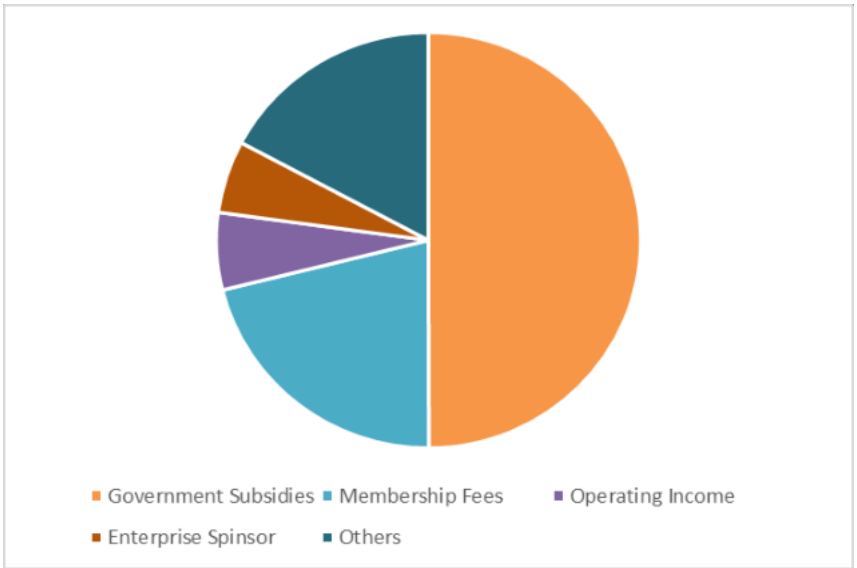

Figure 8. The capital resource of Chinese NGO
Data sources: NGO research institute, Tsinghua University, 2000

Insufficient funds also brought huge obstacle to the benign development of NGOs as many projects can't lay out. The survey of Yiyang City in Hunan province in 2000 shows that 40% of the city's communities have no activities over the past few years. And at least 100 city communities have less than 30 thousand yuan registration charge while there are 160 communities in total.

In practice, NGOs whose main fund source is from government have some difficulty in autonomy. The BGC, from 2003 to 2007, got almost 90% of the fund from foundation, while 60%, from 2007 to 2011, from the government. After 2012, the government pay almost 95% of the cost on social services according to the relevant regulations of the Civil Affairs. In the process, the design of the villages is paid by the government, the cost of the designers is paid by the design institutions which is in cooperation with the Green Cross. That is, Green cross is a platform, providing coordination.

## 5. Analyses the role of NGO dealing with declining rural areas

In response to rural decline in the tide of rapid urbanization in China, advanced ideas and methods used by NGOs have made a lot progress and NGOs are more flexible compared to government dealing with rural decline. But there are still many methods come to a dead end.

Environment management have been the most common way in dealing with the rural decline issues and been ignored for a long time in China. NGOs guide villagers to classify garbage, establish the sewer system to having a good life environment in a short time.

NGOs also help the villagers with the transformation of traditional industries, to seek local advantage in industry development. The rural industry guidance in the master plan conducted by the government is not accurate enough for each village because they usually divide industry areas with different development guidance. One of the industry division might include several towns and the villages are too small to considerate.

NGOs have created a lot of new ways of experiencing culture and folk art which have faded away as the rural decline. Such as the BGC projects, they enriched villagers' daily life by creating new local cultural space, improved the villagers' quality and happiness of life. The most important achievement is that the project have attracted more rural leisure group and backflow of farmers.

However, NGOs come across more difficulties in rural management. The management system of rural areas in China is based on the acquaintance society, and they easily take NGOs as a stranger once encountered with misunderstanding, the methods and concept from NGOs could become the burden of both villagers and NGOs. But the rural regulations combined the villagers' real needs and the developing conditions could really make a difference.

Through the analysis of NGO projects, certain advantages and disadvantages in different types of NGO projects could be summarized compared with the government projects (Table 1).

Table 1. Comparison of the positive and negative effects of NGO rural projects

| Type of NGO project | More positive effect | More negative effect |
|---|---|---|
| Rural environment management | ● | |
| Local industry system guidance | ● | |
| Folk cultural space construction | ● | |
| Rural community democratic reform | | ● |

NGO is equipped with advanced concept and implementation methods while the limits in traditional village governance still exist. If Chinese peasants need a comprehensive development in every aspect in society, they need to change the present scattered and isolated state and form citizens' group of equal right to speek. This is the role that NGOs should be and differs from the government.

## 6. Conclusion

From the development of rural NGOs in China in recent years, the folk organization in the traditional rural China constructed the rural areas more focused on the improvement of the physical space and cultural space. They helped the villagers to build a cleaner and more abundant living space making rural community back to life again. While, there might exist contradiction in the NGO development concept and the rural management system, and this will directly oriented difficulties in NGO project implementation. China is changing, so as China's farmers. And NGOs

should be a new choice for peasants in the transformation and help them to improve the awareness of autonomous management. Based on the development of the local conditions, combining with the advanced idea, the NGO projects should help the rural areas stop decline and change traditional rural society to the new rural communities.

# MANAGING RURAL DECAY. STRATEGIES AND RESPONSIBILITIES FOR DECLINING REGIONS IN AUSTRIA.

Paper presented at the AESOP Annual Conference 2015 "Definite space – fuzzy responsibility" in Prague.

Elisabeth Gruber[1], Alois Humer[2], and Heinz Fassmann[1]

[1]University of Vienna (Department for Geography and Regional Research), elisabeth.gruber@univie.ac.at

Keywords: rural decay, spatial planning, shrinking

*The Austrian population is growing, but not every region is profiting from a positive migration balance, which is the main driver for population change. Especially peripheries are suffering from constant population loss followed by cuts in infrastructure and service provision when the critical mass is not reached anymore. A decline of investments is already taking place according services and infrastructures – from the private side, as well as from the public side: schools, post offices, police stations, public transport lines, retail stores and other services of general interest have been stepwise reduced in many peripheral areas. In a response to the ongoing depletion of mainly rural or formerly industrial areas the - foremost local - political side keeps on introducing growth strategies in order to force a turnaround. Given the bunch of available instruments, program logics and chains of habit it is understandably but for some regions a catching up process will most likely not be successful unless the budgets will be constantly overspent. In the following paper we would therefore like to discuss how strategies on 'advancing backwards' could possibly work out in Austria and who would be public and private stakeholders of which level to get motivated for such ideas? Which planning and development instruments are suitable to accompany 'sustainable decline processes'? The paper will take empirical findings of Gruber et al. (2015) as a starting point. New planning document analyses and stakeholder interviews will further back this paper.*

## 1. Introduction

In total the population of Austria is growing due to a positive migration balance. Still there are areas across the country losing population. Peripheral mountainous regions, border areas or former industrial centres have been experiencing a shrinking population followed by a decline of services and infrastructures, which leads to perpetual loss of attractiveness for new inhabitants and economic stakeholders. A lot of topographically unfavoured regions have been attractive for setting up an intense tourism industry for winter sports having the effect that a lot of former agricultural regions found a different economic path. Nevertheless, there are also areas in Austria characterized by outmigration, population loss and economic `downturn.

The ongoing urbanization process and simultaneous decay of rural areas has led to the idea that withdrawal from certain areas might have to be conceived, but even though this was politically wanted – which it is not at the very moment – which strategies would actually be able to manage a sustainable decline? On the example of Austria this paper tries to bring up some ideas, as well as the perception of politics and planners, on how strategies on advancing backwards could possibly look like and work out.

## 2. Theoretical Background

Before we start to discuss on how to manage decline, we will first approach the question of what actually shrinking means in urban and regional literature. We will further discuss on a theoretical basis what planning theory may offer to address spatial shrinking by means of spatial planning. Strategic spatial planning and soft planning are offered as more appropriate means to tackle a complex socio-spatial phenomenon like regional decline; compared to the means of traditional statutory spatial planning instruments.

The discussion on urban and regional shrinkage is a comparably young problematic in planning literature. Sousa and Pinho (2015) have made an important contribution by reviewing directly and indirectly relevant literature on this special phenomenon of spatial development. They locate the most relevant discourses since the mid 1990ies within North American urban development. In European context, the problematic is best reflected in the UK and Germany. "In a broad and common sense, a shrinking city is a city that is losing population (Sousa and Pinho, 2015, 14). While Wiechmann and Bontje (2015) confirm demographic development as the key or initial driver for spatial shrinkage, they see urban and regional economic development as a complementary prime driver for potential shrinking tendencies, in case regional economics face financial shortcuts or structural changes. Demography and economy in combination are potential drivers of shrinking. Spatial consequences of shrinkage then are expressed not necessarily proportionally to demographic and economic shrinkage. It is rather a separated, or further, step if or how settlement structures, housing stocks, social and technical infrastructures shrink as well (see Ahrens, 2005). Demographic and economic decline might as well first result in lower densities, lower frequencies or fragmentation of spatial functions. A first concern is therefore, what is actually shrinking in spatial terms and how does it change spatial structures? Wiechmann (2003) identifies four types of regions within Europe that face shrinking tendencies. These are: industrial areas in economic decline (foremost in Western Europe), peripheral, depopulating areas (foremost in Northern Europe), regions in or after political transformation (foremost in Eastern Europe), and structurally weak rural regions with falling fertility rates (foremost in Southern Europe). Common consequences are overcapacities in housing and infrastructure, leading to higher costs per capita and inefficient structures. Especially heavy technical network infrastructures do have a certain spatial time lag within. Once established networks of e.g. railways, roads or canalisation cannot flexibly be adjusted to new realities. Social services of education and health care are comparably more volatile (Gruber et al., 2015). Nevertheless, individual standards of accessibility to social services may decrease due to fewer or less frequented locations.

Wiechmann and Bontje (2015, 2) argue very critically how spatial planning systems deal with shrinkage. They identify two major concerns. First, common statutory planning administrative systems and instruments are designated to the principle of spatial development as spatial growth. The supreme aim of growth in spatial development is close to a doctrine in spatial planning systems. And secondly, planning practise has so far not managed to proactively handle shrinking tendencies but the prime goal of intervention is always to counteract shrinkage and return to a growth path. So both, the statutory planning system as well as its practical interpretation follow blind a solely growth oriented path. Much of this derives from the roll out of modern planning principles that happened simultaneously with demographic and economic growth in Western Europe. These diagnosis can be seen in a wider view of unsatisfactory structures and means of recent planning systems and practices across Europe. Albrechts and Balducci (2013) are among the scholars who promote a stronger revisiting of the potentials of strategic spatial planning that is observable in many European countries since the last ca. 20 years. For them, statutory spatial planning as administrative-legal practice is no longer – or never fully has been – able to tackle

complex socio-spatial phenomena and processes. Urban and regional shrinkage can be well counted as one of these complex processes.

Statutory spatial planning in terms of local zoning and building plans however remains a decisive part of spatial planning. It secures legitimacy over land and property rights and delivers certainty. Therefore in planning practice, informal strategic planning can only be a complementary set of instruments (Mäntysalo, 2013; Mäntysalo et al., 2014). The strengths of strategic spatial planning approaches lie, according to Albrechts and Balducci (2013), in the ability of addressing spatial phenomena in a more future oriented, pro-active way that allows for integrating a wider actors sphere besides the formal authorities and for the opening up of new directions or deeper changes in spatial development. Collaborative and communicative planning practices (Healey, 2013) are in this context more appropriate than a rather rigid procedure of statutory planning. What comes together with planning complex socio-spatial phenomena, such as regional shrinking, is the fuzzy situation of their scalar manifestation. Mostly, explicit territories of local or regional administrative units do not represent the spatial expansion correctly. This is true for expanding city regions as well as for shrinking regions. Functional and fuzzy spaces are closer to the problematic of complex socio-spatial phenomena and therefore, planning practice needs to deal with, as Allmendinger and Haughton (2009) call it ‘soft spaces’ (see also Olesen, 2012). Soft spaces represent a flexible, also temporary spatial expansion in which a multitude of actors, interests and concrete problems are addressed in a comparably pragmatic way of planning. It is not the prime target to follow the statutory rules on different scalar levels but what counts more is that issues get solved. For this sake, soft spaces emerge as arena in between public authority competences, different stakeholders’ interests and statutory levels of government as a new planning level.

While soft spaces and soft planning have been mostly analysed in growth contexts, we find it worth analysing in more detail in how far strategic spatial planning in soft spaces opens up an arena for spatial planning that is also able to break with the pure quantitative growth oriented spatial development as well as to break with the refusal of traditional planning approaches in managing shrinkage. We will do so on the example of Austria, explaining the contextual background for regional shrinking, the general attitude of the Austrian spatial planning culture regarding shrinking and new approaches in soft spatial planning, exemplified at the instrument of ‘Regionale Leitplanung’ in the State of Lower Austria. The guiding research questions are: How strategies on 'advancing backwards' could possibly work out in Austria and who would be public and private stakeholders of which level to get motivated for such ideas? Which planning and development instruments are suitable to accompany 'sustainable decline processes'?

## 3. Shrinking regions in Austria

### *3.1. The context of politics and planning*

The Austrian political system is based on a highly federal structure. The state is divided in nine ‘Bundesländer’ (Federal States), which are responsible for certain political fields, as for example the organization of spatial planning. Initially installed as a democracy securing system, the decentralized, counter-checking structure of the federal system today means a tremendous apparatus of administration and concurrence between the federal states. Especially for the spatial organization there are difficulties occurring concerning cooperation across internal borders or introducing national-wide goals or policies.

Besides the ‘Bundesländer’, where the general framework of spatial planning is set in the form of the federal spatial planning laws, the municipalities enjoy a lot of power concerning spatial planning in

Austria. The municipalities are responsible to decide on zoning plans and thus new settlements and growth. This might not be unique in the European context, since also other countries give a strong power to the municipalities in planning agendas (which is also reasonable, since plans can be developed close to the population), but Austria shows a very small-patterned structure of municipalities (Fassmann and Humer, 2013). In total Austria counts 2,102 municipality (2015) on a total area of around 83,879 square kilometres. On average this makes around 4000 inhabitants per municipality (and around 3,200 when the city of Vienna is excluded of the calculation). The smallest municipalities show population sizes lower than 100 inhabitants. Until 2014 Austria counted even 2,354 municipalities. The Federal State of Styria decided in a long lasting process to merge the municipal structure, triggering resistance of local politicians and inhabitants. Although further consolidations seem to be inevitable in the long run, the protest of local population and stakeholders makes further steps of territorial reforms very unlikely to happen in the rest of Austria in the near future.

The municipalities are competing with each other, since for the redistribution of public budgets the size of population is decisive. A growth in population is thus rewarded with a higher allocation of tax money. Additionally the municipalities are competitors concerning the location of industry and businesses, since the according tax in Austria has to be paid at the municipal location of the headquarters.

The highly federal organized structure, the small-patterned municipal landscape and the missing national level of spatial planning make regionally shrinking population a particular challenge. So far regional development policies have received high attention on policy agendas across Austria; not only since the European structural funds have been introduced in Austria, with the accession to the European Union in 1995. Since the 1970s regional development has been performed in the Austrian regions on different levels, with different instruments and paradigms; from heavy infrastructure investments via alpine farming funding to endogenous regional development settings. From a political point of view it seems unlikely that regional development can once be replaced by a withdrawal of the public hand from certain regions, but the constant overspending of budgets makes it extremely difficult to further invest in regions that show a continuous economic downturn and outmigration. Although not strategically coordinated there has been cuts in investments for example in traffic infrastructure, police stations, schools and child care and so on. The decisions for these changes was under responsibility of different actors like the ministry of education, the national railway and so forth. To a serious extent, these measures were rolled-out during a conservative-right government and in a phase of (EU-driven) liberalisation efforts in several public sector domains around the year 2000. In order to have a more integrative and general policy on where investments should go to and where to make cuts, it seems that there has to be a more cooperative structure to be able to take these decisions.

Cooperation in planning has gained more attention in the last years. Especially for regions with declining population, solutions with municipalities working together in order to safe costs, have been introduced in rural areas in the last years. Also initiatives to organize planning on a comprehensive level are of course existing in Austria. On a national level the Austrian Conference on Spatial Planning (‘ÖROK’) is responsible for coordination and developing strategies for spatial development. On a regional basis different initiatives try to collaborate on common topics of spatial planning, which is very important for a thematic basis, not only concerning shrinking, but also other topics in fields of society, economy and ecology.

### *3.2. The spatial dimension*

As already stated in the introduction the population of Austria shows a population growth in total. Between 2004 and 2014 the Austrian population grew by 365,213 people – 92% of the growth can be explained by in-migration (Statistik Austria 2015, 18). Especially urban areas, primarily the capital city region, Vienna, shows a fast population expansion due to international migration, but also a positive internal migration balance. Between 2002 and 2013 the population in Vienna has been growing on average by around 16,300 people each year – 14,700 of it by in-migration (see Statistik Austria). The attractive urban and suburban areas are having consequences for rural and peripheral regions. Not only the missing opportunities for labour and education are leading to an ongoing outmigration mainly of young inhabitants, also lifestyle decisions and educational and labour market preferences are leading to the disregard of some regions. Although shrinking regions in Austria are showing a rather moderate decline compared to peripheries in Eastern European countries, it is still a challenge for example when it comes to the provision with services and infrastructures (Gruber et al., 2015; Machold, 2010). Regional development have not been showing a sustainable effect everywhere and with a continuous low fertility and selective migration patterns population decline to some areas is becoming a permanent status.

In line with the four types of shrinking regions in Europe shown by Wiechmann and Bontje (2003) for the Austrian case there are several types applicable. Comparable to the typology, the following types of shrinking regions can be identified in Austria:

- rural emigration areas with (rapid) decrease of births;
- industrial agglomerations in economic decline.

The most common type in Austria can be described as rural emigration area with decrease of births. Still, in the case of Austria two sub-types can be described, which can be characterised as causes for the population loss. On the one hand inner peripheries and mountainous areas with difficult accessibility and without major tourism industry are suffering most from population decline. On the other hand border areas along the former Iron Curtain still show a declining population, as for example the South of the Burgenland or the North and East of Lower Austria. Although Austria doesn't have a big industrial history (within the today's territory) there is still a small agglomeration of heavy industry found in the Federal State of Styria. The area has lost a major part of its population – in case of the municipality of Eisenerz more than half of the population since the 1950s (from 12,948 inhabitants in 1951 to 4,520 in 2014, a loss of 65% (Statistik Austria)and the decline still continues.

## 4. Managing urban and rural decline in Austria

After having described the dimension of shrinking regions in Austria, as well as the political context of spatial planning we will finally discuss how to manage urban and rural decline in Austria. The content of this chapter is mainly based on interviews conducted during April and May 2015 with stakeholders from politics and planning from different administrative levels on which spatial planning is performed. Additionally a review of planning documents and instruments was conducted in order to reflect on ways to possibly manage population decline. In the second sub-chapter we will bring forward a new planning instrument that has been introduced in one of the Austrian federal states in the last year of which we believe it holds potential for managing rural and urban decay.

### *4.1. Research questions and methods*

As already presented in the introduction we had three guiding research questions for our empirical observations:

- How strategies on 'advancing backwards' could possibly work out in Austria?
- Who would be public and private stakeholders of which level to get motivated for such ideas?
- Which planning and development instruments are suitable to accompany 'sustainable decline processes'?

Four qualitative interviews have been realized with stakeholders of the three statutory levels, where spatial planning is carried out in Austria. In awareness of the differing planning laws and practices within the nine federal states, the interviews have been focused on one case study: the Federal State of Lower Austria. To get a comparable view there has been one additional interview realized with a representative from another federal state: Burgenland. So far the results can only be presented as results of a pilot study; further research and a bigger sample size are intended. While conducting the interviews additional themes around the research topic raised our interest: the priority of the topic as well as the acceptance and awareness. In the following chapters the results will be presented.

### *4.2. Case study: shrinking regions in Lower Austria*

For the case study analysis the Federal State of Lower Austria was chosen to approach how the phenomena of shrinking is dealt with in Austria. Since spatial planning in Austria is a federal concern and there is no national authority with a legal appointment it is necessary to have a look on policies on the federal level. On the national level the Austrian Conference on Spatial Planning (ÖROK) plays nevertheless an important role especially for strategic development and represents in a way a consented opinion at national level. Table 1 gives an overview of the results that will be now described further.

#### *4.2.1. Perception of shrinking*

As already stated in the beginning, Austria's population size is growing and population decline can be observed only regionally. Lower Austria is a good example on how differently population develops within Austria. Certain regions of Lower Austria have experienced a shrinking population since the 1950s and have experienced decline of more than 50% since then. Regions with good accessibility and especially the suburban areas in the vicinity to Vienna have experienced a major growth of inhabitants – for some municipalities this meant more than a doubling of their population. Regions losing population are generally those in peripheral areas, for example in mountainous regions or border regions of the former Iron Curtain. Until the year 2000 one focused on regional development strategies that in some ways had effect on population decline to some regions. Also the opening of the borders had effected the federal state in a positive way.

Still, in the early 2000s for the first time shrinking as a long-standing scenario came onto the agenda of spatial planning. Back then for the first time there it was recognized that at some point (with an ongoing fertility decline) there will be regions of permanent decline in population. This cognition has been perceived by the operating administrative department for spatial planning. From the political side until today dealing with the topic 'shrinking' is challenging, since it is spotted as a possible abandonment by the population. While strategies for shrinking and growing are developed equally from the operating department, the political implementation is more difficult when it comes to the implementation of strategies and instruments to manage shrinking since they are generally connected

to unpopular decisions. But the missing political will is not solely connected to policies of population decline. In general the long-term decisions of spatial planning conflict with the short periods of political activity of certain actors.

The multitude of spatial challenges across Austria give some restriction to the importance of shrinking. From a national perspective, there are many urgent issues to deal with. Among topics of regional competitiveness, social progress and ecological concerns, the phenomenon of shrinking settlements or regions is not of prime interest in Austria but it is more of a regional problem in some parts of the country. However, there have been efforts within the Austrian Conference on Spatial Planning ÖROK to address the issue of shrinking regions, foremost in rural context and in context of demographic change, in the past years; documented in e.g. ÖROK Series No. 171 on the functioning of public services in rural areas (2006), No. 176 on spatial scenarios (2008), or No. 181 on opportunities for peripheral areas (2009) (see ÖROK).

Not only strategies and instruments are important but also sensitization for the topic, common understanding, the collection of apparent fears as well as knowledge of the different interests on the different levels. The interviews showed that although there is a lot of skepticism between the different levels, there are common objectives. Also the local level is interested to have efficient structures but has of course more understanding of the necessity of a local context. While the national level sees the number of small municipalities as inefficient there are other ways in the eyes of the municipalities to save money and to keep alive the close interaction with the local population. Still the topic is given different priority to, as it can be seen in table 1. During the interviews it also became clear that not every region within the federal state that is experiencing population decline is dealing equally with the topic of shrinking. First of all this can be explained by the fact that not every region is equally effected by it and thus not have equal priorities, but to a certain extent this can be also explained by different mentalities in regions and of regional stakeholders. The interaction between the different levels and moderation in order to develop common ideas have been already advanced in the last decades but it seems further steps must be taken.

#### *4.2.2. Strategies and responsibilities*

In order to have more precise ideas on how shrinking and population decline can be managed the following section will present strategies and instruments that are currently implemented or conducted by the different levels. Additionally, potential instruments have been compiled, that are not yet implemented but might be thought of in the future or just are imagined by the different stakeholders. The interview partners of the different levels have furthermore been asked about potential stakeholders that – in their opinion – are able to implement strategies and instruments in the first place.

On a local level strategies for decline are clearly seen to come from the side of regional development policy. Our interview partners have told us that there is a further need to bring in certain innovations to peripheries in order to make the regions attractive again, as for example new job opportunities or educational innovations. Other instruments to tackle population change in peripheries in Lower Austria are those to increase the (physical) accessibility: There are ideas to re-install train tracks to give alternatives to the individual transport. The local level furthermore also sees its own population as an important factor for managing population decline. The inhabitants do have a certain responsibility themselves and need to be involved in managing the withdrawal of public and private services and infrastructures. Being integrated in the process of shaping one's own living environment is not to be seen negative though but more as a chance. Additionally the municipalities are trying to focus activities in order to become a more livable places, e.g. for families, but also for older inhabitants. In both interviews with mayors was a clear message that population decline has to be

handled also on the local level. Although the interplay of higher levels has been described as equally important and the communication between the different stakeholders was said to be essential. There was a strong statement that only the local level is able to deal with sensitive topics and to create acceptance since it is closest to the citizens.

On the federal level regional depopulation certainly was a concern by the planning department of Lower Austria already since years. The federal state has developed strategies in the last years that should help dealing with population decline and its effects in certain areas. Mainly the strategies are trying to implement the ideas of 'decentralized concentration' and 'inner-development' in order to bundle strengths and potentials (see table 1). Despite the planning department's effort in developing strategies the political will is not always strong enough to implement them consequently. Therefore we were told that the implementation might be easier if it was of national concern. The responsibility on a higher level than the federal one was imagined to be more efficient than it is now. So far several pilot studies were performed with quite successful results but not consequently followed up later on. One of the pilot study projects was the regional strategic planning ('Regionale Leitplanung') of the northern suburban area of the capital city of Vienna. This initiative will be presented in the next section since it appears to be a possible strategic planning instrument to deal also with decline. So far it has been only conducted in regions with population growth but it might be a fruitful approach for integrated regional strategic planning also in declining regions.

The national level is missing a formal competence for spatial planning. Accordingly, strategies and instruments express in rather informal, co-operative studies in which best practices are exchanged and communicated; e.g. strengthening small and medium-sized towns and fostering urban-rural partnerships as outlined in the Austrian Spatial Development Concept ÖREK 2011(see ÖROK Series No. 185). An important support for the operative regional and local levels is the provision of background data and research. Small-scaled population prognosis and thematic scenarios belong to the pool of instruments that should help the regional and local levels identifying development paths and setting appropriate policy measures. For the upcoming agenda 2015-2018, the ÖROK will install a respective so-called 'partnership'; a temporary discussion platform that brings together a wide range of actors who have a potential stake in managing shrinkage and secure service provision in foremost rural areas. From a broad perspective, also EU driven instruments may tackle the issue of urban and regional shrinking. ERDF-funded projects under Objective 2 or EAFRD-funded LEADER initiatives are close to the citizens (referring to CLLD-approach) and allow for innovative pilot studies.

The strategies and instruments for managing rural and urban decay, as well as the priority of the topic and possible responsibilities have been summarized in table 1. So far implemented strategies and instruments are generally ones that have been described above. It is still necessary to make clear the different as well as the common points of view within the federal state and on the national level. In the federal state of Burgenland where another interview was conducted, strategies and instruments are generally still very growth orientated. Population decline is perceived as a result of structural weakness that has to be abolished with regional development instruments. Lower Austria seems to have already a different view on the topic so that structural weaknesses can't be eliminated everywhere. The different perception in different regions as well as different instruments that are seen as successful tackling of population decline detect a certain need for the development of a common strategy as well as further communication and cooperation. A way of bringing together the different stakeholders and levels will be exampled in the following chapter.

Table 1. Selective list of strategies and responsibilities concerning shrinking – results of stakeholder analysis in Lower Austria

| **Level** | **Priority** | **Responsibility / Stakeholder** | **Strategies and instruments** |
|---|---|---|---|
| Municipality (LAU-level) | high | local/ regional | • reduction of shrinking (regional development)<br>  ○ innovations<br>• accessibility and mobility<br>• social activities (family-friendly infrastructures and services)<br>• civic engagement |
| Federal State (NUTS2-level) | high | national/ regional | • targeting general principles<br>  ○ decentralized concentration<br>  ○ strengthen potentials (central places)<br>  ○ inner-development<br>• strategic planning |
| National State (NUTS0-level) | low | national/EU | • ERDF and EAFRD investments;<br>  ○ LEADER; CLLD<br>  ○ EU Objective 2<br>• strengthen small towns;<br>• sustain local services<br>• ÖREK partnership<br>• Small-regional population and labour market prognoses |

#### *4.2.3. Strategic regional planning – an instrument for decline?*

Dealing with different implications and consequences of population growth and decline in municipalities in Lower Austria has been realized in the frame of the so called 'Regionale Leitplanung' (see Leitplanung Nordraum Wien), a new strategic regional planning instrument in the Federal State of Lower Austria. The idea behind the instrument was to coordinate population development on a regional level in order to regulate the settlement structure. The concept of Regionale Leitplanung partly fulfills Albrechts' and Balducci's criteria of strategic planning, Allmendinger's and Haughton's criteria of soft spaces as well as Healey's criteria of communicative planning. Its main idea is a collaboratively decided strategy for a certain tailor-made supra-municipal region between formal holders of competence (i.e. municipalities and federal state) as well as representatives and intermediary actors (such as regional management bureau etc.). A direct or pro-active involvement of citizens is not part of the concept which delimits the participatory aspect. However, information on the process is provided to the interested public.

In chapter 3.1 we already described that the Austrian municipalities hold the competence on zoning and settlement development. Municipalities are furthermore competitors when it comes to attract new inhabitants and businesses. Until today municipalities are generally able to decide autarchic – with some juridical restriction for example regarding shopping centers – on the development of new settlement areas or business parks. As a consequence areas are often chosen as settlement areas or business areas that are not appropriate (creating new costs in the exploration and maintenance, increasing traffic, and so on). The necessity of a regional agreement seems obvious, especially when it

comes to handling growth that is expected for example for the areas surrounding Vienna. Despite growth, also for other planning goals a regional strategic planning seems to be reasonable.

Proposed by the Federal State of Lower Austria, 25 municipalities bordering Vienna on the North decided to take part in the regional strategic planning initiative in order to create a structured settlement area. There has been 3 categories decided on to play a key role in the planning process:

- Settlement development
- Development of green spaces
- Development of business areas

Topics like traffic, although of great importance has been laid aside, in awareness that this might be a too conflicting issue to deal with. Within different stakeholder groups discussions and talks took place with the aim to determine statements and principles by all municipalities and federal state together.

According the settlement structure the big question was if there can be guidelines developed on where the expected population growth will be able to settle in the future and where working places should be concentrated. All municipalities together decided on all villages taking part in the process to be categorized in one of the following 3 categories:

- Regional Development Center
- Additional Center
- Village with internal development only

Population growth was determined to take place up to 90% only in the first 2 categories, as well as the development of businesses. The categories has been created with the help of statistical analysis, mainly based on accessibility and the provision of services and facilities. Strategies of focusing on inner-development and decentralized concentration have been thus realized with the regional strategic planning.

Since spatial development mostly unfolds in a diffuse pattern with some areas of growth or concentration and others with decline the instrument of Regionale Leitplanung would also be a feasible option for shrinking regions. Not only has the process led to a sensitization and acceptance of the municipalities through different discussion groups and workshops but also a regional understanding was developed and a comprehensive perspective on the topics of growth and decline was realized. In the region where the planning process took place not all municipalities are experiencing growth but still they have been able to understand that settlement development makes more sense at some certain places than at others. The successful operation of the strategic planning was not expected and was probably also fortune to some extent. Still it is probably worth to give it a try to also moderate sustainable decline in Austrian regions with the described instrument.

The instrument at least seems to be what has been required already – a tailor-made regional development strategy that is able to consider the characteristics and specifics of particular (rural) regions with all structural challenges, its regional history and cultural features (Leber and Kunzmann, 2006, 64). It therefore is able to tackle more complex socio-spatial phenomena, such as shrinking. In Lower Austria great interest was shown by regions with shrinking population to start the process of regional strategic planning. Unfortunately, so far, there is no budget to further elaborate these strategies, so the financial feasibility is again a constraining dimension. The general idea of Regionale Leitplanung would be worth discussing more in-depth in the upcoming respective ÖREK partnership (see chapter 4.2.2). If key stakeholders participating in the partnership get convinced, the instrument

of Reginale Leitplanung and similar approaches will have a future field of application in context of shrinking regions.

## 5. Discussion and conclusion

Although Austria's population is growing, processes of concentration towards urban agglomerations lead to regions with shrinking population and decline. Not only rural areas, also old industrial zones are showing decreasing population sizes, less economic activity as well as a thinning out in terms of infrastructure and services. In this paper we asked the question what planning can offer for those regions: which strategies and instruments can help to manage the decay and which stakeholders can possibly handle the situation in the context of the Austrian planning practice. During our research the question also appeared on the acceptance and awareness of the topic of shrinking among stakeholders and further more we wanted to know which role strategic spatial planning can take over around the issue of regional shrinking.

From the few interviews conducted it appears as if the topic of shrinking has been increasingly discussed in the last years, although achieving (population) growth is still the prime agenda concerning Austria's spatial development. Still, the awareness is rising and also the cognition that shrinking cannot be countered by regional development strategies everywhere is getting more established. For the planners and politicians that are directly confronted within shrinking in their own municipality it is difficult to acknowledge a decreasing population size as a lasting process. Especially since in-migration and integration for small-scale villages in an amount that would keep the population stable does not seem to be an option for many municipalities, coming back on the growth path appears to be difficult. It will be further necessary to work on sensitization and acceptance in order to create understanding of the process of decline. Cooperation of the different planning levels will has to be intensified. A further knowledge on demographic processes seems to be necessary on the local level in order to make clear how the population can possibly develop in the future.

Accomplishing acceptance will be most feasible on local level, close to the citizens. For the execution of greater political reforms as for example structural reforms our interview partners (except for the local level) have seen the national or even the level of the European Union as possible stakeholder, since the federal level (which is in charge of spatial planning in Austria) seems to be too little assertive due to political rationalities. From our perspective the regional level – i.e. between the federal state and the municipalities – is most appropriate to handle population decline. There is no statutory level of spatial planning at this scale but in sense of soft planning, it may be also an opportunity to do plan-making on such an informal, intermediary scale. Regional strategic planning has been performed in our case study region already, as described in chapter 4.2.3. This instrument holds promise to be also useful for developing strategies of decline; respectively for thinking growth and decline jointly. Additionally the interviews made clear that there are similar ideas on the different levels that need to be connected.

Before consolidated spatial consequences due to shrinking tendencies find entry into the statutory planning instruments like zoning plans, the strategic management and communicative preparation of solutions is better be organized within more strategic planning instruments first. The regionally divers coexistence of growth and decline within Austria may be an additional complexity for planning practice but at the same time holds much potential in terms of testing and applying various planning instruments under different conditions. This can foster the set of planning instruments and approaches. Shrinking and growth should be treated comprehensively since it is a question of both phenomena on where to invest and where to draw back.

Strategic regional planning offers further the common decision on focusing on central places to channel investments and to prevent the thinning out. Decentralized concentration as a planning principal is held up high in the Federal State of Lower Austria and which we see as important also in terms of social fairness. Social transfers will also in the future be necessary to cushion tendencies of shrinking. Further it must be recognized that spatial shrinking costs money. It needs public investment – sometimes more than managing regional growth – but efficient spatial structures will pay off in the long run. When it comes to physical consequences of shrinking, so far there is very little experience for conversion or reconstruction in the Austrian context. For handling population decline, socio-politically sensitive procedures must accompany the loss of services and infrastructures over time. Individual solutions will have to be found for small municipalities, as well as the encouragement of civic engagement will play a more pronounced role in the future.

***Acknowledgments:***
We would like to thank our interview partners – representatives of the Austrian Conference on Spatial Planning (ÖROK), the Federal State of Lower Austria, the Federal State of Burgenland, and the municipalities of Unterstinkenbrunn and Gaweinstal – for their willingness, time and expertise.

**WHEN NORMATIVE PLANNING FAILS SMALL TOWNS**

Andrei MITREA[1], Radu-Matei COCHECI[2]

[2]School of Urban Planning, 'Ion Mincu' University of Architecture and Urban Planning, Bucharest, matei.cocheci [at] gmail.com

**Abstract**: *Small towns, with populations amounting to less than 20,000 inhabitants, pose a disconcerting challenge to normative planning practices, mainly because of their dwindling financial resources and increasing democratic deficits. However, there are very few recent works that explicitly combine these two phenomena into simple conceptual models, useful for problem-oriented regional management. Against this background, we feel that there is a strong need for experimental approaches, aimed at developing supplemental instruments to normative planning.*

*Hence, our idea is simple: to develop an experimental, problem-oriented regional management model, aimed at replacing currently ineffectual normative planning practices for Romanian small towns. Therefore, we have constructed a model that links land resources available to municipalities to a more direct community involvement in matters related to public finance.*

*The model works in three stages, using a combination of local and regional scales. Thus, within a first stage, municipalities pool unincorporated areas at their disposal for joint projects, aimed at increasing budgetary revenues. In a second stage, each municipality uses these revenues for reforming their respective tax collection systems. After this financial exercise, municipalities then negotiate a set of regional amenities, which cannot be covered by direct local expenses.*

*The research behind this paper rests partly on an on-going background study, concerned with updating the section examining the settlement network within the Romanian National Spatial Plan. In addition, we have undertaken an extensive empirical study of 221 small towns in Romania, focusing on demographic, budgetary and land use analysis.*

**Keywords**: Problem-Oriented Regional Management Model, Public Finance, Negotiating Platform for Tax Reform

## 1. Introduction

Although more than 38% of Europe's population lives in small towns (DG Regio, 2011 *apud* Servillo *et al*., 2014), they are very rarely considered to be worthy subjects of research (Bell and Jayne, 2009). Unaided by continuous scholarly efforts, small towns generally need to focus on local solutions and capitalise upon their endogenous potential, mainly through strengthening their social and cultural networks (Austrian Institute for Regional Studies and Spatial Planning *et al*., 2005; Engel and Harteisen, 2012).

### 1.1 Policy Support for Small Towns

Governments generally consider supporting smaller towns as a necessary effort, for reasons related to efficiency, to equity, and to the failure of trickle-down mechanisms, especially within the countries facing a process of transition from a totalitarian regime to a democratic government, and from a

centrally planned economy to a functional market economy. In addition, some studies have unearthed a strong link between urban and rural development (Rondinelli, 1983). Against this background, small towns can work as focal points for rural development (Leeuwen, 2010).

Nevertheless, social and economic changes in recent years, along with the changes in agriculture and the reduction of transport costs, has led to a weakening of the links between small towns and adjacent rural areas, which tend to become better connected to larger cities situated at greater distances (Courtney and Errington, 2003).

Public policies targeting the development of small towns can be diverse and specifically tailored to different types of small towns, ranging from the ones located in less developed rural areas to the ones located in strongly urbanised and industrialised areas (Tacoli, 2004). Local development in small towns tends to be best served by two options: First, by policies focusing on slightly larger towns, with populations reaching or surpassing the 20,000 limit, in areas where employment in agriculture is above the national average. The second option is a set of policies stimulating the growth of service-based industries, accompanied by an active promotion of residential and business development and fostering locally grown business start-ups (Mayfield *et al*., 2005).

## 1.2 Aims and Scope of the Paper

Aim of this paper is to develop an experimental, problem-oriented regional management model, closely linked to possible public policy and spatial planning measures, that can aid the development of small towns in countries with rather obsolete, normative planning systems. This is the case of Romania's planning system, whose legislative flaws relate mainly to a lack of operationalization of the law's provisions and the lack of a coherent law on property rights (Ianăşi, 2008). The task of Romania's spatial planning field is thus harder than in developed countries, with the legal, regulatory and institutional framework evolving continuously during the past 20 years, struggling to redefine a new aim of spatial planning functions (Ionescu-Heroiu *et al.*, 2013).

Small towns are known to have a reduced resilience as they face economic decline (Austrian Institute for Regional Studies and Spatial Planning *et al.*, 2005). In the case of Romania, small towns have often been the result of a process of forced urbanization during the socialist regime, with a host of rural communities being declared towns between the years of 1945 and 1989. Centrally-planned industrialization was directly related to urbanization in the communist era, with small towns often considered to be mono-industrial and suffering from important economic decline (Dumitrescu, 2008). After the fall of the communist regime, public authorities continued conferring the urban status upon a wide array of communal seats (Săgeată, 2006).

Within the Romanian dedicated literature, small towns are widely considered to be the urban territorial administrative units with a population of a maximum of 20,000 people (Cucu, 1984). In theory, they can either act as a relay between middle-sized towns and rural areas, thus being a strong link between rural and urban communities. In reality however, most of them stagnate or face decline, as a result of their fragile socio-economic structures. There is a small proportion of small towns that fare better, mostly due to their location in peri-urban areas. In such instances, they have the option of enhancing either their touristic or their industrial functions (Zamfir *et al*., 2009).

While the structural problems of small towns in Romania are most evident, the current planning system lacks operational instruments for dealing with these issues. Consequently, there is a need for devising new models of intervention in small towns, besides the mostly ineffectual, building and

zoning ordinances, such as the General Urban Plans, and the local development strategies, which often propose development projects that require a great amount of co-financing from the local public authorities.

## 2. Methodology

This paper emerged out of a background study, commissioned by the Romanian Ministry for Regional Development and Public Administration in the summer of 2013. Following from the call for tenders, the study forms the basis for a future update of the fourth section of the National Spatial Plan, concerned with the settlement network.

### 2.1 Research strategy

While working on the background study, we noticed that most small towns do not really deserve the town status, as they lack most amenities necessary for an urban lifestyle. Pragmatically, Romanian legislation sets minimal standards for determining whether a given municipality deserves its urban status. If these standards are not met, the municipality is rural in character. This simple observation is most disconcerting, as most small towns, especially the new towns appearing after the fall of the communist regime, have not really earned their urban status. This implies a not very transparent political decision. Nonetheless, most small towns have ceased to fulfill their functions because of structural changes, i.e. the end of the industrialisation process and the subsequent declines in populations and income levels.

Hence, after a perusal of the dedicated literature, we started looking at the structural changes over the past quarter of a century. We then checked whether normative planning took these changes into account. Unfortunately, this was not the case. This was the final argument in convincing us of the need for a problem-oriented regional management model, which we present in this paper (*cf.* Löb, 2006; Janssen-Jansen *et al*., 2008; Alterman, 2010; Hoffmann-Axthelm, 2010).

### 2.2 Data Collection and Quality

We mainly worked with datasets provided by the National Institute of Statistics (NIS) and its online database. We obtained the relevant information on municipal budgets through the official briefings of the Ministry for Regional Development and Public Administration.

We have taken all datasets at face value, since a coherence and consistency check was nearly impossible, given their levels of aggregation. However, we did notice some inconsistencies, especially in demographic data, which we corrected whenever possible.

### 2.3 Data Processing

In order to assess the current social and economic situation in small towns in Romania, we concentrated on analysing population dynamics, the change in the average number of employees and the number of functional public hospitals, during the period between 1990 and 2012.

Furthermore, we undertook a budget analysis for the year 2013, taking into account the following elements: total revenue, total expenditure, revenue from own sources, pre-financing (EU funds), co-

financing and public investment. As a result, the overall profit, percent of revenue from own sources, percent of pre-financing from total revenue, percent of co-financing from total expenditure and percent of investment from total expenditure was determined.

Subsequently, we determined the likely impact of normative urban plans, by comparing the increase in built-up areas from 1993 to 2012. We then compared this data to the rise in number of dwellings between the same years, in order to determine whether the increase in built-up areas was justified.

We then focused on analysing available land, i.e. unincorporated surfaces, within the territorial administrative units of small towns (LAU 2). We accompanied this exercise with identifying the main categories of unincoroporated land under public property, at the national level.

## 3. Findings

There are currently 221 small towns in Romania, with a combined population totaling 2,195,038 inhabitants, i.e. about 70% of the total number of towns and cities, and housing approximately 10% of the total population.

However, the total population residing in small towns has diminished over the last two decades by about 8%, with individual values ranging from 52% to 141%, while the entire population of Romania dropped from 23,211,395 inhabitants in 1990, to 21,355,849 inhabitants in 2012 – a total decline of 7.99 %.

Thus, the decline in the populations residing in small towns accurately mirrors the national decline. Of the 221 small towns, only 34 have had a positive evolution in population of over 5% since 1990, most of them being located near large urban centres, especially around the capital.

Furthermore, between 1992 and 2012 the average number of employees in Romania's small towns has decreased by about 54%. Only 19 towns have had a positive evolution in this timeframe, with most of them having either a touristical function, or being located near larger urban cetres. Besides the economic decline, there has also been an important decline in the provision of social and health services provided: thus, between 2002 and 2012, 35 public hospitals have been closed in small towns, mainly due to under-financing from the central government, following the 2008 economic crisis.

Regarding the local authorities' budget analysis, an overall value of approximately 47% of the total revenue of these small towns comes from own revenues, i.e. local taxes (*cf.* Figure 1). The rest comes from state financing, under various guises, accompanied by a meagre share, of about 7%, of EU pre-financing revenues. However, individual values for state financing ranging between 8.11% and 91.16%.

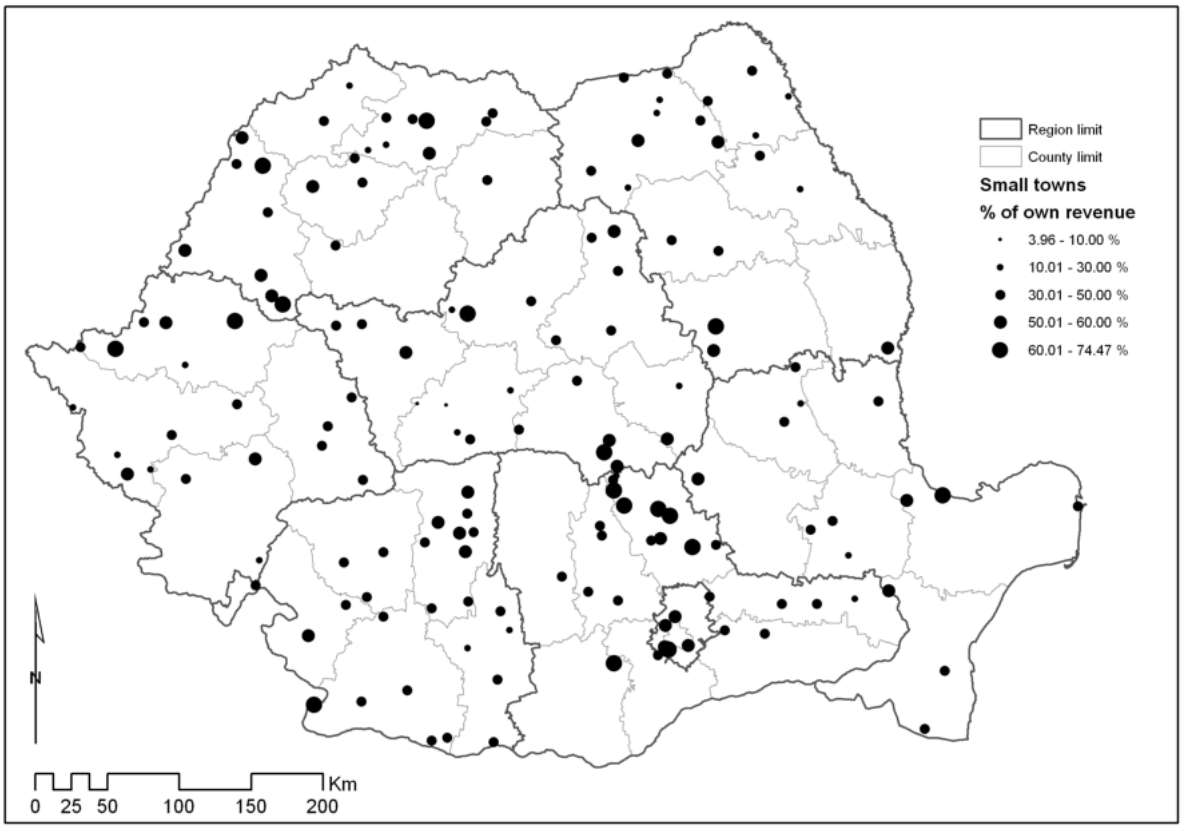

**Figure 1**. The Share of Own Revenues within the Budget of Small Towns
*Source:* The Authors.

As far as the expenditures are concerned, an overall value of approximately 14% are made of public investments, while about 10% represent co-financing of EU funded projects. These values illustrate the rather low expenditure of small towns in development areas and the fact that large amounts of funds are directed into areas such as education, healthcare, social services or public administration personnel costs (*cf.* Figure 2).

Table 1 provides a synthetic review of the main findings, with 93.67 % of the small towns in Romania having under 30 % of their expenditure dedicated to public investment.

**Table 1.** A Budget Analysis for Romanian Small Towns

| | **Percent of Own Revenue from Total Revenue** | **Percent of Public Investment from Total Expenditure** |
|---|---|---|
| **Total Value** | 47.36 % | 14.04 % |
| **Maximum Value** | 91. 89 % - Otopeni | 0 % - Calafat |
| **Minimum Value** | 3.96 % - Negreşti | 70.34 % - Călan |
| **Values under 10%** | 2 small towns | 115 small towns |
| **Values between 11 and 30%** | 28 small towns | 92 small towns |
| **Values between 31 and 50%** | 107 small towns | 8 small towns |
| **Values between 51 and 60%** | 54 small towns | 5 small towns |
| **Values over 61%** | 30 small towns | 1 small town |

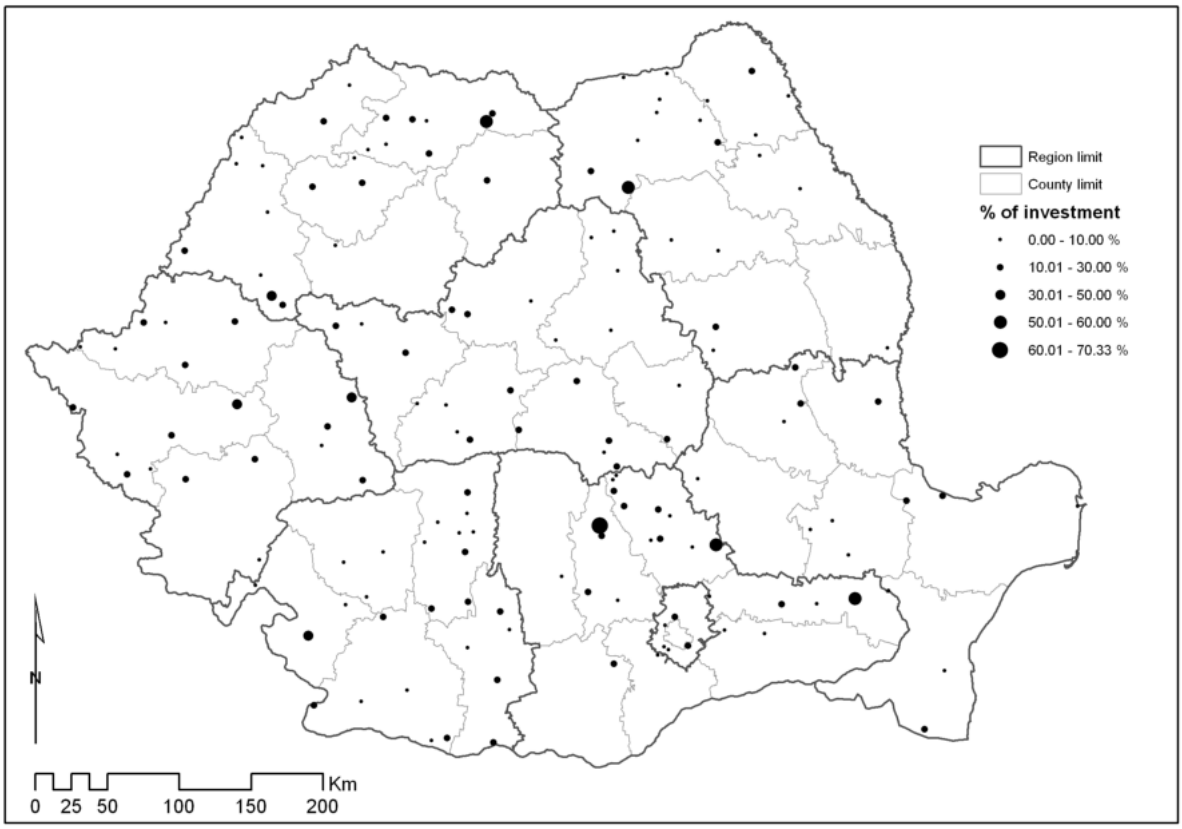

**Figure 2**. The Share of Investment Out of the Total Revenues
*Source:* The Authors.

The reliance of small towns on own revenues has very often determined the gradual incorporation of more and more lands in the built-up areas, in the hope of increasing the taxes collected by the municipality.

This is reflected by the fact that normative urban plans in the last twenty years have produced an average expanse in the regulated built area surface of small towns of approximately 115%, which was meant to be dedicated to real estate investors. However, these investors failed to materialise, since the overall increase in the number of dweelings between 1990 and 2012 amounts to only 14%. Nonetheless, repeatedly increasing the built-up area essentially means that the scope for extensive growth has been exhausted.

## 3.1 Two Types of Planning Responses to the Question of Small Towns

Basically, there are only two types of response that the planning system can offer to this state of affairs described above: firstly, planning authorities can establish land use patterns through normative plans, and secondly, the ministry can attach financial mechanisms to the spatial development strategies it produces.

The first type of response is in line with the orthodox perception of the role of planning. Within this perspective, planning is regarded to be a set of procedures, a process of determining future actions

through a sequence of choices (Davidoff and Reiner, 1962). Spatial planning has, on the one hand, a regulating function, as government authorities need to authorise some activities, and, on the other hand, a development function, as different structures need to develop instruments for providing services and infrastructure, determining directions for urban development or protecting natural resources (United Nations, 2008). These planning instruments can be further divided into four categories: national policy instruments, strategic instruments, framework instruments and regulation instruments (European Commission, 1997).

The second type of response revolves around financial mechansisms. These, in turn, are financed by structural funds, which yield to the priorities of the European Commission.

However, neither approach has yielded significant results with regard the development of small towns. This is evident from the data regarding the decline in the average number of employees. Moreover, normative planning has been used mainly as an instrument to increase built-up surfaces in order to increase tax revenue, while the financial instruments set in place for strategic planning have often failed because of issues related to the amount of co-financing the cities can afford.

However, small towns still have valuable land resources, with 91.56% of their territorial administrative surface consisting of arable land, forests, pastures, vineyards etc. As a result, if we take into account the available pool of unincorporated areas in public ownership at national level, it amounts to 6.37% agricultural lands, 50.43% forests and 27.32% unproductive lands. Thus there is ample room for leasing land to development projects.

## 3.2 A Third Type of Response: The Management Model

Following from these findings we have constructed the conceptual model presented in Figure 3. It consists of three stages, which work as follows:

- The first stage implies a financially determined co-operation between municipalities. This co-operation seeks to involve municipalities either in common projects yielding high returns or, if this option does not prove feasible, their integration within existing commercial micro-financial cycles. Within this first stage, municipalities pool some of their available unincorporated areas for larger-scale projects, such as bio-energy production;

- Within a second stage, the initial capital thus formed is transformed into a negotiating platform for tax reforms, between administrations and their communities. A simplified tax collection system should revolve around an inclusive tax based on the concept of the urbanised area consumed by users. The urbanised area should contain all costs incurred by the municipality in the process of urbanisation. Repeated rounds of public negotiations ensure community involvement;

- The third stage implies a reactivation of the regional dimension. Thus, based on the previous negotiations, municipalities decide upon how many amenities can be provided from local taxes, and how many need regional co-operation or applications for state financing.

The most important point to be stressed however is that a problem-oriented management is logically possible, and, furthermore, that it can partially compensate for failures within spatial planning practices, at least until the planning system adjusts.

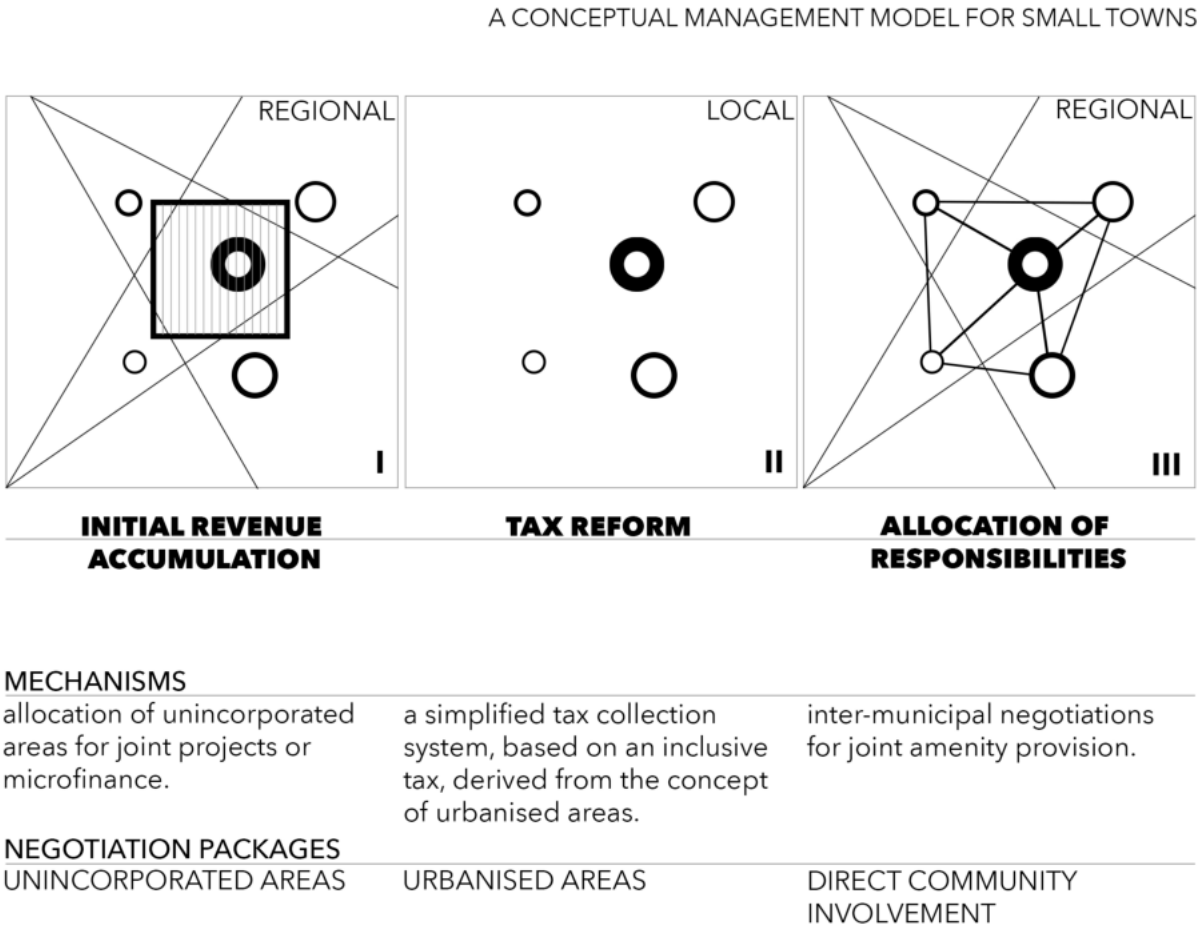

**Figure 3**. A Conceptual Management Model for Small Towns
*Source:* The Authors.

## 4. Conclusions and Open Questions

We set out to construct our model on a very simple question: How should municipalities react in times when money is scarce? The exercise proved highly rewarding, as it resulted in some new perspectives:

- First, by perusing the literature on the subject, we learned that there are very few authors who systematically engage with the relationship between spatial planning and municipal taxing systems, especially in the case of small towns;

- Second, by trying to construct a planning model centred around budgets, we found out that there is very little detailed data to support a complex model. This means, on the one hand, that there is little academic interest in such data, and on the other, that all current models should limit themselves to general assumptions, thus making them understandable to the public administration and to the general public alike;

- Finally, we became aware of the explicit ways in which the regional dimension becomes indispensable to local development, in the case of small towns.

Generally, questions regarding small towns have been addressed either in terms of demographic and economic profiles, or in terms of urban functions. However, there is little detailed research available on the topic of municipal finance in small towns. Similar to other European countries, municipal finance in Romania is subject to equalisation payments. The stated rationale for these payments is an offset of regional imbalance. However, when this dependence is significant, municipalities tend to become vulnerable to political pressure. Therefore, a higher degree of political immunity works as a strong incentive for municipalities to increase the share of their own revenues within their budgets.

This is essentially a question of tax reform. But given the fact that very few municipalities have the initial capital to start such a negotiation with their respective communities, there is a need for co-operation at the regional level within projects with high returns on investment. Thus, when viewed from this angle, the regional dimension to local development is determined financially.

There is, however, an additional local dimension to it: the need for a simplified tax collection system, which should link urban users to the public administration, via an inclusive tax on urbanised areas (*cf.* Hoffmann-Axthelm, 2010). In principle, this solution is possible. However, the following questions will need to be addressed:

- How much of the traditional tax collection system can be streamlined, in order to produce a single, transparent tax on urbanised areas?

- What is the degree of non-financial compensations that has to be allowed for in such a management model?

- And, most importantly, how open are normative planning systems to such experiments?

Keywords: disperse urbanization, urban-rural fringe, regional policies

**Abstract**

*In 2003, the State Government of Santa Catarina State, Brazil, launched a new decentralized administrative network, aiming to balance development in different regions of the state and to avoid a significant decrease of population in small and medium cities of the hinterland with a strong migration towards the seaboard's cities. Nevertheless this action was not followed by an appropriate political and institutional framework linked to strategic goals for the vitality in most regions of the State. Those strategies should involve the creation of structures: to reproduce the local workforce, to improve the capital circulation system, to improve the quality of people's livelihood, for the sustainable use of the environment, to inter institutional cooperation, among other things. Within this context, this work sought to follow the development of the Far West Region of the Santa Catarina State in the last twenty years, marked by a complexity of urban-rural interactions, an important urban dispersion process and slight population shrinkage. In this region a "periurbanization" process arose creating newly dispersed urban settlements within the rural environment, with an unplanned and diffuse morphology developed by unconnected stakeholders. This paper's aim is to analyze the change in territorial patterns and its effects due to both political and socioeconomic factors, and point out weakness and gaps that make the regional balance difficult (in terms of population density, infrastructure and economic issues) and its socioeconomic equity.*

## 1. Introduction

The urban and rural are constant objects of study in the social sciences due to contemporary social changes. Consequently, the rural and urban concepts have had a mutant character in the last fifty years. If in the 1950s agricultural activity was needed in the countryside and the city was characterized by the existence of industrial activities and services; in the 1960s and 1970s the rural appears as the territory which will house an irreversible urbanization, confirming the fate of an urban-rural continuum (Mathieu *apud* Bernieri, 2002, p. 23). In the 1980s, the economic paradigm shifted due to globalization and brought ambiguity to urban and rural concepts. On the one hand it reinforced the concept of the rural through their productive and environmental characteristics and the local/global debate encouraged an endogenous development, while the rural concept seeks to mitigate differences with the city within a "productive liberalism" (Bernieri, 2002).

In this context, this article seeks a reinterpretation of the concepts of the urban and rural, trying to characterize the process of territorial occupation and structuring of the urban network of the Far West of the State of Santa Catarina region, Brazil. This study may provide an opportunity to

discuss topics of more general scope as the "urban sprawl" and the "demographic mobility" in its different manifestations and scales.

The Far West of Santa Catarina houses an economic dynamism focused in agriculture and agribusiness (swine, poultry and dairy cattle) and their related productive chains, as well as an increasing expansion of the tertiary sector, especially polarized by cities such as São Miguel do Oeste and Dionisio Cerqueira (Figure 1). The dynamics of economic output in this region are characterized by the interdependence between the urban and rural, and between family farms and agribusiness. Here we will report specifically the case of the city of São Miguel do Oeste and municipalities polarized by it. The effects of the intensification of the urban-rural interaction are seen on the reorganization of activities and its consequence on both, on the urban spatial restructuration and on the composition of the regional network of cities, causing structural changes in the intra-urban and interurban scale as well in the rural environment.

## 2. Diffuse Periurbanization: building a concept

Nowadays, regional planning science overpasses the urban-rural divide. One of the most obvious aspects of this bridge in contemporary capitalist society are the landscapes of urban and metropolitan edges, marked by the unbounded extension of the urban-rural territory developed as a model that combines functions and is able to reorganize the territory, producing these different territorial contexts within the globalization and economic neo-liberalism logic (Baldini, 2008).

Apart from this dichotomy, the center-periphery model no longer meets the dynamic construction of the territories that unfold nowadays in urban fringes. Today, heterogeneous, expansive and diffuse territorial structures that go beyond legal urban perimeters are driven by an economic policy that facilitates industrial dispersion and the strengthening of a higher tertiary beyond the urbanized territory. In this context the urban, periurban or metropolitan landscape becomes dominated by large enterprises that will structure the main socio-spatial relationships, many times overwhelming actions of State and local solidarity networks (Queiroga, 2004).

Thus, the construction of an analytical structure of space "extra-urban" (peripheral, "rural-urban" or even metropolitan) requires an understanding of both the multiple connections that insert the different territories within the context of a globalized world, and the understanding of different forms

that stakeholders build and establish their dialogues with the natural, rural and urban world. Specifically, the marks of the contemporary processes of change in urban networks in Southern Brazil arouse particular interest, since its conformation results from a peculiar way as the urban agglomerations and productive structures have been built in the region.

The extensive study of Reis Filho (2006) on the characteristics of urban sprawl in São Paulo can be a starting point for an understanding of the political-economic and infrastructural conditions that have defined the territorial profile of the cities of south-central Brazil and in particular the southern region, which includes the micro-region of São Miguel do Oeste. In that study, Reis Filho shows that the expansion of areas "perimetropolitanas" have been reorganized on the basis of communication networks, especially the mobility system with the creation of new automotive arteries as well as increasing the efficiency of those already existing.

The new urban networks settings are no longer only guided by the periphery-center duality, but also between "peripheries", which allows "inter-regional" accessibility. The immediate consequence is the regionalization of the labor market and the decentralization of industrial plants, followed by residential and tertiary decentralization. This model also implies a mix and fusion of economic functions and activities in the related reorganization of the rural and urban (Baldini, 2008). Although traditionally the city is moving forward and penetrating the rural territory, modifying its original agricultural vocation, cases should be noted where depopulation induced a resumption of urban areas with agricultural functions[1].

Another important approach needed in this argumentation are the concepts of "diffused city" and "urban sprawl". The notion of "diffuse city" was defined to qualify peri-urban areas of the Italian region of Veneto by Francesco Indovina in 1990. Since then, the term has been appropriated by various authors to characterize different situations (Grosjean, 2010). Grosjean (2010) proposes possible and significant territorial characteristics that can suit link the use of the terms "dispersion and diffusion" to the complex structures that define them.

A first aspect noted by the same author relates to the exponential spread of mobility and communication in the regional space, which takes away the dominant aspect of polarization of the urban centers. The second point is the lack of planning on this scale (which can also indicate the absence of the State) and the great spatial fragmentation, resulting in a territory built according to different and competitive rationales. The third important feature highlighted in the "urban diffuse territories" is the absence of centrality able to organize displacements and infrastructure. This leads to the fourth point, which is the isotropy of the network with multidirectional relationships. Finally, the character of low density on land use, showed by different configurations and functional accommodation expressed on territory by the urban-rural mix (Grosjean, 2010).

## 3. Santa Catarina – between urban sprawl, rural shrinkage and rural industrialization

Regarding its process of colonization, the State of Santa Catarina State is unique in Brazil, showing a balanced net of cities and well shared spatial distribution of the population up until the last decades of the last century. Mainly due its fragmented geography, the State of Santa Catarina had an occupation pattern characterized by a “small proprieties rural structure” and by an absence of an

[1] Flaminia Paddeu (Encouraging urban agriculture: land-use planning innovations in Detroit) and Joe Schilling (Emerging Networks of Urban Greening NGOs in Shrinking Cities) papers presented at City Futures, Paris, 2014, showing as new urban agriculture movements are taking care of shrinking areas in USA.

"urban pole" with a broader coverage. Within this structure, independent and diversified economic regions emerged through the State territory (Siebert, 1996).

Despite this welcome economic diversification, the lack of roads infrastructure and the geo-economics fragmentation kept the Santa Catarina cities isolated from the more dynamic centers of the country until the middle of the 20th century. By this date the development of the road system in the State had increased the connection between West and East, including in the State's economic flows areas previously excluded, and also facilitating the population flows. Road improvements along the coast also changed the economic State trends, pushing city developments by a reinforcement of the tertiary economic sector (Pereira, 2003) and increasing the tourist flow to the seaboard, impacting the cultural and behavioral local patterns.

The significant migration towards the seaboard also caused an important decay of small scale agriculture in the centre-west (Pereira, 2003) and expanded the coastal cities periphery towards rural areas. On the other hand, it allowed a good diversification of productive activities that embraced several successful local productive arrangements within the State (Turnes, 2008).

Due to concerns about the migration towards the seaboard, in 2003, the State Government launched a new decentralized administrative network, aiming to balance development in different regions of the state and to avoid the significant decrease of population in small and medium cities in the hinterland. However this action was not followed by an appropriate political and institutional framework able to link economic strategic goals to spatial aims that would rebalance territorial occupation, increasing the economic vitality of the region with a better share of educational, cultural, leisure and basic health services (Moraes, 2006).

In this context, different processes promoted by both the private sector and the State, led to the expansion of the cities network, and metropolization process occurred in Santa Catarina regions. Near the Atlantic Coast, where the economic dynamic was stronger, the process was characterized by a socio-spatial structure with the emergence of bigger urban poles, and with more complex urban-rural interactions, contrasting dynamic economic regions and shrinking rural regions. Away from the coast in the west of the State, economic issues delayed urban development while maintaining the primarily rural economic base, reducing population growth and increasing migrations index (Siqueira, 2010).

In spite of this delay, the less dynamic regions such as those in the west, displayed in the last three decades a steady economic performance, due mainly to the major agro-industries of the State. Since the 1980s, the neoliberal national policies have changed the economic scenario for the small and familiar agricultural producers of Santa Catarina. , since they were not prepared for the new productivity levels (Rodolfo and Teixeira, 2011). At the same time, the growth of the agro-industries had a positive economic performance.

Those economic changes due to a "productive modernization" have induced important changes in the populational index in the west. Singer (1990) relates strong migration flows due to new capitalist order, where a share of the inhabitants has their capital influx lost and migrate to new opportunities in more dynamic regions. This process was observed clearly in the west of Santa Catarina, where many authors identified a populational shrinkage due to the relationship between family agriculture and agro industrial complexes (Silva *et al*, 2003 and Mattei e Alves *apud* Rodolfo and Teixeira, 2011).

This scenario changed the previous well-structured network of cities, creating new urban settlements close to large cities, in its limits and near major roads, as a transition border between the urban and rural environment. Within this context, a new environment emerged transforming the urban-rural edge in an unplanned and diffuse urban territory, disconnected from basic infrastructure offer, and developed by disconnected stakeholders. The new developments had several impacts (social, economic and environmental) on the previous rural and urban (peripheral) communities due to the lack

of a spatial restructuration able to promote better tertiary activities, which could be polarized by basic urban services.

## 4. The Far West of Santa Catarina: a peculiar region

The Far West of Santa Catarina is a peculiar region in the country due to its colonization process, its current economy and to its urban network configuration. This urban network consists of 19 small towns (under 40,000 inhabitants) and low levels of urbanization (Figure 2 and 3). According to the IBGE (2010), 13 of these municipalities have the majority of the population in rural areas. The industrial and service sectors have significant importance in some cities, and the predominance of small plots in rural areas differentiates this agricultural region from others in the country dominated by extensive land proprieties.

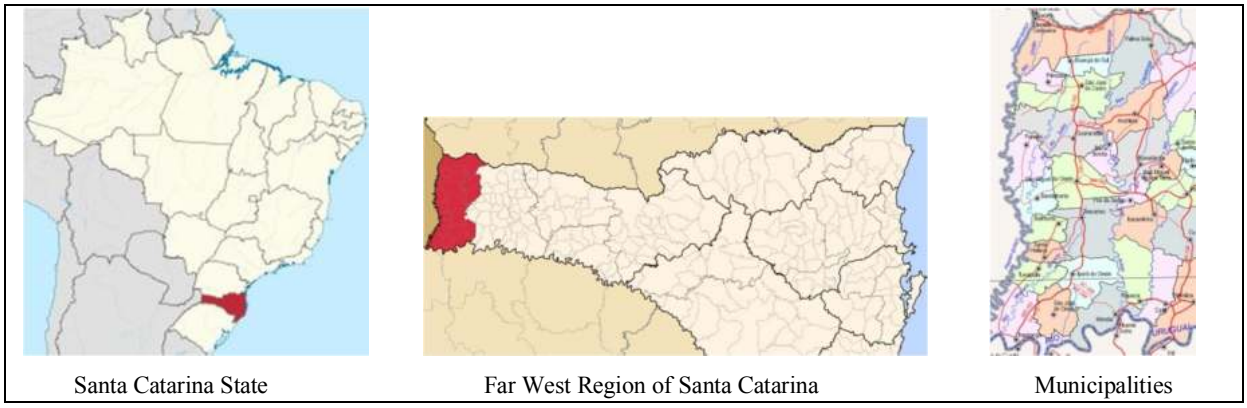

Figure 2 – Far West Region of Santa Catarina State. Source: fecam.org.br

Figure 3 – São Miguel do Oeste City and satellites cities.
Google Earth, 2015

Until the 1940s, the region was predominantly used as farms for livestock that supplied the regions of Paraná, Minas Gerais and São Paulo. In that decade, subdivisions and big estates appeared due to a land granting process started in the nineteenth century to farmers willing to promote the occupation of this region of the country. Also, in that decade, a "corporate colonization" began with the installation of small farms, modifying the peasant way of life in the region (Bavaresco et al, 2013).

Moreira and Medeiros (2006) report that colonizing corporations of that period created a land structure in which each property was usually composed of lots sized at most thirty hectares and counting on the participation of members of the family of settlers in territorial planning. The production process was carried out by settler, itinerant or nomadic agriculture (a land rotation system). Production for family subsistence was the priority; later the production surplus was exchanged with local home business for other products unable to be produced on the farm, thus creating a dependency with the urban merchant. As the exchanges were not paid in money, the farmer had a system of credit or debit sales, with prices dictated by the merchant. So began the dependency between the farmer and the merchant, between the rural and the urban.

At the end of the 1960s, agribusiness multinationals (seeds, pesticides and machines) began to be present in the countryside, marking the start of a modernization process in the Far West of Santa Catarina State. The date is also marked by the indebtedness of small producers seeking to follow this modernization investing in inputs. In the following decade agribusiness created a small producer dependency system (called "integration system") where the costs of the inputs from big enterprises was deducted from the sale of the final raw products (pigs, wheat and soy) for the same enterprises, dissolving the self-sufficient mode of production adopted in colonization (CEAG / SC, 1980, p. 74 *apud* Bavaresco, 2003).

So, in this period began a gradual change that brought settlers of small properties close to so called "modern industries," a new, more urban, reality, with technological, mechanical and informational innovations, and waged labor. (Saquet, 2010). Abramovay refers to this reality as the "New Rural", where many non-traditional activities are carried out in the countryside, such as industries producing new agricultural inputs, services and entertainment activities. Thus, the countryside is no longer linked only to agriculture, and more and more inhabitants are binding on the tertiary activities (Abramovay *apud* Endlich, 2010), breaking the countryside traditional features linked to specific productive relationships, industry at artisanal stage, incipient division of labor, population dispersion, neighborly relations and identity in the villages and districts.

Nevertheless, it is important to note that the development of agribusiness played an important role in the regional working force development and on the cities network organization (Fujita et al, 2002), because they have articulated a productive chain that includes several branches: logistics, mechanical engineering, furniture, packaging, cold rooms, biotechnology, equipment and others. On the other hand, nowadays the relationship between the small producer and agribusiness is that this is the only access to the international market. As this is a very limited access, the producer has become a hostage of the internal market. Their alternative for overcoming this economic insecurity is looking to the urban market where they will find more dynamic labor conditions.

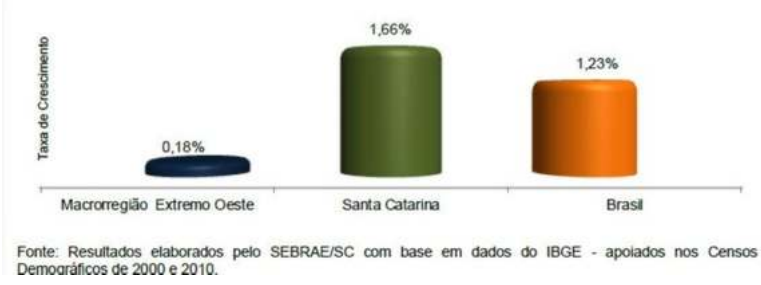

Figure 4 – average population growth index.
Source: SEBRAE, 2013

This may explain the population reduction in the region, where the population growth index is quite below the national and State average. In the last fifteen years, many municipalities have lost population or stagnate. Between 2000 and 2010, while the population in Santa Catarina State grew 1.66%, in the Far West of the State growth was only 0.18% (Figure 4) (IBGE, 2010). The mechanization of agriculture, added to the loss of rural land to urban areas are possible reasons for the population stagnation in the region. In spite of not many new enterprises are created between 2006 and 2011, the number of jobs growth significantly. At the same time, data from 2010 shows a bigger participation of rural dwellers in the regional economy (Figure 5 and 6). These observations may indicate also that a share of rural dwellers is actually working in urban (transformation industry, services or commerce) jobs or indicate that urban workers have been seeking the countryside for housing.

## 5. The Current Urban-Rural Relationship in Far West Region of Santa Catarina

In the last half century there were important changes in Brazilian cities, at the intra-urban level as well as in the urban network, with an expansion in the growth rate and the number of cities. This reality promoted the redefinition of some roles, since there is a concentration of functions in some cities while others have lost functions due a new technical, social and territorial division of labor within a diverse and complex urban network (Bernadelli, 2010).

Specifically in the Far West of Santa Catarina, some cities have had a gradual increase in industrial activities as well as a diversification of trade, boosting the consolidation of urban centers as São Miguel do Oeste, the largest city in the region with 88.31% of its 36,306 inhabitants in urban areas (IBGE, 2010). However, the region's economy is still dependent on the primary sector -

agriculture - and its agro-industrial local value chain. 1991 data (IBGE, 1991) shows how this region is marked by small farmers, where 75.19% of farms have between ten to twenty hectares, favoring the occupation of a regional work force in rural areas.

Nevertheless, since the 1980s, the demand for rural labor has decreased due to the increasing modernization of agriculture, industrialization and urbanization. This low labor demand also instigated a part of the rural population to migrate to larger centers in other regions, or to seek insertion in the urban environment through commercial and services jobs (Veloso et al, 2005). In this context, the urban network of the Far West of Santa Catarina is currently marked by the relationships established between the small cities (that arose as complementary to them) and between cities and their now diversified countryside.

In Brazil, the official "urban condition" is linked to legal, economic and political criteria. The municipalities have autonomy to define the physical limits of their urban areas by their own criteria. As municipal taxes in Brazil are collected in urban or urban expansion areas, and the federal taxes in rural areas, it is easy to conclude that the expansion of the urban area increases municipal tax revenues. However for a certain area be considered urban the municipality has to provide infrastructure facilities, such as: I - curb or pavement, with rainwater channeling; II - a water supply; III - sanitary sewage systems; IV - a public lighting network; V - a primary school or health center within a maximum of three kilometers. (Federal Law n° 5172 of October 25, 1966 - Article 32, paragraph 1). Thus, by extending the areas of urbanization, the municipal power often causes the retraction and disqualification of rural areas, as these services are denied to rural conditions. (Wanderley, 2009). Specifically in the Far West of Santa Catarina, urban-rural relations with asymmetries and discontinuities in supposed complementary relationships can be observed.

These asymmetries can be highlighted as opposing the housing conditions of the rural workers of small farms with the new real estate projects aimed at the middle and upper class, which accentuate the dispersion of industries, retail and services between small towns and countryside. However, in spite of many Government initiatives aiming to keep the "family farmers" on their land, an illegal process of land subdivision aiming to expand urbanization is going on in the region along with the municipality's complicity. The former thirty hectares colonial estates in rural areas began to be sold to major real estate corporations and changed to second leisure homes for the economic upper classes, even though the Federal rural legislation allows subdivisions for estates in rural areas for urban land use, only in exceptional cases[2].

While decent housing, with access to all basic public services, is only recently and gradually being achieved by the rural population through specific governmental housing programs (Sordi, 2006), the occupation of non-urban areas by projects with good infrastructure is indicative of an increased presence in rural areas of urban-origin residents. This may indicate an increase in the capacity of rural areas to provide comfortable living conditions, including so-called "modern amenities" (Wanderley, 2009). Also, the rural communities may benefit from the dispersion of urban activities in the countryside, since the new links between the urban and rural increase the access to jobs, goods and services within rural areas. The development of these new net of services tends to reflect the demands

[2] Instrução Incra nº 17-B - 22/12/80:The land subdivisions with urban purposes, outside the city limits must have the prior consent of INCRA (National Institute for Colonization and Agrarian Reform) and can only be approved if the area is a) by their characteristics and situation, are opportune for the location of community services in rural areas surrounding (b) of urban expansion or specific urbanization defined by the Master Plan or regulatory Municipal Laws (c) officially declared a tourist area or characterized as a health resort or seaside, (d) has demonstrably lost their productive characteristics, making uneconomical its agricultural use. This proof must be made through report signed by a qualified technician submitted by the owner or by the Municipality, being the INCRA to investigate its veracity (Silva, 2012. p. 326).

of agricultural households indispensable for their families to remain in the countryside such as electricity, water systems, and recently, an internet connection.

In the studied region, due to the proximity of the rural and urban areas, and due the multiplicity of small towns, there is a strong regional interconnection between rural and urban spaces, facilitating a "regional" structure of life, contributing to setting up a different conception of distinguishing rural and urban spaces. In this sense, as observed in our field study, a holiday home for leisure, a new road in the countryside, a mall along this road, are elements of a "new urban fabric" that is not restricted solely to the built-up area of the city.

## 6. Conclusion

Not different from several regions in Brazil and around the world, the bigger and growing cities keep attracting rural populations away from low paid agricultural jobs and from a precarious lifestyle. Notwithstanding, several infrastructural improvements and the diversification of activities in the urban-rural fringe generates a "counterurbanization" of population as wealthy urban dwellers choose to live in rural areas around the cities and commute to work.

In the region of São Miguel do Oeste, this regional dynamic is evident, and it is controlled by four main stakeholders, which do not always share common goals.

Firstly, there is the Federal and State Governments who promote diverse programs such as housing, production (qualification and product diversification, encouraging agro-ecology and rural tourism) and infrastructure for rural residents, in order to avoid rural-urban migration.

The Municipality appears as a second actor, concerned more about the expansion of the urban context for increased tax collection. Thereby, municipal laws aimed at simplifying the implementation of projects in rural areas (often dodging federal laws), ends up changing the character of the area and making room for a scattering of urban activities in rural areas.

Thirdly, there is the agribusiness, which promotes the dispersion of industries in rural areas. On the one hand the agribusiness expansion brings new employment opportunities and development for defined areas; on the other hand it submits the small agricultural producer to an economic dependence that encourages rural-urban migration.

Finally, the real estate market, which seeks to take advantage of the infrastructure implementation by the government and industrial dispersion in the countryside, buying agricultural land and turning it into leisure residences for the more privileged classes. Thus it acts both in stimulating rural-urban migration, as in the urban-rural one.

The end result of the convergence of actors seems to be especially perverse with small-scale agriculture, as local political and economic forces do not create appropriate strategies that could increase and facilitate their rural activity as well their everyday life quality, stronger enough to avoid rural workers migration. On the other hand, Federal government programs of productive diversification and a more balanced and widespread distribution of basic services (education, health, and infrastructure) by the municipalities of the region could place the small farmer as a potential key element for regional development in a changing economy.

Therefore, a preliminary analysis shows that it is essential to improve the quality of life for family farmers who are reliant on public policies aimed at expanding the countryside citizenship beside policies for productive diversification. Making attractive and qualified "periurban" areas, with decent homes and adequate public services can transform the region as a whole, boosting the economy and environmental sustainability. Today this reality is made possible by the mobility and accessibility to the countryside. One should not however consider those improvements as a strategy to requalify

the rural, because the choice of country life should not mean the renunciation of goods and services, which were previously identified as urban.

Nowadays, to develop possibilities in territorial planning and management policies it is important to understand territorial structures and their key components. The policies have to deal with the socio-economic and territorial complexity of rural and urban spaces, intertwined in urban and metropolitan fringes. This article sought this understanding through the observation of territorial relations, which can be references in the constitution of new development paradigms of urban areas on the countryside and on the periphery of large Brazilian cities and metropolises.

# Research on "The trinity model" of the implementation of traditional village planning ——A Case Study of the Traditional Village Clay Figure Wang in Wuhan City

Ning JIan[1], Shuai Yue[2]

[1]College of Architecture and Urban Planning, Huazhong University of Science and Technology, ningjian71@126.com

Keywords: Traditional Village, Planning and Implementation, Trinity

**[Abstract]** *Traditional village represents the root of the Chinese culture and essence of the agricultural civilization, it is an organic combination of material culture and non-material culture which bears the value of history, culture, science, art, social and economics. In recent years, due to external influence and internal imbalance , Chinese traditional village has stepped into a "hollowing out" recession, the number of rural population is declining sharply, and economic development is faced with stagnation. Besides, the traditional village culture is waning. For better conservation of Chinese rural cultural heritage and promotion of the re-construction of beautiful villages, a sustainable plan to protect traditional village is attracting more attention.*

*Based on domestic and foreign case studies, this research attempts to establish a "trinity model" of planning and implementation which covers and unites three aspects: supervision,*

*operation and self-organization mechanism for village conservation. This paper in detail elaborates the framework and contents of this model, and rambles on the dominant roles of government, developers and villagers in the revival of traditional village. Specifically, government's regulation is the guarantee of sustainable development, developers' business operation is the driving force, and villagers' self-organization is the endogenous force for future development of the village.*

*Case study selects the traditional Village Clay Figure Wang in Wuhan City, as one representative of first batch of traditional villages in China, it has maintained a lot of intangible cultural heritage, and it is the cradle of clay sculpture making skill in Huangpi, which has a history of 1400 years. This article embarks from the village cultural inheritance, by analyzing the different functions and inter-reaction of the various roles in the revival of traditional village, to provide the revival of intangible traditional village culture with a practical planning implementation system.*

## Introduction

Chinese Traditional Villages are the essence of Chinese farming culture，different with the general rural settlements, it carries a large amount of material cultural heritage and intangible cultural heritage of organic cultural settlements. In 2012, the Chinese government established the Traditional villages in

protection and development of the expert committee, and put forward the cultural concept of "traditional village", with all over the country launching the protection and census of traditional village, the protection work of traditional village has been mentioned to a new historical height. In china, facing the rapid development of urbanization, the traditional village at the object edge of protection and development. In the actual process of the planning management, due to the lack of support of the typical cases of successful practical planning and enough founds, a mass of traditional villages are facing the dilemma of empty nest and cultural decline. Based on this, this paper mainly discusses the cultural specificity, starting with main-body participation in the process of implementation in the process of planning and management, focusing on the separation of power in the process of management. Effective collaborative relationship can promote the implementation of the protecting traditional villages, to ensure the sustainable of the village development Anderson protection.

## 1. Analysis of the problems on Planning and implementation of Chinese traditional village

### *1.1 multi-lead planning management and the regulatory standards lag behinds*

Because of the traditional village protection planning practice in China is emerging relatively late, the building of legal system has lagged behind, and protection work is also a multi-management issues. One hand, the township construction planning, natural heritage conservation planning are managed by the Ministry of Housing and Urban-Rural Development, the intangible Cultural Heritage managed by the State Administration of Cultural Heritage, and the Intangible Cultural Heritage is managed by the Ministry of Culture. However, as a material and non-material cultural heritage of the special cultural units, the traditional village is lacking clear responsibility for sector and targeted preparation and guidance. On the other hand, most of the traditional villages contain a large numb of material and on-material cultural heritage, so the Protection of Cultural Relics and the Regulations on Protecting Historical Famous Towns and Villages cannot and should not be all covered in scope of protection, and canned make specific requirement and regulation for protection. In some places it has introduced some of the local laws and regulations which have significant limitations, and it is difficult to achieve a fundamental sense in the protection of traditional villages, and thus result in a large number of villages can't be include in heritage conservation areas of traditional villages, and they are facing with the damage of legal protection.

### *1.2 The subject of planning and implementation is not cleat, the public participation is missing*

In china, according to the Urban and Rural Planning Law, The Town and Country Planning should be made by the township people's governments, and must be reported to the superior people's government for examination Anderson approval. However, due to the administrator body of the over laws is the city, the design, implementation and management which made by these inevitably make the village

planning ultimately reflect the develop model of city, which will continue to remain in the “top-down” planning model. Particularly, for the traditional village areas, the public participation is relatively weak, the plan cannot reflect the "bottom-up" of the self-governing organizations in traditional villages, which instead of by using he "top-down" management system. Mostly, the planning and management decision-making depends on the sense of the government leadership, it lacks the effective participation of villagers and cannot reflect and meet the villagers’ universal needs and aspirations, as well as to coordinate and balance the public interests.

### *1.3 The contradiction between protection and development*

The government, market and the villagers are three major stakeholders of planning and development of traditional villages, as they have a fierce competition for all kinds of benefit and resource contention. One hand, the farmers' own culture is limited, as well as the information network of underdevelopment, resulting in the local villagers' lack of the awareness of preservation of the cultural heritage of in traditional villages. And they even self-destruct, resell the old building and heritage in traditional village. On the other hand, the local government’s supervision on traditional village are not yet in place, under the impact of negative concept of government’s achievement, the local government are eager for quick success and instant benefits, which make the protection planning of traditional village is lacking of a strong regulatory mechanism. In addition, accompanied by the accelerated pace of agricultural modernization, rural urbanization and suburb urbanization, traditional villages has been subjected to the destruction of constructive, developmental and tourism. With the internal resources have been absorbed by the city, there even appears the phenomenon that “hollow villages” and “aging village”. On the other hand, because of the lack of guide from relevant regulation and laws, some of the local governments lead too excessive tourism development without a field trip about traditional villages’ actual situation, economic development and cultural heritage, most villages take a unified model of the protection and repair, over time, the “thousands of the city shows the same” appear frequently in various parts.

### *1.4 A shortage of the financial resource*

The protection and rehabilitation of traditional villages require a lot of financial support, in particular, the substantial material and non-material cultural heritage need a lot of funds for scheduled repairing and maintenance. But the reality is not optimistic, due to the protection of traditional villages has been neglected for a long time, and the government funding for protection is limited, resulting in many of the traditional building and historic building are not very well preserved, and even some of them are damaged. In addition, due to the lack of professional training of vernacular architecture and traditional crafts talents, the protection work of local culture and the material space are seriously restricted.

## 2. The overseas and domestic cases

### *2.1 Taiwan: community construction ---- the promotion of subjective consciousness*

Taiwan's "community construction" is actually a "radical movement"-----a claim for returning to land, community and life. With the goal of the existence and awareness of the community, the community residents take an active part in local public affairs, to gathering community consensus, develop the community self-sufficiency. The community members can co-run the "industrial culture" and participate in the local cultural mission and community-based organization.

The "community construction" has 3 modes: one of which is the "NGO", it more easy success, the "Tou-Mi Eco-village" is a typical case of successful; another one is "retuning young intellectual" with the biggest probability of success. The core value of community construction is strengthening the indigenous identity and starting the social reconstruction. What it creates is not only a community, but to create a new society and a new culture. The main body of construction is generally composed of the non-government, the local government and the communities, but in these 4 sections, the community is the main body throughout the whole process of the construction, the villager's common awareness is also the core strength for success.

### *2.2 South Korea: New Village Movement---- the government's drive*

In the 1970s, the Korean rural economic development gap is widening, resulting the large flow rural population and some rural parts of agriculture have collapsed. In such a social background, the South Korean government has introduced the "new village movement" to achieve a full recovery of village. By establishing an efficient unified official organization and management agency, and investing considerable amounts and resources to strengthen the villagers' educational level and promote the characteristic development of rural area in an all-round way.

During this new village movement, the national government's investment has played a tremendous guiding role. One hand, the government inject a large amount of material resources, and in the 1970s, the government's financial expenditure has accounted for 10 percent, mainly for the provision of free cement and steel, and has driven villager's devotion and social support. On the other hand, the government is focusing on helping the farmers playing the main body role and learning the basic spirit of new village movement: diligent, self-organizing and synergy.

### *2.3 Japan: One Village One Product----the endogenous driving force of culture*

In the 1980s, japan launched the "one village one product", this campaign not only hence flourish the rural economy, but also promote the development of cultural and entertainment industry. In order to promote the development of the "one village one product", Japan attached great importance to explore the local resources, traditional techniques, and the use of new technology to upgrade the traditional products. This movement fully revitalized the economic development of rural area. By strengthening farmers' self-awareness, mining and using the cultural resources, to extend the industrial chain in rural

areas is the core values campaign of “one village one product”.

## 3. The connotation of "The trinity model"

### *3.1 The connotative definition of “The trinity model”*

The trinity model is an overall system altogether constructed by regulatory mechanism, operation mechanism and spontaneous mechanism of all three. In this system, the regulation is the core of the planning implementing of traditional village, the operation and self-development of the protection of traditional villages should be run under the perfect and legitimate government regulation; the operation is the momentum of traditional village, is the effective means and approach for effective using of traditional villages; the spontaneous mechanism is the necessary condition for sustainable development of the traditional villages. Regulation, operation and spontaneous are complementary and inseparable, which have been formed an organic integer. (Figure.1)

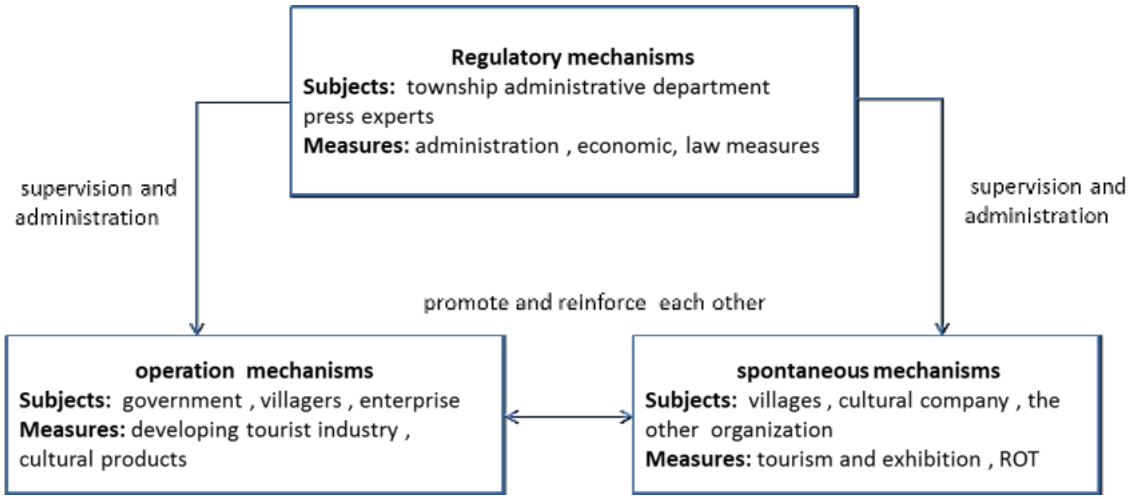

Figure.1.The paths of "The trinity model"

### *3.2 The timely significance of planning and implementation of traditional village*

The implementation of planning has the task to put the pre-coordinated program and established plan into action, and the result is achieved. At present, most system construction of traditional villages is newly-built, and lack practical experience. Besides, in the process of planning and implementation, it more ties to the urban planning itself, but for the understanding and tap of the historical, artistic, scientific value of historic cultural heritage lack of depth. As a result, the industry lack of the perception and thank rational knowledge about this kind of protect planning, besides, the too specialized language of planning and superficial protective realization is hardly to earn the emotional identify from the public and government. To ensure the scientific, forward-looking and characteristic of the protection, the implementation of rural planning need an effective planning mechanism which promote the optical allocation, place equal stress on development and protection, overall considerate

the short-term and long-term, for the overall protection of cultural heritage in traditional villages, and promoting the sustainable development of traditional villages.

### *3.3 The traditional villages' implementation way of the "The trinity model"*

#### *3.3.1 Strengthen the traction of government*

A perfectly supervised and management system can ensure that the protection planning and development of traditional villages can implement effectively. In the process of implementation and management, it should take a management mechanism of "government-led, villagers spontaneous, enterprise's facilitating"

In the development planning of traditional villages, the government should transition from a leader to a guider, by establishing a government-led census system, and in-depth investigation to have a comprehensive survey of cultural heritage resources in jurisdiction. Based on the local selection criteria, develop and introduce a list of traditional village, and make practical measures for protection and management, defining the responsibility and building the protection agency. Besides, the government should encourage the villagers to build educational institution of the cultural heritage spontaneously, and give a certain degree of incentives and support to the villagers, and to encourage them return to traditional village, make them the protector, operator and beneficiaries.

By strengthening the cooperation between government, villagers and enterprise, it can effectively enhance the operational efficiency of the protection planning of traditional villages. On the overall organization, it transforms form the horizontal missing coordination to vertical effective synergy. (Figure.2.) In addition, with the external force, forming a three-party supervision mechanism, perfecting the effecting institution, and make the protection planning of traditional village more efficient and, scientific and implemented.

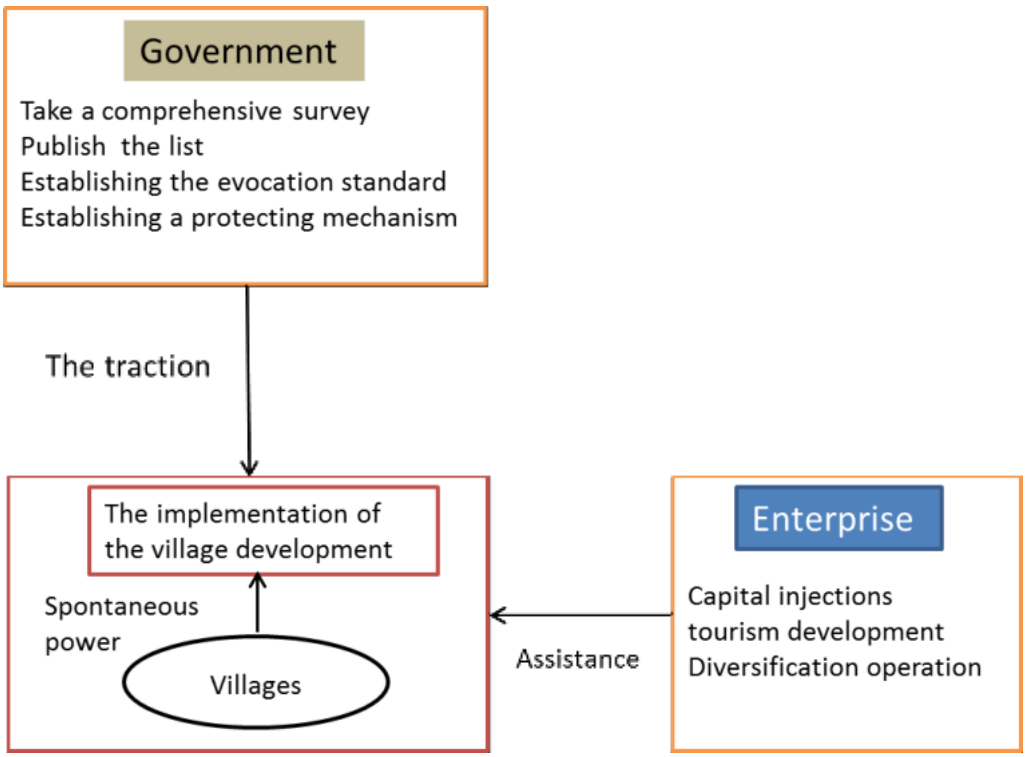

Figure. 2.
The collaborative power between crosswise and vertical

### *3.3.2 Mining the spontaneous mechanism of traditional village*

Under the waves of urbanization, the traditional village has been in the edge of urban growth and expansion, showing a phenomenon of resource shortage and hollowing. Despite the fact that many of the traditional village has a lot of valuable cultural heritage resources, but because its geographical location Ian mostly remote and inaccessible, without geographic advantage, it hardly gets the people's full understanding and attention.

Hollowing is main problem facing the development of traditional village, within the origin of hollowing, mainly because the village lack of the endogenous power for self-change and automatic development, the necessary human resources and economic power for reconstruction is also deficient. During the exploration of the path for traditional villages' sustainable development, the cultural ecological resource should be fully used. One side, excavating the economic value of traditional, take the traditional village of nonmaterial cultural, by enhancing the industrialization of culture, building a new contact of village and pulling the endogenous impetus, and then promote the economic development of traditional village to raise the funding for the protection and construction in the future, and explore a new model of protection and development. On the other hand, making a combination of protection and tourism development, for the villages where the traditional building is well-preserved, it can use opportunity of tourism market to enhance the construction of infrastructure and strengthen

the protection and use of the old buildings.

In addition, since the village formed, the villagers have been playing a leading role in the building and development of village. That is why during the constituting and actualizing protect planning, it is necessary to fully respect the villagers' sense of autonomy, and transform the action program from elitism-oriented to public-oriented. Mobilizing villager's enthusiasm in participating the rural planning and development, by the way of questionnaires and group meeting to collect villagers' opinions, and disclose the planning design drawing, to make the villagers to be the protector, operator and benefactor.

### *3.3.3 Establish a scientific and effective operational mechanism*

In the planning and implementation of traditional village, an incomplete operating mechanism can always cause the village sunk into the developing predicament, the lack of funds as one of the key issues has constraint the rehabilitation and development of traditional village. Take a certain "blood-transfusion" type of protection may have a positive effect to promote the protection of traditional village. One hand, by strengthening the government financial input, using and coordinate the funds from all departments on the construction of Chinese traditional villages properly, and bring the protection fund of cultural heritage into the budget to make sure that the vernacular architecture and important cultural heritage can get plenty of protection funds. In addition, the government can encourage the social capital investment, and take a responsible for investment, and the professional development company takes charge of planning and development. Besides, the villagers' self-organizing cultural industries are welcomed, so that there is forming a diversity financing mode and establishing a investment mechanism.

In the subsequent operations management, by respecting the villager's autonomy, to make the villagers realize the value of protection of traditional villages as well as their vital Internets, land lead the public to realize the right of use and transfer the vernacular architecture and on a voluntary basis, and encourage the social organization, enterprise and individual to participate in the use and protection through claiming, adoption. It would like to promote the protection and operation of traditional village to transfer from the inside-out profit-driven to the inside-out resource competition, and the village would transfer from the passive recipient to the active applicant.

## 4. The case study ---take the Traditional Village Clay Figure Wang in Wuhan City for example

As one representative of the first batch of traditional villages in China, the Traditional Village Clay Figure Wang has maintained a lot of intangible cultural heritage, and it is the cradle of clay sculpture making skill in Huangpi, which has a history of 1400 years. The village locates in the Yunwushan scenic spot of Huangpi district, as one of the most concentrate place of craftsman, successor and artists, the clay of farmer in Huangpi has spread fame overseas, and attracted a large number of tourists come

to visit. Nevertheless, with the accelerating development of the word's modernization and urbanization, the development is far from satisfactory, and the implementation of planning is restricted, the problems of the protection of material and non-material cultural heritage there is disturbing, the thinking on preservation of village remains to be discussed.

### *4.1 The problem and obstruction of the planning implementation of Village Clay Figure Wang*

#### *4.1.1 The lagging management and planning of village, the damage and hollowing is serious*

The Village Clay Figure Wang located in the edge of the city area, the village's superiority resources have been obliterated in the rapid expansion of the city, the out-migration is growing, and the hollow of village is increasing severely. Besides, because of the lack of effective planning and manage, the traditional architectural heritage is lacking of professional maintenance and repair, which could result in further the flavor of rural life waning and the erosion of spirit. At present, there are only 10 the old and the children living in the old village, the village lacks of energy and the memory space of clay craft are faced with lost.

#### *4.1.2 The traditional arts and crafts is facing with disappearing and lacking the protect*

The clay sculpture in Huangpi has gone through 1400 years, but in the market economy, because of the shrinking of the form of clay and the shock of the outside market economy, the number of craftsman drop sharply and the technique is in danger of disappearing. Because of the poor sales, a few of the clay factory were closed down. In the absence of special protection and external financing, the protection of Traditional Village Clay Figure Wang is under threatened. However, the government administrative departments often put the focus on the protection of physical entity on building, and lacks of the protection of spiritual culture and craftsmanship heritage, this evolution thread is biased, which might go against the sustainable development of traditional village.

#### *4.1.3 The economic development of traditional village is low, and over-reliance on "tourist-development"*

A reasonable tourism development has a positive guidance for the development of traditional village, but many villages are faced with problem of over -exploitation. A lot of renovation and reconstruction not only undermines the original local architecture and traditional building, as well as the overall outlook of village. Under the impact of market economy and modern civilization, there are lots of "counterfeit antiques", which not only goes against the protection and continuity of cultural heritage, as well hollowing the valuable natural and cultural resources in traditional villages.

### *4.2 The "The trinity model" of the implementation in Traditional Village Clay Figure*

***Wang***

### *4.2.1* ***Planning first ----make sure the scientific of protection***

Protection planning is made on the basis of research, analysis and scientific judgment, after having an in-depth analysis of values of material culture and non-material and cultural, and having a research on the historical and cultural information the village contains, then put forward the countermeasure of protection and development. Therefore, the protection planning is largely be objective, scientific and existence, ant it is precisely because of the objectivity it has, the protection and rectification have a more scientific and fixed standards. For the same type of traditional village, the protection planning should be similar. For this reason, it is only through the planning first and all-round implementation to make sure that the protection planning of traditional village area rules, and recovering the history appearance as far as possible, to show the cultural characteristic of traditional villages and achieve a better protection.

### *4.2.2* ***the public participation----rely on the people's strength to enhance the awareness of protection***

Stimulate the villager's initiative in Clay Figure Wang, widely soliciting the villager's suggestions about protection, and have incentives for the residents who have positive contribution. For the "non-legacy" project which has been included into conservation projects, the inheritor and successors have the participation rights on affirmation. The government should implement polices benefiting residents to encourage them to work in Clay Figure Wang, and engage in the tourism industry, so that they can truly be involved into the protection work. It should also encourage the research on closely related topics and strengthen the international cooperation and exchange.

### *4.2.3* ***The policy guarantee----improving the government's legal and regulatory mechanisms of protection***

In the future work, the planning should made specific and targeted local Protection Ordinance of the protection of non-material based on the actual situation in Huangpi Wuhan, and make corresponding method and procedure for protection and saving, clearing the intellectual property right to provide a strong legal basis for the non-material and cultural protection.

The protection of non-material cultural heritage is not only the work of Culture Sector, but also the responsibility of society as a whole. There is a need for the department at all levels participating, and form a long-term mechanism for the protection of intangible cultural heritage.

### *4.2.4* ***The financial security----strengthening the investment on the carrier of non-material cultural heritage***

The investment on the carrier of oral and non-substantial heritage is in fact indirectly through the carrier's construction to achieve the goal of protection. Because of the inheritance of intangible cultural heritage needs from generation to generation, the investment should also be uninterrupted on the individual or groups who can inherit the heritage successfully. In addition, the non-material culture can be made tangible by some related carriers, which can make the non-material be more easily to be understood and grasped, and closer to the population and normal life. It contributes to the achievement of education, and helps people to awareness and develops a non-material culture, and then realizing the inheritance and promotion of the non-material culture.

### *4.2.5 The innovation model---- the measures of protection*

The traditional culture needs change and innovation to get vitality. The innovation of non-material cultural heritage in clay Wang has three ways: the one is adding new content on the basis of the traditional culture, to make it more applicable to the contemporary people's way of life; the second one is to use the modern technology to manufacture the traditional cultural products, to lift the traditional culture to the modern civilization. Having a break on the traditional process to meet the people' live. It endeavors to make the two promote each other for sustainable development. The third one is to increase the influence of the clay as a non-material cultural heritage, and raise the people's awareness. Besides, it can utilize an appropriate non-material cultural heritage in different places.

## 5. Conclusions

In face of the multiple challenges of new round of urbanization, the development of town-country integration and rural tourism develop, an effective planning and management mechanism for implementation is the important security to ensure that the traditional villages to be able to withstand the external interference and maintenance the steady-state of the development. This artic is based on a perspective of innovative methods, attempt to build a monitoring mechanism of traditional village, start with the management, implementation and self-motivation of three areas to explore a new ideas of villages' implementation entirely and systematically. Through an emphasis on the multi-orientation regulatory role of government, enterprise and the villagers on the development and protection of traditional villages, the village can get a sustainable development. Are present, in china, the protect system of traditional village is still not perfect; it is only by a multi-faceted cooperation to improve the regulatory system. Making a practicality monitoring system has important research significance for three sustainable protection and development of traditional village.

## Abstract

*Current debates in urban development display a rising awareness that several cities in Europe and the US have to deal with challenges of long-term urban shrinkage. However, on an international scale it is still not clear if and how planning paradigms, planning systems, planning strategies and planning cultures are changing when shrinkage and decline are taking place. This paper investigates how planning is transformed in view of shrinking cities. For this purpose, the paper introduces four cities' storylines framed by shrinkage. Particular focus lies on the question if and how dealing with decline and shrinkage led to changes in urban planning and brought about different planning styles.*

**Keywords:** planning cultures; shrinking cities; comparative planning

## Funding

This paper presents results of the project PlanShrinking – 'Planning Cultures in the USA and in Germany in Comparison – the Example of Shrinking Cities', which is funded under the European Union's Seventh Framework Programme (People Program).

Grant Number: PIRG07-GA-2010-268296

## 1. Introduction

Urban shrinkage and economic downsizing in structurally weak areas – e.g. in old industrialized 'rust belts' or in peripheral rural areas – are most commonly symptoms of transformations that can be observed in Europe and the US likewise (Pallagst & Wiechmann, 2005), and current debates in planning demonstrate alertness of the phenomenon of shrinking cities. Many cities around the globe have to deal with challenges of long-term demographic and economic changes leading to urban shrinkage associated with housing vacancies, underutilised infrastructure and other negative impacts, often triggered by the effects of globalization pressures (Pallagst, Wiechmann, & Martinez-Fernandez, 2013).

However, extent and spatial distributions of population decrease differ significantly between Europe and the US. In Germany, declining birth rates and the effects of the German reunification are main triggers of shrinkage. Due to the overall population growth generated by immigration, many cities in the US have to provide for redevelopment in shrinking areas and growth-related development at the same time (Pallagst, 2008).

In current planning debates the term 'shrinking city' usually describes a densely populated urban area that has on the one hand faced population losses in large parts and is on the other hand undergoing economic transformations with some symptoms of a structural crisis (Pallagst, 2008).

The research presented here sets a basis for identifying traces of paradigm shifts, and possible changes in planning systems, planning styles, and planning cultures by means of comparative evidence based urban research. However, planning cultures is a new field when it comes to evidence based research, as in the field of comparative planning studies no systematic conceptual framework exists (Othengrafen, 2010, p. 86) Moreover international comparative work on the topic planning cultures is lacking a concise methodology (Fürst, 2009). In this respect, the paper combines the topics shrinking cities and planning cultures in a research approach that is new and experimental.

## 2. Identifying changes in planning for shrinking cities – defining an analytical frame

The following paragraphs will briefly introduce contemporary shrinking cities-research and define an analytical framework for case studies on shrinkage and changing planning styles derived from the research of planning cultures.

The existing body of literature on shrinking cities has well documented that the loss of urban population is not entirely a new phenomenon (ARL, 1995, p. 1010; Göb, 1977, pp. 151, 162; Häußermann & Siebel, 1987, p. 29; Oswalt, 2004, p. 20). What is new, however, is the extent to which shrinkage occurs on a global scale, and the complexity of its causes (Pallagst, Wiechmann, & Martinez-Fernandez, 2013). Meanwhile, shrinking cities have become a worldwide multi-dimensional phenomenon appearing in many post-industrialized societies.

Meanwhile, the policies and strategies applied when it comes to dealing with shrinkage are manifold. An interesting fact is that how shrinkage is perceived and accepted largely influences the choice of planning approaches in shrinking cities. Here, two directions can be distinguished: either growth or non-growth is adopted as a path for future development.

In order to investigate changing planning strategies and planning policies for shrinking cities, the correlation between perception and strategies might be helpful. In search of this correlation, the authors merged two typologies for shrinking cities: one based on phases of perceptions of shrinkage (Farke 2005, p. 179), the other based on types of strategies (Danielzyk et al. 2002, p. 25). Farke's typology suggests four stages of perceptions of shrinkage: ignoring, observing without acceptance, certain acceptance and acceptance, Danielzyk reveals the following typologies decline as vicious circle, expansive strategy, maintenance strategy, and planning for decline. Interestingly, both typologies correspond with each other as displayed in figure 1. Nevertheless, since shrinkage is a very complex problem, it is difficult to distinguish sharply between planning strategies and the underlying perceptions (see figure 1).

Figure 1: Strategies to cope with shrinkage depending on the perception of shrinkage

| Strategies to cope with shrinkage in dependence with the perception of shrinkage | | | |
|---|---|---|---|
| perceptions of shrinkage | | | |
| phase of ignoring | observation without acceptance | certain acceptance with or without limited public communication | acceptance |
| **Decline as vicious circle** | **Expansive strategy** | **Maintenance strategy** | **Planning for decline** |
| Without goals | Keep population within city borders | Maintain attractiveness and spatial structure | Orderly shrinkage, development of qualities |
| Hope for regional planning or financial support | Substantial expansion of residential areas | Development of existing land use, target groups programmes | Adaption and reduction of infrastructure, development of recreational areas |
| **passive strategies** | **active strategies** | | |

Sources: Own design based on Farke, 2005; Danielzyk et al, 2002

In search of planning strategies to deal with shrinkage, policies, plans and projects have been applied with different contents i.e. substitute industries, master plans, urban regeneration, urban redevelopment, urban renewal, or greening. These measures can either serve as part of a planning strategy for expansion as well as a strategy for managing decline. The common denominator is their focus on improving the quality of life in the respective area. However, measures taken on local level, often with financial support by the national governments cannot always be credited to one specific policy or strategy.

In order to investigate how planning is changing in view of shrinking cites, the authors turned to the research sphere of planning cultures. Research work by Othengrafen (2010) specified the criteria for defining planning cultures. Table 1 distinguishes the following criteria:

- *General context* displays the basis of a planning culture comprising more general understandings,
- *Planning context* displays the values and beliefs of the planning profession,
- *Planning toolset* refers to the strategies and applications at hand.

The authors of this paper have modified this list in two ways in order to use it as a basis for comparative research on planning for shrinking cities: Firstly, some of the terms were redefined, including an addition of the factor of change. Secondly, in order to broaden this typology for a possible applicability for shrinking cities, the authors introduce ‘shrinking context’ as a new criterion (see table 1).

The new category, ‘shrinkage context’, comprises aspects which most likely trigger change within a planning culture. In this respect and based on the definitions of shrinkage laid out earlier, criteria for mapping the shrinkage context of a planning culture are defined by demographic change, post-industrial transformations, and the perception of shrinkage. ‘Demographic change’, a factor highly influencing the shrinkage of German, Italian or Japanese cities, was selected in order to display changing population. ‘Post-industrial transformations’, visible in countries all over the world (Pallagst,

Wiechmann, & Martinez-Fernandez, 2013), include economic change and possible structural crises. The variable 'perception of shrinkage' demonstrates the selection of policies and strategies in order to deal with shrinkage.

Table 1: Criteria for defining planning culture's facets and layers

| **Shrinkage context** | **General context** | **Planning context** | **Planning toolset** |
|---|---|---|---|
| • Demographic change<br>• Post-industrial transformations<br>• Perception of shrinkage | • Socio-economic or socio-political societal models<br>• People´s respect for and acceptance of planning<br>• Social equity, planning ethics and values<br>• Consideration of environmental aspects<br>• Stakeholders in planning | • Major planning paradigms<br>• Objectives and principles planning is aiming at<br>• Traditions and history of planning<br>• Scope and range of planning<br>• Legal framework<br>• Planning system and governance<br>• Adaption to change | • Urban design and structures<br>• Urban plans, programs and policies<br>• Urbanand regional development strategies<br>• Planning Law<br>• Decision making process<br>• Communication and participation<br>• Financial tools and incentives |

Source: Own design based on Othengrafen, 2010, p. 93

In the next step of the research, the authors applied the analytical framework by selecting and examining case studies of shrinking cities. The authors selected Germany and the USA as planning cultural areas of investigation, as vast experience with shrinking cities has been made in these countries. Four case studies were selected for this comparative research: two cities from Germany (Zwickau and Kaiserslautern), and two cities from the USA (Flint/MI and Youngstown/OH). The choice of cities is based on the following attributes: All cities are comparable in the number of inhabitants, all cities have applied strategies to counteract shrinkage, and three of them share a history of car-manufacturing. All four cities demonstrate wide-ranging planning approaches regarding shrinkage processes, and thus can be considered as appropriate testing grounds for changing planning styles and cultures.

Case-study analyses carried out by the authors focused on exploring literature, archival records, data bases, and planning documents regarding planning and rebuilding activities in the selected case study cities. A stakeholder-based analysis (by means of surveys and interviews) is the main part of the research work. This aimed at gathering in-depth knowledge about experiences with steering planning and development of four shrinking cities, Zwickau, Kaiserslautern, Flint, and Youngstown.

The following paragraphs will highlight how shrinkage affected the four cities mentioned above, and point at the cities' struggle with addressing the problems of shrinkage. In terms of the analytical framework displayed in table 1, particular emphasis is placed on the criteria 'shrinkage context' and 'planning toolset'.

## 3. In search of evidence for changing planning styles: Four case studies

As mentioned before, the four cases represent different planning cultural realms of shrinking cities, and a large number of tested and applied planning approaches. The nest paragraphs will briefly introduce the cases (3.1), showcase their shrinkage context in terms of trajectories of population

development and decline (3.2), and in particular present policies and planning tools for dealing with population decline and shrinkage (3.3).

## 3.1 Brief introduction to the cases

*Zwickau: A shrinking East German city*

Shrinkage in East Germany is a well-known phenomenon in the national and international discourse of the field. Smaller cities like Zwickau are struggling with the effects of German reunification and the demographic changes affecting population development, as much as the prominent cases Dresden and Leipzig.

The city of Zwickau is among those not so well known examples of East German shrinking cities. It is the fourth largest city in the state of Saxony in Germany and located in the metropolitan region 'Mitteldeutschland' in proximity with the cities Dresden, Leipzig and Jena. Zwickau's former growth and prosperity were related to coal-mining, manufacturing and development of the automobile industry. Today the city's population extends to 93,750 inhabitants (Bertelsmann Stiftung 2012a).

*Kaiserslautern: Post-industrial transitions*

The city of Kaiserslautern is located in the German state Rhineland-Palatinate, within the district of Kaiserslautern. The city is undergoing economic transformations since the 1970s. Moreover, like most cities in Germany, Kaiserslautern has to deal with the effects of demographic change and an aging population. During the postwar period up to the 1960s the region was prospering due to the high level of industrialization in the manufacturing sector. Today, from an economic perspective, the city is one of the weakest areas in West-Germany with an unemployment rate of 11.2% in the city of Kaiserslautern as of April 2013. The city also ranks number one on the list of the most indebted German cities since 2012. Interestingly, despite the severe economic transformations the city's population remained relatively stable for the last 40 years.

*Flint: Motor-town collapse*

Flint is one of the showcase examples of shrinking American industrial medium-sized cities: according to the local government's website, the town 'was the most publicized example of the effects of the 1970s collapse of the US auto industry on surrounding communities' (City of Flint, 2013). The city is located in the North of the United States, in the state of Michigan within Genesee County, in close proximity to the city of Detroit. In the beginning of the 20th century Flint emerged as an automotive town with General Motors being Flint's principal economic pillar: in the 1970s, GM employed almost half of Flint's population, but ever since the company has downsized jobs in the area by 90% (Badenhausen, 2011).

*Youngstown: A Rust Belt classic*

Youngstown, located in Mahoning County in the state of Ohio, is another typical US example of a medium-sized city affected by industrial decline. Youngstown emerged in the 1800s as an industrial town, based on coal and iron processing. From the early 1900s, the industry base shifted towards steel processing and Youngstown became a major site for steel production in the US during the first half of the 20th century (Aley, 1950, p. 43), followed by a downturn from the 1950s on.

## 3.2 The shrinkage context: Trajectories of population development and recent paths of decline

Based on the investigation of the shrinkage context (see table 1), the following paragraphs will display paths of shrinkage in terms of demographic change, post-industrial transformations, and perceptions of shrinkage for the four cases.

Population growth and decline of all four case study cities is compiled in table 2, which is followed by a description of the cities' individual paths of growth and decline. Major turning points in population development are highlighted in bold. For all cities a turning point in post-industrial development can be detected in the range 1950s to 19606. For Zwickau a second major turning point can be traced with the German reunification around the year 1990.

Table 2: Population development of the case study cities

| **Zwickau** | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Year | 1900 | 1910 | 1920 | 1930 | 1940 | **1950** | 1960 | 1970 | 1980 | **1990** | 2000 | 2010 |

*Zwickau's shrinkage context*

Zwickau's population growth was attributed to times of industrialization. In the 1950s, the flourishing coal mining industry led to an in-migration of people to the city, and the population peaked at a number of 135,751 inhabitants in 1955 (Stadt Zwickau 2006, p. 19).

But, the population of the city has changed in recent history. Main factors of shrinkage in Zwickau are the structural transformations of political and economic nature, which most East German cities experienced after German reunification in 1989/1990. Before 1989, the loss of population was induced by economic structural changes in the mining industry and the supporting branches. Due to the political and economic system, the outmigration was not as extreme as in the years after the reunification but still significant. Only two months after the opening of the border, 2.835 people or 2.4% of Zwickau's inhabitants had left the city. By the end of 1990 more than 7.000 people had out migrated from Zwickau. During the following ten years, a tremendous loss of population took place until the year 1999 (see table 3).

The increase in population in 1999 of 5.4 % to 104.146 inhabitants was only achieved by incorporating surrounding villages and towns into the city of Zwickau and its administrative borders (Stadt Zwickau, 2006, p. 19). However, this did not change the main trend of population decline the city has to face. Based on population figures of 2007, forecasts estimate a number of 84,860

inhabitants for the city in the year 2020, and only 75.990 in 2030, which resembles losses of 20.7% (Bertelsmann Stiftung 2012b). In addition to economic decline, suburbanization to surrounding towns and villages set in. These changes were motivated by out-migrating younger residents looking for new job opportunities in West Germany, and new chances of a suburban lifestyle.

The alertness for shrinkage turns out to be high as Zwickau is embedded in the East German context where vast transformations placed shrinkage on the federal agenda. In relation to the typology in figure 1, shrinkage is accepted.

*Kaiserslautern's shrinkage context*

The city's population growth becomes significant after 1850, when industrialization brought new jobs in the manufacturing of textile, machines and metal processing (Statistisches Landesamt Rheinland-Pfalz 2012). Today almost all companies involved in Kaiserslautern's growth of population during industrialization are either bankrupt or have significantly reduced their number of employees.

In the year 1969, Kaiserslautern incorporated several smaller municipalities, which led to a growth in population over 100.000 inhabitants giving it the administrative status of a major city (Stadtverwaltung Kaiserslautern, 2012, p. 30; Stadt Kaiserslautern – Chronik 2012)[1]. Structural changes started to take effect during the 1970's. After that the city slowly started to lose inhabitants (see Table 4). Compared to other industrial cities, Kaiserslautern was not affected by an immediate loss of jobs like e.g. cities in the Ruhr Area. The reason for this can be seen in the fact that Kaiserslautern's industry showed a stronger diversification to the branches of textile, car manufacturing, and consumer goods.

Kaiserslautern is affected by both industrial transformations and demographic change. The perception of shrinkage is somewhat given, though not largely accepted. In relation to figure 1, the perception of shrinkage can be labelled as 'observation without acceptance'.

*Flint's shrinkage context*

From 1900 until 1930 Flint's population increased from around 13.000 to more than 150.000 people demonstrating the enormous pull factor the developing automotive industry presented. Since the 1960s, however, a constant loss in population can be observed (see table 5).

Unemployment rates in Flint range at 9.1%, a figure near the present Michigan state average of 8.5%, yet they are exceeding the US average of 7.6% (US Bureau of Labor Statistics, March 2013). Apart from unemployment, major problems in Flint involve high vacancy rates and depopulated urban areas, safety risks for citizens (e.g. Manzella, 2011) and a diminishing tax base for basic municipal services such as police or garbage collection (Janz, 2011).

The city of Flint does not only showcase an example of a city depending on one industrial branch, but also one of a corporate town, tied to the fate of one single company. With General Motors downsizing, the city was destined to share this company's misfortune. Genesee County however, has not suffered a similar loss of population over the last 30 to 40 years. The rapid decline of the city is also attributed to urban sprawl and suburbanization processes accompanying the industrial shrinkage (Gilotti & Kildee, 2009, p. 141).

After decades of denying shrinkage, the city has reached a point of acceptance of shrinkage as a fact to be dealt with actively when looked at the typology of perceptions in figure 1.

[1] This status allows the city to receive a higher share in funding from the state, in return the city is required to provide services for the city and its surrounding areas in terms of culture and education, which is one of the reasons for the high debts of the city.

*Youngstown's shrinkage context*

The wave of plant shutdowns which started in the late 1970s entailed a loss of 50,000 manufacturing jobs in the city of Youngstown – equating to over one third of the city's population at that time (Linkon & Russo 2002, p. 131). Moreover, this represented a loss of $414 million in personal income and of 33-75 percent in school tax revenues (Bruno, 1999, p. 10). Current unemployment rates in Youngstown and surrounding suburban areas are as high as 8.4%, well over the Ohio state average of 7.0% and higher than the US average of 7.6% (US Bureau of Labor Statistics, March 2013). The city's population peaked in the 1950s, from then on it declined continuously (see table 6). In the year 2009 around 4.500 buildings and 22.000 sites were abandoned leading to the highest rate of vacancies in the USA (Mahoning Valley Organizing Collaborative, 2011, p. 13).

Youngstown's shrinkage problems sound familiar, deriving from unemployment and out-migration and they induce high crime rates and hence a negative city image (Linkon & Russo, 2002, p. 235). Social segregation is increasing and land management due to under-populated areas and under-used infrastructure places a challenge. Moreover, the provision of both private and public services is threatened due to a narrowing tax base.

Youngstown was among the first US cities to publicly announce that shrinkage is accepted as a fact. Perception and awareness of shrinkage in terms of the typology in figure 1 are high.

### 3.3 Policies and planning tools for dealing with population decline and shrinkage

This section presents the planning toolset applied in the case study cities in connection to the typologies of strategies presented in figure 1: expansive strategy, maintenance strategy, planning for decline.[1]

*Zwickau*

The city government recognized shrinkage as a challenge and fait accompli for the city of Zwickau, which is expressed in the range of strategies and planning tools applied in the city.

Maintenance strategy: Image and attractiveness

As for the strategies until 2002, the city focused on increasing its attractiveness by renovating buildings in the centre, in particular in order to strengthen the retail sector. Despite these efforts, including the development of an inner city mall in the year 2000, large area retail businesses opened up on the edge of the city by the end of the 1990's. As a reaction to the ongoing sprawl, the state of Saxony passed a new law banning the development of malls and retail business on the edge of cities in the year 2012, yet most edge city-type business parks had already been created until then (Interview with Mr. Spanger, IHK Chemnitz, Regionalkammer Zwickau, September 6, 2012).

The inner city developments were also supported by the state of Saxony after Zwickau's participation in the contest 'Ab in die Mitte! Die City-Offensive Sachsen' [engl.: Back to the centre! The Saxon City Initiative] in 2006. Within this program the city tried to further strengthen the inner city by establishing public services like a library and a new city hall. Despite the efforts to strengthen the inner city particularly for retail businesses, developments like malls on the edge of the city make it difficult to achieve positive results.

Planning for decline: Right-sizing

[1] The type ‚decline as vicious circle', which is also mentioned in figure 1 does not apply to the selected case study cities.

Due to ongoing suburbanization and high vacancy rates in the older settlement areas, in particular pre-fabricated housing (Plattenbausiedlungen), strategies shifted towards demolishing these buildings and as a result towards adapting to a smaller and compact city model. Before the federal program 'Stadtumbau Ost' (Rebuilding the City – East) started in 2002, more than 16.000 vacant housing units had cropped up in Zwickau. The main target for the federal program was to demolish vacant buildings and stabilize the real estate market as well as reduce maintenance costs for underused infrastructure. In 2010, approx. 5.060 housing units were demolished in Eckersbach and approx. 1.900 in Neuplanitz, the areas with the highest vacancy rates. In general, the East German right-sizing strategies do not only include demolition actions, but also solutions like partial dismantling, which means reducing the height of buildings of five or six floors to two or four floors. In addition, strategies aim at stabilizing older residential areas by improving the social environment, the transformation of vacant areas to green spaces, and reusing some buildings for different functions e.g. as kindergartens, medical centers, or senior citizens' clubs (Bundestransferstelle Stadtumbau Ost, 2012).

Planning for decline: Comprehensive planning strategies

The city tried to develop several plans in order to deal with the aspects of shrinkage; the first one was the integrated urban development concept of 1997. This concept did, however, not succeed in fulfilling its targets as it was lacking a detailed urban strategic plan (Pfefferkorn, 2003, pp. 83f). Another concept was developed in 2006. The 'SEKo ZWICKAU 2020' is an integrated development concept that takes into account not only specific aspects of urban development. In order to deal with the economic and demographic development of the city, strategies and measures have been enacted with regard to demolition of underused structures and to revitalizing the city centre. (Stadt Zwickau, 2006, p. 73). Another plan developed most recently was the integrated urban development concept 2011 'INSEK Zwickau 2025' (Stadt Zwickau, 2012).

In addition, as a result of an estimated vacancy rate of 15% in 1997, urban planners and housing companies arranged a 'Housing Policy Forum' ('Wohnungspolitisches Forum') in May 1997. The results included impeding the development of new urban land-use plans for multi-story apartments and the development of a concept to improve the social environment in existing housing areas.

Maintenance strategy: Substitute industries

The West Saxon University of Applied Sciences of Zwickau (WHZ) was already established in the year 1897. Today it plays an important role as an employer as well as a think tank for the city. WHZ can be considered a small university with only about 5.200 students (Westsächsische Hochschule Zwickau, 2012), yet it is embedded in the city's policy against shrinkage.

*Kaiserslautern*

Expansive strategy: Incorporations

For the last 40 years, Kaiserslautern was able to gain enough people to balance the low birth rate and keep its population on a constant level. Since 1975 the migration balance of Kaiserslautern shows only small differences between around +1000 people and -500 people (Stadtverwaltung Kaiserslautern 2012, p. 32). This was possible because the city of Kaiserslautern incorporated a number of surrounding smaller villages.

Another significant strategy for population increase was tax regulations for secondary residences installed in the year 2009. The new tax regulations made swapping to a status of primary residency more attractive, in particular for students. This encouraged a net growth of almost 2200 inhabitants (Statistisches Landesamt Rheinland-Pfalz, 2012).

Maintenance strategy: Substitute industries and redevelopment

The University of Kaiserslautern was founded in 1970 by the state of Rhineland-Palatinate which brought new employment opportunities to the city and laid the foundation for several economic developments, such as spin off companies or large research centres.

One major factor for employment in the city and in the region was and still is the military presence by US and French forces installed after World War II. Military bases, however, are continuously phasing out, and the French forces are no longer present at Kaiserslautern. The reduction of their military bases caused not only job losses and a loss of purchasing power, but at the same time it opened up new development opportunities for the city. Beginning in 1997 a former military site was developed as a new business centre on the edge of the city. The redevelopment can be seen as a success, as today there are about 90 small businesses located in this area. Many of them are spin-offs from the Technical University and belong to the high-tech sector. In total about 3.000 jobs were created. However, military downsizing is quite unpredictable, and with the latest cutbacks in the US military budget it is likely that further reductions of employees on the remaining military bases will take place.

Another substitute industry area was established in 2002 on the site of a former fright rail terminal close to the university campus. This redevelopment project was aimed at further strengthening the scientific potential of the city, and large research facilities were established here, which was part of a national competitive process of research excellence. These developments were facilitated by the scientific reputation and networks established by the University of Kaiserslautern (WFK 2012, p. 12).

Nevertheless it must be noted that the overall success in managing structural change stands in sharp contrast to the high rate of unemployment in Kaiserslautern and the entire region. Although a large number of jobs were created in public and private services, the job losses in manufacturing account for the enduring unemployment (IAB Rheinland-Pfalz-Saarland, 2007, p. 11).

*Flint*

Maintenance strategy: redevelopment and small enterprises

By the end of the 1970's the city's development focused on private investments supported by federal funds in form of Urban Development Action Grants (UDAG) and Community Development Block Grants (CDBG). Flint was successful in receiving federal funding for certain projects, mainly focusing on downtown redevelopment with private investment. However, the majority of these projects could not achieve their intended goals (Gilman, 2001, p. 57). During the 1980s the city turned towards supporting small businesses in order to improve the desolate job situation. These efforts were partly successful, but the number of jobs which were created was far too small compared to the ongoing layoffs in the automotive industry (Gilman, 2001, p. 58).

Planning for decline: land banking

Recent efforts concentrate on lank banking as a tool for managing shrinkage. In 2003, Michigan passed one of the most progressive land banking laws in the US, based on the work carried out in Genesee County, in particular the city of Flint. With the tool of the county-based land bank, Genesee County was able to adopt a brownfields redevelopment plan which utilizes a tax increment financing strategy. This enables the Land Bank to redevelop its properties in a highly effective way (Gilotti & Kildee, 2009, p. 144). Before the land bank was in place, abandoned properties were either sold to private investors or transferred to the state of Michigan. Options for the city to influence this process were limited thus hindering a strategic approach to manage the growing number of vacancies (Phaneuf, 2012). With the land bank as the managing institution for vacancies in Flint, the foreclosed properties now offer a chance for urban development instead of being a part of the problem.

Planning for decline: Comprehensive planning strategies

In 2010, the city of Flint received a Sustainable Communities Challenge grant from the U.S. Department of Housing and Urban Development (HUD) for developing a comprehensive master-plan.

The new master-plan was developed in a bottom-up collaborative process involving numerous suggestions by the citizens. The plan proposes several aims capitalizing on Flint's citizens by encouraging small businesses, developing community assets and strengthening neighbourhoods. Based on existing vacancy rates a set of designated place types was mapped out, laying out which areas of the city will remain as built up areas in the future (for residential and commercial uses), and which areas will be designated for right-sizing and tear-downs mainly of residential areas. The latter are declared as 'Green Innovation Areas' where former residential areas will be transferred to urban agriculture. In particular green infrastructure is supposed to strengthen Flint's position as an employment centre on neighbourhood level.

*Youngstown Actions for dealing with population decline and shrinkage*

Expansion strategy: Economic growth projects

After the loss of so many jobs within a small period of time, several projects were initiated to re-gain employment for the local population. There were for example plans to restore the economy by means of investments like a riverboat casino, a NASCAR race track or a car factory, which were intended to bring back jobs in huge numbers. Also a branch of the Pentagon (US Ministry of Defense) was intended to relocate to the city. These plans were, however, not implemented or failed their expectations e.g. in case of the car factory. Also it was not clear if these enterprises would have generated jobs for the local population which mainly consisted of low skilled workers, or if it would have attracted new people to the city better suited for specialized work. This development might in turn have increased social segregation, yet it never materialized.

Maintenance strategy: Substitute industries

The city is slowly shifting towards a service-based economy, while employment is also provided to some extent in the automotive and steel processing industries (Youngstown-Warren Regional Chamber, 2008). The jobs created were however much fewer than the ones lost with the decline of the steel industry and could not combat the rising out-migration.

Substitute industries took a peculiar path in Youngstown. During the 1990's the County turned the increasing crime rate in the area into a business plan and gave permission to build four prisons in the area (Linkon & Russo, 2002, p. 234), three of which are still in use. This development helped to support the local economy and to improve public finances, but the city's image degraded during this process (Linkon & Russo, 2002, p. 235).

Another popular substitute industry is education, and Youngstown followed this path with an expansion of Youngstown University by the end of the 1990's. This development was planned close to downtown in order to support this highly distressed part of the town. Youngstown's downtown improvement, much due to private capital investment, is connected to the relocation of the university campus to an adjacent site and to the setting of the new business incubator. Several start-up companies are located here and interestingly Youngstown was labelled one of the 'best 10 cities to start a new business' by 'Entrepreneur Magazine' in 2009 (Zeller, 2012).

Planning for decline: Right-sizing

Due to the high vacancy rates in the city, the costs for maintaining infrastructure and public services like roads, sewage systems and waste disposal were increasing beyond the city's financial capacities. These situation lead to drastic solutions. Abandoned buildings were bulldozed and unnecessary roads were removed. In addition, people in sparsely populated areas were offered to move, so entire neighbourhoods could be demolished (Christie, 2008).

Planning for decline: Comprehensive planning strategies

A new master-plan (named 'Youngstown 2010'), was initiated in the late 1990s. 'Youngstown 2010' was developed as a process of collaborative planning and strong participation of the local community. The main feature was the agreement that Youngstown would not regain its former population but instead would stay a smaller city in the future. The aim was to improve the quality of life for the current population (City of Youngstown, 2011). Following the efforts of the plan, some neighbourhoods remain stable – benefiting from the Youngstown Neighborhood Development Corporation, an NGO set up under the 'Youngstown 2010' framework. However, the downsizing of larger neighbourhoods remains one of the most problematic aspects of the plan, meeting difficulties with absentee owners as well as opposition from both political actors and residents.

## 3.4 Overview on the four cities' planning toolset for shrinkage

Table 3 shows an overview of planning tools and styles utilized in the case study cities as it was revealed in the analysis and interviews with stakeholders. This is not a display of all planning tools enacted in the cities, but those who are particularly intertwined with shrinkage. The table is derived from the analytical frame for shrinking cities and planning cultures presented in table 1. The purpose here is to highlight the many effects shrinkage has had on planning instruments, styles and culture in the case study cities. From the four cases it is difficult to derive any general trends, however, an active embrace of shrinkage seems to take place in Zwickau, Flint, and Youngstown.

Table 3: Overview on planning tools used in the case study cities

| | **Zwickau** | **Kaiserslautern** | **Flint** | **Youngstown** |
|---|---|---|---|---|
| **Financial tools** | | | | |
| Local tax incentives for secondary residences | - | + | - | - |
| Federal funds: | | | | |

## 4. Conclusions

This paper presents a starting point for identifying changes in planning styles and tools when faced with shrinkage based on an analytical frame. While the four cases display insight in similarities and differences of shrinking cities' planning styles, the authors are well aware that – based on their specific paths and localities – the four cases can only represent a short glimpse of the situation shrinking cities in Germany and the USA. Nevertheless, they help to better understand the shrinking cites phenomenon which might in turn lead to further developing innovative ideas for dealing with shrinkage.

In terms of the individual cases, the following observations could be made:

Zwickau

Only a few years after the German reunification, Zwickau's government realized that the situation would not improve and out-migration as well as strong economic competition will be the future trend. Zwickau's planning style applied the brakes to growth oriented planning and focused on adapting to a smaller footprint. For Zwickau, right sizing seems to be a major factor in combating shrinkage, as well as comprehensive and strategic planning. In addition to local strategies the city's administration recognised that in order to keep up with the growing competition also with neighbouring cities of similar size, it is important to be part of a larger network of regional, national and even international partners.

Kaiserslautern

The city of Kaiserslautern is an exceptional case because – despite the loss of jobs and the increasing influence of demographic change in Germany – the number of residents remains stable in this city. One possible explanation might be that in general the German system of unemployment benefits reduces the pressure to find a new job in a short time. In addition the city of Kaiserslautern provides a large amount of public services while living costs are comparably low. Both aspects could be the reasons why people stay in this city even when unemployed. But, the high level of service provision is the reason for the soaring debts the city administration has to face. For the future development of the city it will be important how the chances and risks of further downsizing e.g. of military bases can be utilized for the urban and economic development of the city, and if and how former industrial areas can be redeveloped.

Flint

The example of Flint demonstrates the vulnerability of cities with a mono structured economy. Like in other cities the somewhat unexpected decline of the leading industry placed city officials and the population in some kind of 'structural shock'. Today, planning for decline is the key, where right sizing and redeveloping residential neighbourhoods is essential for Flint's future development path. The change of legislation in favour of land banking offers a radical yet feasible approach for dealing with the large changes in the urban fabric. In addition it becomes clear that the city is embracing its new and smaller footprint: With the ongoing process of implementing the new master plan, Flint has at least a new perspective for its future development.

Youngstown

Much as the path of Youngstown has been praised for being realistic, it shows the struggle over the years to adjust to a smaller footprint. Now that this insight has been delivered, the city can embrace new paths of development, some are experimental, but based on collaboration and serving Youngstown's community and neighbourhoods. In the long run, growing smaller might be the only chance to regain liveability for a city such as Youngstown.

Comparative reflections on the cases and lessons learned

All of the examples showcased in this paper demonstrate that industrial transformation affects manufacturing towns to a large extent, both in Germany (East and West) and in the USA, inducing unemployment, housing vacancies, and population losses – the usual downward spiral.

When it comes to shifts in planning, all of the cases show that substitute industries play an important role, although they can differ from location to location: today high tech, prisons, education, urban farming and others are the new pillars of the economy. In fact, the presence of a university proves to be a strong motor for development as demonstrated in Kaiserslautern, Zwickau, Flint, and Youngstown.

Moreover, all of the cities have meanwhile applied some sort of a comprehensive planning strategy in order to offer a vision or guideline for future development, but also as a basis for community building. Still it appears that redeveloping vacant land is probably the main opportunity for shrinking cities to adapt to past and future challenges. This might be facilitated by tools such as land banking, or comprehensive planning strategies.

When looked at the types of strategies to cope with shrinkage, most cities (Zwickau, Flint, and Youngstown) have found their way past the phase of ignoring shrinkage and – except for Kaiserslautern – are in an intermediate state of maintaining the urban fabric and actively planning for decline. For these shrinking cities it is a fact that planning has changed to a dramatic extent from growth as the main focus to reusing abandoned land and managing vacancies. Yet, due to the large extent of economic, social and urban fabric related problems, shrinking cities' challenges will be intertwined with the cities' planning and development paths as long term phenomena.

Keywords (maximum 3): urban gardening, urban food production, community

***Abstract***
*In the changing world, urbanized areas and their growing population show us emerging necessity of the improvement of their social responsibility. Reaching towards this kind of civic responsibility may be carried out through the increase of networking, innovation and creativity support in the spatial planning theories and practise at the local level. Various bottom-up movements and participatory tools for engaging local people into the neighbourhood community life might help improve diversity and strengthen social responsibility of communities and individuals. This paper aims to discuss the potential of using social capital of local communities, which is inherently connected to the space and its quality, to foster local sustainability.*

*Social capital may be expressed also by the presence and activity of different groups and individuals, including those called "urban gardeners". Urban gardeners (or farmers) are focused on local production of food, largely for local consumption. This contribution is based on the knowledge on guerilla urbanism, community gardening, food production concepts in the urban areas and recent research of Andres Duany on agrarian urbanism. According to Duany, agrarian urbanism opens up the whole new perspectives on the role of community and considers the potential to shift leisure time activities into the commitment to the local sustainability. However, this study also attempts to extend prior research on agrarian urbanism by examining possible innovative ways of using vacant and underused spaces, such as brownfields, for the implementation of the "agrarian urbanism concept" into the planning practice.*

## 1. Introduction

Community gardening became a popular leisure time activity in the cities around the world. Participation in urban community gardening gives participants a full-fledged alternative experience in food production, even with limited time and space conditions. American Community Gardening Association defines community gardens as any piece of land, which is collectively gardened by a group of people. According to various studies and researches, community gardening provides not only experience in food production, but has also numerous positive health, social and environmental effects. Potentially, community gardening could also affect the way communities think and perceive food, environment and health (Frumkin 2005, Conradson 2005, Hale et al. 2011). As Michael Pollan argues, food production of the 21st century must change. Technologies such as food preservation, transportation and arching over seasonal and regional food production modified the relationship between food, culture and society (Pollan 2011). Community gardens are often viewed as one of the strategies, which may improve sustainability of urban environment as well as improve health and affect lifestyle of individuals. More than half of world´s populations lives in cities, which opens up a new perspective, particularly on involving society – communities, on food production in urbanized areas. Andres Duany´s concept of agrarian urbanism is one of the most beneficial methods to develop and dwell on land. Rather than agricultural, agrarian urbanism involves society into food production

and processing (Duany, 2011). This paper aims to discuss the possibility of implementation of larger-scale community gardening in the capital of Slovakia, Bratislava, with perspective of future transformation towards agrarian urbanism. Bratislava has different relicted areas, underused buildings, unused land or building gaps, which are potentially suitable for implementation of such strategy. These may become a component of urban food system in the form of community gardens.

## 2. Health and social aspects of community gardening

Social cohesion and informal social control are two major preconditions of collective efficacy. The result of solidarity, mutual trust between community members leads to the environment, where individuals are able to take action and follow the same goals together. (Sampson, et.al., 1997; Teig et al. 2009; Jacobs, 1961) We assume that community gardening may play significant community-defining role, if supported and applied widely in cities. Community gardens support social inclusion and positive social and psychological effects, which lead to healthier society (Hale et al. 2011). Moreover, community garden researches show increase of collective efficacy, neighbourhood attachment, and strengthened sense of safety. They also foster environmental knowledge, connect people and create emotional connections to the garden. At the local level, community gardens and the gardener experience provides a great opportunity to connect sustainable and productive landscape within the urban food environment (Hale et al. 2011; Teig et al. 2009).

Community gardens support local sustainability of cities and improve health of their residents. Apart from their race, age, ethnicity, social status or income, gardening supports diversity within local communities and also within greater national, or multinational movement of community gardeners. This social movement is a part of sustainable food production, which reaches also to people outside this community. Community gardeners also influence local and national policies, mainly in supporting healthy and active lifestyle and use of vacant spaces (Teig et al. 2009; Hyens, 1996; Armstrong 2000). Healthy and sustainable landscapes, to which belong also community gardens, constitute of the relationship between physical and social structures. Biological and environmental factors are meant by physical structures as well as manmade objects are meant by social structures, e.g. political, economic or cultural factors. Connecting food, environments and health through emotional, spiritual and value-driven experience is a challenge for designing places that connect individuals and shape communities (Cummins, et al. 2007; Hale et al. 2011). For planning and supporting sustainable cities it could be crucial to plan urban gardens for community activities based on these experiences.

Donna Armstrong´s survey of 63 community gardens grouped under twenty community garden programs in upstate New York resulted in the description of numerous benefits of gardening:

- Improved social connections, raising awareness and activity of local policy
- Interactions between gardeners´ groups through different programs
- Identification of children with cultivated land
- Participation also of lower income households
- Stronger community cohesion – recognition of people on the streets
- Higher knowledge about local actors – easier action initiation process
- Social control of the neighbourhood
- Landscaping attempts not only on the community garden
- Establishment of neighbourhood organizations
- Establishment and maintenance of parks and playgrounds (Armstrong 2000)

## 3. Urban and environmental aspects of community gardening

Community gardens are usually defined as any piece of land gardened by a group of people in different locations. Community gardens are very flexible and adaptable to different conditions. From spatial planning point of view community gardens can be classified by different criteria, such as location, area, connection to public/ private objects, ownership, and type of production:

- Location: urban, suburban, rural settlement
- Area: individual plots, mid-sized communal plot, large plot for urban agriculture

- Connection to objects: kindergartens, schools, hospitals, community centres, churches etc.
- Access: opened, semi-public, semi-private, private
- Ownership: public, private, unknown
- Type of production: ecological, permaculture, limited use of chemical fertilizers
- Production for: individual consumption, community, youth, local farmers´ market
- Support received: city, community budget, none etc.
  (Kaplan, et al. 2005)

Community gardens often create an environmentally sustainable alternative to the conventional rural agriculture. Gardeners grow flowers, fruits, vegetables and herbs to connect back to the nature and enjoy gardening as relaxing leisure-time activity (Kaplan, et al. 2005; Teig et al. 2009).

## 4. Challenges and perspectives of community gardening in Slovakia

According to Michel Pollan, it is necessary for our food production process to change, and this change should be made by our communities. Gardening communities might become an important part of the shift towards sustainable local food production.

Local food conditions are strongly affected by the way food is produced, transported to the shops/markets and finally distributed to the consumers. Community gardens may serve as one such landscape and are especially relevant in urban settings where residents, especially children, often lack experience with the fundamental processes associated with growing food (local farms, gardens). They are also connected with the lack of opportunities to purchase food from alternative, healthier and more personal, sustainable sources (farmers' markets, community-supported agriculture, small-scale grocery venues, food cooperatives) (Brown et al. 2000)

Challenges and perspectives in Slovakia:

- Limited research done yet (mapping of vacant spaces)
- Number of vacant/ unused plots in cities
- Brownfields as potential space
- First successful examples: community garden Sasinkova, Bratislava – Old Town, community vine yard and garden Pionierska, Bratislava – Nové Mesto
- Missing complex strategy for public spaces and legal support
- Missing support instruments for attracting gardeners (passportisation of available plots, clear rules,
- Promotion for land owners – usual fear of something new (gardeners will "stay forever", fear of plot degradation, administrational difficulties…)
- Transition of our cities
- And many others.

## 5. Conclusions

Urban environment can have positive effects on creation and growth of communities as they have the opportunity to build a local identity and a sense of localism around a certain space. Community gardens can have a huge impact on this process as well as on the quality of urban life beginning from producing fresh food to strengthening neighbourhood bonds. It can also have positive impacts on distressed neighbourhoods where vacant lots can be converted into community gardens or community green spaces and these improvements can have an effect on residents´ perception of safety outdoors, reduction of social problems and cultivation of social responsibility.

# THE ROLE OF THE ARCHITECT AND HIS DECISION-MAKING POWER IN THE TRANSFORMATION PROCESS OF SHRINKING CITIES. LEARNING FROM TWO FRENCH EXPERIENCES.

Sowa Charline
PhD student in Architecture, Laboratoire MHAevt, Université Grenoble-Alpes, Ecole Nationale Supérieure d'Architecture de Grenoble (ENSAG), sowac@bv.upmf-grenoble.fr

Keywords: France, shrinking cities, urban and architectural projects

## Abstract

*In France, the phenomenon of shrinkage is particularly visible in old industrial cities and in small cities and villages in rural regions. The impact of this process on lands, buildings, uses and landscape asks local stakeholders to act and architects to adapt his thought of space and project at this new urban condition. Until now, the architect answered commands which integrated in urban policies for revitalizing the territory, transforming the image of the city and attracting new populations and new investors. In this way, some cities developed flagship projects and invited often a "starchitect". Today, with more knowledge of the process, local stakeholders search new alternatives to transform the urban environment for maintaining inhabitants and improving their wellbeing. The architect has an important role in this new position. This communication will focus on the importance and the influence of the architect in the decision-making power of the project ownership to transform the urban fabric and to propose new forms of collaboration between local stakeholders and inhabitants. Two characteristic projects will be study: the project Îlot-test Franche-Amitié at Saint-Etienne and the urban study Habiter les centres-bourgs proposed by the Parc Naturel Régional of Livradois-Forez.*

## 1. Introduction

### *1.1. The issues of urban transformations in shrinking cities: between urban policies and architectural and urban interventions.*

At the beginning of the XXIth century, being interested in shrinking cities and their urban evolution participates in the improvement debates about the adaptability, the reversibility and the resilience of the city. How to continue to transform the city, growing or shrinking, when the global system is questioned after successive crisis (economic, social, political, environmental, etc.)? How urban planners and architects contribute?

The shrinkage phenomenon transforms the city spatially: lands, buildings and infrastructures, uses and landscapes. A diversity of abandoned spaces appears on the same territory: flats, buildings or plots, public spaces or urban infrastructures (Oswalt, 2005). Wastelands can be industrial, residential, commercial or still agricultural. They are in old (city centre) and suburban fabrics, in neighbourhood of blocks of flats, or in villages centres in rural spaces. It exists a new form of porosity in the city between the abandonment of spaces of big dimensions and spaces of small size, which are multiplying and integrated in the urban fabrics. It is particularly visible in Europe (Vigano, 2012). When the built, the plot and the public place are not occupied and maintained, their process of degradation tends to accelerate. The landscape is quickly transformed and the man has to "live" with these abandoned spaces (Anizon, 2010). The perception of empty can vary according to urban morphology. This distinction is perceptible between European and American cities (figure 1). The spatial impacts of this process accentuate or allow several urban issues (social, environmental, security, hygiene, etc.) to

emerge. For example, abandoned spaces can become impassable, participating in the spatial fracture of the city and the isolation of individuals. Abandoned buildings often become place of squat and traffic; and their fragility can threaten nearby inhabitants and the housing (Oswalt, 2005).

Figure 1. The different perceptions of the vacancy. Detroit (Chalmers district), Liverpool (Anfield district) and Saint-Etienne (Tarentaize-Beaubrun-Severin district) between 2013 and 2014.
Source : google street view / google.maps.com

In front of these numerous urban issues, urban planners and architects have to act. This new urban condition is an opportunity to think the city and urban environment differently. However, the climate (difficult and uncertain) and the constraints, linked to demographic, political, socioeconomic and spatial changes, might complicate the urban intervention. The state of the urban environment, -the quality and the degradation of existing building, plots and grounds-, might affect the choice of orientation of the project and its costs. The instability and the uncertainty of the socioeconomic context have to be integrated, but they can impact on the implementation of the project and its sustainability. The capacity of action is often limited because of the lack of human and financial means of the project ownership (public, private or inhabitants) and the public authorities (ex.: depts, bankrupt). It restricts possibilities of the project management to intervene.
Practitioners have to confront with another difficulty: the capacity to think the project and its process. Current tools and methods were developed to answer urban growth and not to this specific phenomenon of shrinkage. Constraints and problems due to the shrinkage ask to adapt themselves and new tools are necessary (Oswald, n.d; Rienets, 2006; Ryan, 2012). For example, the big scale of the vacancy asks to requestion the land management and its tools especially when owners left or when public authorities are little means. It is an essential aspect for the transformation and the reorganisation of shrinking cities, but it is a real difficulty for local authorities.

Today, urban planners and architects with public stakeholders think together about the future of their cities and alternatives approaches to the classic system. The relation between various stakeholders seems essential to find solutions and to realise projects.
This paper will focus on the role of the architect in the definition of new tools to adapt the shrinking cities and his influence on the decision-making power of local authorities. How does the architect participate into thinking of urban strategies ? How does he make the connection between urban policies, the urban strategy and the architectural intervention? Has he a particular influence? How does he lead the project?
Three hypotheses will be explored:

- The architect would highlight the architectural and urban qualities, the potentialities of the territory which was until now depreciated. Like for “urban design theory for the shrinking city ideal”, he “will, by necessity, have to value and incorporate these attributes” (Ryan, 2012). He would allow to change the look of local stakeholders and inhabitants with his specific analysis and knowledge on the site;
- In front of difficulties to lead the project, the architect would propose new forms of collaboration between local stakeholders and inhabitants to facilitate the realisation of project, in short and long term;

- With his operational approach, the architect is capable to think about new ways and tools to manage lands, but also to test it *in situ*. This approach would help owners and project ownerships for the evolution of the city and to anticipate complex situation. Furthermore, it is an opportunity to develop new options for enriching documents and tools of urban planning.

The architect give an essential support of the project ownership at the between the urban strategy and the urban and architectural interventions.

*1.2. Case studies and method*

To explore these questions, the context of France is interesting. The first remark is that it exists more and more studies and projects treating of issues of shrinkage, in urban and rural region. The second element is that there is a participation and an investment of public authorities in most cases. This choice is also due to my knowledge of the project practice in France, further to my training of architect and urban planner. This work has allowed myself to initiate a reflexion on the condition of the architect and the development of specific roles in front of current cyclical crisis in the profession.
We will analyse two experiences in cities declared in shrinkage by European researchers and statistical datas when projects were started. We have the urban project, th*e Îlot-test Franche-Amitié* at Saint-Etienne, and the study *Habiter les centres-bourgs* (Living in center-villages) proposed by the Parc Naturel Régional of Livradois-Forez.
For the analysis, they exist research documents for understanding the process of shrinkage and to explain urban policies in this context. About the project, the analysis made with documents of project presentation (websites, brochures, etc.) and with interviews of architects, teams of project management and local stakeholders when it was possible. These discussions helped to have information, which is not accessible or visible in the communication of initiatives, by the architect or by the municipality. It does not exist currently scientific documents about projects presented here.

Firstly we shall see the current positioning of the architect in reflections on the shrinkage in the international research and in the practice of the project. Then, we shall observe the role of the architect in the passage between the urban strategy and the architectural intervention. We will try to understand why he takes a more and more important place in the assistance for the project ownership and the community project management. This evolution is particular in the case of shrinking cities. To finish, we will explore this question in the specific case of France.

## 2. The architect, stakeholder involved in the reflection about the urban shrinkage since the 2000s.

*2.1. A noted involvement in the international research.*

Works of research and scientific debates about the phenomenon shrinkage are linked in general to the fields of geography, sociology, urban planning or political sciences. Many studies interpret mechanisms of shrinkage, but they analyse urban politics too (Großmann and al., 2013; Cunningham-Sabot and al., 2014) like: the governance, the economic development, the management of urban infrastructures (water network, public road network, etc.) or programs of housing and urban renewal.

Architecture, as urban design, is little visible in the international researches until now, in proposed topics in symposium and research networks. The architect can give however a specific vision of space. It is an element on which the architect is presently called to intervene (Corboz et al., 2009). The relation is different from the one of the geographer, be it in methods of analysis, tools or the way of intervening. Even if the architect is trained to intervene in contexts of growth, he is also in capacity to analyse the urban shrinkage. He leans on concrete data, in particular from his field experiences, for

formulating the project and imagining the future. Another track of the research is the capacity to reflect on the transformation of shrinking cities through the process of project and its analysis. To conclude, the architect is able to bring complementary knowledge in definitions, in descriptions of cases studies, in the way to intervene at the scale of plot or block, or in prospective approaches.

One of the first to take an interest in urban and architectural aspects was the research team of the architect Philipp Oswalt, in the framework of the German program *Shrinking City*. One part of their work was to collect experiences in the world, which dealt with the management of the urban shrinkage, as well in term of urban policies and urban actions by the architects, as initiatives of inhabitants. All the work was mediatized between 2004 and 2006. Further to the study, a web site, a set of books and an exhibition was created. This exhibition was presented in Germany, in Europe and in the United States. A striking event was its installation at the 10th International Biennial of Architecture at Venice in 2006. In the fame of this event, numerous practitioners (architects, landscape-architects, urban designers, urban planners, etc.) were able to discover this work and became aware of the urban phenomenon.
Today, the interest for this topic among young researchers in architecture is also to underline and is beginning to distinguish. This assessment is perceptible with PhD students of the network SCRIN[1], and during training schools organized in 2011, 2012 and 2013 by the European program EU-COST action: TU0803 Cities Regrowing Smaller (Wiechmann, 2009) and the University of Dortmund (Germany). For the last workshop in 2013 entitled *Scenarios 2030 - Possible Intendeds of Shrinking Cities in Europe*, there were 5 architects and 1 landscape-architect among 14 invited students.
In the architectural research in France, the shrinkage in all dimensions still little is object of research, even if some interventions and cases of study are submitted to the debate in specialized French periodicals such as *Ecologik*, *D'A, Archiscopie*, *AMC*, *Les cahiers thématiques : architecture, histoire, conception,* or *Urbanisme* and *Traits urbains*. The case of Detroit is become one of the inescapable grounds for these five last years. Research programs, studies and thesis are developing in different laboratories of architecture schools (ex. : Nantes, Versailles, Grenoble). Works are about questions of ambiances, inhabitant initiatives, architectural projects and masterplans or the urban agriculture and the landscape evolution. Even if this context is interesting, Detroit should not to become the support for generalities on the debate and the research on the urban shrinkage. The multiplicity and the diversity of spaces in shrinkage ask to the architect to adapt in every situation.

### *2.2. A fertile ground for experimental reflections about the architectural and urban project.*

For more than ten years, at the international scale, shrinking cities has become new playgrounds for architects, urban planners, artists or inhabitants for exploring and testing alternative urban experiments. It exists a diversity of projects at various scales and we can see that in some specific books as: *Shrinking cities 1, International research* (2005), *Shrinking cities 2, Interventions* (2006), *The unreal estate guide to Detroit* (2012) and *Urban catalyst: the power of temporary use* (2013). Some projects and calls of ideas are open to debate.

One can note that shrinking cities became a veritable fertile ground for numerous architectural projects since the last crisis of 2008. The highlighting of more and more cities in shrinkage[2] and the images of empty plots indeed had an effect of electric shock in the profession. This event also accelerated an already present process where "many young architects, themselves affected by the crisis in the building sector, have taken on this new role and turned their misery into a professional challenge, exploiting the possibilities of low rents and empty spaces to set up small enterprises or cultural

[1] SCRIN : Shrinking Cities Research International Network
[2] In the media as in the scientific literature, like Leipzig in Germany or in United States (Detroit, Pittsburgh, Buffalo, Cleveland, etc.).

initiatives" (Rienets, 2006). Shrinking cities, like all territories in crisis, the post-disaster reconstruction ask the architect to "include the ability to do more with less"(Aquilino, 2011) and to define the construction neither "as the goal of architectural/urban planning action" but as "the starting point" (oswalt, n.d.). All kind of vacant spaces become the base of the intervention before favouring the artificialisation of new grounds and are questioned: do you need to preserve, to transform, to deconstruct or to recycle? Which reflection to have on plot pattern? etc.
This interest is perceptible through two examples. There is a multiplication of student works in architecture and urban design. The researcher Brent Ryan organized with the MIT different workshops on Buffalo in 2010 and Baltimore in 2011 and 2013. In France, more and more students work for their diploma in architecture about the urban shrinkage. They choose study grounds in France (Thiers), in Germany (Leipzig, Essen), in Japan or in the United States (Detroit, Saint-Louis). By the innovative dimension of propositions, some of the projects are published or awarded. This year, the topic of the European workshop *Oikodomos*[3] is about "contemporary living patterns: growth / shrinkage", with cases of Berlin and Cottbus (Germany).
This trend is also noted for the Europan competition which is recognized by the profession of architect at the international scale. For the two last sessions, Europan 12 (2013) and Europan 13 (2015), the topic is "the adaptable city: inserting the urban rhythms" and it is the occasion to highlight potentials of territories in favour of the urban innovation. The concept of *shrinking city* was presented (Rebois, 2011) in the edition 2013, and there are some selected cities are considered in shrinkage: Vichy and Moulins (France); Wittenberge, Bitterfeld-Wolfen and Gera (Allemagne); or Seraing (Belgique).
All experiences around the world contribute to reflections and debates on the practice of project in territories in crisis and the research in architecture. Some aspects and questions are recurring and we can note for example: the evolution of uses of vacant lands; the reduction of costs to realise the project at different levels (participation of inhabitants; the recycling of materials; the construction site, etc.); the place of architect in the project process.

### *2.3. An opportunity to rethink our urban model?*

The urban condition of shrinking cities re-questions our current urban models (Mateo, 2011) and the approach of development by growth. The evolution of the urban form, of the uses and of the landscape is in the heart of debates. Besides ecological issues and the ambition to reduce the human impact on the territory, to think about these questions in context of shrinkage is an opportunity: everything can be newly define. Some cities use it to think the city more "green" from the demolition of the unused and unhealthy built, and the renaturation of spaces, but these approaches are sometimes distorted for purposes of "urban marketing" by municipalities (Baron and al., 2010).

In more theoretical approaches in specific contexts, the architect contributes at the exploration of new urban models in proposing radical urban strategies.
The team of architects, composed of Rem Koohlaas, Oswald Mathias Ungers, Peter Riemann, Hans Kollhoff and Arthur Ovaska, were the first ones to explore new urban models with the case of Berlin, in the 1970s. For them, the demographic decline is an opportunity to identify vacant spaces and to determine spaces which have to be protected and those to be renatured for forming a *city-archipelago*. This theoretical project was re-communicated in 2013 with the research work of Florian Hertweck and Sébastien Marot in the book *The City in the City. Berlin: A Green Archipelago*. It still is current.
Since, more and more cities experiment new forms of urban strategies and urban policies for engaging the mutation of the city. They can be quoted in different plans and programs. In Germany, the city of Halle is exploring the *compact cit*y (De Gasperin, 2009; Roth, 2011). They are also the tool

[3] Oikodomos is a virtual campus to promote the study of dwelling in contemporary Europe. Different european schools and universities of architecture, urban planning and urban design work together. website : http://www.oikodomos.org

*International Architecture Exhibition*[4] which was used twice by authorities to think the transformation of cities and regions in shrinkage. The first experience was the IBA Emscher Park during 1990s in the Ruhr region. An important part of work was the improvement of the environmental frame and the renaturation of brownfields with the creation of cultural and sports facilities. Between 2002 and 2010, the urban shrinkage was at the heart of the *IBA Urban Redevelopment Saxony-Anhalt in East Germany*[5]. Selected cities served as experimental territories to find alternatives in their re-energization and re-organization. Dessau was the exploration territory to try the concept of *urban archipelago* through the project *Urban Cores – Landscape Zones* (Wiechmann et al., 2013). In the United States, the rightsizing of the city is more often experimented and especially for "greening" vacant spaces (Schwarz, 2012). Perspective projects like *Youngtstown 2010*[6] and the *Detroit Future City Strategic Framework Plan*[7] are two characteristic examples. In Japan, the project of *Fiber City 2050*[8] for the metropolis of Tokyo proposes a different approach of American cities in focusing on the urban development and the concentration of inhabitants on urban fibers as existing green armatures and railways.

On the short term, these examples offer various ways to adapt the city of human (demography) and urban realities (vacancy). It is an opportunity to think about to have a better urban management, to reduce artificial spaces and to renature grounds, or still to preserve the proximity and the social links between inhabitants which are scattered on the territory. In long-term, it might be a veritable impact of way of life. Nevertheless, these urban strategies still have not much impact in the documents of town planning (Ryan, 2012), or in the architectural and urban projects lead by the local authorities.

## 3. From urban strategy to urban intervention: a role of assistance for the architect with different stakeholders more and more marked in shrinking cities.

*3.1. An evolution of the public commission which re-questions the role of the architect in projects.*

Even if the shrinkage are being accepted as a "decisive factor of the evolution to come from territories, societies and activities" by local stakeholders (Baron and al., 2010), alternative urban strategies which integrates this situation (as seen previously - part 2.3.) still are exceptional.
In some cities in Europe, the architect until now answered requests which integrated in urban policies for revitalizing the territory, transforming the image of the city and attracting new populations and new investors (Baron and al., 2010; Cunningham-Sabot, Fol, 2010). The urban strategy was to recapture important brownfields and developed flagship projects (urban projects and public buildings), often linked with the culture (Grésillon, 2011) and with the invitation of a "starchitect". The Guggenheim museum of Bilbao by Frank Gehry was the first example. The "choice of architectural and design about a cultural policy of international scale" and " a new communication of the project on the outside scene"(Nicolas, 2014) made a deep impression on people and the concept was took again. Thereafter, were built: "la Cité du Design" (agency LIN with Finn Geipel) at Saint-Etienne; the Louvre-Lens museum (SANAA); the University Library of Cottbus (Herzog & De Meuron); the Riverside Museum of Glasgow and the Phaeno Science Center of Wolfsburg by Zaha Hadid, etc. In parallel of these initiatives, there are often projects of urban renewal on the existing urban fabric, treating problems of the housing and the management properties and buildings. Architects are generally in front of commissions asking to maintain, to demolish, to recycle building or to product new constructions.

[4] Translation of German *Internationale Bauausstellung,* more famous with the acronym IBA.
[5] The topic was "less is future". 19 cities participated.
[6] wedsite: http://www.cityofyoungstownoh.com/about_youngstown/youngstown_2010/
[7] website : http://detroitfuturecity.com
[8] website: http://www.fibercity2050.net

Since the beginning of 2000s, other projects have been emerging outside these important and mediatised urban and architectural projects. With more knowledge of the process and their capacities, local stakeholders searched new urban strategies and alternatives to transform the urban environment for maintaining inhabitants and improving their wellbeing (Baron et al., 2010). It allows architects to have more liberties and to experiment new ways of thinking the process of project. The architect and the team of project management are important stakeholders on the territory and its transformation. The model of urban strategy marked by cultural policies has begun to be criticized as these architectural flagship projects which can be characterised of "*machines célibataires"* (single machine). Olivier Mongin took over this concept of Marcel Duchamps illustrating architectural objects which are not in relation with its environment (Mongin, 2005). There is a "standardisation" of architectural production. In this continuity of these argument, Jean-Louis Violeau remind that "to design a project (of architecture) means to open a space, and no to try systematically to fill it as try to make it these single buildings" (Violeau, 2013, p.19). In shrinking cities, the analysis shows us that flagship projects are currently disconnected of the obsolete urban fabric and they are not accessible to all the population. It is "disembodied, on the scale of "consciousness" collective, by the construction of a "city branding"(Baron et al., 2010, p. 293).

*3.2. Actual trend in shrinking cities: more and more architects with a role of assistance.*

The current trend in Europe is an evolution of the role of the architect towards the council and the mediation "in interaction with a multitude of partners (State, local authorities, society of planning and developers)"(Bonetti, 2004). We can note this evolution especially in shrinking cities like in Germany or in France. For example, public project-ownerships (ex.: municipalities, regional structures) have little ways to act on their territories. Consequently they will lauch calls for ideas to have several possibilities to act. In France, it is very common in rural regions. In this situation, the architect as project manager might become project ownership supporter. The result is not the finalised project but the development of tools for accompanying public authorities and inhabitants in the definition of new urban strategies and urban projects. In this continuity, we have the international competition, *Future Ground*[9], organized by the Van Alen Institute in collaboration with the municipality of the New Orleans. Three multidisciplinary teams were invited to think about the transformation of landscapes and the reuse vacant lands through the experimentation of flexible designs and policy strategies.
It is more frequent to see the architect becoming "project manager supporter". His assistance is more and more asking from a specific project-ownerships, particularly present in shrinking cities : the community groups composed of inhabitants, non profit organization or association, etc. In United State, it is very visible where the State and local authorities are not any more invested (Detroit, Buffalo, Philadelphia, etc.). These community groups are the project-ownerships but also the project manager. They are themselves who think and realise projects of urban renewal at the scale of their neighbourhood. At Detroit, we have the example of the transformation of Old Redford district by the non-profit organisation Motor City Blight Busters (MCBB) and the One Mile Project in the New Center district.

With constraints of shrinking cities, architects envisage also in the process or project to give a part of project of inhabitants and became "project manager supporter". One of most significant project is "Urban cores, Landscape zone" at Dessau (Germany). The pluridisciplinary team of project management defined important axes of the urban strategy. The choice was to offer inhabitants (citizen, family, company, group of young people, etc.) the possibility of defining, producing, managing and controlling these spaces freely. The objective was to make inhabitants aware of their responsibilities in

[9] website: https://vanalen.org/projects/future-ground/#about

front of their environment, and also to reduce cost of project on short and long term, to maintain public spaces (Brückner, Stein, 2007; Wiechmann and al., 2013).

We can analyse that the architect and the team of project management have an important role to assist these stakeholders, public as private, to defend this new position and to succeed the urban intervention. It is important to take into account (Ryan, 2012). Exchanges and interactions allow to feed into the knowledge on the common territory and to bring new looks on its future. They accompany also stakeholders and inhabitants in the re-appropriation of their space by thinking about new ways of life, with proposals, which are short-term and long-term, ephemeral, as lasting.

**4. The study of the French case: example of two experimental projects.**

*4.1. The phenomenon of shrinkage in urban context like rural: two potential sources of reflection.*

The research work of Emmanuèle Cunningham-Sabot, Sylvie Fol, Hélène Roth, Daniel Florentin and Manuel Wolff in France introduce us with a diversity of shrinking cities. There are more particularly old industrial cities, small cities and villages in rural regions (Cunningham-Sabot and Fol, 2009; Wolff and al., 2013). Even if the question of the shrinkage is not directly highlighted in political speeches, there is generally a good knowledge of spatial realities by practitioners (architect and urban planner) and local stakeholders.

This multiplicity of contexts offers architects and urban planners the possibility to explore all dimensions of shrinkage. Today, these territories know an increasing interest by these professions, be it for brownfields, small vacant plots in city center or the reconquest of public spaces.
We were able to see it previously with works of students, the Europan competition or the multiplication of call for ideas. Saint-Etienne is one of the cities which explores most of possibilities, between flagship projects (building and urban project) on brownfield and alternatives projects on the existing urban fabric. The public space was also a ground of experimental initiatives in Saint-Etienne. We have for example: the transformation of the site of the cardboard industry in temporary public spaces (since 2010); the competition «Défrichez-là» (2011) to occupied a vacant plot; a competition for urban furniture for the last biennale in 2015.
Concerning policies of the urban renewal, the shrinkage is not always affirmed. We have maybe an exception with the international consultation organized to Saint-Dizier for the transformation and the extension of its historic center (Scoffier, 2011). But there is a research to have solution concerning the unhealthy and vacant habitat in shrinking cities. Since 2003, these cities are very often helped by a financial support of the State to lead their projects, through the Agence Nationale pour la Rénovation Urbaine[10] (ANRU) in charge of the Programme National pour la Rénovation Urbaine (PNRU). Among 600 neighbourhoods which received of the PNRU, about fifty cases are in shrinking regions (Kacza et al., 2013).
In 2014, the State decided to help villages centres in escheat in rural regions, further to a demographical decline or a weakening of their functions of centrality, sometimes accompanied by the development of peripheral suburban zones[11]. 300 villages centres was eligible the call of manifestation of interest “Centres-bourgs”, but only 50 were chosen to try this an experimental tool.

The French context is very regulated. How to lead the project when this framework can force or limit the action between specific constraints of the shrinkage and the regulatory system? Both two examples presented then, the urban project *Îlot-test Franche-Amitié* and the study *Habiter les centres-bourgs*,

[10] the website : http://www.anru.fr/
[11] Presentation of the project on the link : http://www.territoires.gouv.fr/revitaliser-les-centres-bourgs-un-enjeu-majeur-pour-l-egalite-des-territoires

we will observe how the project try to surpass these constraints. We will analyse : the role and the place of architect in the process of project and between different stakeholders; the spirit of initiative of architect in the arranging of alternatives solutions for allowing the realisation of project; the awareness of different components of urban fabric (plot, build, uses) to act an urban renewal of quality.

*3.2. Assuming the dedensification: Saint-Etienne and the project Îlot-test Franche-Amitié*

Saint-Etienne lost between 1968 and 2010 around 23 % of its population. The departure of the activities and the inhabitants for the first urban rings and for other regions engendered a vacancy in the city centre and an advanced degradation of the urban fabric. From 1990s, the municipality became aware of its state and have been trying to revitalize (Miot, 2009). Architectural and urban projects punctuate from now on the landscape as the "Cité du Design" or the requalification of the site of the Manufacture-Plaine Achille entrusted to Alexandre Chemetoff's team.
In parallel, the municipality searched also other approaches for its urban renewal with the priority objective: the improvement of the environment built in the unhealthy neighbourhood. It began an experimental initiative which aimed to acquire plots and building for acting on the urban fabric and for reducing the vacancy by the creation of quality public places[12]. The project of the *Square Hauptmann* designed by the local agency YES Architectes (now, A-MAS) was the first experimentation (2000-2002) of this kind. In the continuity, it is interesting to look more specifically at the project *Îlot-test Franche Amitié*, because the approach of plots repurchase was applied on the scale of a block. Realised between 2006 and 2014 by the team of project management composed of Eric Clavier (architect), François Chomienne (landscape-architect) and the BET[13] Gépral, the site is integrated into the perimeter ANRU program in the Tarentaize-Beaubrun-Séverine neighbourhood. This block was chosen because it was the most degraded of the district and had to serve as model for a process of larger-scale urban renewal[14]. The objective of the tender was to de-densify of the heart of the block, to regenerate obsolete buildings and to create public and private places with collective management for maintaining the local population.
One of the major difficulties was to act on the block. The population living in the neighbourhood is essentially poor and owners had few financial means for acting. The municipality had no stranglehold (land) on the site. The choice by local authorities was to acquire plots to intervene and to lead a global action. Before the project begun, the SEDL[15] started to acquire some plots and buildings by anticipation on the future urban renewal. But to continue this process, the solution was to do a "*déclaration d'utilité public*" (DUP - declaration of public utilities) by the creation of a road and 20 garages. This axis had to allow the deconstruction of unhealthy buildings and the connection between the site and the rest of the district. The *Etablissement Public Foncier de l'Ouest Rhône-Alpes* (EPORA) helped the team of project ownership ( SEDL and the municipality of Saint-Etienne) to acquire and manage all plots with the obligation to restore some plots to the owners after the arrangements of private open spaces (gardens). It was a complicated assembly work in order to make the project feasible. The project proposed an intervention in the inside of the block, without affecting directly the building situated at the outside.
The team of project management had a real role of assistance with the project ownership composed with local authorities to succeed in an urban project of quality. They were stakeholders of decisions and took part in the operational arrangement of project. They worked and negotiated more than 3 years with the team of project ownership to adapt the project; on one hand to answer budgets and regulatory

[12] Remarks collected with Stéphanie David, architect to the agency A-MAS (20/03/2014) and with Lauranne Ponsonnet, director of the Mission Project Urbain of the municipality of Saint-Etienne (03/06/2014).
[13] BET is the acronym for "*bureau d'études techniques*". It can be translated in english by "engineering department".
[14] Remarks collected with Anne Lebeau and Jean-Paul Chartron, assignment managers of the housing, Municipality of Saint-Etienne(02/07/2014)
[15] Acronym of *Société d'Equipement et de Développement de la Loire*

requirements, and on the other hand to allow the production of a quality public place for transforming the road into pedestrian alley. In the work of the project definition, the qualities of the existing (plot pattern, situation of buildings) helped to define buildings to preserve or to deconstruct, as well as spaces opened to clear (Horticulture et Paysage, 2012).

Figure 2. Explicative maps of the project Îlot-test Franche-Amitié. 1: Two project ownership / 2: Influence of the action of the project manager / 3: Orientations of project / 4: Current state of block
Source : Charline Sowa, 2014

Although the approach had to facilitate a global intervention, the project management team did not intervene on the built, only for the definition of its future: maintenance and renovation or demolition and recycling. The propositions of design are only on the open spaces. The architectural interventions (only buildings) were led by others architects which had to respect specifications. It was still not simple to have a global vision on the urban renewal of the block. Nevertheless, the architect played the role of advisor for projects of renovation or new building was led.
The architect knew how to highlight his capacity to have a global vision on the project, allowing him to be: the interface between the complex project ownership and the spatial realities; an important stakeholder throughout the project : from the definition of the operational frame of the constructive details, with the period of construction site. The thinking of all steps of project process allowed to limit expenses and to remain in the projected budget.

Figure 3: Point of view in the interior of block. Source : Charline Sowa, 2014

*3.3. Re-adapting the existing: the Parc Naturel Régional (PNR) of Livradois-Forez and the study on "Habiter les centres-bourgs"*

During the XIXth century, the rural region of Livradois-Forez knew an economic development engendering a demographic boom and a densification of urban fabric. Free plots were filled quickly in front of the continual growth of population It was at this period that villages took their current urban form. Until the 1950s, the centre of small cities and villages in the Livradois-Forez and all Auvergne region were populated. With the evolution of ways of life, practices in rural environment and new demands of population, there was a demographic decline with the departure of population, an escheat of center-villages and the increase of the vacancy (Gaudey and Terra, 2008; Bernard et al., 2014). The housing has become inadequate and the territory weakened.

Until now, reflections and projects on the territory answered approaches one by one, without a long-term vision, according to needs and opportunities (Bernard et al., 2014). This approach was questioned since and abandoned spaces in villages centres are beginning to be envisaged as real of equipped and serviced land-reserves. The compact form of the urban fabric also tends to facilitate exchanges between individuals. To re-adapt villages centres would so offer an alternative to the urban sprawl. With this analysis, the PNR of Livradois-Forez went into an invitation to tender in 2011 for a study about the question of the living in village centre, with the financial support of the DATAR. 6 sites of study (Cunlhat, Châteldon, Courpière, La Monnerie-le-Montel, Saint-Germain-l'Herm, Saint-Dier-d'Auvergne) served as support of reflection which were divided between three teams of project management, mainly consisted of architects, and two school of architecture.

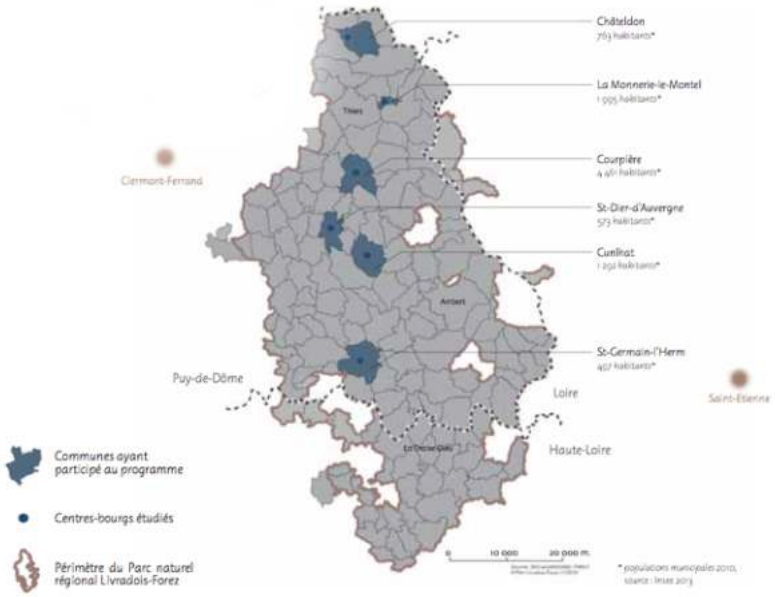

Figure 4. Situation of cities participating to the study in the PNR of Livradois-Forez.
Source: PNR Livradois-Forez, 2014.

Through this study, one of questions was the land management by municipalities and inhabitants. The architect had to propose one or several adapted solutions. The analysis presented that very often, municipalities had no idea of the state of land, little information on plot and its uses. Even if it existed, it was not always updated.
The work of the Collectif ETC on municipalities of Cunlhat and Châteldon was interesting for this dimension. To develop new tools, the team was inspired by tools of agricultural-land management

conceived by the French association *Terre de liens*. It established a protocol of actions to collect information and to develop an operating tool of land management. It was to allow then to define actions on plots which would be adjusted to needs and real practices of space. The objective was to engage a dynamics of the land observation and to integrate the inhabitants into this work. After the mass of data, the team proposed different options about the way to manage plots and especially to execute a land assembly. The first one is to connect inhabitants and to raise awareness among them. The second one is in the longer term, to assist the municipality to take the role of mediator between owners for allowing the emergence of projects with a bigger scale.

Figure 5. Tools of of analysis on Châteldon. Source: Collectif ETC.

Figure 6. Theoretical reflections for Châteldon to test different possibilities for the land assembly and the land management by public authorities and inhabitants. Source: Collectif ETC.

The architect had an important role in this reflection. Many recommendations were given on the improvement of the offer of the housing and the image of villages and the attractiveness. It was proposed innovative and alternative tools for helping municipalities and inhabitants.
Another dimension is interesting to present: the place of the communication in the appropriation process of the study by differents stakeholders (inhabitants like municipalities and the PNR Livradois-Forez). For Cunlhat, Châteldon, Courpière and La Monnerie-le-Montel, there was an important place for a blog which became a veritable space of communication and exchange.

The objective was to test and to retranscribe transposable methods of work in other territories which know the same difficulties that the villages centres of the PNR. But today, there are not continuity with different teams on the territory or applications. But this initiative inspired other territories, in the PNR Livradois-Forez (Ambert, Chabreloche, Olliergues) or in France.

**4. Conclusion: which lessons to learn of these French experiences?**

Through these examples, we saw that through the process of project, it is looked for to exceed the constraints linked with the shrinkage and in regulations of town planning. They try to propose adapted solutions for the transformation of the urban fabric. Architects and the team of project management was the interface between temporal and spatial scales for local actors and inhabitants.
Whether it is with the work of demolition and recycling in Saint-Etienne or with the reflection on the land assembly for Châteldon, the architects managed to offer another image of these spaces which were pending. They revalue as well the qualities of the plot pattern as the built and they propose a new quality of the housing environment in reply with the new demands.
In both cases, the relation between the various stakeholders was essential for a good understanding of the commission and proposals. In these collaborations, we were able to note some trends. For Saint-Etienne, the project management did the interface with the project ownership in the redefining of the commission. The architect brought his expertise and was a stakeholder in negotiations between the double project ownership and the owners. Secondly, he had a role of advisor to the architects acting on the built that to owners who wished to invest on the project in asking advices on the arrangement of private gardens. In the Livradois-Forez, we were able to see that different local stakeholders were requested at various stages of the project process. The architects valued their capacity to be porter of knowledge on their territory. They then found solutions to help municipalities to manage the land, and in particular with the investment of the inhabitants. This method aimed to allow for the inhabitants to reinvest their village and for the public stakeholders to have a better knowledge of them inhabitants and of the urban environment.
In the Livradois-Forez, the commission was complex in front of land problems. The collective ETC. gave tools to help municipalities to manage the urban fabric (land, built, uses) and to adapt it to the demand. Among other reflections on sites of the call for ideas, the proposition for the village centre of Monnerie-le-Montel proposed keys for reading of issues and a prospective vision to allow to the municipality to organize into a hierarchy their actions according to their capacities in time. A good relation between different levels of stakeholders allows to experiment new tools of project. For Saint-Etienne, they succeed to manage the project by exploring all the regulatory possibilities and by facing the multiplicity of owners.
It would be interesting to develop this analysis on other examples in France, in Europe or in United-States. For the American case, it is possible to see very often approaches in *pro bono* to help community groups to realise their project, from the program to the construction, in co-production or as project management supporter.
To conclude, projects were possible with invested local stakeholders and help of public authorities with specific funds by the ANRU or the DATAR. The position of assistance was integrated in the process of project and it is not annexe. While in the case of the commission of the PNR of Livradois-Forez, proposals might be a potential impact in the decision-making power of the municipality to develop a territorial strategy; in the case of Saint-Etienne, it is to nuance. Even the project was realised and it is a interesting urban project at different levels, the temporality of the process and this expansive cost reduced the ambition to continue this approach at the scale of neighbourhood.

# A comparative study of the European and Japanese definitions of shrinking cities as applied to Japan

Tetsuji UEMURA[1]

[1]Nomura Research Institute, t-uemura@nri.co.jp/tetsujiuemura@yahoo.co.jp

Keywords: Shrinking cities, Definition of cities,

**Abstract**

Population decline and industrial decline are obvious phenomena not only in Europe but also in Japan. Issues related to population and industrial decline have been actively discussed, and academic knowledge and analysis based on international comparative studies are expected to develop countermeasures to the most critical situations.

The definition of shrinking city that is applied, however, is not necessarily the same, and such a fundamental element of the discussion has not been fully examined so far.

This study, therefore, aims at comparing the different definitions of "shrinking cities" used in Japan and Europe and developing the best way to provide a reliable basis for future discussion on shrinking cities' topics.

The results of this comparative study suggest that COST Action's definition allows an analysis of Japanese cities to include the so-called "depopulated area issue" because the Japanese population in municipalities is rather bigger than the population in European municipalities, and Japanese cities may have lower figures for population density distribution and artificial land use within their territory.

In conclusion, Japanese sampled cities based on the Japanese definition are not necessarily suitable for the basis of a comparison study. This is because some Japanese "cities" do not satisfy objective criteria such as population size because the "city" has never been downgraded having once been upgraded to "city". Rather, the European definition of "city" better reflects the elements of the city, so that Japan should also follow the European definition of "city" for future discussions on shrinking cities.

## 1. Introduction

### *1.1. Background*

In Japan where nationwide population decline started, not only rural depopulation but also urban depopulation has now become obvious. Population decline in cities and industrial decline has been studied in the context of "shrinking cities". The 5W1H of shrinking cities and countermeasures for it have been discussed in many previous research studies around the world. In this context, the definition of "city" used is not necessarily the same in different regions and countries.

For example, there are quite different local government systems and regional structures. These differences do not allow us to compare the problems of shrinking cities easily. To cope with this situation, a common definition of the "city" was provided in COST Action[1]. Based on this definition, shrinking cities were identified and the demographic change of the cities was analyzed (Wiechmann and Wolff, 2013).

Many case studies of shrinking cities in Europe have already been introduced in Japan. For example, there are the German shrinking cities cases (Uemura and Uto, 2010), the case of Berlin and Brandenburg (Takami and Harada, 2009), the case of French vacant house countermeasures (Koyanagi, 2014) and the Torino regrowth case in Italy (Yahagi, 2014).

When we compare the best practice for regional development around the world, we should bear in mind the premise of the case, such as the attributes of the region. In a discussion of shrinking cities, we should bear in mind the definition of "city" and "urban". Unfortunately, the difference in the definition of the city in Japan and the city in the context of the shrinking cities in Europe is still not clear.

From now on, to promote an international comparison study between shrinking cities in Japan and other countries, it is important to clarify the differences in the definition of the city in Japan and in Europe in the context of shrinking cities, and also to evaluate the impact of these differences on the discussion.

### *1.2. Aim*

In order to clarify the differences between cities in Japan and Europe and also to evaluate the impacts of this difference, the definition of "city" used in the COST Action Programme in Europe is applied to the Japanese municipalities' attribute data, and then the Japanese municipalities are categorized. By using the definition of the "city" used by COST Action, we can identify the reasons for the differences between Japan and Europe. Accordingly, this study aims to also examine the causes for the differences. In addition, the definition of demographic change used by COST Action is also applied to the demographic change of

[1] http://www.cost.eu/COST_Actions

shrinking municipalities in Japan. This study also examines the geographical distribution of cities according to each categorization.

### *1.3. Structure*

In section two, the methodology including research steps, the introduction of the definition of "city" and demographic change, and data set are introduced. In the third section, the results of the application of the definition to Japan are presented. In section four, the validity of the definition of Japanese "city" and the geographical distribution of categorized "shrinking cities in Japan" are examined. Also, the reason for the variance between Japanese "cities" and European "cities" is discussed. Finally, the summary is presented and further research topics are also indicated in the concluding section.

## 2. Methodology

### *2.1. Research framework*

This study follows the three steps below.

First, this study examines the validity of the definition of "city" in Japan by applying the European definition used by COST Action to Japanese municipalities' data and the results are plotted on a map of Japan, and the coverage of classified municipalities are confirmed.

Second, the demographic change of Japanese shrinking cities is analysed based on the European definition of dynamic typology used by COST Action and then the results are drawn on the map of Japan.

Third, a comparison between Japanese cities and "cities" categorized by the European definition is conducted. The number and ratio of Japanese cities according to the Japanese definition but not cities according to the European definition, and cities following the European definition but not cities according to the Japanese definition against the total number of municipalities in Japan are also confirmed. Moreover, the causes of such a mismatch are also discussed.

Through these three steps, the possibility of the application of the European definition of "cities" used by COST Action is examined.

### *2.2. Definition*

#### 2.2.1. Definition of "city"

Under the COST Action definition, "cities" are defined by three criteria, "size of population", "population density", and "artificial land use" as shown in Table 1. Hereafter, municipalities classified by these criteria are called "Cities by European definition" to be identified from "Cities by Japanese definition".

**Table 1 Three criteria for defining cities by COST Action**

| Items | Criteria |
|---|---|
| Population size | Total population in 2010 in the municipality > 5,000 inhabitants |
| Population density | Density of the population living in densely populated parts of more than 1,000 inhabitants per $km^2$ > 50% |
| Artificial land use | Share of urban area (artificial surface) within the municipality > 5% |

Source: Wiechmann and Wolff (2013)

### 2.2.2. Definition of dynamic typology

In order to describe the demographic change in shrinking cities in Japan, three types of shrinkage of the demography in the region are defined in COST Action: "continuous shrinkage", "episodic shrinkage" and "temporary shrinkage".
The same definitions of dynamic typology as used in COST Action are applied. In COST Action, the data between 1990 and 2010 are used for the analysis. This period may be identified by the reunion of Eastern and Western Germany in 1989, the democratization of the former communist countries of Eastern Europe in the 1990s and the enlargement of the European Union that occurred in the early 2000s. This time, the same definition should be used to confirm the validation of the definition by COST Action for Japan. The date between 1990 and 2010, therefore, is used for the analysis.

**Table 2 Dynamic Typology in COST Action**

| Dynamic typology | COST Action |
|---|---|
| Type A<br>Continuous shrinkage | These cities have lost at least 0.15% of their residents annually in all four five-year intervals since 1990. |
| Type B<br>Episodic shrinkage | These cities have lost in at least one five-year period a stable (+/- 0.15% p.a. ) or even growing population (> +0.15% p.a.). |
| Type C<br>Temporarily shrinking cities | These cities have not lost population of at least 0.15% p.a. over the entire period, but have in at least one five-year period. |

Source: Wiechmann and Wolff (2013)

### *2.3. Data*

The data for analysis are the "population" and "area" of municipalities, and land use information in a 100m × 100m grid of "Land utilization segmented grid data".
The 500m ×500m grid population data is used for the Population density criterion. The population in 500m ×500m divided by 2.5 is equal to population density (people/$km^2$) in the grid. The ratio of grids satisfying the criterion for population density against all grids within the municipality is calculated, and the result is used for classification.
For classification of artificial land use, the 100m × 100m grid of "Land utilization segmented grid data" is used. "Site of building", "trunk transport site" and "other site" are regarded as artificial land use in the data set. By counting grids used for these land uses, and by comparing the number of grids against all grids belonging to the municipalities, the

percentage of artificial land use area in the municipalities is calculated. Based on the percentage, the municipalities are classified.

**Table 3 Data for analysis and data source**

| Criteria | Data name | Data source |
|---|---|---|
| Population size | Population in 2010 | Statistics Bureau (2012) POPULATION AND HOUSEHOLDS OF JAPAN 2010 |
| Population density | Population in 500m × 500m grid | |
| Artificial land use | Land usage classifications | National Land Numerical Information, Land utilization segmented grid data |

## 3. Results

### *3.1. Result of city classification by COST Action criteria and dynamic typology*

#### 3.1.1. Size of population

The result of applying the population size criterion is that more than 85% of municipalities in Japan have achieved this criterion. The distribution of municipalities on the map suggests that municipalities located in almost all regions except the northern part of Hokkaido and mountainous areas of Honshu, Shikoku and Kyusyu could meet these criteria. Accordingly, it is suggested that the size of municipalities in Japan is rather larger than that in Europe.

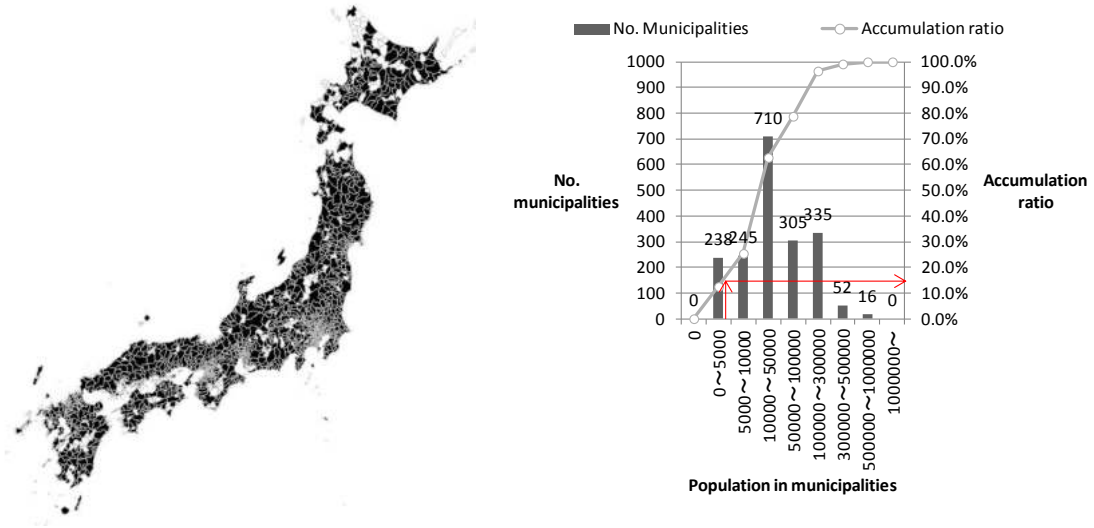

**Figure 1 Municipalities with more than 5,000 people**

#### 3.1.2. Density of population

In terms of the population density criterion, more than 60% of municipalities in Japan could meet the criteria of more than 50% of the population living in densely populated areas (1,000 people/km$^2$). Interestingly, when we confirm the distribution of these selected municipalities on the map of Japan, most areas of Hokkaido, the urban areas in Honshu, and coastal areas of

Honshu, Chugoku and Kyushu regions as well as a part of Shikoku are identified. The possible reason for this result may be due to the limited inhabitable areas as mountains and rivers are common in Japan. So that even if the municipalities have a lower population, it is natural that most of the residents in the municipalities tend to concentrate in the inhabitable areas. On the other hand, where municipalities meet the criteria for "city" in population size and are located on plain areas, the population is sometimes scattered throughout the area of the municipality. In this case, consequently, the municipality cannot meet the population density criterion.

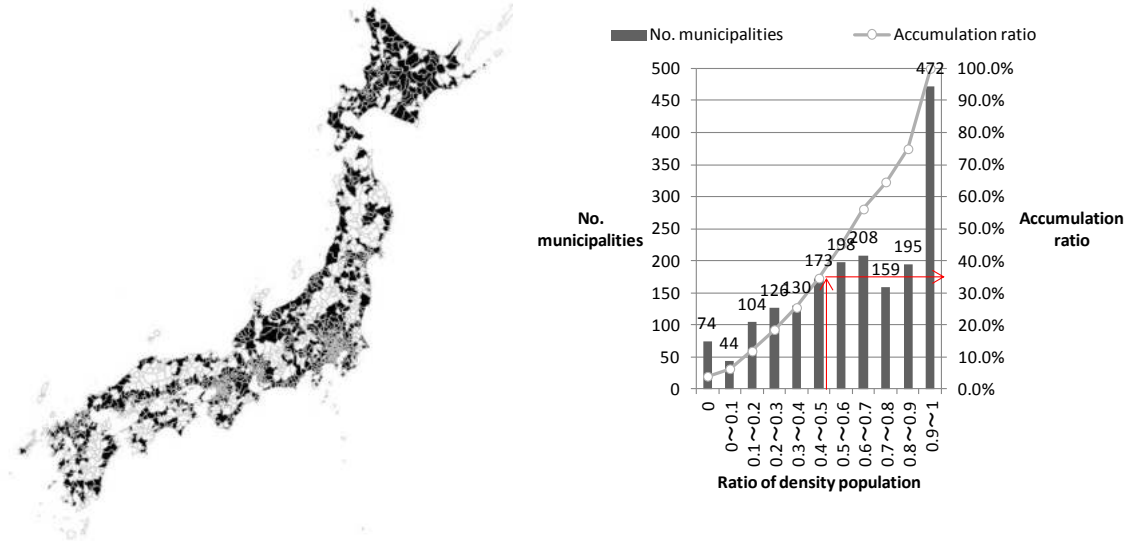

**Figure 2 Municipalities with more than 50% population living in densely populated area (1,000 population/km$^2$) in the municipality**

### 3.1.3. Artificial land use

On the condition of artificial land use, more than 60% of municipalities in Japan could satisfy this criterion. When the municipalities meeting this criterion were projected on the map, we found that only urban areas were identified. This is because urban municipalities tend to meet the criterion easily, but the area of municipalities in rural areas is typically larger than the area of urban municipalities, explaining why rural municipalities were not identified as meeting the land-use criterion.

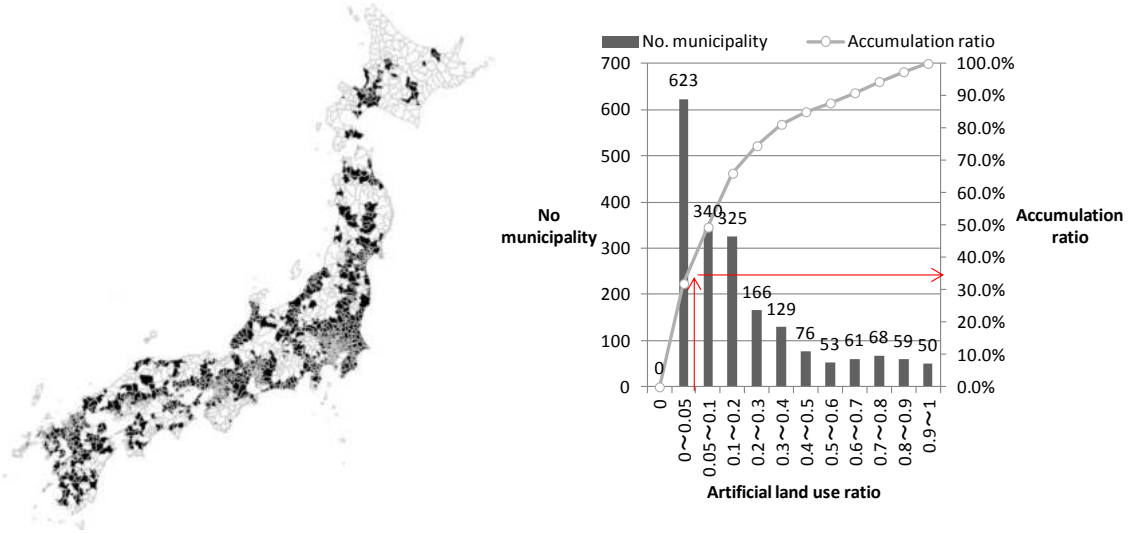

**Figure 3 Municipalities with more than 5% artificial land use compared with all municipality areas**

3.1.4. Results of the classification of municipalities

Consequently, 987 municipalities out of 1,856 municipalities in Japan are identified as "cities by European definition". The ratio of "cities by European definition" is around 53.2% of total municipalities in 2010.

**Table 4 Results of the classification of municipalities by applying the definition of the city in COST Action**

| Number | Continuous shrinkage | Episodic shrinkage | Temporary shrinkage | No shrinkage | subtotal | Total |
|---|---|---|---|---|---|---|
| Not "City" | 580 | 180 | 82 | 27 | 869 | |
| City | 142 | 148 | 293 | 404 | 987 | |
| Sub total | 721 | 325 | 374 | 436 | | |
| Total | | | | | | 1856 |

| Proportion by the city category | Continuous shrinkage | Episodic shrinkage | Temporary shrinkage | No shrinkage |
|---|---|---|---|---|
| Not "City" | 80.4% | 55.4% | 21.9% | 6.2% |
| City | 19.7% | 45.5% | 78.3% | 92.7% |
| Total | 100.0% | 100.0% | 100.0% | 100.0% |

| Proportion by shrinking pattern | Continuous shrinkage | Episodic shrinkage | Temporary shrinkage | No shrinkage | subtotal | Total |
|---|---|---|---|---|---|---|
| Not "City" | 66.7% | 20.7% | 9.4% | 3.1% | 100.0% | |
| City | 14.4% | 15.0% | 29.7% | 40.9% | 100.0% | |

When we conduct further analysis on the demographic change between 1990 and 2010 in these municipalities, 14.4% of Japanese cities (European definition) are classified as "continuous shrinkage", 15.0% of them are classified as "episodic shrinkage", 29.7% of them are classified as "temporary shrinkage" and the remaining 40.9% of cities are classified as "no shrinkage". On the other hand, 66.7% of non-city Japanese municipalities are classified

as “continuous shrinkage”, 20.7% of them are classified as “episodic shrinkage”, 9.4% of them are classified as “temporary shrinkage”. Only 3.1% of non-city Japanese municipalities (European definition) are classified as “no shrinkage”.

### *3.2. Demographic change pattern of Japanese cities (European definition)*

Next, the distribution of municipalities classified as Japanese cities according to the European definition is projected onto the map of Japan. The Japanese cities (European definition) classified as “continuous shrinkage” are located mainly in Hokkaido, coastal areas of the Japan-sea region, the western Chugoku region and Kyushu. In particular, the top 10 continuously shrinking cities in Japan are Amagasaki (Hyogo), Nagasaki (Nagasaki), Shimonoseki (Yamaguchi), Hakodate (Hokkaido), Kure (Hiroshima), Hitachi (Ibaragi), Kushiro (Hokkaido), Suma ward of the city of Kobe (Hyogo), Imabari (Ehime), and Ishinomaki (Miyagi). They are commuter towns in the Kansai district and the prefectural capital cities or second or third largest cities in the prefectures.

Japanese cities (European definition) classified as “temporary shrinkage” are mainly located in not only three major urban areas in Japan namely Tokyo, Osaka and Nagoya, but prefectural capitals as well, for example, Setagaya (Tokyo), Ota (Tokyo), Adachi (Tokyo), Suginami (Tokyo), Itabashi (Tokyo), Higashi-Osaka (Osaka), Nishinomiya (Hyogo), Kouto (Tokyo), Gifu (Gifu) and Nagano (Nagano). Twenty-three cities in the Tokyo metropolitan areas and Osaka suburb cities such as Higashi-Osaka, Nishinomiya and Neyagawa are influenced by the trend of inner migration to the city centre following outer-migration from the city centre to the suburbs.

The areas classified as “episodic shrinkage” seem to be located between “continuously shrinking” areas and “temporarily shrinking” areas. The population decline has halted at least once, but overall the areas have lost population over 20 years. The prefectural capitals more than urban areas and regional centres are regarded as “episodic shrinkage”.

Furthermore, the distribution pattern for these three types of Japanese cities (European definition) in the three major urban areas such as Kanto (Tokyo), Kinki (Osaka) and Chubu (Nagoya) is completely different. In Kanto, most of the 23 cities of the Tokyo metropolitan area are classified as “temporary shrinkage”, but the suburb areas surrounding the 23 cities of the Tokyo metropolitan area are not classified as any of the three dynamic typologies. Of course, the northern Kanto, Kamakura and southern part of the Boso Peninsula have faced shrinkage as well as most of the 23 cities of the Tokyo metropolitan area. On the other hand, the centre of Osaka cities faces “continuous shrinkage”. On the map, we can see the red marking in the central areas of Osaka. In addition, there are many temporary shrinkage areas in the suburbs of Osaka. Some municipalities next to these shrinking municipalities also face “episodic shrinkage”. In general, most municipalities in the Kinki urban areas seem to be more or less suffering from population decline.

In contrast to these two urban areas, only central Nagoya city areas show shrinkage. Apart from limited municipalities, almost no Japanese cities (European definition) are classified as shrinking areas. For reference, when we turn to the Fukuoka urban areas, the shrinkage in the suburbs is more severe than the other three urban areas, but the city centre of Fukuoka still maintains its population and is not classified as having any shrinking dynamic typology.

**Table 5 Top 10 municipalities in three demographic change patterns**

| | **Continuous shrinkage** | | **Episodic shrinkage** | | **Temporary shrinkage** | |
|---|---|---|---|---|---|---|
| | Municipality, Prefecture | Population in 2010 | Municipality, Prefecture | Population in 2010 | Municipality, Prefecture | Population in 2010 |
| **1** | Amagasaki, Hyogo | 453,748 | Yokosuka, Kanagawa | 418,325 | Setagaya, Tokyo | 877,138 |
| **2** | Nagasaki, Nagasaki | 443,766 | Toyonaka, Osaka | 389,341 | Ota, Tokyo | 693,373 |
| **3** | Shimonoseki, Yamaguchi | 280,947 | Wakayama, Wakayama | 370,364 | Adachi, Tokyo | 683,426 |
| **4** | Hakodate, Hokkaido | 279,127 | Asahikawa, Hokkaido | 347,095 | Suginami, Tokyo | 549,569 |
| **5** | Kure, Hiroshima | 239,973 | Iwaki, Fukushima | 342,249 | Itabashi, Tokyo | 535,824 |
| **6** | Hitachi, Ibaragi | 193,129 | Kita, Tokyo | 335,544 | Higashi Osaka, Osaka | 509,533 |
| **7** | Kushiro, Hokkaido | 181,169 | Sasebo, Nagasaki | 261,101 | Nishinomiya, Hyogo | 482,640 |
| **8** | Suma, Kobe, Hyogo | 167,475 | Neyagawa, Osaka | 238,204 | Kouto, Tokyo | 460,819 |
| **9** | Imabari, Ehime | 166,532 | Hachinohe, Aomori | 237,615 | Gifu, Gifu | 413,136 |
| **10** | Ishinomaki, Miyagi | 160,826 | Tarumi, Kobe, Hyogo | 220,411 | Nagano, Nagano | 381,511 |

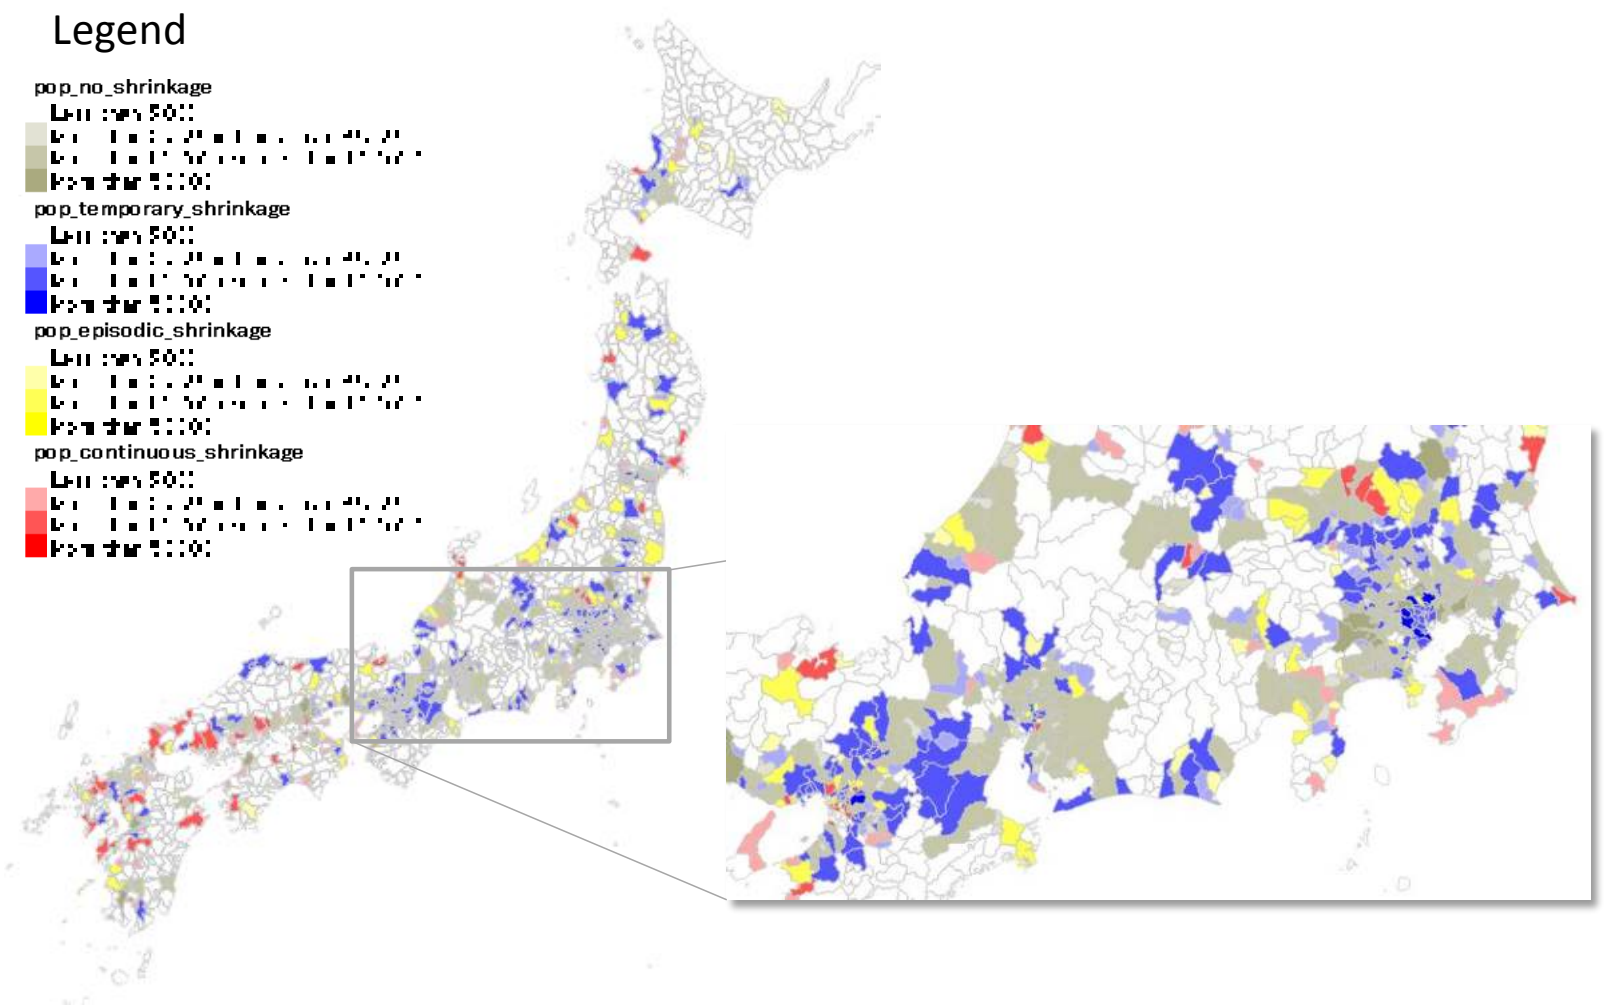

**Figure 4 Dynamic typology results following the definition of COST Action**

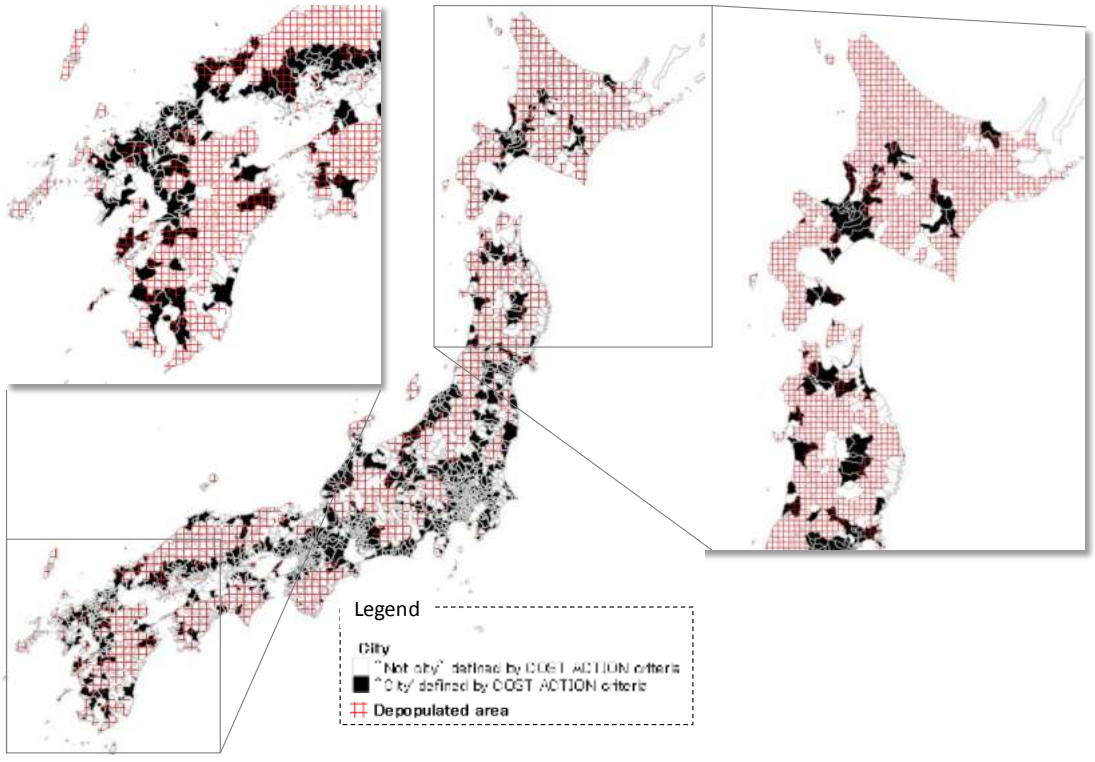
## 4. Discussion and analysis

This section mainly discusses the validity of the definition of the "city" by COST Action.

### *4.1. City as defined by COST Action criteria in Japan*

Figure 5 shows the Japanese cities (European definition) and depopulated areas on the map of Japan. The municipalities in urban areas are naturally selected as "Japanese cities (European definition)" but some municipalities in Hokkaido, Kyushu, Shikoku are also selected as "Japanese cities (European definition)".

Interestingly, some cities in Hokkaido and Kyushu are typically hatched both black and also red grid. Red grid means that the municipalities belong to traditional "depopulated areas" in rural areas as determined by the Act on special measures for the promotion of independence for underpopulated areas (enacted on 31st March, 2000). Accordingly, it is very difficult to regard them as shrinking cities. In short, these are examples of the error by which municipalities that should not be defined as shrinking cities are selected as "Japanese cities (European definition)".



Source: The data for "depopulated area" is from National Land Numerical Information, Underpopulated Area Data

**Figure 5 Cities in Japan based on the definition of COST Action and depopulated areas**

### *4.2. Comparison of the definition of "city" between Japan and the Europe*

Next, the opposite case is discussed. Namely, Japanese cities as defined in Japanese legislation are not necessarily selected as Japanese cities (European definition).

Basically, Japan has two layers of local autonomy system, namely prefectures and city-town-village. The following Table 6 shows the cross tabulation of population size and classification of "city" and "others" including town and village.

**Table 6 Situation for meeting the criterion for "city in Japanese legislation"**

| | 2005 | | 2010 | |
|---|---|---|---|---|
| | Population of less than 50,000 | Population of more than 50,000 | Population of less than 50,000 | Population of more than 50,000 |
| City | 259 | 712 | 265 | 706 |
| Others | 928 | 2 | 928 | 2 |

Generally in Japan, cities according to Japanese legislation subsume urban areas, and towns and villages are typically located in rural areas. In fact, cities in Japanese legislation are distinguished from towns and villages by the objective criteria as shown in Table 7, when the municipalities are upgraded to cities in Japanese legislation. It should be noted that once upgraded, the city will not be downgraded to town or village as long as can be anticipated. Consequently, sometimes the local situation and the classification of municipalities do not match completely.

As shown in Table 7, which compares the definition of cities by COST Action and Japanese legislation, the definition of cities is, actually, similar, but different. In particular, the population size criteria differ, and the Japanese population size criterion is 10 times greater than that of COST Action.

**Table 7 Definitions of "city" by COST Action, Japanese legislation and this study**

| Criteria | COST Action | This study | Japanese legislation (Article 8, Local Autonomy Act) |
|---|---|---|---|
| Population size | Total population in 2010 in the municipality > 5,000 inhabitants | Total population in 2010 in the municipality > 5,000 inhabitants | In principle, a municipality with more than 50,000 people |
| Population density | Density of the population living in densely populated parts with more than 1,000 inhabitants per $km^2$ > 50% | More than 50% population living in the 500m × 500m grid areas with more than 250 people in the municipality | More than 60% of households located in densely populated area, and more than 60% of population engaged in urban occupation like commerce and industry |
| Artificial land use | Share of urban area (artificial land use) within the municipality > 5% | The number of grids with mainly artificial land use like multistorey buildings (0701),factories (0702), lower buildings (0703), densely located lower buildings (0704), road (0901), railway (0902), public facilities (1001), vacant area (1002), park and green spaces (1003) and golf courses (1600) in 500 m square areas is more than 5% of the total number of grids in the municipality | — |
| Others | — | — | Other necessary conditions in each prefecture |

In terms of population density, the description is slightly different, so that we cannot compare them completely, but it suggests that the European criteria require more than 50% concentration, but Japanese criteria require more than 60% concentration of population in the densely inhabited areas. Accordingly, the European criteria may be more relaxed than the Japanese criteria.

Furthermore, the artificial land use criterion is not included in the Japanese criteria.

According to these different criteria to select "cities", the cities in Japanese legislation, which do not meet the definition of Japanese cities (European definition) number 199 cities (26.0% of all cities in Japanese legislation). Within these 199 cities, 137 cities in Japanese legislation do not satisfy the population size criterion of having more than 50,000 people. Out of 137, only one city in Japanese legislation does not satisfy the European criterion of population size of more than 5,000 people. Also, 87 cities in Japanese legislation do not satisfy the artificial land use criterion in Europe and 94 cities in Japanese legislation do not satisfy the population density criterion in the European definition.

**Table 8. Reasons why 199 cities according to Japanese legislation are not classified as "Japanese cities (European definition)"**

| | Population size (population<5,000 people) | Artificial land use criterion (Ratio of artificial land use is more than 5%) | Population density criterion (Densely populated area should be more than 50% of municipality land) |
|---|---|---|---|
| Reasons for not meeting the classification as a "city" | 1 | 127 | 124 |
| （incl. No. of municipalities with less than 50,000 population） | 1 | 87 | 94 |

The major reasons why cities in Japanese legislation are not classified as Japanese cities (European definition) are not meeting the artificial land use criterion and population density criterion. This suggests that even if the municipalities are regarded as cities in Japanese legislation, dense inhabitation is not met and population is scattered throughout the municipality.

Table 9 shows the results of the classification of municipalities in Japan based on the Japanese and European criteria.

**Table 9 Results of the classification of municipalities in Japan based on Japanese and European criteria**

<table>
<tr><td colspan="3" rowspan="2">N=1,856<br>(Municipalities)</td><td colspan="2">European definition</td></tr>
<tr><td>City</td><td>Others</td></tr>
<tr><td rowspan="3">Japanese definition</td><td colspan="2">City</td><td>567</td><td>199</td></tr>
<tr><td colspan="2">Others</td><td>367</td><td rowspan="2">670</td></tr>
<tr><td></td><td>Depopulated region</td><td>53</td></tr>
</table>

The situation is very complicated, but it can be said that the criteria used in COST Action could produce a completely different list of shrinking cities in Japan. The difference amounts to 26% between Japanese cities as defined in Japanese legislation and the common set between Japanese and European criteria (567 municipalities).

When the Japanese definition is applied, and researchers intend to include the Japanese cities in Japanese legislation as much as possible, the artificial land use criterion and population density criterion should be relaxed. Given that the objective criterion of population size for upgrading to "Japanese cities in legislation" is, however, not necessarily observed, it can be said that it is not appropriate to meet the Japanese criteria. In this regard, the European criteria in COST Action for identifying "cities" in Japan in order to discuss shrinking cities issues can be regarded as a more appropriate way to give the common basis for future international comparative study.

## 5. Concluding remarks

This study examined the validity of the definition of cities used by COST Action to discuss shrinking cities issues in Japan using data from Japan.

As a result, the "Japanese cities in Japanese legislation" and "Japanese cities (European definition)" are not the same, and two types of variance could be observed; namely, Japanese cities in Japanese legislation that were NOT Japanese cities (European definition), and Japanese cities (European definition) that were NOT Japanese cities in Japanese legislation.

One of the reasons for this situation may be that the criterion of population size has not been strictly applied for municipalities upgrading to "Cities in Japanese legislation", and some municipalities with less than 50,000 people have still been defined as "Cities in Japanese legislation". In addition, there is no criterion on artificial land use for defining "cities" in Japan. Accordingly, when we define cities around the world in order to conduct an international comparative study, it can be concluded that the Japanese criteria are not appropriate. In other words, the criteria to select cities used by COST Action should be applied to Japan to provide a good foundation for future international comparative studies.

The COST Action definition, however, also has a weak point. Bearing in mind that the cause of weakness of the Japanese criteria is the failure to strictly implement the criteria, the same can be said for the COST Action definition. This is because the COST Action definition of cities was introduced in 2013 and has not stood the test of time. In 5 years and 10 years time, researchers will update the analysis in Europe based on the COST Action definition of cities; some of the cities selected in 2010 will not be selected at that time. The situation is continuously changing and any definition will receive the evaluation of time.

In order to allow continuous research based on the same definition, researchers have to develop a more concrete and reliable definition of cities and objective rules for selecting cities to facilitate the discussion of shrinking cities. This point is still open to discussion.

Keyword: urban and rural integration; rural renaissance; peri-urbanization

Abstract
*After analyzing the characteristics of Chinese "peri-urbanization" and its the main reason, the thesis discusses the problem in peri-urbanized rural areas. Based on domestic and foreign research results of rural renaissance and China's actual conditions, the thesis puts forward a new idea: current research on the rejuvenation mode of peri-urbanized rural areas should be integrated into the overall development pattern of Chinese urban and rural integration and should include the whole rural areas rather than a single village, in order to achieve the overall rejuvenation and help rural areas produce and promote their unique output value. Therefore, the thesis takes significantly peri-urbanized villages as research object and explores the renaissance mode of China's rural areas in the case study of their development planning. The thesis proposes the rejuvenation mode of integrated development of villages in the whole district with city as the service object, country as the carrier, agriculture as the basis, tourism development as the means and cultural renaissance as the foundation. And accordingly, strategies of three aspects are given to guarantee the rejuvenation as follows: the first is scientific planning by improving its overall layout and constructing transportation organizations and supporting public services at all levels; the second is protection first by establishing supervision mechanism in the three categories (nine subcategories) of ecological protection, living environmental protection and farming culture protection; the third is four-win outcome by building a balanced and interacted mechanism for four parties (the government, businesses, villagers and tourists).*

## 1. INTRODUCTION

### *1.1 Research Background*

Since the Chinese government proposed the policy to resolve the "Problems about Agriculture, Rural areas and Peasantry" in 1998 and the urbanization strategy was came up in the 10th 5-Year Plan of Chinese development, 170 million surplus labor force have been moved from rural into urban areas.

However due to the strict regulation of the long developed city-countryside binary development pattern and the city-countryside household registration system, a great number of peasants who have entered into the urban areas engaging in the secondary and tertiary industry living there for a long period cannot be the citizen of the area, let alone enjoying the rights and interests equal to the citizens. In China, such a peri-urbanization group of population who are "non-farmers and non-citizen" is called "migrant rural workers". Under the restriction of the city-countryside household registration system, although the migrant rural workers are working and living in the urban areas, their census register still remains in rural areas. The land they owned (including agricultural and curtilage) and their self-built house are still in rural areas. Thus the rights and interests of citizens based on the census register can only be realized in the place where their census register is located. This formulated the situation with Chinese characteristics of "leaving the land but belonging to the rural" and migrant-bird-like peri-urbanization population（Liu Shenghe, et al, 2004;Liu Shuchun, et al, 2010；Li Aimin，2013；JIAO Xiaoyun，2015）.

The extended rural areas in China are in a trend of deterioration under the peri-urbanization due to great loss of population and lack of development motivation. This declining trend is mainly presented as hollowing-out of the countryside space. "hollowing-out" means that the decrease of actual residents in the countryside due to peasants being seasonally out-migrant for work or moving into cities with the whole family. However in inheriting the Chinese rural cultural convention of "set up a home and establish a business", residence is an important reflection of a family's social and economic status. Wherever the peasants are living in the rural or the urban areas, they will build or reconstruct their residence on the basis of the original curtilage. Therefore although the actual residents are continuously decreasing, the construction land and houses are not decreasing correspondingly(Liu Y S, et al, 2010). Instead they are built taller and stronger, resulting in a fictitious prosperity in space. The sharp contrast between fictitious prosperity in space and population losses has made the countryside seem even more lack of vitality. Besides, the problems of aging population, indifference relationships as well as the environmental deterioration derived from the "hollowing-out" phenomenon have accelerated the countryside industry deterioration and society depression. These deteriorated rural areas with peri-urbanized population are facing the plunder of its various resources by the urban area, which undermines their own economy and social pattern and crumbles the local culture, left a waned circumstance behind. Will our urban-rural planners not to stir a finger to this problem and left it to fend for itself in the process of urbanization? The answer is definitely no, because the countryside with the inborn values of "food production", "safeguard the Eco environment" and "deferring nostalgia" is the basic necessities of human society. It is the inescapable responsibilities for the modern planner to reserve countryside and protect its value of existence and unique characteristics that are differentiated from cities. This is also the fundamental starting point of this paper, which is to explore the renaissance pattern for the deteriorated countryside in the new era.

*1.2 Literature Review*

In recent years Chinese academics, according to the condition of China, have focused on different topics comparing with foreign scholars in studying "peri-urbanization" and "rural renaissance". The concept of "peri-urbanization" is originated primarily from a French classic geography term. Through almost a hundred years' accumulation of study, based on the two forms of "peri-urbanization region" and "population peri-urbanization", the concept has been extended to the two dimensions of geography and demography. In studies abroad, the research findings are mainly concentrated on the dimension of geography, e.g. the research of C. Kontgis et al. (2014) on the metropolitan edge of Ho Chi Ming City in Vietnam, the research of Andreas Haller (2014) on the middle area of the Andes in Peru, the research of A.O. Tavares et al. (2012) on the hinterland city in Portugal about the evolution process of countryside space and land use of these areas and the peri-urbanization geographical characteristics. In China, since Wang Chunguang(2006) first brought up the idea in the study of countryside population peri-urbanization that population peri-urbanizing is a non-integrated state in the process of urbanization, scholars tend to conduct researches from the demography dimension, analyzing the current situation, originating background and advantages and disadvantages of population peri-urbanization in China and proposing suggestions of census register system reform concerning this problem (Li Aimin, 2013; He Wei and Huang Xianjin, 2012). Whichever dimension the researches are focused, however, the content must involve the peri-urbanized rural areas and relentlessly pointed out the weakened status and deteriorated circumstances of such countryside in the city-countryside development. So how to help the deteriorated peri-urbanized countryside realize renaissance? Chinese and foreign scholars have also discussed positively about the renaissance patterns. For example, the development pattern of"one product for one village" taken as a model in Japan, combines the rural regional development with localized featured products to improve the competitiveness of the agricultural products, which realized the renaissance of countryside by industry upgrading (Shen Mingrui et al, 2015); in Korea, the modernization and urbanization of countryside developed simultaneously by peasants' autonomous "community establishment" and set-up of government, countryside as well as agriculture system, to ameliorate the elements of urban and rural areas' healthy two-way communication (Piao Longzhu, 2011); countries of New Zealand and Ireland etc. drew up regulations and policies to make countryside tourism as an important approach to avoid rural population migrating blindly to cities (Clark G, Chabrel M, 2007;Lu Xiaoli et al， 2014); The Netherlands, France, Belgium and other European traditional agricultural country to choose the "multi-function country" model(Wilson G A, 2001； Van Huylenbroeck G et al，2003)； the countryside in Taiwan emphases its originality, the providing of countryside leisure tourism souvenir and the establishment of guarantee mechanism to export rural areas' unique values to other regions, to achieve the healthy and positive development of the countryside (Liao Huiyi, 2014); Canada carries forward the transformation of countryside through the integrated approaches of market incentive, government intervention and peasants autonomous actions (Mao Dan et al, 2010); the construction of "beautiful countryside" that China is carrying out is exactly the starting

point of the renaissance of its rural areas.

### *1.3 Research Targets*

This paper reviews the research findings at home and abroad of the "peri-urbanization" and "rural renaissance pattern" in recent years through sorting out the problems in the development of peri-urbanized countryside. It combines the concept of city-countryside integration and the strategic requirements of the new urbanization pattern in the new era of China, which jumps out of the long dominated target orientation of city growth. At the prerequisite of city-countryside equality and from the point of the countryside's development endowment and its demand analysis, it proposed the idea that " in modern China studying the renaissance pattern of the peri-urbanized countryside should consider the pattern of city-countryside integration development in China and the study of this pattern should focus on the groups of countryside communities instead of the individual ones, so that to realize the overall return of vitality as well as the creation and strengthen of its unique exporting values". Based on this guideline, this paper chooses the obviously peri-urbanized countryside communities located at the two sides of Huaijiu Road in the town of Fanchang in Anhui Province, China as the research object and takes its development planning as the example to conduct the countryside renaissance research. It proposes the countryside renaissance pattern in the new era, which not only helps the countryside communities with innate self-support and developing prosperously, but also facilitates its coexistence with the outer cities harmoniously. Thereupon on the basis of positioning the main role of such countryside's renaissance, a series of relevant strategies are brought up to ensure the realization of countryside renaissance goals in these areas.

## 2. THE STUDY OF COUNTRYSIDE RENAISSANCE'S CONNOTATION

Countryside sociology professor He Xuefeng (2014) has pointed out that "Chinese traditional countryside is at the Yin and slow side as well as the pole of stability in the "Yang-to-Yin, fast-to-slow and developing-to-stability poles" of the unity of opposites. Its actual function is to provide a stabilizer to the rapid development of China in joining in the globalization system; such a unity of opposites is actually the real experience of China's stable development in the overspread of global economic crisis." It punctures a fallacy with one remark of the significance of countryside to social stability, economic development and succession of the nation. The Chinese government has paid great attention to the development problems of countryside, agriculture and peasants (the three rural issues) since 2004. In 2006, the launch of the No. 1 Document of the Central Government *CPC Central Committee and the State Council on promoting the construction of a new socialist countryside views* marks the official start of the New Countryside Construction with more than 3.2 million villages has been involved in the new socialist countryside construction. In 2012 the Eighteenth CPC National Congress first came up with the concept of "Beautiful China" pointing out the direction of the countryside construction in China.

Table 1 clearly shows the Chinese government's shift of policy-making trend in the requirements of countryside development and construction --- from purely emphasizing the space construction to the overall development of economy, society and culture.

Table 1. The emphasis changing process of the relevant policies on Chinese new countryside construction

| Stage | Period | Policy emphasis | Core contents |
|---|---|---|---|
| Fermenting stage | Between the 16th CPC National Congress to the 5th Plenary Session of the 16th Central Committee of the Party | The priority in all works is to resolve the three rural issues successfully | Requires "industry nurture agriculture and cities support the countryside". |
| Strategicall y planning stage | Between the 5th Plenary Session of the 16th Central Committee of the Party to the 17th CPC National Congress | Take the construction of socialist new countryside as one of the big strategic tasks of China's comprehensive construction of the well-off society and carrying out the socialist modernization | To construct the socialist new countryside of "product development, living in affluence, custom civilization, appearance neatness and managing democracy". |
| Large-scale practice stage | After the 17th CPC National Congress | To accelerate formulating the new pattern of city-countryside economic and social development integration | Comprehensively promote the socialist new countryside construction. Follow the agriculture modernization road with Chinese characteristics. |
| Reflection and adjustment stage | After the 18th CPC National Congress | Strengthen the integrated city-countryside development, enhance the countryside development vitality, decrease the urban-rural gap and facilitate the co-prosperity of city-countryside development. | Construct the beautiful countryside with "ecological soundness, beautiful environment, reasonable layout, complete facilities, developed industries, affluent farmers, unique local features and harmonious society". In promoting the city-countryside integration |

At the current stage, the countryside renaissance work that China has done is reflected more on the aspects of physical space landscaping and the complementary configuration of all the facilities. But the nature of the work emphasizes more on the following points: the dependence of the countryside to urban areas and industry should be transformed to the status of supplement to each other and relatively autonomous in development (He Huili, 2012), which contains the renaissance of countryside's humanistic spirit, regain of economic vitality, optimization of the spatial environment and innovative social governance etc.

The author believes that the relatively complete connotation of "countryside renaissance" should include two dimensions: **The first is about its content,** namely the village attract rural population to reflux by industry padding and reconstruction, enhancing the quality of living environment and perfection of all

kinds of facilities etc. Taking this as the basis, restructuring the rural population, updating rural governance mode, and rebuilding rural cultural charm to achieve the multifaceted spatial, economic, social and cultural autonomous updating inside the individual countryside and the internal complementary development and overall prosperity of the countryside communities. **The second is about its values,** namely in achieving the internal self-sufficiency and the common development of the communities, the values of "providing food", "conservation the ecology" and "ease the homesickness" that are irreplaceable effects and differentiated from that of the cities will certainly be strengthened. When the countryside regains the equal importance with urban areas and its unique value and charm, the majority of rural areas will began to fully reversely absorb a variety of resources and elements from cities and thus achieving its revival in a real sense(Zhao Chen，2013).

In short, the connotation of countryside renaissance lies in the two dimensions of content and values, reconstructing the unique rustic demographic, social, economic and cultural structure in the new era and realizing the integration development pattern that is equal to and complementary with the urban areas.

## 3. METHODOLOGY

### *3.1 Selecting the research object*

Anhui Province is an inland province across the Yangtze River, middle and lower reaches of the Huaihe River and neighboring the sea. It is located at the hinterland of eastern China, connected with Jiangsu and Zhejiang in the east, Hubei and Henan in the west, Jiangxi in the south and Shandong in the north. The town of Fanchang is subordinate to the Wuhu City in Anhui Province, linked with Golden Waterway of Yangtze River, located at the Mawutong area (the Mawutong Economic Zone is the three most prosperous areas in Anhui, namely Maanshan, Wuhu and Tongling) and the middle of the industrial zone along the Yangtze River, where 39 km east of Wuhu, 50 km west of Tongling. It is right adjacent to the lower point of the “Nanjing-Wuhu-Hefei Economic Triangle” and 152 km away from Nanjing. Adjacent to the Yangtze River Delta, it is 390 km away from Shanghai, the leading city of the Yangtze River economic belt. The Hutong railway line, G50 Shanghai and Chongqing Expressway and Ningan intercity railway intersect here, which indicates obvious location and transportation advantages. At the meantime, there are rich resources within the town of Fanchang, with 22 km Yangtze River bank line and the Marenqifeng, a national forest park and a 4A level scenic spot.

The object of this study is the rural area located at both sides of the Huaijiu road, which connects the town of Fanchang and the scenic spot Marenqifeng. The total length of the line is 12.6 kilometers, with 88 villages, 4955 households and a population of 14855 scattered. Same as many rural areas in small inland cities, since the decline of their traditional industries in the process of urbanization and the strong attraction from neighboring developed big cities, the region is facing a huge loss of rural population, presenting a typical situation of deterioration and hollowing-out due to population being peri-urbanized.

According to the statistics at August 2014, villages located on both sides of the Huaijiu road are emerged with varying degrees of hollowing-out, with the highest rate of 90%, the lowest 52%. Although with a high degree of hollowing-out, this rural area retains the typical rural living space and traditional farming production of central China. Moreover, as the town's "spectacular scenery" conservation area, the villages bear the dual function of serving the cities and the scenic spot. In short, the rural area on both sides of Huaijiu road in Fanchang is not only a typical representative of China's vast rural peri-urbanized population, but also bears significant rural characteristics, with a relatively unique natural resources endowment and development conditions. Therefore, the article chose this rural area as the research object.

### *3.2 Coming up with the renaissance pattern*

The rural area on both sides of Huaijiu road in Fanchang bears the dual function of serving the cities and the scenic spot on the basis of maintaining the lifestyle, production and ecological space with extremely rural characteristics and relying on the intersection and the only route for tourism of Huaijiu road connecting the city and the scenic spot. The dual functions are: firstly export various agricultural products to urban residents and second, provide tourists with leisure experience space and services with rural characteristics and complementary in tourism types with the Marenqifeng scenic spot. In recent years, with the increasing amount of tourists in Marenqifeng and the expanding demands of leisure tourism in rural areas, the modern agriculture and agricultural leisure industry in the area has obtained greater development. In the 24 villages of the area there has been 6 modernized agriculture technology enterprises and 10 happy farmhouses being launched currently. By the end of 2014, there had been 5 provincial-level models in the 10 happy farmhouses in the area, including one five-star one, three four-star ones and one two-star one. However due to lack of integrated management and guidance, they are all confronted with the development dilemma of "lack of image, taste and integration". These dilemma are presented in three aspects: firstly, although the current enterprises have developed to an extensive scale with some star-level ones, on the whole there exist the problems of extensive operation mode, low quality of space environment and fragmented business operations; secondly the peasants are in low participation of the newly emerged enterprises and hardly able to convert their own land resources into relatively high-end space and products to export due to the constraints of their own competences and skills; thirdly, the government is lack of management platform and control mechanism, failed to guide the area to escape the dilemma of homogenization and low-end development effectively.

Through the analysis of resource endowment, development dilemma and the advantageous conditions of the rural areas on both sides of the Huaijiu road in Fanchang, we proposed the idea of "formulating the integrated development renaissance pattern for all the rural communities that takes the city as the serving object, countryside as the carrier, agriculture as the foundation, tourism development as the method and the cultural renaissance as the root" in its development planning.

This planning suggests that firstly it should be guided to an industrial upgrade, by optimization and improvement of the first industry and injection of the tertiary industry, creating a wide-long type of leisure agricultural industry chain structure; secondly under the guidance of "distinctive themes, optimizing the use of resources and narrowing down the industry types", select the three types of projects (farming experience park, happy farm houses and bamboo industry project) as the priority to introduce into the development of the area; lastly, formulate the projects joint development guidance brochure of the area and put it into practice of the countryside space (Figure1). Guided by the industrial development, it will lead the enterprises out of the dilemma of homogenization and actively encourage villagers to integrated into the new industries' development, helping them increase streams of revenue, realize self-improvement and thus to revive the whole countryside individuals and community.

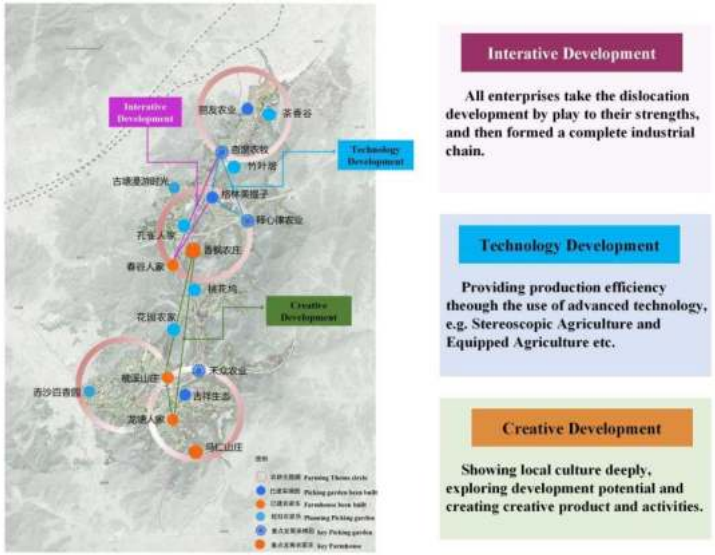

**Figure1 The guid chart of space layout of regional project's interactive development**

### *3.3 Studying the subject of the renaissance*

In general circumstances the subject of countryside renaissance should include government and villagers. However, according to the core content of the connotation of the countryside renaissance mentioned before, we consider enterprise should be added as the injector of the countryside industrial vitality. Meanwhile, tourists should also be included as part of the subject concerning the influence and the huge market they brought to the countryside development, thereby forming a four-party subject of the countryside renaissance by the government, enterprises, villagers, tourists.
