Elected members of both local and national political assemblies expect that the assessment of road projects considers effects for the district traversed by the relevant road section. Equally important, there seems to be political consensus on not applying any decisive criterion for rejecting a proposal, and on the need for regional balance in the prioritization of projects. Such balance has been observed over a number of years (Elvik 1995). It follows that a particular road project is very likely to be implemented sooner or later, even with a low benefit/cost ratio, provided that the local agreement to back up this project persists over a few four-year planning periods. The political will to regional fairness and thus geographical dispersion of investments leads to a selection process where the seniority of the project idea takes precedence and trumps the consideration of net economic benefit to society at large. This seniority principle plays an important role in the regional offices of the NPRA propose to the Directorate of Public Roads.

The required compliance with municipal plans in combination with the political desire to ensure progress in all regions gives local authorities a strong hand in the process of selecting road projects for

NTP. Some projects can even jump the queue if the local administrative unit offers to co-fund the road improvement by collecting user fees. This is increasingly common in Norway. In 2013, 47 per cent of the investment costs related to classified roads were covered by road tolls. From 2003 to 2013, the contribution from tolls to investments on national and county roads has increased fourfold (Samferdselsdepartementet 2013: 93). The rationale of user payment is most convincing where traffic is considerable. High traffic does in itself strengthen the utility side of the cost-benefit account, when the project gives motorists more attractive trips. Taken by itself, an increased share of toll-financed projects should therefore bring the selected portfolio of investments more in line with the CBA-results. On the other hand, toll-funded projects are often realized after massive local pressure. Experience from the five biggest urban areas in Norway shows that local funding comes with strong influence on the local package of transport projects (Norheim et al. 2013). This may lead to more expensive solutions.

*Top-down political signals*

Signals from the Ministry help the Directorate foresee the response to recommended road investments. The Directorate may find it less than useful to propose projects that are likely to be dismissed by the superior authority. Such anticipated reaction has, over an extended period, been analyzed several times in Norwegian civil service and is a useful aspect of how the Directorate perceives its role (Christensen 1991, Egeberg 1995, Jacobsen 1960). The Directorate may fear doing futile work and perhaps consume political goodwill if neglecting signals from the Ministry when working on the list of recommended projects. However, if the Directorate tends to regard ministerial signals as directives, the Government will not receive professional advice built on an independent expert basis. The Directorate might then furnish some political wishes concerning construction and improvement of classified roads with a veneer of undeserved technical-economic desirability.

When a political decision has been made by the Ministry, the Directorate must act loyally, whether or not the decision is in accordance with the agency s recommendation. The Norwegi Agenda reports that the MoT sees the Directorate of Public Roads as very loyal to the Ministry s decisions and signals. In light of the problem dealt with in this section, which is the infiltration of politics into technical-economic expert selection of projects on the classified road network, an extended quotation from Agenda s report is warranted:

> On one point, the Ministry expresses the wish that the NPRA takes a closer look at its own practice. The problem area is the relationship between expert recommendation and necessary compromise in political-administrative decision processes. Professional expert recommendations will often be adjusted and modified in the planning processes they are going through at the local, regional and national levels. It is the judgment of the Ministry, that the NPRA could, on some occasions, articulate a clearer expert position, and then leave it to the subsequent process to determine the final outcome of the deliberation on the case. The NPRA sometimes anticipates certain adjustments in the process to come, and incorporates these into the agency s own expert assessment and conclusion. (Agenda 2006: 103-104)

The anticipated reaction can thus be too strong, even as seen from the perspective of the superior actor. In the preparatory work for NTP 2018-2027, it seems like the rightwing government under Prime Minister Erna Solberg s leadership is pushing to make CBAs more influential. The Ministry instructs the four national transport administrations to develop a system for presenting variables, other than estimated economic effects to society, that are underscored in priority settin (Samferdselsdepartementet 2014: 12). The gradually stronger emphasis put on the obligation to explain departures from profitability, indicates that the Minis Directorate s possibly insufficient professional independence of political signals, may have increased.

Over several periods, a tendency in the NTP guidelines from the Ministry of Transport and Communications has been to more clearly underline the need for a profitability strategy. This tendency also involves demands for clear explanations from the national transport agencies why massive divergences from maximum benefit/cost ratios are the rule rather than the exception, as in the

guidelines for the NTP period 2014-2023: It is important that the proposed plan makes the setting transparent, and makes visible the criteria that really counts in the decision-making (Samferdselsdepartementet 2011: 17).

## 6 Process characteristics counteracting cost-effectiveness

Some planning tools, such as CBA, have the potential to affect both the process and the product of planning. CBA is product-oriented, but affects the information collected in the process, the deliberation of investment criteria, and the discussion of transparency and the role of experts. The influence goes both ways, though, as the organization of the planning process affects the attention directed to CBA and its possibility of bringing about projects with positive net benefit to society. The section first deals with some consequences of a multi-goal planning process, and then briefly mentions some other process features challenging cost-effectiveness.

*Economic results fall out of sight in broad expert assessment*
Similar to Agenda, the Agency for Public Management and eGovernment (DIFI) also analyzes the relationship between ministries and directorates in a report about the professional expert role of the directorates (DIFI 2008). Directorates must adapt to the fact that they are part of the political apparatus serving the minister. They therefore base recommendations on a somewhat broader perspec professional skill in their respective fields; for example, by incorporating their own expert viewpoints into a more comprehensive societal perspective (ib: 10). Some of the informants to Agenda (2006 131) also mentioned this, and opined that the Directorate of Public Roads should to a greater extent consider environmental effects, land use, and wider economic impacts to industry and commerce in the assessment of big road projects. Taking this advice would mean continuing a long-lasting trend towards expansion of the CBA, for example, by adding new entries concerning consequences to environment, climate, and health. More comprehensive CBAs contain an increased number of items with highly uncertain monetary estimates, and this does not necessarily improve the scientific quality of the analysis. Neither are there clear indications that higher comprehensiveness has made application of CBA results more attractive to the politicians, as discussed by Sager (2013).

The Norwegian Productivity Commission (Produktivitetskommisjonen 2015) follows up on the theme of comprehensive project assessment. The unranked political main goals of the NTP-period 2014-2023 concern traffic safety, climate and environment, universal design, and accessibility; competitiveness and reduced transport costs being part of the latter. The task of the national transport administrations is to transform Government policy to practical action. When desired economic gains do not have a prominent place in the main goals and thus in the politics of the Ministry of Transport and Communications, the priorities of the Directorate of Public Roads are likely to be less marked by cost-effectiveness as the overriding guiding principle (ib: 368).

Low correlation between final political priorities and economic net benefit to society does not necessarily mean that professional considerations are superseded by political judgment. It might equally well entail that purely economic criteria take a secondary position compared to other professional criteria neglected by the CBA. When selecting projects for the maximum profitability strategy of the transport administrations, the NTP secretariat notes that the project portfolio has to satisfy legal requirements, such as protection against pollution, and in addition has to further the goals of improved environment, safer transport system, and accessibility for all (Sekretariatet for Nasjonal transportplan 2012b: 2). A shift in the project selection process away from the criterion of maximum benefit/cost ratio and towards these other criteria can be partly professional and partly political. A broad basis for taking decisions, supplementing the benefit/cost ratio with a range of other quantitative and qualitative criteria for setting priorities, affects the balance between politics and professional considerations when composing the prioritized portfolio of road projects. Such a shift would not necessarily mean more influence for party politics, as there is a high degree of consensus in the Storting on the goals favouring environment, safety and general accessibility.

In other words, the broader the professional assessment, in the sense that more decision criteria have to be balanced against each other, the more difficult it becomes to determine what is a professional and what is a political ranking of the projects. When more professional criteria are taken into account, more political trade-offs between them must necessarily be made. In a comprehensive assessment of what best serves society, planners cannot have the one without the other. The application of a number of professional evaluation criteria makes a purely professional priority setting impossible. This is so because the criteria have to be balanced, which means setting social values off against each other, and such trade-offs are unavoidably political.

It might well be that the Ministry of Transport and Communications includes purely political considerations among its project assessment criteria, even if the political judgment criteria are never mentioned in planning reports or official documents. Priorities may be set in accordance with, for example, what was promised in the latest election campaign, the wishes of powerful local party organizations, the agitation of protest movements against certain road projects, or what central county politicians insist is necessary for the local production industry. It is rarely possible to determine whether a decision in line with one of these interests was made on the basis of politics or a broad set of professional criteria. Every political actor builds a collection of professional and matter-arguments indicating that it will serve society best to realize exactly the project alternative favoured by the political player in question. In order to move an old and difficult road to a new and costly tunnel farther from the town centre, the local party organization may invoke, for example, threatened natural habitats, protection of farmland, safety against avalanche and landslide, more room for future development of the centre, and better competitive situation for local, export-oriented businesses depending on faster transport of fresh food, such as salmon. The national Government can use the same arguments. It would be very difficult for potential critics to prove that these professional arguments are not what really motivate the Government s decision to move the worries about the voter support of the local branch of the party, and its chances of getting the mayor in the next municipal election. Political reasons can very often be hidden under a cover of professional arguments that gain higher acceptance among political adversaries and in the public opinion. CBA-results may thus be substituted by political considerations in the prioritization of road projects without giving the impression of leaving the professional sphere.

*Other process features challenging cost-effectiveness*

A partisan planning process, in which political decision-makers tend to allocate projects to the districts of their supporters, would clearly invite significant differences from CBA-ranking. Eliasson et al. (2014) found a positive relation between Government project allocation and voter support in Norway, but did not find such a relation in the Directorate s selection. In a precedi paper, it was shown that the road project portfolio recommended by the planners for NTP 2014-2023 did not deviate much from the set of projects selected by the Government. This means that a possible partisan bias in project allotment cannot be strong.

Some effects of toll roads are already mentioned. The point here is that national politicians may be affected by the fact that more new road per budget-million is achieved with user charging. They may tend to give higher priority to partly toll-financed projects than to projects fully funded over the national budget. The projects heavily backed by local politicians applying for toll-funding are not necessarily those providing the highest net benefits for the society at large.

The planning process can be designed as a search for optimal solutions taking cost-effectiveness into account, or be more rule-based or guided by heuristics. Prioritization according to rules sometimes follows from international agreements. A recent example is the EU Directive 2004/54/EC on minimum safety requirements for tunnels in the trans-European road network. This document has a bearing on the current and the next NTP, bringing tunnel projects higher on the agenda. A planning heuristic with some practical thrust says that one should invest to comply with official guidelines and standards for classified roads, starting with road sections lagging most behind.

The heuristic above is likely to give results correlated with the principle of first implementing the projects addressing the most serious problems (Eliasson et al. 2014: 15). However, recognizing an acute problem does not mean that the project under consideration is able to solve it, let alone solve it cost-effectively. The Norwegian front-end governance regime of major public projects tries to amend this by mandatory reports on the choice of a feasible problem-solving concept (Samset and Holst Volden 2015). With regard to island access, for example, bridge, tunnel, and car ferry can be alternative concepts. A rudimentary CBA is an element in the Norwegian quality-at-entry assurance system. For each problem-solving effort costing more than ¾ billion NOK, at least two promising concepts have to be assessed, in addition to the reference alternative (the do nothing option). This procedure has the effect that even if a severe problem is identified and has to be addressed, it is less likely that the decision-makers are led to accept an unnecessarily cost-ineffective project.

Communicative planning has occupied a central position in planning theory for three decades (Forester 1989), and its heavy emphasis on co-operation, dialogue and citizen participation is apparent in the Norwegian Planning and Building Act, which provides the legal framework for road planning. The Act states that the planning authority should arrange for active involvement of affected individuals and groups. Electronic presentation and dialogue should be facilitated in all phases of the planning process. Furthermore, public agencies have an obligation to co-operate, and regional planning forums should be established to coordinate the interests of municipalities and regions with those of the state.

The Norwegian Productivity Commission points to a little-discussed consequence of such communicative planning: Throughout the long-lasting and dialogue-oriented planning and fac finding process, high expectations are built regarding the subsequent implemen (Produktivitetskommisjonen 2015: 375). The more enthusiasm and positive engagement during citizen participation, the harder for politicians to say no to the realization of the project. Successful dialogue may lock the decision-makers to a cost-ineffective line of action. The start-up of land acquisition and other preparatory work prior to formal political decision even for projects that have been found to have a benefit/cost ratio less than one does not make things better. It raises local hopes further, and it complicates the task of making a collective decision serving national interests.

## 7 Weaknesses of CBA as seen from the Storting

Since the 1990s, the Storting s standing Committee on Transport and C (Samferdselskomitéen 1993: 33-34) and the MoT have repeatedly stated that CBA is to be an element in the assessment of road projects: Cost-benefit analyses and the calculation of effects on sele variables will be the fundament of the project assessments (Samferdselsdepartementet 2011: 17). Under the incumbent rightwing government with ambitions to present NTP 2018-2027, the Ministry even proclaims that economic analyses from the perspective of society should be given more in the evaluation of the use of resources in the transport sector (Samferdsels This is not self-evident, as many elected representatives express low confidence in the CBA as evaluation method. Researchers have established the existence of such distrust since the middle of the 1990s (Nyborg and Spangen 1996), and reasons for the scepticism are discussed by Sager and Ravlum (2005b). The negative attitude grew stronger on some occasions, when the debate among economists and planners about the estimated value of core parameters and about the comprehensiveness of the analysis revealed to the parliamentarians that CBA does not find its shape on the basis of purely objective considerations alone (Sager and Sørensen 2011: 227-230).

The completeness of the Norwegian version of CBA authorized by the state has been much debated since the millennium shift. One reason is the idea of wider economic impacts , wh can follow from new transport infrastructure and would like to see added to the utility estimated as the value of travel time savings. The assumed wider economic impacts are due to more flexible labour markets, productivity gains resulting from increased geographic density, and efficiency-enhancing interplay between transport supply and land use (Finansdepartementet 2012: 87). In the guidelines for NTP 2018-2027, the Ministry instructs the four national transport administrations to clarify whether

wider economic impacts should be analysed and possibly presented as a supplement to CBA (Samferdselsdepartementet 2014: 11-12). It is a drawback that economists are far from reaching consensus on how to estimate the wider impacts in real-world planning cases, so results still vary to a disquieting degree (Graham and van Dender 2011, Mackie et al. 2011, Wangsness et al. 2014). The risk is that calculations of wider economic impacts that give an arbitrary impression, will not corroborate the belief of the parliamentarians in economic analysis as a basis for political ranking of roads, but rather strengthen the suspicion that those ordering such analysis can get results to their own liking.

Many politicians in the Storting are of the opinion that wider economic impacts should be included, that the value of increased punctuality is insufficiently valued, and that the discount rate is still too high (Transport- og kommunikasjonskomitéen 2013: 54-56). The Progress Party wants to delete the item in CBAs of public projects that consists of 20 per cent extra costs due to inefficiencies from taxation (Stortinget 2010). The economic reason for this cost mark-up is that projects funded over the national budget require tax income of the same size as the appropriation, and taxes cause inefficiency in the Norwegian economy, which investors should be forced to take into account.

The requested changes all pull in the same direction, in that they will make a number of projects on classified roads appear more beneficial to society. Representatives both left and right on the political spectrum see a need for upgraded calculation of social benefits; that is, higher values and higher number of positive effects. It can then be less problematic for them to deviate strongly from CBA-suggested ranking, as a higher number of politically motivated projects will seem to be worth implementing with the revised economic calculations, even many projects that are not among the most profitable. Politically motivated project portfolios then become easier to defend. Decision-makers may be tempted to judge an analytic tool more from the method s ability to serve a poli from the method s knowledge-producing capacity.

The demands for methodological improvement of CBA can be observed in practice. The committee report on the first national transport plan NTP 2002-2011 shows that the majority of the members of the Committee on Transport and Communications did not accept that predictions of consequences documenting expected goal achievement, only existed in the road sector. The majority appealed to the Government that such impact models be made operative in all four transport sectors (Samferdselskomitéen 2001: 16). When preparing the Storting s debate of NTP 2006-20 Committee requested a better system for economic analysis, demanding more consistent design and use of CBA, making it a tool for meaningful comparison of infrastructure projects for different branches of transport in one and the same corridor (Samferdselskomitéen 2004: 25-26). Four years later, when discussing NTP 2010-2019, the Committee s majority (from the red-green coalition) of the opinion that the international models, with which the EU has some experie considered (Transport- og kommunikasjonskomitéen 2009: 6). This was a demand for closer study of how to deal with wider economic impacts. The Committee s comments to NTP 2014 that the main recommendations in the Official Norwegian Report no. 2012:16 on economic evaluation from the perspective of society, should be implemented (Transport- og kommunikasjonskomitéen 2013: 202). In addition to estimation of wider economic impacts, this concerns mainly (1) real price adjustment of certain goods with strongly deviating expected price changes, (2) forecasting periods that are so close to the expected economic lifetime of the projects as feasible, and (3) use of trajectories for the price development of emission of climate gasses (Finansdepartementet 2012).

Parliamentarians may be influenced by all the publicity on the omissions and defects of CBA, even if several studies have found cost-benefit analyses to be quite robust (Börjesson et al. 2014, Holz-Rau and Scheiner 2011). If so, they will be apt to look for alternative decision support. Not least the Progress Party houses the attitude that old-fashioned calculation methods lead to systematic downgrading of investment in infrastructure (Stortinget 2010). However, even old-fashioned algorithms, the number of projects on classified roads that is benefits to society, by far exceeds the number that can be accommodated within the budget limitations

of NTP (Sekretariatet for Nasjonal transportplan 2012b: 5). When investment in classified roads is not higher, it is predominantly for political reasons and not because calculations underrate benefits.

Consideration for traffic safety, climate, private business, and unique nature (wildlife reserves, national parks, special landscape areas) is actually a weak argument for deviation from the profitability strategy based on CBA. The reason is that project selection according to maximum benefit/cost ratio gives just as good or better results on all these accounts compared to the Gove project portfolio for the NTP period 2014-2023 (Sekretariatet for Nasjonal transportplan 2012b: 7-8). Even if the new roads in the profitability strategy occupy more agricultural land, the negative effect is hardly serious enough to provide a decisive professional reason to forego a net gain of around 40 billion NOK (2011-value), which is what the nation could gain by choosing the profitability strategy instead of the Government s planned strategy (ib: 5). Under the circumstances basis for so vast divergences from complying with the CBA-results is very likely to contain a significant political component.

## 8 Conclusion

The intention has not been to argue that the benefit/cost ratio should be decisive when setting priorities among projects on classified roads, but rather to highlight some circumstances that tend to push CBA-results into the background. The economic loss to society resulting from the current selection procedures in the road sector is too serious to leave the issue undebated. If the Directorate of Public Roads is too sensitive to signals from the Ministry and from local
political actors, the Government will not receive recommendations that are sufficiently professional. Some political initiatives concerning building and upgrading of classified roads can then adorn themselves with undeserved professional legitimacy.

The Ministry instructs the national transport administrations to improve their explanations of deviations from the CBA-based profitability strategy. It should be considered if this needs to be followed by an analysis of feasible institutional changes. One should aim for a system in which CBAs are not only carried out, but are also effectively taken into account by decision-makers. CBA should be used in a way that makes an imprint on the prioritization of the NTP and can be easily revealed when studying the portfolios of investment projects on classified roads. The Norwegian Productivity Commission requests a binding principle that requires each national transport administration to put more weight on net benefits to society (Produktivitetskommisjonen 2015: 362). The Commission also suggests that the NPRA should be instructed to discard more of the economically inefficient projects in an early planning phase (ib: 372). These changes and clearer priority-setting criteria can serve democracy through transparency, and serve people in economic terms through implementation of projects that road users have greater willingness to pay for.

The parliamentarians complain that incomplete cost-benefit accounts are used for assessing road projects. They have not yet perceived as problematic that complete CBAs, including every consequence that people care about, may outstrip their own political deliberation on the projects and make democratic treatment of NTP-investments less important. Surely, big projects on classified roads have significant economic impacts, and they engage people from government bodies and civil society at all levels, from neighbourhood to nation. Consequently, decisions about large-scale interventions and use of resources in the road sector should be made on a foundation of combined economic and political reasoning (Diesing 1962, Sager 1999).

Economic decisions are reached on the basis of a means-end analysis, where the goals reflect the economic interests of society, and the means are employed so as to achieve the goals with the least possible waste of resources. Economic problem solving abstracts from the multitude of groups with special interests and from the turmoil of intersecting conflicts. The rational procedure is to compute which planning alternative should be top-ranked, given the weighted goals and the available means, and then adopt the result without further ado. Compromise is irrational in economic problem solving.

Political authorities must look beyond the issue at hand to the maintenance and protection of the decision structure of society. Without a well-functioning system for making collective choices, neither plans for classified roads nor other projects serving society will be democratically enacted. A political decision is therefore not based primarily on the quality of the proposal in itself, but rather on who gains from its implementation, and who opposes the proposal. Communication between the decision-making authority and the affected parties is necessary. A political proposal is not passed just because it comes out as the best in a means-end analysis. Even economically good proposals are rather postponed, discussed, revised, substantiated in new ways, and re-launched sometimes in several rounds until the most intense opposition has calmed down. In contrast to economics, compromise is nearly always a rational line of action in politics. This also goes for compromises between road proposals that are good in economic terms that is, profitable according to CBA and proposals that are economically weak.

The white papers on NTP, and in particular the reasons offered by the Government for each unprofitable road project that is included, clearly demonstrate that the technical and professional arguments of road experts are in great demand. Apparently, not a single one of the many unprofitable projects is included because of local pressure, political obligation to distribute investments to all parts of the country, horse-trading between the governing parties, or need to satisfy the grass roots of the party organizations. Political explanations of this kind are much too vulnerable to attack by political rivals and critical voices in the general public. Hence, they are not found in the NTP, and obviously, neither are purely political considerations listed in the CBA-accounts. Conflict and loss of support and goodwill are nevertheless real political costs. This gives reason to hypothesize that the parliamentarians use of CBA, also in the future, will be quite limited when they are dealing with controversial prioritization.

# AN OVERVIEW OF THE MAJOR CAUSES BEHIND THE LOW EFFICIENCY OF LIGHT RAIL SYSTEMS IN RUSSIAN CITIES: THE CASE STUDY OF THE PERM URBAN TRAIN PROJECT

Ekaterina Saveleva[1], Svetlana Maksimova[2]

[1] Department of Architecture and Urban Planning, Perm National Research Polytechnic University, Perm, Russia, ekaterina.starodubzeva@gmail.com
[2] Department of Architecture and Urban Planning, Perm National Research Polytechnic University, Perm, Russia, gradcenter@mail.ru

Keywords: light rail system, Russian cities

Abstract. *Light rail systems seem to present an optimum solution to the current mobility issues of Russian cities. Yet most cities are not ready to invest in development of such systems and the attempts to create them on the basis of existing infrastructure fall short soon after the projects' launch.*

*Like many other Russian cities, Perm - a city of slightly under one million inhabitants in the European part of Russia - suffers from sprawl, inadequate transportation system and consequent mobility problems. The population is scattered over the comparatively large area (Perm is the 6th largest Russian city in terms of area being only 13th in terms of population) and most of the remote areas of the city are not well integrated with the city centre.*

*Being aware of the problem and seeking to improve the connectivity between different areas of the city local authorities have launched the project Perm Urban Train in 2004. Th set up using the existing railway lines with an ambitious aspiration to become a skeleton of the city transport system . The goal, however, was not achieved so far. The paper years experience of Perm to develop its system of light rail trying to reveal the factor determined the project's modest performance and hampered its successful implementation. Based on the results of the analysis, optimisation steps and recommendations for further development of light rail system in Perm and other Russian cities are proposed.*

## 1. Introduction

Urban mobility is one of the most critical issues for all Russian cities. Current mess in urban mobility is the result of the lack of effective planning and short-sighted and uncoordinated policies on land use and transportation. Tracing the history of urban transformation in socialist and post-socialist eras provides an insight into the roots of today's mobility problems. Starting from the 1960s many socialist cities adopted the pattern of massive residential development at the periphery of cities resulted in longer commuting distances (Golubchikov, Phelps,2011; Becker et al, 2012). The problem was further exaggerated during the transition period characterized by suburbanization of housing, retail, and jobs.

At the same time, the system of public transport was completely devastated during the 1990s and was not longer able to cope with this growing demand (Engel, 2007). While the socialist cities generally possessed highly developed and efficient public transport network, the transition period was characterised by the heavy reliance on the private automobile and the fact that public transportation system was largely neglected and underfinanced. The current level of service in the field of public transport is far below that of the past.

The transition period was characterised by the heavy reliance on the private automobile. The majority of public policies of the last decades also have been aimed at accommodating the growing number of automobiles at the expense of undermining all other modes of transportation. Thus, most of the public financing for improvements in the transportation system has been directed to expanding the vehicle carrying capacity of streets by adding new traffic lanes and building multi-level intersections, with the main purpose of moving more cars faster. To date, it is generally known that this kind of policy is not able to solve the problem of traffic congestion instead creating a vicious circle of increasing automobile dependency. Such policies achieve little but induce more automobile use, thereby considerably aggravating the existing traffic and transport problems, and eroding the quality of public space (Stanilov, 2007).

In Russian cities these negative trends still persist today (Vuchic, 2011). Dispersed urban structure coupled with an ill-conceived approach to transport planning cause serious mobility problems. Post-socialist cities seem to repeat the mistakes made by Western European and North American cities after World War II when the West embarked on ambitious projects to reshape the urban environment in order to clear way for the automobile. In order to avoid repeating the mistakes made by Western cities, Russian cities should look for new ways to meet the growing transportation demands of the densely built periphery.

## 2. The Untapped Potential of Urban Railways in Russia

When it comes to improving the connectivity between different areas of the city, introduction of rail transport systems is one of the commonly used type of contemporary urban interventions. Starting from 1970s many cities around the world have introduced different rail transit systems and the most popular one is Light Rail Transit (Topp, 1999). LRT along with tramway and metro belongs to a rail transit family of transport modes providing fast and convenient service to large masses of people. Being a high capacity transport mode LRT at the same time requires much lower investment cost than underground metro (Vuchic, 2002). Depending on the city's structure and its transportation system LRT may function as a suburban feeder to metro or serve as the principal transport mode. In any case rail modes of transport are in most cases superior to motor transport in terms of stability, speed, comfort and environmental impact (Morozov, 2010).

In Russia there are no systems that fully comply with the concept of LRT in the conventional sense. To date seven Russian cities have underground metro systems, and most major cities have one or another kind of electric rail transport, be it a tram, commuter rail, or light metro (Table 1). There are also dozens of unrealised projects, some of which date back to the Soviet era.

Apart from underground systems the most successful example of urban railway is probably a light rail system operating in Volgograd. The Volgograd Metrotram was opened in 1984 and became a relief for the city which stretched for more than 80 kilometres along the Volga river. The line has a total length of 17.3 kilometres with 7.1 kilometres built underground and the rest is within a surface-level right of way rebuilt from the ordinary tram line. But the system of Volgograd remains unique for Russia, its efficacy is determined by the city's linear urban structure.

In most other cities without underground metro rail transit is far from being dominant transport mode. The transition period was marked by the gradual failure of tram systems in many major Russian cities (Merkushev, 2011). First, tram lines located in the street network were seen as an obstacle to the increase of road capacities. At the same time drop in manoeuvrability and speed of trams in the conditions of high traffic density (with cars often blocking the lines) led to a decrease in the number of passengers, which made city authorities abandon and dismantle the system. Tram

systems continue to operate efficiently and develop only when they are separated from the road traffic and put in the conditions of almost total exclusion of single-level crossings with other transport modes. However, isolation of the existing tram lines from the roadway is either not always possible at all in the current urban conditions or demands large capital investments.

Table 1. An overview of rail transport systems in Russian cities

| City | Population, million people | Underground metro | Light rail system | Tram |
|---|---|---|---|---|
| Yekaterinburg | 1,43 | + 1 line | - Medium-term plans | + Highly developed |
| Chelyabinsk | 1,18 | - Uncompleted | - No plans | + Highly developed |
| Kazan | 1,21 | + 1 line | + Segments of Big Kazan Ring | + Moderately developed, dismantled in the city core |
| Khabarovsk | 0,61 | - No plans | - No plans | - Moderately developed but mostly separated from road |
| Krasnoyarsk | 0,98 | - Uncompleted, frozen until 2020 | - No plans | + Moderately developed, partly dismantled |
| Nizhny Novgorod | 1,26 | + 2 lines | - No plans | + Moderately developed, partly dismantled |
| Novosibirsk | 1,57 | + 2 lines | - Long-term plans | + Moderately developed, partly dismantled |
| Omsk | 1,17 | - Uncompleted, frozen | - No plans | + Moderately developed, partly dismantled |
| Perm | 1,04 | - No plans | - No plans | + Moderately developed |
| Samara | 1,17 | + 1 line | - No plans | + Highly developed |
| Volgograd | | - No plans | + Metrotram | + Moderately developed |

In addition to the reviewed modes of rail transport most major cities have electrified intracity sections of railways used for commuter trains and long-distance trains. In cities where these lines pass through the city centre they present a ready-to-use solution to the problem of connecting the cities' cores and peripheries. In the last decades several cities including Perm made attempts to use these existing lines for developing Urban Train systems. Urban Train is a kind of electric rail intracity transport, usually using an existing rail infrastructure. Urban Train projects were to become Russian version of LRT resolving the mobility problems without much effort and investment on the part of the cities.

Urban Trains are very similar to commuter trains with only two differences: 1. smaller serviced area, allowing a smaller number of trains serve the entire area while maintaining small intervals.; 2. shorter trains consisting of six or less carriages. One relatively successful example of such project is Yekaterinburg, where the Urban Train is the fastest and cheapest way to get from the southern outskirts to the city centre (SPK, 2014). However, even there the number of urban train's passengers is far below than for other transport modes.

In some cities the projects are shut down (Ryazan) or close to it (Omsk), in others it remains an experiment (Tuymen). In Ryazan, the project was cancelled due to the lack of demand. The Ryazan Urban train system was introduced in a test mode using existing lines and passenger stations on April 30, 2009. The test period, which lasted until 17 June, showed the need to build additional stations and bypass lines for overtaking commuter trains (RZN.info, 2013). In Rostov-na-Don the Urban Train Project was launched in 2012 and lasted for only five days.

In Perm the Urban Train system was introduced in 2004. Although the number of trains decreased threefold the service is still in place. Thus Perm presents an opportunity to ana experience of developing the system of the Urban Train. Using the case study of Perm this paper will try to reveal the factors that determine the Urban Train projects' modest performance and hamper their successful implementation in Russian cities.

## 3. The Perm Urban Train: 2004-2014

Like many other Russian cities, Perm - a city of slightly under one million inhabitants in the European part of Russia - suffers from sprawl, inadequate transportation system and consequent mobility problems. The population is scattered over the comparatively large area (Perm is the 6th largest Russian city in terms of area being only 13th in terms of population) and most of the remote areas of the city are not well integrated with the city centre. Being one of the hubs of the Trans-Siberian railway Perm has more than 100 km of railway lines.

The idea of introducing some kind of rapid railway system in Perm also has a long-standing tradition. Soviet norms required that any city of 1 million people be equipped with metro. The first official project of Perm metro was published in 1982. However, construction has not begun due to the financial constraints. Since then Perm authorities have come back to this issue repeatedly. The in-depth analysis of the feasibility of the project was performed in the Integrated Transport Scheme of Perm (KTS, 2008) commissioned by the Department of Planning and Development of Perm. At that time the transportation planners have concluded that the efficiency of metro in Perm will be very low due to "the lack of sufficient volume of passenger traffic concentrated in one direction" (Petrovich, 2010). In the KTS (2008) it was proposed to make greater use of intracity sections of the Trans-Siberian railway and the further development of the existing tram network.

The project «Perm Urban Train» was launched in 2004 with an ambitious aspiratio «skeleton of the city transport city». The new route was set up using the existing ra including intracity sections of the Trans-Siberian railway. It had a total length of 51 km and included 8 stations and 14 stopping points on both sides of the Kama River. All other modes of transport, namely buses, trams and trolleybuses, were to be connected with this newly established route.

The Perm Urban Train project was the first attempt to develop LRT-like system in Perm. As stated in the project's official description (PPK, 2013) the project pursued the following goals:

- Provision of the higher level of service at the rates equal to the rates of alternative modes of public transport (mostly buses) within the city limits;
- Increase in the number of passengers transported by rail and subsequent road transport load reduction in the same direction;
- Improving the environmental situation by reducing the number of bus routes;
- Ensuring the timely delivery of workers to the industrial sites with introducing the train timetable linked to work shifts schedule;

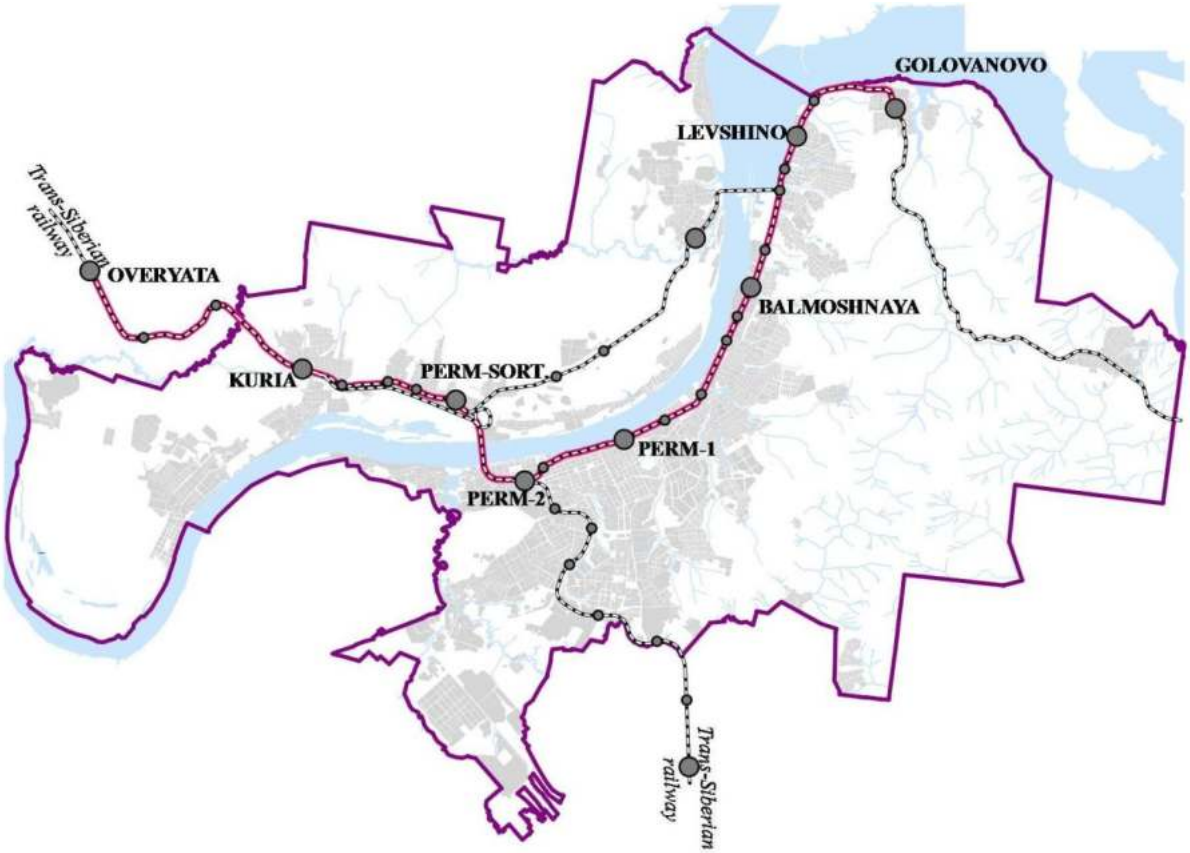

Figure 1. Railway network of Perm and the Perm Urban Train route

The city's form and the location of the existing railway in relation to the residential neighbourhoods and places of employment is a significant factor determining the success of the urban train project. For Perm with its linear urban form and the existing railway lines along its structural axis, the

project seemed like a perfect fit into the city's urban structure. If implemented properly it could potentially become the basic network for the city's new, more comfortable and efficient, transportation system.

A decade has passed since the project launch and it is possible to draw some conclusions. The total number of passengers of the Perm Urban Train from 2004 to 2013 amounted to more than 8 million passengers. In the years 2004-2008 the number of passengers was stable at around 1 million people annually but starting from 2009, when several trains were removed from the timetable, the number of passengers dropped significantly every year reaching around 0,6 million in 2013 (Figure 2).

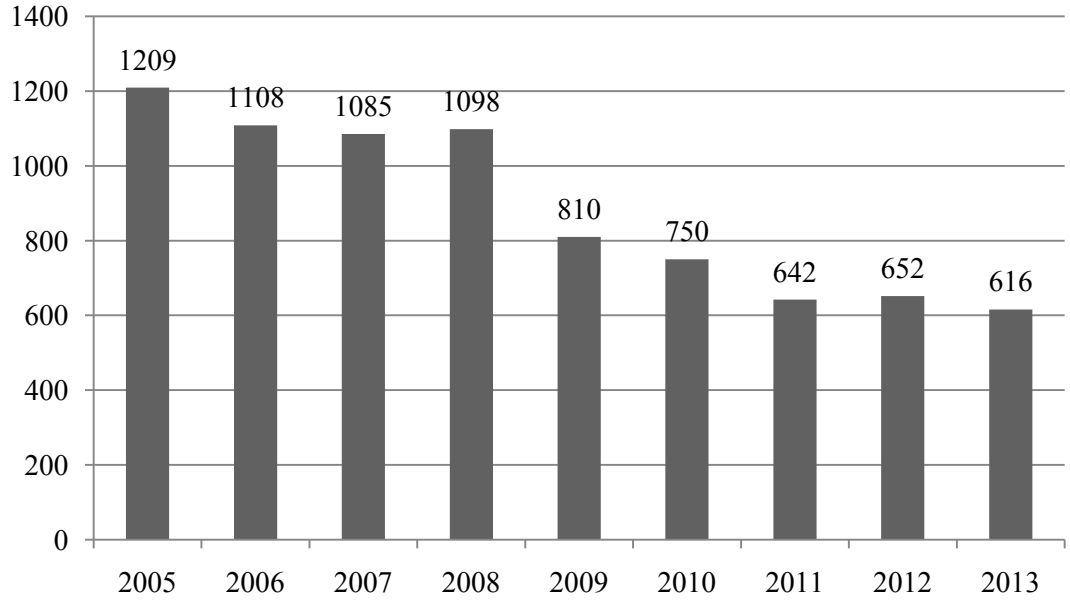

Figure 2. The number of passengers of the Perm Urban Train from 2004 to 2013, thousand people. Source: PPK, 2013

Despite the fact that the Urban Train has obviously failed to become city s pri provided several remote areas of the city with comparatively fast and convenient way to get to the city centre. Perm Urban Train is the fastest means of public transport to the city centre from many areas. For example, it takes 38 minutes to get to the terminal station Golovanovo by train while the same trip by bus may last between 60 and 120 minutes depending on the time of the day. The table of comparison between travel times to some other stations by train and by bus is presented below (Table 2).

Table 2 Comparison of travel times by bus and by train. Source: personal observations

| Points of departure and arrival | Travel time by bus, min | Travel time by train, min | Reduction |
|---|---|---|---|
| Perm I - Golovanovo | 90 | 38 | 58% |
| Perm II - Levshino | 60 | 39 | 35% |
| Kuria - Perm II | 90 | 23 | 74% |

So if this train does provide faster access to the city centre and backwards, what are the reasons for its low popularity and the constant decline in the passenger traffic?

## 4. Uncovering the reasons behind the Urban Train's low efficacy

The reduction in the number of passengers is due to the fact that a significant portion of them opt for alternative modes of public transport. The preferences of passengers were determined by the following factors:

- cancellation of a number of trains and simultaneous increase in the number of bus services, taxis, parallel to the route of the Perm Urban Train: there were 32 trains per day when the project was launched in 2004 and only 9 trains per day were running by the end of 2014 ;
- poor accessibility resulting in long travel times to the railway stations;
- high non-competitive price: by the end of 2014 the cost of the journey (regardless of the distance) was 21 roubles, while the trip by bus cost only 13 roubles;
- poor quality of station infrastructure.

According to passenger survey held in 2013 the factor having the greatest influence on the popularity of the Perm Urban Train is its irregular timetable(UralINSO, 2013). There is no regular interval timetable and there can be gaps up to 2-4 hours outside the rush hours. The inconvenience of the current schedule coupled with higher price outweigh all the advantages of the Urban Train over alternative means of transport.

Yet the need to increase the number of trains and to reduce the intervals of their movement is an issue that cannot be easily resolved. There are two main factors impeding this: 1. an insufficient capacity of rolling stock and 2. an insufficient capacity of railway lines in some sections. According to the General Plan of Perm (Generalnyi Plan Permi, 2010) the left bank section of the Perm Urban Train line (Perm II-Golovanovo) has an excess capacity and the main problem with the capacity of the railway network is related to the Trans-Siberian Railway. The latter is already running at its capacity while the two-track railway bridge over the Kama creates a real bottleneck.

One possible solution is to build a by-pass track to the south of the city (Perm Strategic Masterplan, 2010). The proposed track would remove the burden of immense freight traffic from the Trans-sib section going right through the city centre. However, the construction of the by-pass demands such amount of investment that is not currently available to the city. Increase in the number of trains will also require considerable investment.

It may be argued that using the same railway lines dedicated for fast trains and freight traffic generally creates a number of problems. In the Urban Train schedule there should be 'windows' left for passing long-distance trains. Moreover, deviations from the schedule of long-distance trains results in unexpected cancelations and delays of the Urban Trains. In Tyumen congestion on the Trans-Siberian section of the Urban Train route is also an obstacle to the realization of this project in full. After the launch of the project in 2009 finding timeslots for the Urban Trains turned out to be very difficult during peak hours (NashGorod, 2014).

However, implementation of these infrastructure developments may not guarantee the raise of the urban trains' popularity. Even when existing infrastructure is sufficient for launching an adequate number of trains, there still may be lack of interest on the part of passengers.

The root of the problem lies in the way public transport market is organized. In Russian cities there is a system of self-regulation of public transport services. Today regional and municipal carriers (running urban train, trams, trolleybuses) are put in conditions of uncontrolled competition with private carriers (running buses). Bus carriers offer services of low quality often delivered by obsolete fleets but at affordable rates.

The competition in the system of public transport in Russia leads to oversupply in some routes and irrational costs. In the last years private carriers almost completely replaced municipal carriers in the bus transport market. Private carriers become the main operator in this important sphere of municipal economy. They have entrepreneurial mindset and are not ready to carry the burden of social responsibility instead being focused on quick payback and revenue at any cost. Reducing tariffs without compensation make carriers reduce operating costs by saving on the repair and maintenance of the rolling stock.

Such a policy not only adversely affects the performance of the Urban Train and electric transport operated by the city but inevitably leads to the overall ridership losses and forces passengers to switch to private automobiles.

It the competition with other modes that became the main problem for the Urban train project in Omsk. Proliferation of routed taxis (a form of public transportation such as a share taxi using minibuses, often illegal) which is characteristic for most Russian cities make passengers opt for cheaper and ubiquitous mode. Although the company running the Urban Train in Omsk is looking for new ways of attracting passengers such as free Wi-Fi or a 'library on wheels', it does not make much difference (Top55, 2014).

The model of market self-regulation is regarded by most experts in the field as ineffective (Ganin, 2012). It does not properly work in most cases. State regulation is important to ensure compliance with public interest and protecting this area from undue commercialization. It is necessary to establish mechanisms for regulating public transport services in order to overcome chaotic patterns of today's public transport system, which 'steals' passengers from regular routes. Current legislation in the field of public transport in Russia does not imply centralized and coordinated transport planning and operational management but at the same time it does not prohibit it.

In order to facilitate integration of all modes of transport in one efficient system an intermodal transportation company may be established in cooperation with the Government of the Perm region. This will increase the level of coordination and co-operation between all public transport providers and allow to prioritize more sustainable modes such as urban railway.

The Perm Urban Train project is currently run by the Perm Suburban Company, which is a subsidiary of Russian Railways (51 percent owned by Russian Railways and 49 percent by Perm region). Around 58 percent of operating costs are covered by transportation fees, the rest is subsidised by the regional budget. In 2014 the regional government raised the question of the abolition of funding for the project since it was not ready to subsidy intra-urban public transport. The city budget also does not have the necessary funds. The service is still in place but the question of financing remains open.

Meanwhile, the problem is not unique for Perm. Many other Russian regions have similar Suburban companies operating commuter rail transportation. During their creation in the early 2000s the rolling stock was not included in their authorized capital. As a result the rental payment for the carriages and locomotives accounts for almost 70% of their operating costs. This rental

payment and the tariff for the use of railway infrastructure are charged in favour of Russian Railways. Many regions consider the pricing policy of Russian Railways as opaque and refuse to subsidy the Suburban companies (Terentyeva, 2015). This issue, however, lies beyond the scope of the current study.

## 5. Possible organisational and administrative reforms

In order to increase the effectiveness of the existing system of rail transit in Perm we propose several organizational improvements which do not require much capital investment but strong political will.

The following reforms are suggested in order to improve the service and to encourage rail transit ridership:

1. Reducing the intervals of the train, as already mentioned, is the most needed step towards attracting more passengers since the inconvenience of the current schedule for many passengers outweigh all the advantages of the Urban Train over alternative means of transport. This may achieved either by rearrangement of the existing fleet, e.g. splitting longer trains into two on the routes running with intervals, or by investment into new rolling stock, thus improving both the intervals and the level of comfort.

2. Improved coordination among modes and integration of the Urban Train into the city's public transport system is a foreground transformation that may be beneficial not only for rail transport system, but also for the city's public transport network as a whole.

This can be achieved in several ways. The first and most obvious step is to introduce a single (and simple-to-use/understand) ticketing system compatible with other modes of public transport. Such systems are in place in most cities with developed public transit since the mid 2000s.

Better modal integration on stations and stopping points is also a very important step towards attracting the new passengers. Possible developments in this field include turning at least the major stations into proper transportation hubs with exchange opportunities from train to buses, trams and other modes of transport with simultaneous harmonization of their schedules. Other ways of modal integration include:

- Arrangement of near-station parking lots allowing car users to leave their vehicles safely and change to train;
- Organisation of short bus routes between places of residence and train stations as a feeder service to the Urban Train;
- Improving pedestrian accessibility and approaches to the stations and stopping points.

One of the feasible perspectives of mode integration in Perm is the formation of the tram-train system. The basis for such system will be the left bank section of the railway and the well-developed tram network in the south part of the city.

3. Finally, it is important to make the use of the Urban Train clearer and easier. Improved availability of passenger information combined with various marketing programs aimed at popularisation of the Urban Train and rail public transit in general will make a significant contribution to the development of the project.

## 6. Conclusions

To sum up, it may be argued that at the time of its establishment the Perm Urban Train Project presented a promising solution to the Perm s issue of low connectivity raised fro fragmented urban fabric.

Unfortunately the Perm Urban Train has not received due attention from the regional authorities who initiated the project nor it has attracted enough support from the authorities of the city. Despite the initial plans it was not integrated into the city's network of public transport leading to the competition with other modes and the gradual loss of passenger volume.

Planning and developing of effective transport system requires an integrated approach. The fragmentation of urban administration, which is evident both in post-socialist and developing countries, hampers the success of policy planning and implementation. Many authors call for organisational change and for better co-ordination of structural units of administration having urban transport responsibility as a crucial element of efficient performance of city's transportation system (Cervero, 1998; Dimitriou, 1990; Stanilov, 2007). The creation of the intermodal transportation company or the local government body managing the whole transport system seems to be a most urgently needed reform in Perm and other Russian cities.

The development of the efficient transportation system with the rail transit as a backbone presupposes the abandonment of the current overreliance on private automobile transport and adopting a new systematic approach to transportation planning. Overcoming chaotic and inefficient traffic patterns characteristic of most Russian cities requires sufficient political will and civic drive to give the priority to more sustainable modes such as rail transit and to allocate needed resources. Subsidies in the system of public transport should be evaluated against the costs associated with road traffic: capital investment into road construction, the cost of road maintenance, road safety, organization and construction of parking spaces and so on. The investment into urban rail systems in the long term may be the most cost-effective solution improving mobility at a lower total cost, including costs to government, consumers losing time in traffic jams and the city's environment.

Abstract

Vancouver, Canada s third largest city, has often been held up as a best-pra transport and land use planning in a New World context. Accordingly, in the a Network Analysis for Multimodal Urban Transport Systems (SNAMUTS) tool to Australasia and North America, Vancouver scored top results on the majority of a public transit. But how does a successful big-picture outcome translate int relate to historic factors that predate Vancouver s focus on sustainability-o during the past quarter century? This paper will contrast the SNAMUTS result wi measuring public transit accessibility based on a time line spanning three dec history and the assessment of recent spatial priorities in land use and transp that despite high recent growth and intensification rates, much of Vancouver oriented urban form can be traced back to the city s light rail and streetcar 20th century, and that the spatial correlation of public transit service intensification over the past 30 years has been anything but consistent. We assessing the contributions of both methodologies towards a comprehensive repres accessibility in Vancouver, and will evaluate the magnitude of the shortfalls policy and practice across other cities in the SNAMUTS sample across the New Wor

Key words: public transit, accessibility measures, land use-transport integratio planning.

## 1. Introduction

In the 1960s citizens of Vancouver protested against government plans for freewa downtown. They opposed the destructive impacts that freeway construction would city neighbourhoods, the modernist plans for post-freeway urban renewal, ar congestion and pollution of more cars in the metropolitan core (Lash, 1976; P organised opposition, together with a lack of government funding and mounting e associated with automobile dependence, led to cancellation of the plans. A c government authority then recommended an extensive rail rapid transit system t strong core and transit-oriented land development concentrated in regional t 1976). In 1986 metropolitan Vancouver s first SkyTrain line began operations, a land surrounding stations and an overall restructuring of urban form were well SkyTrain line was followed by an inter-city regional commuter rail line in 1995, in 2002, and a light metro line in 2009. The policy transition saw a new tra focussed on accommodating growth in urban movement on the existing road system alternatives to the automobile (Price, 2012). Despite some to-and-fro over both such policies between municipal and provincial governments, this compact pr resilient over a forty-year period (Filion and Kramer, 2012; Stone, 2013).

Today a wide range of scholars describe Vancouver as an exemplar of effective
strong sustainability overtones (Punter, 2003; Berelowitz, 2005; Schiller, Bruur
Legacy, 2012). These achievements relate to successes in metropolitan growth ma
on urban intensification, the integration of expanding public transport infras
fabric, people-friendly and environmentally adapted urban design outcomes, and
inclusive culture of decision making. The development of the public transport
consolidation in recent years, accompanied by an annual population growth rate
Vancouver region, has seen public transport become a more prominent element of
356 million passenger journeys in 2011, a rate of 154 per capita (Translink

2012) this is an exceptional and well-resourced multi-modal integration of tran
service planning that has made a critical contribution to enabling the public t
up with population growth as well as the transit-oriented objectives of the regi

## 3. Methods

### 3.1 Transit coverage over time

This study of Vancouver s public transit service coverage, measured in freque
unit, was undertaken in three main stages. The first stage involved the acquis
bus routes and timetables obtained in paper format for the years 1981, 19
downloaded from the transit operator s website for the year 2011. The challenge
allows for the comparison of change over time. If relatively large spatial unit
over time were used to quantify service change, expected small scale changes s
routes in favour of a larger and faster train, would be missed. While Vancouve
ferry stations, route and timetable information are all now available in elect
and schedules existed only on paper, in the timetables or the paper archives o
time line was commenced in 1981 because there was a full set of timetables, it

## 5. Results: Transit Accessibility in the Vancouver Region

### 5.1 Service intensity

The accessibility tool (SNAMUTS) sets a minimum standard for inclusion of public
It uses the weekday inter-peak public transport network and stipulates a
frequency on surface routes and a minimum 30-minute frequency on segregated rai
The rationale for this is that this comes closest to serving the daily acti
traveller who compares a public transport journey with one by car. The service
1) captures the number of public transport vehicles or train sets in simultaneou
minimum standard. The figures shown are in relation to metropolitan population.

Table 1: Public transport service intensity in Vancouver and nine other New World ci
number of vehicles/train sets in simultaneous revenue service during the weekday inter-
minimum service standard, and relative to metropolitan population.

| 2011 12 | Number service | Services 100,000 |
|---|---|---|
| Vanc | 448 | 19.3 |
| Adelaide | 223 | 18.1 |
| Sydney | 654 | 14.9 |
| Melbourne | 536 | 13.4 |
| Perth | 218 | 12.6 |
| Brisbane | 233 | 11.6 |
| Montreal | 399 | 10.4 |
| Portland | 168 | 10.2 |
| Seattle | 271 | 10.2 |
| Auckland | 135 | 9.2 |

The index is influenced by the propensity of public agencies to put resources
operation and offers a proxy for the priority with which public transport is t
funding with other public tasks. These figures also reflect an efficiency chara
a large number of small and/or slow-moving vehicles as part of the public tran
buses running in traffic in congested conditions), service intensity figures
significant number of services are offered through large and fast vehicles (such
alignments) service intensity figures are reduced.

In Vancouver, there is a more pronounced role for buses and trolley buses in th
example, in Montreal (which has only a handful of bus services entering the CBD
of the difference in service intensity results between the two Canadian
Vancouver s bus network expansion and average service frequencies are also su
every other city in the comparison, including Adelaide which is only marginally
the overall result, but suffers from a far greater degree of bus congestion in t

5.2 Ease of movement (closeness centrality) and transfer reliance (degree cen

The closeness centrality index (Table 2) comes closest to a traditional measu since it only depicts the accessibility of the transport network; it does not t (or land use). The index measures travel impediment as experienced by users mov transport network. In addition to measuring travel time, it includes service important to public transport travellers. Cumulative impediment scores per jou impediment value on each route segment traversed. The node-based figures in N average, non-weighted travel impediment (closeness centrality) between the ref other nodes in the network, selecting the route with the lowest cumulative imp case. Lower values indicate greater ease of movement.

The degree centrality index (Table 2) measures the reliance of the network on tr transport services on different routes to make journeys on the network. The fi refer to the average, non-weighted minimum number of transfers required between and all other nodes on the network. Lower values indicate lower transfer reliano

Table 2: Average, lowest (best) and highest (poorest) SNAMUTS closeness centrality and centrality results in Vancouver and nine other New World cities.

| 2011 12 | Closeness cent (average) | Closeness cent (lowest valu | Closeness cent (highest val | Degree centr (average) |
|---|---|---|---|---|
| Vancouver | 42.1 | 25.0 | 162.1 | 1.13 |
| Montreal | 47.1 | 28.1 | 130.1 | 1.38 |
| Portland | 57.4 | 34.6 | 171.5 | 0.79 |
| Auckland | 59.0 | 33.5 | 133.2 | 0.95 |
| Perth | 59.3 | 35.2 | 130.9 | 1.03 |
| Adelaide | 61.1 | 33.8 | 147.3 | 1.09 |
| Melbourne | 62.3 | 36.0 | 165.2 | 0.91 |
| Brisbane | 64.1 | 35.1 | 187.6 | 0.91 |
| Seattle | 64.3 | 36.4 | 149.6 | 1.07 |
| Sydney | 81.5 | 46.4 | 281.5 | 1.04 |

On the ease-of-movement index, Vancouver (alongside Montreal) significantly ou World peers. This measure is influenced by the spacing of the activity centre urban compactness as well as average speeds and service frequencies of the that link these centres. Missing links and a convoluted urban geography e away from desire lines, in contrast, will negatively impact closeness results.

Vancouver s exceptional performance on this index can be associated with the the SkyTrain system as the network s backbone: its high commercial speeds separation) and high frequencies, generally of five minutes or better (facilit operation, which reduces the marginal cost of additional services), minimise tr its routes. Map 2 shows how the best closeness values in Vancouver follow th Montreal s metro system, though not driverless, shares similar characteristics In contrast, the heavy rail systems of the Australasian cities and Portland s have daytime service frequencies of fifteen minutes at best.

Another contributing factor for Vancouver s relative ease of movement on public grid-shaped surface network, made up of buses and trolley buses also operated than in most comparison cities. This can be seen in the relatively smooth deca across most of the Burrard peninsula where the density of the surface network is

Vancouver s constrained geography appears to assist, rather than obstruct, effectively containing a significant part of the urbanised area on a relatively in contrast to Sydney, Seattle and Auckland, where water bodies act as segregat of the metropolis which public transport, as well as the road system, struggle t

Vancouver and Montreal have the highest reliance on transfers in the New World both, there is a hierarchical network design which designates the (limited) ra backbone corridors and the (more widespread) bus networks as feeders and distr however, retains a greater role for surface modes in the city centre and thus number of transfer-free connections between CBD and suburban nodes than its Qu (see Map 3). The most transfer-dependent nodes in the Vancouver region ar municipalities to the north, east and south where bus routes act more as class than as connectors along corridors that extend across several local government a

5.3 Network coverage and contour catchments

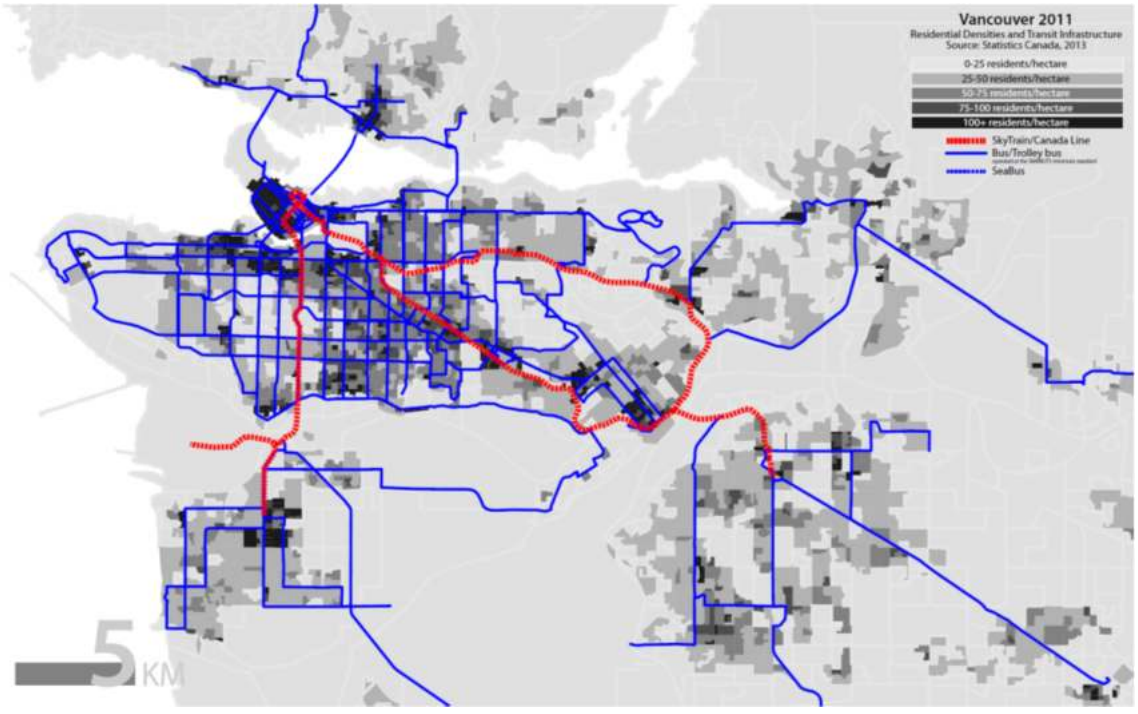
These two measures introduce a land use component to the transport assessmen
Network coverage (Table 3) measures the percentage of metropolitan residents
walking distance (roughly 800 metres around rail stations and ferry terminals,
bus and tram corridors) of public transport routes that meet the minimum ser
measure provides an answer to the question who gets access? It is an indicat
city as a whole is by public transport. The ideal result would be 100%. Conto
measures the percentage of metropolitan residents and jobs that can be reache
node by way of a 30-minute public transport journey with a maximum of one trans
indicate larger contours. This measure is more usefully considered for each cen
used diagnostically to explore how well served are activity centres that dra
population (such as a university or main hospital).

Table 3: Network coverage and average 30-minute contour catchments in Vancouver and nine World cities.

| 2011 12 | Network coverage (percentage of met residents and j | Average 30 min contour (percentage of metrop residents and jobs |
|---|---|---|
| Vancouver | 61.4% | 19.5% |
| Sydney | 54.6% | 8.3% |
| Montreal | 49.3% | 15.0% |
| Adelaide | 48.8% | 10.7% |
| Melbourne | 46.8% | 9.3% |
| Portland | 41.7% | 10.5% |
| Perth | 41.4% | 10.6% |
| Brisbane | 37.5% | 10.6% |
| Seattle | 35.2% | 8.4% |
| Auckland | 32.8% | 10.2% |

Network coverage can be read as a proxy indicator for the willingness of public bring a good level of service to as large a share of the population as possible in competition with the deployment of operational resources on those corrido potential for ridership growth (Walker, 2012). Hence, good results on this in compact urban form which makes it easier to allocate limited resources to a residential and employment areas.

Map 4: Relationship between residential density and movement lines of public transport i

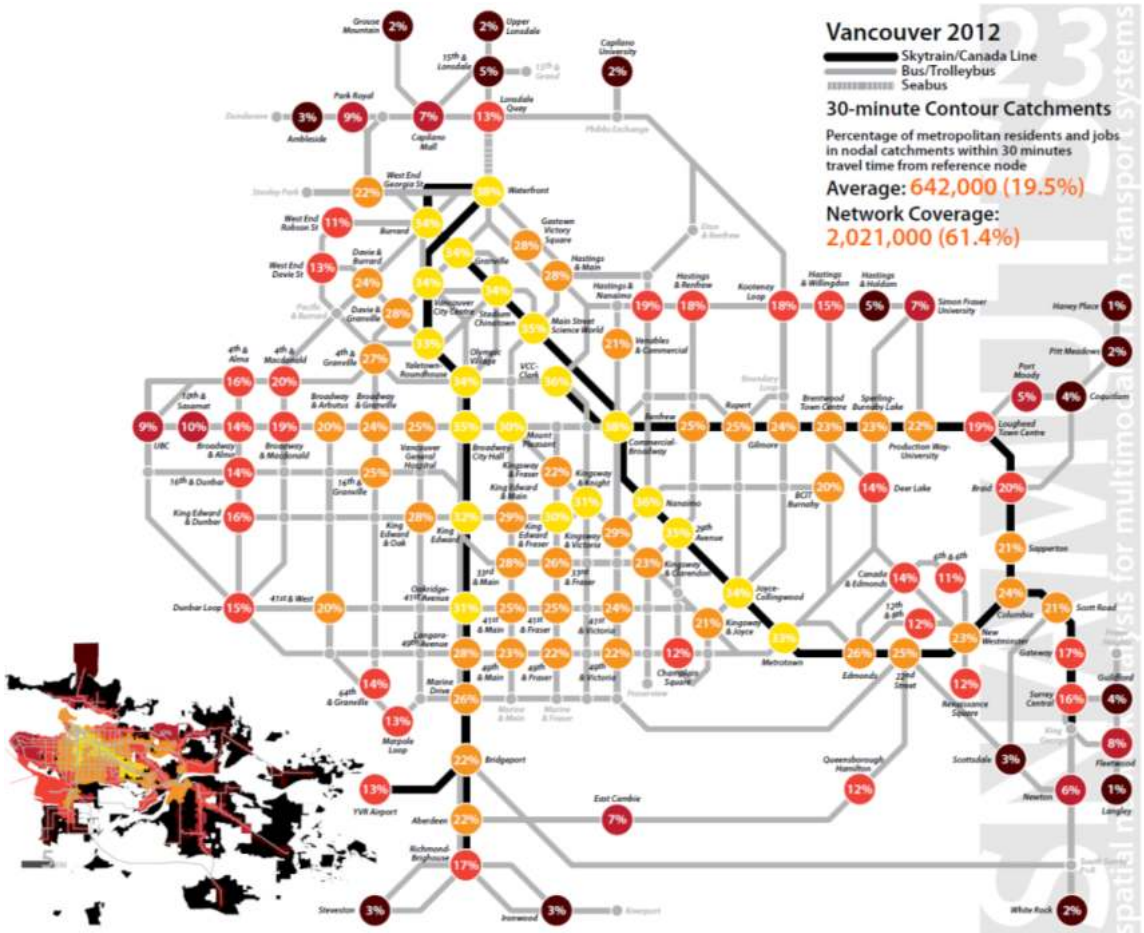


Vancouver s network coverage is greater than that of any other New World city an achievement associated with the core city s dense surface network that cove within walking distance at the minimum standard. In suburban areas, public trans corridor-based though, unlike in Montreal, these corridors serve all signific metropolitan area. While Greater Vancouver, like every other city in the New significant share of low-density, dispersed suburban development, the phys waterfronts, mountain ranges, an area of protected farmland and the Canadian-U limit the spread of this urban form to the foothills in North and West Vancou fringe of the metropolitan area.

Vancouver also leads the cohort of New World cities on the average 30-minute c result associated with several factors that work in favour of successful land The speed and frequency of the rail system in conjunction with the relativel expansion of the bus and trolleybus system continues to exert an influence her geographical size of contour lines. In addition, it is likely that Vancouv relatively effective policy to concentrate urban intensification programs into transit-oriented locations is succeeding by agglomerating urban growth around t public transport, thus also increasing the density of origins and destinatio contour line (Filion and Kramer, 2012; see also Map 4). Vancouver beats Montrea city which benefits from a larger heritage of older and traditionally denser ur Columbian counterpart, but arguably has a weaker policy to facilitate further around transit (Filion and Kramer, 2012).

Map 5 illustrates the importance of the SkyTrain corridors as well as the d connecting them especially in the south-east of the core city (Main Street, Fra corridors) to maximise the expansion of contour catchments for a broad range of

Map 5: 30-minute contour catchments in Vancouver s public transport network in 2012



5.4 Spatial distribution of travel opportunities (betweenness centrality)

This index visualises how potential preferred travel paths (those that offer while also considering transfers and service frequencies) between any pair of weighted by catchment size and travel impediment, are distributed across the ne which routes and nodes potentially attract the most through-put from travel opp the land use-transport system as a whole? Higher values indicate greater network

The concept of betweenness centrality has several sub-measures. Nodal betweenn betweenness describe the number of potential travel opportunities attracted t route segment (Map 6). Global betweenness (Table 4) is a measure adding the (number of activities connected divided by the travel impediment that separates nodes on the network, extracts the square root of this sum per node and then e proportion to the total number of metropolitan residents and jobs. It is used t level of presence of public transport movement opportunities for trip mak typical path length measure (Table 4) is a proxy for the percentage of metropol located alongside a public transport journey of average length; it is influence land use activities around public transport nodes on the one hand (with higher the figures), and by the configuration of the network to facilitate travel al journey path (with greater encouragement for passengers to take detours in order higher-frequency services also inflating the figures).

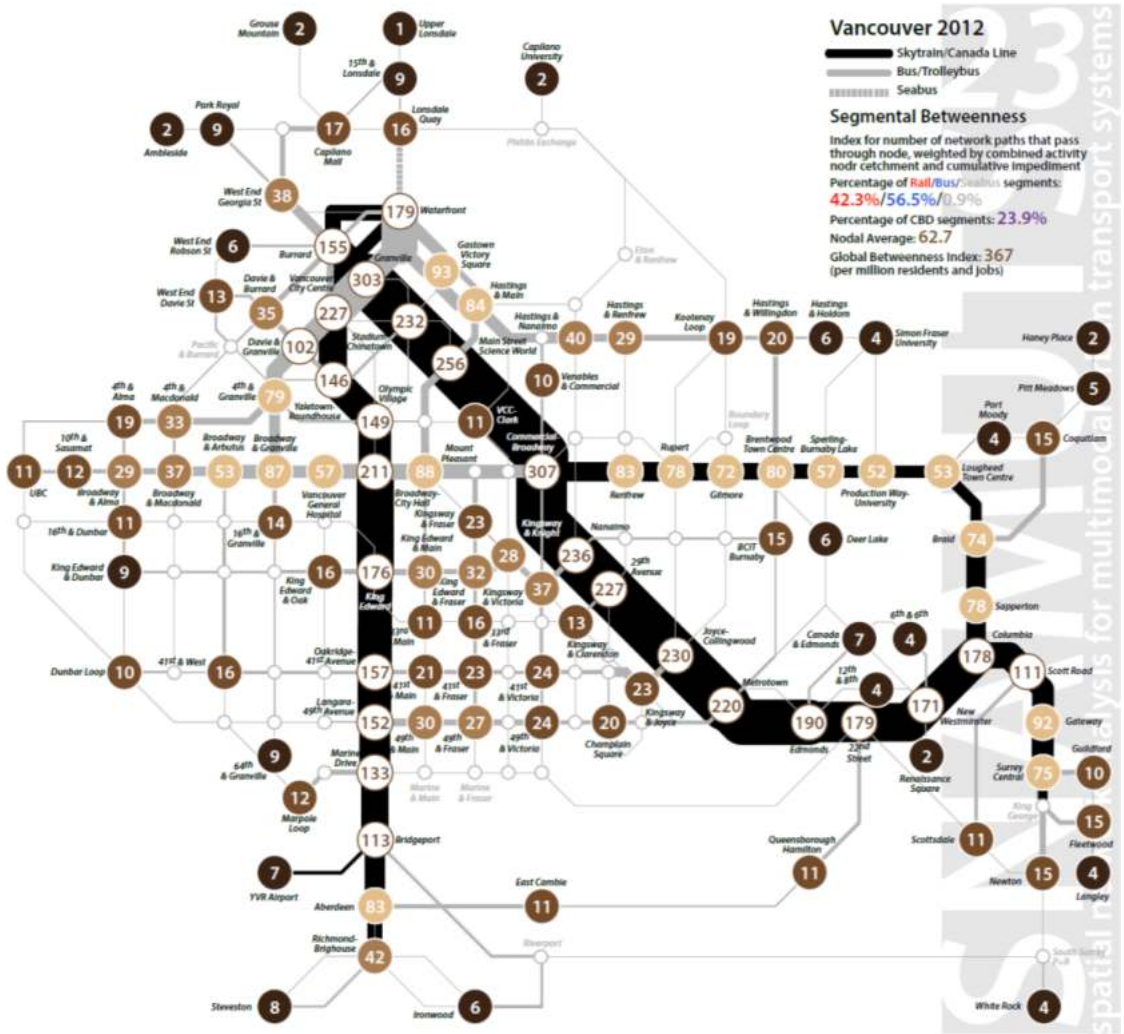
Table 4: Global and nodal betweenness centrality, and catchment of typical path length nine other New World cities.

| 2011 12 | Relative glo betweenness i | Average nodal between | Catchment o typical path |
|---|---|---|---|
| Vancouve | 367 | 62.7 | 3.22% |
| Adelaide | 289 | 24.4 | 2.36% |
| Montreal | 274 | 77.6 | 2.51% |
| Perth | 249 | 30.9 | 2.06% |
| Auckland | 239 | 30.5 | 2.17% |
| Portland | 230 | 35.3 | 2.67% |
| Brisbane | 227 | 33.6 | 1.93% |
| Seattle | 201 | 34.0 | 1.54% |
| Sydney | 198 | 40.5 | 1.80% |
| Melbourne | 175 | 33.1 | 1.55% |

On the relative global betweenness measure, Vancouver significantly outperforms the New World sample, indicating a public transport system richer in travel op ranked nodal betweenness figures, however, which place the British Columbian ci so Montreal) much higher compared to the relatively even field of the Australas point to some problems. They can primarily be attributed to the performance g dominant modes operating in both cities heavy rail and buses which is elsewhere due to the SkyTrain s (and Montreal s metro s) high service freq speeds. In combination with the easier legibility of both cities still quite characteristics have the potential effect of attracting passengers to ra geographically direct connections may be available on the bus network. Vancouve for example, includes a big loop enclosing the core city s south eastern subur neighbouring Burnaby. A number of bus routes cut through this area in relativel circuitous SkyTrain trip will get most passengers to their destination faster th travel opportunities are then counted at every rail station along their geogra and together drive up average nodal betweenness results. The same observation f average catchment of typical path length measure, on which Vancouver also lead considerable margin. It responds to common geographical detours making average and traversing a greater number of intermediate centres than strictly necess effects may be of great disbenefit to the user per se, the potential concentra limited number of high-performance corridors away from their desire lines congestion, as well as higher than necessary energy use per passenger. This is to the public transport planner wary of the system s overall efficiency.

Map 6 shows the extraordinary concentration of potential travel opportunities SkyTrain and Canada Line corridors, complemented by only a limited number of st chiefly along Broadway, Granville Street, Main Street and Hastings Street.

Map 6: Betweenness centrality in Vancouver s public transport network in 2012



The segmental betweenness index can also be queried in terms of the percentage travel opportunities attracted to congestion-prone areas such as the CBD, and peak performers in terms of passenger capacity and competitiveness to the speed and amenity. Table 5 shows the rankings of the New World cities – the h greater the share of travel opportunities captured by rail modes or within the C

| 2011 12 | Segmental between (all rapid rai |
|---|---|
| Vancouver | 42.5% |
| Brisbane | 35.7% |
| Adelaide | 21.3% |
| Auckland | 15.2% |
| Seattle | 8.8% |

| 2011 12 | Segmental between (CBD area) |
|---|---|
| Melbourne | 32.7% |
| Auckland | 35.4% |
| Perth | 40.0% |
| Seattle | 42.8% |
| Adelaide | 62.0% |

Despite the aforementioned potential sponge effect of high-performance rail of travel opportunities over the network, Vancouver s overall rail share on slightly below that of New World cities where heavy or light rail systems were the backbone of public transport in recent decades (Montreal, Portland and Vancouver s SkyTrain network arguably lacks the maturity of Montreal s metro 20 years earlier) or Perth s suburban rail system which, like Sydney s and Me lines that have been continuously operated as commuter rail services for a cer extensions currently under way, such as the Evergreen Line extension to Port M (under construction) and the proposed Broadway corridor along the spine of should lift Vancouver s share of travel opportunities on rail modes, and thus time-competitive public transport for choice travellers, towards (or even beyond

Of all the ten New World SNAMUTS cities, Vancouver has the lowest concentrati travel opportunities in the CBD area, despite the city centre s relatively hig transport routes. This measure, which one would usually expect to drop with gro regarded in the context of the relatively peripheral location of Vancouver geographical heart of the regional settlement area, a circumstance that also Moreover, it is indicative of a network configuration that succeeds in deflect away from the CBD area by offering an array of strong orbital connections, and developed in Vancouver than in any of the other cities in the sample. The advan is the ability of public transport to penetrate into markets other than classic and thus provide viable travel alternatives to a larger share of everyday transp

5.5 Network resilience

This index extracts a ratio between the betweenness index and the actual carryi each component of the network, determined by the service frequency and the m size). It is designed to assist in differentiating network elements by their increases in patronage derived from further urban growth or improvements in pu share. The index follows a scale from a positive value of 30 to open-ended negat figures indicating greater potential stress or lower resilience. Individual r invite closer scrutiny whether they constitute a cause for concern.

Table 6: Network resilience (segmental congestion index) in Vancouver and nin
World cities.

| 2011 12 | Average network resil |
|---|---|
| Perth | +11.4 |
| Adelaide | +9.1 |
| Melbourne | +7.6 |
| Auckland | +6.2 |
| Brisbane | +5.6 |
| Portland | +5.6 |
| Vancouver | +4.1 |
| Sydney | +2.4 |
| Seattle | +2.1 |
| Montreal | 0.9 |

Network resilience figures are influenced by the operational input provided (
concentration of land uses around public transport relative to levels of servi
network to offer several alternative routes for as many origin-destination pa
helps distribute the transport task). In the real world, low resilience can t
overcrowding of services or into a form of latent or suppressed demand for publi

Vancouver s average network resilience is lower than that of any Australasian
is also inferior to Portland; in turn, it is greater than that of Seattle an

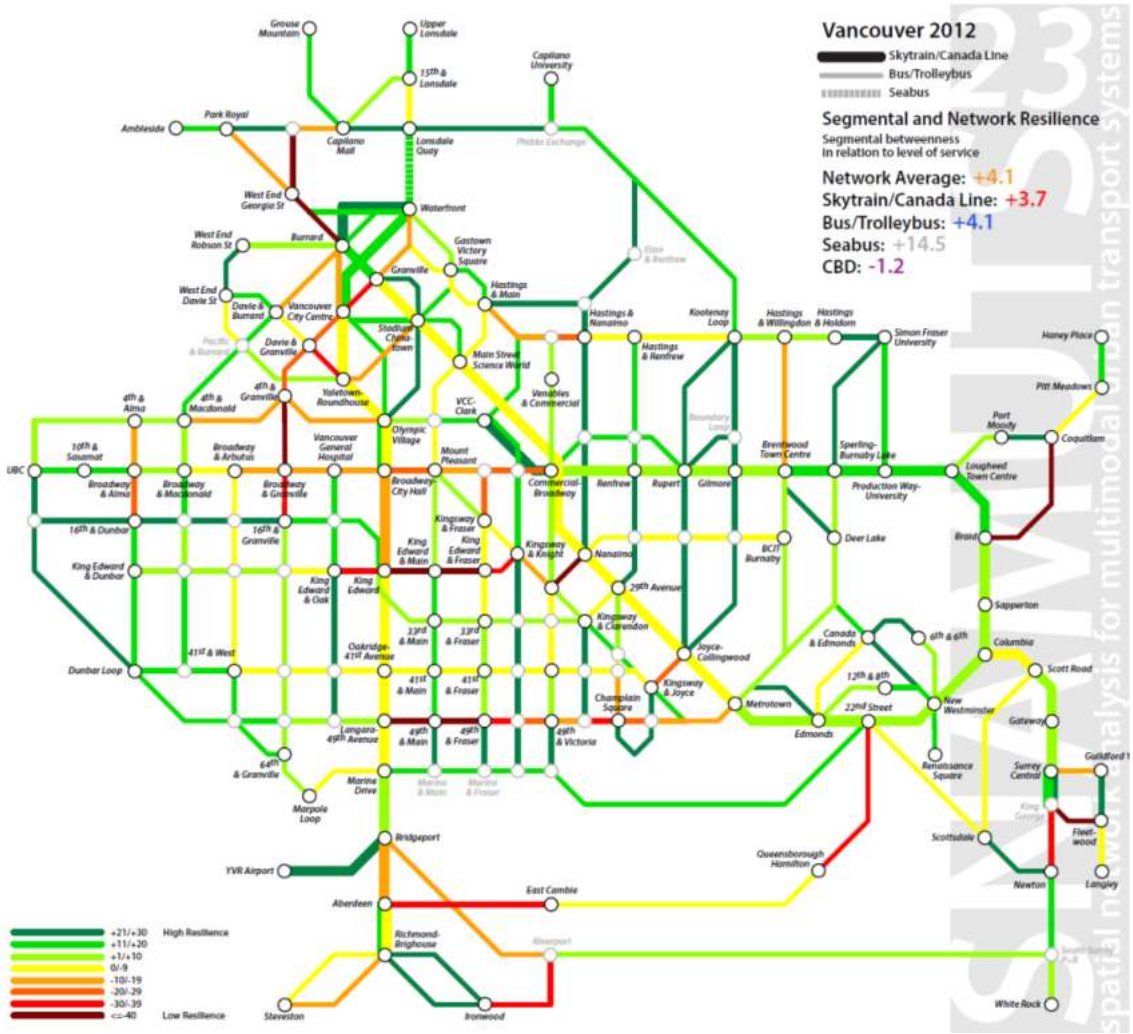
these resilience gaps can manifest as an inability of the public transport
passenger growth of the magnitude experienced during the last decade, unless n
expansion continue at a rapid pace.

Map 7: Network resilience in Vancouver s public transport network in 2012



5.6 Flexibility of movement (nodal connectivity)

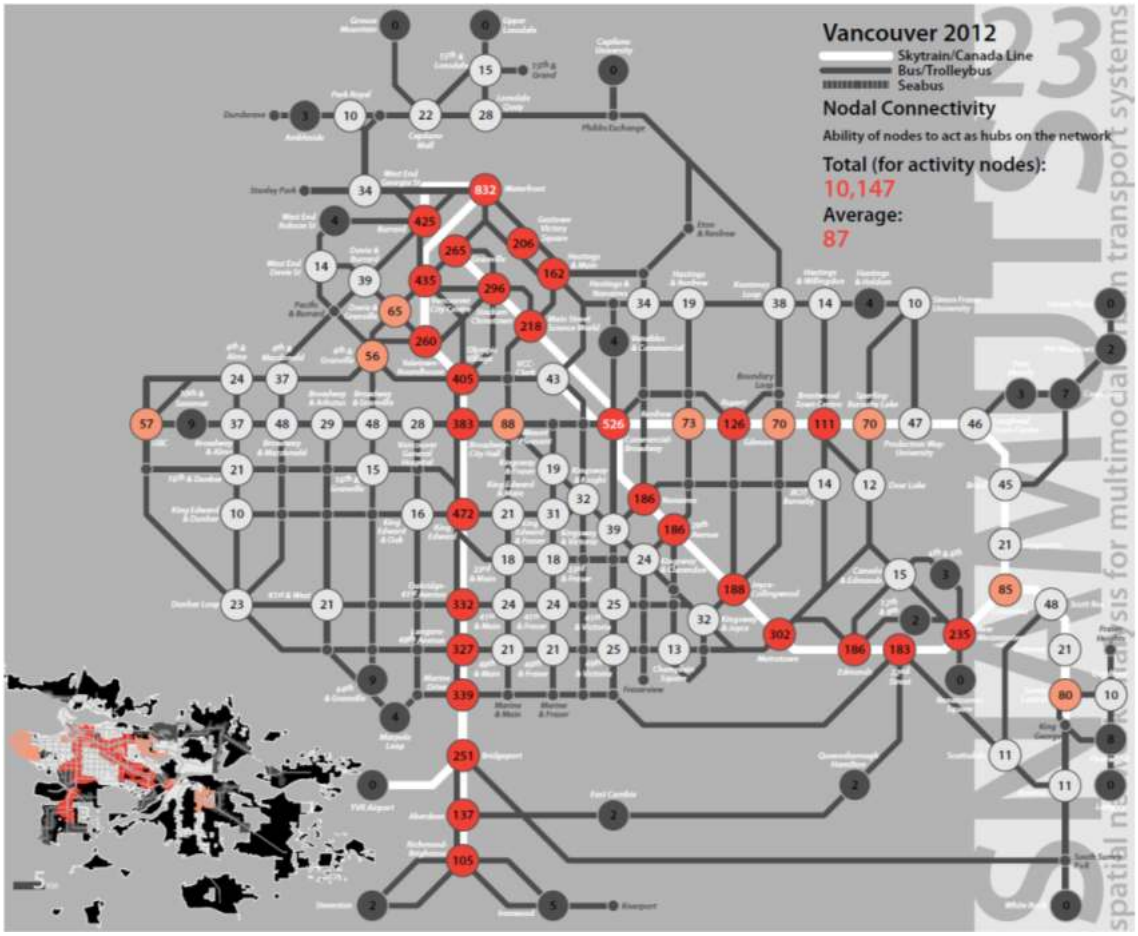
This measure captures the flexibility of users to incorporate particular locatio without having to rely excessively on timetable consultation or other forms of composed of the number of links converging in each node as well as the averag transport mode(s) provided on each link. It is thus designed to assess the suit to enable go anytime, anywhere mobility across the urban structure. It car indicator of the suitability of particular locations for land use intensificat better connectivity, and a node with a result in excess of 100 can generally be perceived as easy to reach on public transport by both trip makers and property

Table 7: Nodal connectivity in Vancouver and nine other New World cities.

| 2011 12 | Nodal connect (average) |
|---|---|
| Vancouve | 87 |
| Melbourne | 82 |
| Sydney | 77 |
| Montreal | 52 |
| Brisbane | 42 |
| Seattle | 26 |
| Portland | 26 |
| Perth | 19 |
| Auckland | 13 |
| Adelaide | 12 |

Nodal connectivity results are influenced by the frequency and utilisation of p as well as the configuration of the network: the more multi-modal transf opportunities to travel in a range of directions there are, the higher the nodal illustrates that all but two nodes with a count on this index higher than the are located along the SkyTrain network, highlighting the importance of this inf land use-transport integration in Vancouver. The very high scores along the Car are supportive of the proactive plan for land use intensification along the C Vancouver, 2011). Vancouver leads the sample on this index (Table 7), even th can be expected to drop with declining city size and hence, network comple underscores the relative success of transit-oriented development strategies in unplanned passenger movement between a many centres along Vancouver s key urb most other New World cities of Vancouver s population size or smaller, re scores (100 or above) are confined to the respective CBD areas.

Map 8: Nodal connectivity in Vancouver s public transport network in 2012



## 5.7 Composite accessibility index

The composite index is designed to provide a benchmark measure. It is derived several individual indicators (closeness centrality, degree centrality, aver catchment, nodal betweenness, nodal connectivity and resilience) weighed by a c of the absolute presence of travel opportunities (global betweenness) in rel population and employment, and network coverage in relation to network res geographical congruity of the network. A high score in the composite index indi integration of land use and public transport is strong, and a score in excess o node in the highest (dark green) colour bracket on Map 9.

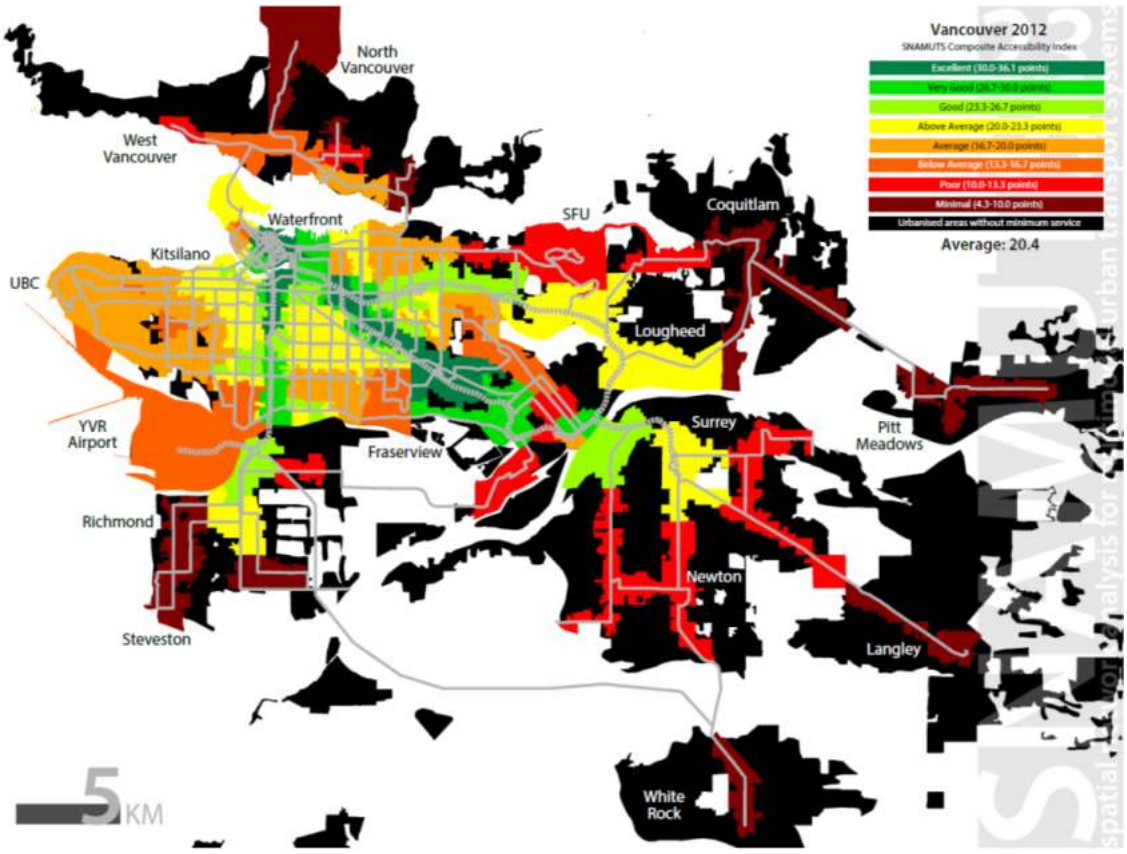
Table 8: SNAMUTS benchmark composite accessibility index in Vancouver and nine other N cities.

| 2011 12 | Benchmark compos (average) |
|---|---|
| Vancouver | 20.4 |
| Montreal | 17.1 |
| Melbourne | 14.9 |
| Portland | 14.5 |
| Brisbane | 13.7 |

| 2011 12 | Benchmark compos (average) |
|---|---|
| Perth | 13.5 |
| Sydney | 13.2 |
| Adelaide | 12.9 |
| Auckland | 12.4 |
| Seattle | 12.2 |

On the average result for this index, Vancouver leads its cohort of New World c considerable margin. This is primarily the outcome of a comparatively widespre network facilitating relatively fast and frequent movement over an urbanised compactness is achieved by both topographical factors and a long-standing intensification around public transport nodes. This is most visible along the almost all activity centres return composite scores above Vancouver s high a neighbourhoods of Kitsilano–West Broadway, Shaughnessy, Mount Pleasant–Riley Pa Cedar Cottage, South Hill–Sunset and Hastings–Sunrise are located away from th their above-average accessibility results to the multi-directional grid formed and trolleybus lines. In contrast, composite accessibility drops towards the including in the CBD fringe neighbourhood of the West End as well as in the UB and Marpole. North and West Vancouver suffer in accessibility terms from their core city by way of the Burrard Inlet, while the outlying suburbs of Richmond, Coquitlam, Langley and White Rock are characterised by a public transport acces familiar from other New World cities where corridors with reasonable bus servic accessibility in city-wide terms) alternate with sizeable patches of disperse where public transport services fail to meet the SNAMUTS minimum standard (if th

Map 9: SNAMUTS Benchmarking Composite Index in Vancouver s metropolitan area in 2012



## 6. Conclusion

The SNAMUTS analysis characterises Vancouver s public transport accessibility a a New World context, albeit with a mounting resilience problem that calls int ability to sustain its recent rate of growth in transit patronage without accelerating, the pace of network and service expansion. Of interest from a integration perspective, however, is the degree of consistency of these trends regional growth strategy. Did the infrastructure program of the past three dec transit supply in already transit-rich areas (see Walker s thesis above) while so, this would contradict the finding for Vancouver having the best network cov and Asia.

Furthermore, did transit supply increases favour the metropolitan strategy s The result of this appears mixed. Four categories are evident:

- designated centres that grew strongly in transit supply (central Vancouv Westminster)
- designated centres that grew moderately in transit supply and/or infrastruc Coquitlam)
- designated centres that grew weakly in transit supply (Langley, Pitt Meadow Vancouver)
- and centres without a strategic designation that still grew strongly in tr Broadway, 29th Avenue/Joyce-Collingwood, Edmonds-22nd Street, Marine Drive, UBC)

Are these outcomes primarily a result of market forces or of planning regimes? accessibility play in this? Other than UBC, all examples of the fourth type a

excellent categories of the SNAMUTS composite index. This brings us back to the has Vancouver s investment program since the 1980s divided the city more in transit-poor components? Or is the situation more aptly described as a case of corridors of transit-richness into what was previously a uniformly transit-poor not possible to improve the situation in every neighbourhood simultaneously w major infrastructure is involved, but what is evident is that most of the Sky historic regional light rail lines that likely had a considerable impact on sett 20th century and thus laid the groundwork for the urban intensification around r was also more continuity with the surface transit system (and possibly, associat Vancouver than elsewhere due to the survival of the fixed infrastructure trolle research endeavours, we hope to explore howthese transitionsfrom a 20th century orientation to 21st century transit orientation in the same locations can be character fit into evident transit supply and accessibility trends.

# IMPROVING COHERENCE BETWEEN URBAN AND TRANSPORT PLANNING IN THE NETHERLANDS: TOWARDS IMPROVED ACCESSIBILITY

Dani°lle Snellen, David Hamers and Joost Tennekes

PBL Netherlands Environmental Assessment Agency
Danielle.snellen@pbl.nl; David.hamers@pbl.nl; Joost.tennekes@pbl.nl

Improving the coherence between urban and transport planning is an ofte
policy makers and planners. Coherent planning provides more and better c
participation and travel (better accessibility) and allows for more
spending.

However, this paper shows that improving coherence is far from straight
an empirical analysis of recent developments in both housing and employm
patterns in the Netherlands, and taking an institutional (policy-oriente
to analysing the current Dutch (national, regional and local) urban
policies, the paper shows how financial arrangements, (formal) regulati
habits prevent better co-operation.

After analysing the most relevant obstacles in the Dutch policy and plan
strategies for improving the coherence between urban and transport plann
and elaborated: increasing proximity; transit oriented development (TOD)
chains and smooth transfers. These strategies can be implemented in the
they can be valuable for urban and infrastructure policies abroad as well

lower, for example because of cheaper land acquisition, yet the total transport development may well be much higher.

The Dutch MIRT program (multiannual funding program for infrastructur transport planning) aims to provide more coherence between urban and tr This works relatively well in the strategic agenda setting phase, but pr successful when actual decisions have to be made to fund projects. In thi and benefits of national investments are balanced with national policy urban planning is decentralised to local and regional governments, th national urban planning aims, making it very difficult to justify investm projects. As a result, almost all of the MIRT funding goes to transport transport budgets to help implement urban planning projects that would investments in infrastructure or would improve opportunities for urban difficult: regional or local authorities have to bear the (extra) costs t

In the Netherlands, regional and local authorities only receive revenues. Most of their budget consists of grants from central government a funding program for infrastructure and transport that decentralises bu level. It is an important way to bring infrastructure funding closer to that also makes urban planning decisions. However, the BDU budgets are cover operational costs of public transport, leaving very little mone coherent transport and urban planning. Furthermore, the BDU is managed at of government, while urban planning decisions are made by local governmen

At the local level, the grondexploitatie (land account) is the mai projects. In the land account, municipalities can balance the profits developers against the costs of other elements of area development, such amenities[1]. Infrastructure expenditures can be financed from the benefits of The instrument therefore offers the opportunity for coherent urban and since the costs of both are balanced at the same time. However, the s accounts is limited to the location itself. Often, these developments transport infrastructure other than local roads and these costs are onl equation. Most of those costs are funded by the central government and partners. The profitability of land accounts have been an important driv decisions. However, since not all costs have been taken into account, t have not served as an adequate integration mechanism between transport a at a larger level of scale. For example, developments with high costs for low costs for additional infrastructure, such as developments within exi systematically underrated.

## 3. PROMISING COURSES OF ACTION FOR IMPROVING COHERENCE

Many strategies for improving coherence between urban and transport plan in academic literature, professional debates and policy documents. In identified the eight most prominent strategies and investigated their pitfalls. These eight strategies were:

- Transit Oriented Development

*** draft version  please do not quote without contacting the autho

- Transit corridor planning
- Creating a diverse palette of urban milieus (urban environment typ
- Increasing proximity
- Small-scale and/or incremental urban development
- Providing multimodal access
- Increasing travel speeds
- Improving transport chains

From the analyses of these strategies we derived three most promising c
order to improve the coherence in Dutch policy and practice between infra
developments. The following sections elaborate on each of these, espe
necessary to make them work.

### 3.1 Proximity: Making Better Use of Existing Infrastructure and Built E

Bringing activities closer together is a very effective way of improvi
example, research has shown that the number of jobs within reach for pe
dependent on the amount of jobs within close proximity than on differe
supply (PBL 2012, 2014a, 2014b, Snellen and Hilbers 2013). In additio
proximity facilitates making better use of existing infrastructure and
and therefore of earlier investments made. Furthermore, it supports e
amenities.

This sounds like a simple solution: just work on urban densificati
developments instead of ever increasing urban sprawl by developing new gr
close to motorways. However, there are some hurdles to jump. Often, ac
developers are under the impression that there is more demand for subu
business parks than for urban living and working. Furthermore, green fie
often easier and cheaper.

Policies aiming for more proximity in the built environment, for
urban densification, can only succeed if the planned supply fits with dem
offices et cetera in the property markets. Recent property market analyse
with urban qualities such as a central location, mixed land use and a re
urban functions close by are most vital (Jones Lang LaSalle and Tordoi
over the past decade, most additions to the property market have been ma
locations often close to motorways. For housing developments urban densi
policy for many years. However, developments have predominantly taken pla
locations. This does not mean that there is no future for urban densific
there are many locations still available in the existing urban areas to b
purposes. Furthermore, research has shown that in the years to come the
demand for housing in urban areas to justify approximately 40 percent of
developed within the boundaries of existing cities and towns. The dema
single-family housing (Bouwfonds 2011). Building this kind of housing w
city is certainly possible. There are many forms of building in higher
single-family housing in green neighbourhoods. When these are develope
proximity of transport facilities such as train stations and light rail

*** draft version  please do not quote without contacting the autho

connected for walking and cycling, coherence between urban and transport improved.

In spite of convincing evidence of demand for more urban living and wo proximity will not happen in the Netherlands without extra policy atten office developments will have to be critically evaluated and balanced ag before planning consent is granted. The same holds for new housing devel within the existing urban fabric should be prioritised over suburban or Provinces can play an important role in this process under Dutch pla regulations. Potentially, more small-scale, organic forms of (re)de increase proximity and better utilise existing urban facilities and in Urhahn Urban Design 2012).

Unfortunately, however, the rules and habits in Dutch infrastruc planning funding are not very supportive of urban developments within ex as discussed in section 2. Since 2008, the situation has only deterior balance out costs for infrastructure needs with benefits obtained from p have reduced. The economic crisis has had detrimental effects on the pr developers can hardly make a business case for new projects. It has bec infrastructure investments can be financed from land and property deve Local governments have hardly any funding available to pay for infrast sources. As we have discussed in section 2, budgets for infrastructure a the central and regional level of government and municipalities have opportunities to secure income from local taxes.

Reconsidering the planning and funding processes in order to support inte urban planning is necessary. The current crisis might just be the perf What better time to change direction than when driving ever so slowly. national planning department is rethinking the MIRT procedures. It w investigate how the program could be geared more towards investing in a instead of mainly in infrastructure line developments, and how the progr options for incremental developments.

Furthermore, the departments  policy for beter benutten (improving existing infrastructure could be broadened to the urban planning domain, thinking about better use of transport infrastructure and the existing bu time. New developments at well-chosen locations, incremental development demand and risen opportunities, can make optimal use of existing c infrastructure networks and at the same time support the amenities in u enable better returns on previous investments. However, the system of recovery act is constructed for large-scale developments and in some ca development it constraints balancing costs and benefits between transport (Sorel et al 2014).

The fact that local and smaller-scale developments are not the respo government is not a valid argument against national investments in these The national government has a  system responsibility  for planning: it well-functioning planning system. This means that central government has preconditions for urban development, including a workable set of rule

mean a drastic change in how government finances work in the Netherlands
an option that deserves serious consideration when aiming for better
infrastructure and urban planning.

## 3.2 Improving Implementation of Transit Oriented Development (TOD)

TOD is probably the most commonly propagated strategy for improving cohe
urban and transport planning, both in the Netherlands as well as in ma
TOD is a generic term used for different ways of concentrating urban d
public transport stops and nodes. Many policy documents of national, r
governments in different countries show TOD aspirations and expectations
high (Bertolini, Curtis and Renne 2009; Calthorpe 1993; Cervero 1998, 200
Tan et al 2013 and numerous policy documents from national, regio
governments).

However, implementation of TOD proves difficult (Bertolini 2013; Ko
Rutten 2011; Tan et al 2013). The authority for decision making on and t
funding opportunities of different elements of TOD plans lie on di
government or are in the hands of other actors. This hinders coherent dev

where coordination of planning efforts is most lacking in the Netherlan
Thomas and Bertolini 2014).

The regional body of Arnhem–Nijmegen chose to work on more coheren
transport planning through co-operation within the region (Stadsregio
2007). Its role was to develop a strategy for public transport, roads a
invest in transit and, by working as a broker, bringing actors togeth
planning in the region was mainly geared towards transit provision, part
locations that were already being developed and partly to develop new
aiming for new developments.

This process took place in a complex administrative and financia
regional body operated on a limited budget and with limited authority
making, the latter especially with regard to urban planning issues. Neve
body attempted to take the lead in several ways, an attitude that is cert
come to successful TOD. The regional body stimulated integrated plann
possible by investing in transit, temporarily compensating for losses
transit until urban development generated the necessary amount of patron
administrative agreements to link urban development to transport investme

Most innovative was the attempt to connect transit development, urb
rights near transit stops and the operation of public transport in one
almost succeeded. Market actors were interested and new coalitions were
the differences in planning horizons and timing in implementation be
transport planning sectors and an emerging economic crisis put a spoke
innovative plan (Matthijsse 2013; Mulder et al 2013).

The economic crisis forced the regional body to lower ambitions a

result it was very difficult to coordinate limitation of urban de

*** draft version  please do not quote without contacting the autho

municipalities and in this case it created enormous pressure to continue areas, whereas locations elsewhere would better fit TOD ambitions.

In the years to come, the abolition of the regional bodies in the N subsequent reshuffling of BDU grants (see section 2) can provide the oppo responsibilities in such a way that transport and urban planning decisio together. Again, this is not straightforward. With the loss of a regio decision making on BDU funding of transport will have to taken either provinces or a level down to the local level. The latter comes with q municipal competition and resulting oversupply of developments and appear option.

Bringing the BDU responsibilities to the provincial level would me will have to become much more actively involved in urban planning policy al 2013; OECD 2014). This would be a major change in the mutual rela provinces and the larger cities.

When rethinking the new rules and regulations for the BDU funds i worth considering to increase the opportunities to use BDU money in a manner, for instance making it possible to use funding for public transpo developments if that increases the cost-effectiveness of public transport

In Copenhagen and Tokyo other options for coordination of urban planning efforts are used and we can learn from these experiences. Due t in the administrative, legal and cultural circumstances foreign best prac transferred to the Netherlands. However, certain elements of the Dan approaches can be translated to the Dutch context.

In Copenhagen the urban and transport policy of the Fingerplan has history. Continuity and clarity of policy are important factors in it adaptations have been made, yet the basic principles of the policy have sixty years now. An important element in this policy is the fact that stimulation of development near transit stops but also includes planning distances. These restrictions are established in national regulations. S are used to obtain the desired results (Hartoft Nielsen 2013a, 2013b).

Despite the enormous difference in density and size comparing Toky cities, we can even learn from their approach to TOD planning (Chorus rules and regulations in Tokyo are such that development at a distan restricted. At the same time the metropolitan government gives market freedom to develop property close to transit stops and even more when the public policy goals. Instead of investing itself, the public secto development, while the private sector submits plans and builds. The same develop and own transport infrastructure and operate public transport ser from urban development. Since public funding for urban and transport pl being reduced in the Netherlands, the Tokyo approach may be an inter investigate. It is not just useful in periods of economic growth. I arrangements promoting transformation and redevelopment. Again, the gove invest, it only facilitates. The framework of rules and regulations en public interests.

choose multimodal (chained) trips if their destination has limited c
instance due to infrastructure limitations or parking restrictions. For
urban areas, this is relatively often the case. For trips to locations
accessibility, public transport cannot compete with the car.

Since public transport is not equally important in all locations,
selectively in improvement of transport chains. On locations with excell
investments in public transport are less likely to flourish, as are in
transport chains to these locations. However, there may be other legitim
in public transport and transport chains, for instance serving social
transport equity.

Reducing the travel impedance of trip chains requires careful design of t
chain and there is room for cost effective improvements (Brons and Rietve
Klinkenberg 2014). This is not just a transport challenge, since the expe
trip chain also strongly depends on the quality of the (urban) enviro
transfers take place. On a very local level, this requires coherence
transport design. Especially around nodes that are both interchange as we
most TOD nodes are  this is a challenging task. Swift and fluent tran
modes in general require different design characteristics than an invitin
in and interact with other people. Designers will need to find quality
these quite different requirements. Especially transfers between car and
between bicycle and public transport set some interesting challenges.

Improving travel chains is not just a design challenge but also requ
planning process. The whole process of planning and decision making in t
design in the Netherlands is currently not geared towards focussing on
chain is nobody s responsibility. A quality interlinking of transport

operation between many actors. This can be challenging since they all
interests an ambitions.

A complicating factor is that in current policy a culture of it s y
developed, which means that actors tend to work independently of each oth
on their own element of the chain instead of working together towards a
culture is most unproductive for obtaining low impedance travel chains a
overcome.

There is a need to formalise the responsibility for the quality of
chains. Simply relying on good links making a strong chain and on the go
work together will not yield the desired quality. Which actor must be mad
whole chain will depend on the situation.

## 4. CONCLUSIONS

Coherence between Dutch urban and transport planning can be improved in m
of which are neither straightforward nor easy yet worth the effort. Both
planners have a role to play. This research project has led to the conclu
main courses of action. These three differ in the way they focus on
planning, yet they have the intention to strengthen the link between both

Improving proximity of destinations can improve accessibility and ma
of existing urban and transport infrastructures. It requires concentrati
the existing built-up area. This is currently safeguarded insufficient
urban developments in a more dispersed direction. Examples are the way i
are attributed to building plans, the fact that many municipalities and p
invested in land for development outside the current built-up area, and t
the consequences of urban planning choices for transport demand and acce
in cost attribution, selectiveness in where to develop, and a shared resp

# UNRAVELLING THE FLEMISH MOBILITY ORGWARE
## Analysing the role and relations of governmental institutions from the view of actor-networks in the transition to a sustainable mobility

Suzanne Van Brussel[1] and Luuk Boelens[2]

Keywords: Governance, Sustainable Mobility, Actor Network Theory (ANT)

## Abstract

*Mobility policy in Flanders faces major challenges regarding the liveability and sustainability. The Flemish government therefore wants to update the mobility system to the present needs and to launch the sustainable mobility transition. In this respect most mobility transition research focuses on (socio-) technical innovations (software) or infrastructural innovations (hardware), managing the demand side of mobility. However, the role and innovations of the organisational struct remained unclear. This research addresses this hiatus, by analysing the actors and factors of importance and their interconnections within the Flemish mobility system, and secondly by proposing possible orgware improvements. Hitherto there is no clear idea of how different mobility (related) organisations, e.g. companies, lobbies, governments, institutions and projects, are associated with each other. Moreover various innovations of the socio-technical nature challenge the present governance. Because the existing institutions and formal rules are regularly not (yet) harmonized with these innovations. To overcome these challenges and to accomplish the sustainable objectives, one needs to discover the underlying mechanisms and potentials of the mobility systems with regard to the travel, transport and traffic mobility markets. For that purpose, the analysis draws upon the literature of actor-network theory combined with institutional theory insights, both applied on conceptual mobility frameworks. Accordingly, we finally propose a conceptual framework for the analysis of the Flemish orgware, in order to come up with possible improvements regarding sustainability objectives.*

## 1. Introduction

Mobility policy in Flanders faces major challenges in setting out the policy objectives for 2020 and beyond, in making or maintaining Flemish cities attractive, liveable and also sustainable. First transport emissions are to be reduced and the factual footprint of transport (infrastructure) has to decrease over the next decades as well, to make a real transition towards sustainable mobility. But while most mobility transition research focuses on (socio-) technical innovations (software), or infrastructural innovations (hardware), the role and innovations of the organisational structure (orgware), has remained unclear. This is hiatus is also addressed by Jessop (2001, p. 1221), an authority in the field of institutional theory:

*Further steps on a research agenda might include questions about institutional embeddedness or about institutional governance, i.e., the governing of institutions and inter-institutional relations and their systemic environments* (Jessop, 2001, p. 1221). This research wants to address this hiatus, by setting out a framework for the analysis of the actors and factors of importance and their interconnections in the Flemish mobility system. Further research will include the factual state of affairs of the Flemish orgware and the proposal of possible orgware improvements.

Hitherto there is no clear image of how different mobility (related) institutions (organisations, companies, lobbies, governments, projects, funds, ) interact with each other. Moreover various inn of the socio-technical nature make the present governing strategies more difficult to manage. In order to make important decisions, e.g. selecting niche-innovations to be implemented, and in order to launch the sustainable mobility transition, one has to know the leading mechanisms and potentials of the mobility system. The decision-making levels are to be questioned as well. For instance, decision-making powers could have to be reallocated to other policy levels or other arenas to increase efficiency.

Consequently the research question here is how the orgware could be adapted in order to make the Flemish mobility system as an actor-network assemblage more sustainable. Therefore the mobility system itself has to be unravelled first. How does the Flemish mobility system looks like? Which underlying arenas are to be defined? Which actors or institutions hold key positions in these arenas? These questions are addressed in the research. Based on the literature of actor-network theory combined with institutional theory, a literature framework is set out and applied for the conceptualisation of the Flemish mobility system.

The paper is structured as follows. The second chapter elaborates on the conception and definitions of the term 'governance'. In a third chapter some insights of institutional theories are adopted. The *what?* and *how?* of institutions is theorized and the conditions for an institutional chapter four, a framework for the mobility system is then to be considered, next to the already conceptualized context of institutions. In chapter five the actor network theory (ANT) is discussed. This theory proves useful in the conceptualization of how actors organize themselves and form actor-networks in order to survive. In a sixth chapter, the institutional theory insights, the mobility framework and the ANT are then combined in a conceptual research framework for the unravelling of the Flemish mobility orgware. Finally, outlines for possible new governance systems and further research are discussed.

## 2. Governance

The term Governance is used in many ways and covers many aspects. Hence, befo literature for the theoretic framework, we need to clarify our perception of the term governance . This paragraph tries to overcome the vagueness of governance by giving an short overview of important literature on governance.

Jessop (1997) describes governance as *the complex art of steering multiple agencies, institutions and systems that are both operationally autonomous from one another and structurally coupled through various forms of reciprocal interdependence* (Jessop, 1997, p. 1221). Or in other words, as the complex of mechanisms behind (or resulting in) the network. The word governance is in the litera advocated for as the more de-centred and horizontally organized counterpart of a strongly top-down and vertically oriented government (Boelens, 2010; Scharpf, 1997). Governance is gaining importance i todays world, where public-private partnerships are no longer an exception, and where small decentralized initiatives are gaining ground (Jessop, 1997). Sharpf describes governance by advocating for another way of governing since *the advantages of a hierarchical coordination are lost in a world that is characterized by increasingly dense, extended and rapidly changing patterns of reciprocal interdependence, and by increasingly frequent, but ephemeral interactions across all types of pre-established boundaries, intra- and inter-organizational, intra- and inter-sectorial, intra- and international* (Scharpf, 1997, p. 37). Stoker (1998) also discusses the duality between government and governance, but argues that it is not a harsh one. According to Stoker governance is rather a change in meaning or interpretation of the existing term government , implying a new p (Rhodes, 1996, pp. 652-653). Governance is about creating the conditions for ordered collective action , also referring to the bottom-up approach instead of the top-down approach government used to have. But governance is used in many different ways. The baseline however is that governance, as Stoker (1998) says, has to do with the *governing styles in which boundaries between and within public and private sectors have become blurred* (Stoker, 1998). In some cases, though we will not elaborate on this, Governance is also used to provide covering for Consequently governance is in this manner used as a *code for less government* (Stoker, 1998, p. 18).

Jessop formulates three levels of embedded social organization, or thus governance levels. Going from rather simple to more complex, first there is the social embeddedness of interpersonal relations (Granovetter, 1985), second and more complex, there is institutional embeddedness of inter-organizational relations (Keohane & Nye, 1977), and the third and most complex form of governance exists in societal embeddedness of functionally differentiated subsystems (P Pearson, 1957). However from Jessop s work probably the most important thing to acknow

*Successful governance is always provisional, localized, and partial and always has unintended consequences which operate to the detriment of other subjects, interest, and projects and may eventually prove counterproductive even for those who instituted the governance mechanisms and projects in question* (Jessop, 1997). Jessop provides also outlines for further research in the context of the embeddedness of institutions and institutional governance, the latter seen as the governing capacity of institutions and the inter-institutional relations and their environments (Jessop, 2001, p. 6).

## 3. Institutionalism

According to ANT and institutionalism the key players or actors, the variables and the context in the field of mobility and the tangent policy fields are to be analysed in order to gain insights in the Flemish mobility system (Boelens, 2010; Giddens, 1984) . The context or structure determines possible outcomes and is in itself determined and changed by the players within this structure, in order to enable their objectives. Hence the focus can not only be on the actors, while neglecting the broader context of institutions. For Law denotes that actors, thus people, entities, resources that are connected, only have meaning within and through their network (Borgatti, Everett, & Johnson, 2013; Law, 1986) and Jessop states that *institutions never exist outside of specific action contexts* (Jessop, 1997, p. 8). Thus, before examining and listing all important actors and factors within the mobility field, we need to indulge in the institutional theories. Next, the focus is on the institutional turn, since the objective of making the mobility system more sustainable needs such an institutional turn. Therefore the conditions for this change are discussed in order to identify or see possibilities in making it possible.

### *3.1 Why Institutions?*

Why do we have arrangements called institutions? North states that *the major role of institutions in a society is to reduce uncertainty by establishing a stable (but not necessarily efficient) structure to human interaction* (North, 1990, p. 6). Also DiMaggio already mentions in 1988 the uncertainty-reducing capacity of institutions, and Giddens (1984) denotes the institutions as solidity-giving features across time and space. He calls them *the more enduring features of social life* (Giddens, 1984, p. 24). Lock-in, then, is the result of the uncertainty reducing activities of actors-networks (assemblages). According to Greener (2002, p. 616) *Lock-in is not the exception, it is the rule, in fact it is required by markets in order to allow actors to order the complexity which would otherwise dominate. Once the market is organised, and the actor-network stabilised, it is possible for agents to make decisions within it* . Here Greener makes the connection between institutional theories and actor-network theory, which proves useful in the conceptualization of a framework for the Flemish mobility system as well.

#### 3.1.1 Path-dependency & Lock-in

Ideas of path dependency and lock-in are important to understand the context and the need for institutional change. A few quotes grasp the meaning of path-dependency well: *In the path-dependent model, actors are hemmed in by existing institutions and structures that channel them along established policy paths. Therefore, in any system, big (non-incremental) change is unlikely, however not impossible.* (Wilsford, 1994, p. 251). Or as Machiavelli ones acknowledged: *There is nothing more difficult to manage, more dubious to accomplish, nor more doubtful of success t order of things. The reformer has enemies in all those who profit from the old order and only lukewarm defenders in all those who would profit from the new order* (Machiavelli: as in Wilsford, 1994, p. 251).

A path-dependent sequence of (political/economical) changes is one that is tied to previous decisions and limited by existing institutions. For in path-dependent models a choice made in the past, albeit random or not, and by individuals or not, has consequences and can limit options and choices in the future. Hence, one can speak of a depended path . Very early in the evolution of th can be equally suitable. But once a given path is chosen, it becomes increasingly likely to continue along this path. Because, over time little adaptions along this path will have the lowest transaction costs, which leads onto incremental changes all within the margins of this chosen path (Greener, 2002). Moreover

these choices in the past, initiate a certain course, that is already trodden. In essence there is nothing wrong with this kind of path dependency; it will save energy and support added value. But also lead to lock-in situations, in which possibilities are limited just because of those (small) decisions from the past (Greener, 2002; Wilsford, 1994). However, change is still possible, following Wilsford (1994) *it is the combination of path-dependent limits along with occasional windows of exceptional opportunity, or conjunctures, that determine the ways small or big that a political system responds to policy imperatives* (Wilsford, 1994, p. 252). This view has some things in common with the ideas on institutional change of Burch et al. (2003) and Kingdon (1995) namely, the critical moments and windows of opportunity . Path-dependency differs from historical determinism, in the way that one can choose to reshape the path incrementally or to create another path, because history matters, but history doesn t determine everything. Path-dependency theories thus allow for deviations from the trodden path (Greener, 2002; Wilsford, 1994). Path dependency theory looks upon institutional change as follows: *It is the combination of path-dependent limits along with occasional windows of exceptional opportunity, or conjunctures, that determine the ways small or big that a political system responds to policy imperatives* (Wilsford, 1994, p. 253).

In institutional theories, the path dependency perspective brings us the notion of history matters . In this respect, North states that the structure for human interaction possesses already future developments and thus future institutional changes in itself. Thus one can speak of an institutional path, (partially) determined by events, made choices, in the past (North, 1990, p. 6). Also Giddens struct theory follows in a certain way the path-dependency perspective, because both structure and recursively make changes upon each other and in this way change through time, along a path shaped by the structuration process. Giddens provides with his structuration theory an ontology of time-space as constitutive of social practices, which begins from temporality and thus, in one sense history (Giddens, 1984, p. 3). Furthermore, Giddens proposes with his structuration theory that *rules and resources drawn upon in the production and reproduction of social action are at the same time the means of system reproduction* (Giddens, 1984, p. 19). In institutional path-dependency approaches the focus is predominantly on rules and routines, and their importance within organisations (Olsen & March, 1989).

3.1.2 Sociological institutionalism

But critiques to all of the above mentioned institutional perspectives are that, in spite of the bounded rationality (Simon, 1986) of actors taking into account the uncertainty in the world, not all institutional changes bring forth an increasing efficiency. Therefore the sociological perspective on institutions draws attention to the more symbolic and cognitive dimensions of institutions and institutional change (Olsen & March, 1989). The main finding here is that institutions have cultural significance. They start from the idea that not technical rationality but social rationality, which is value-based, guides institutional change. Furthermore, institutional change is assumed to be initiated internally in this approach, while it in the path dependent perspective the incentives for change are perceived to be caused externally. Here, in the sociological perspective, the process of institutionalisation is defined as *a process in which fluid behaviour gradually solidifies into structures, which subsequently structure the behaviour of actors* (Arts & Leroy, 2003, p. 31). Although Giddens structuration theory adopted predominantly the pa dependency perspective, his view refers to the sociological perspective; *structure* is not external to *individuals: as memory traces, and as instantiated in social practises, it is in a certain sense more* internal than exterior to their activities ( ) Structure is not to be equated wi *both constraining and enabling* (Giddens, 1984, p. 25). Following Weimer (1995) institutions result from a gradual evolution that is punctuated by acts of purposeful design (Weimer, 1995). Buitelaar *et al.* (2004) add that institutionalisation is *accompanied by the development of particular discourses, power and resource relations* . (Buitelaar, Jacobs, & Lagendijk, 2004). Furthermore, specifically in the context of policy-making, Linder & Peters (1995) recognize institutions *as both socially embedded practices and frames and historically contingent responses to collective action* (Linder & Peters, 1995, pp. 133-158).

According to these ideas, institutions are often seen as *social practices that are regularly and continuously repeated, that are sanctioned and maintained by social norms, and that have a major*

*significance in the social structure* (Jessop, 2001, p. 6). But on the other hand, institutions are popularly seen *as organizations or social bodies that have major significance for the wider society and act in a quasi-corporate manner* (e.g. the branches of government, thus institutions as part bodies) (Jessop, 2001, p. 6).

*3.2 Conditions favouring Institutional Change*

3.2.1 Institutional insights for institutional change

Following Giddens (1984); Jessop (2001) institutions are both constraining and enabling. They refer to the reciprocal relation between agents and institutions (or structure); institutions are the resources and simultaneously also the means for institutional change. Consequently structure and institutions change predominantly incrementally. On the how and why of this institutional change, the perspective of Buitelaar et al. (2004) seems useful, because their research focus is about *why, under seemingly comparable conditions, some cases show substantive institutional transformations while others do not* (Buitelaar et al., 2004, p. 4).

DiMaggio (1988) already suggested the necessity to bring interest and agency more centrally into the institutional debate to gain progress in defining the conditions for institutional change. He stressed that actors always (but not always explicitly) strive certain objectives, and for this they have always some interest in acting in certain ways. Moreover, some researchers acknowledge the tendency of (key) actors to use institutionalized rules for their own objectives, which typically refers to the regime theory (Jacobs, 2004; Stoker & Mossberger, 1994). The conceptual institutional theory of Buitelaar et al. (2004) elaborates the alignment of the interests of three streams: the societal stream, the policy at hand, and the political endorsement and support base (see later). For arriving at an institutional change, they underline the importance of alignment in time of these streams, and the availability of a viable alternative that has to be accepted by institutional regimes to change (Buitelaar et al., 2004). But while focussing on the actors of the system, resulting in the three streams, also the different degrees of power or the acting of the actors within the framework have to be taken into account in order to identify conditions of institutional change (DiMaggio, 1988, p. 12). The latter will be addressed in the chapter on actor network theory, with the concept of translation .

Burch et al (2003) theorized the critical moment for institutional change as *sufficient pressure, whether internally or externally driven* [ ] (Buitelaar et al., 2004; Burch et al., 2003). In this moment, leading and existing institutional frames or hierarchies are questioned and there are alternative discourses rising. The critical moment can then further evolve into a criti opportunities are actually grasped and changes are effectuated (Burch et al., 2003). But to recognize these critical moments, linked to certain conditions, one has to look at Kingdon s ela stream approach, which is specified for policy agenda setting. In his conceptual model three streams of development are simultaneously aligned, the first stream being the societal problems that are conceived important , the second one the policy solutions at hand and the third stream is formed by the political endorsement and support (Kingdon, 1995). The critical moment in Kingdon s conceptualizatio formed by the matching of these three streams and is named the window of oppor point in the latter theory is based on the existing institutional organizations and frameworks. As in Burch et al. (2003) also in Kingdon s conceptual model, there has to be sufficient pressure, caused int by alternative ideas (or solutions) and actions affecting the present situation and/or externally by societal trends. At the same time acceptable other logics and discourses[1] need to be present to lead onto the

[1] The definition of discourse as provided by the Oxford dictionary of Geography is suit specific assembly of categorizations, concepts, and ideas that is produced, reproduced, *performed*, and transformed in a particular set of practices . This dictionary refers to the definition of Schott (2007) *Tijdschrift* **98** defines discourse as a social process which can be called inclination of sense or, in a manner, genesis of meaning Mayhew (2009) also proposes to take a look at the sense o proposed by Foucault (1980) in which a discourse is like a system of exclusion. *Discourses create their own*

possible opening of a window of opportunity. Following Buitelaar et al. (2004) after the first window of opportunity, a moment follows where alternative discourses can compete with each other for support base and where they can enforce their positions within the disturbed institutional hierarchy. Buitelaar et al. (2004) contribute to the conceptual model by adding a second window of opportunity after this in-between moment, where problem and solution ideas have to be matched. Or thus, when one can speak of a consolidation of a particular problem-solution combination, which is followed by a critical juncture leading onto institutional transformation (Buitelaar et al., 2004, p. 14).

3.2.2 Transition management approach

In the research field of transition management, the multi-level perspective (MLP) is widely accepted (see figure 1). This approach starts from the assumption that transitions are non-linear[2] processes resulting from the concurrence of various developments considered at three levels (ranked from the least stable to the most stable): the first level is the niche (or the locus for radical action or cha second level is that of the socio-technical regimes. At this level the established practices and rules are situated. The third level consists of the exogenous socio-technical landscape (Frank W Geels, 2002; Frank W. Geels, 2012). These different levels, as Frank W Geels (2002) calls them, have their own rhythm or inertia and will react upon changes during another moment or even period. Although on an overall scale the general transition coarse of innovations is well represented by the MLP, we want to express a few remarks here. The first one is about the level in multilevel perspective. Acco ideas, these levels should not be named levels , since this suggests a kind of barrier or threshold wi the evolution or transition process to attain the label of the next level. Secondly, and related to the first critique, we want to underline that this gradual evolution can be subject of discussion. Not every innovation is equally successful after all. Some innovations never leave the niche sphere, or some will never become institutionalised in the regime. Thus, not every innovation will have trodden the same path or will have followed the same stages in the proposed order. We conceive these levels of actors as contingent and coevolving over the various levels. Consequently, we would preferably speak of arenas , and accordingly of a multi-arena perspective instead of a multilevel perspective.

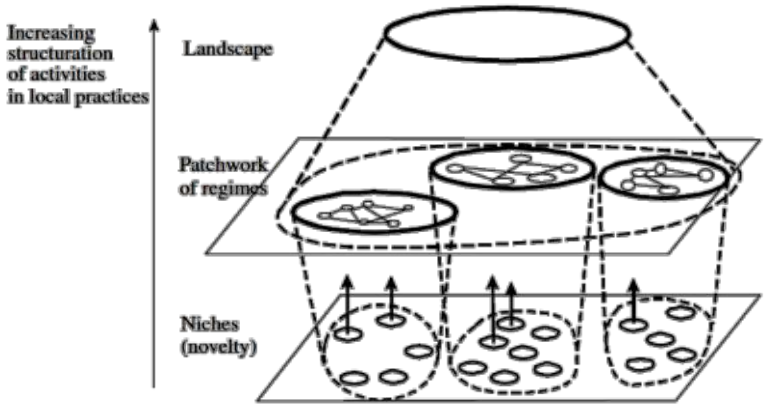

Figure 1: Multiple levels as a nested hierarchy (Frank W Geels, 2002, p. 1261)

However from this framework the distinction between the levels provided by the multilevel perspective proves useful. Representing these levels, e.g. whether or not an actor s initiative or a institutionalized or not, can be interesting in order to define or estimate the capacity to change and the accessibility to resources as a means for change. However to capture what these levels or this transition approach means for mobility, we have to elaborate on mobility frameworks first, in order to merge these transition arenas with a conceptual framework for mobility.

regimes of truth *the acceptable formulation of problems, and solutions to those problems* (M. Foucault, 1980 as in Mayhew, 2009).

[2] Non-linear processes, here conceived as following an s-curve. In general, typically with very low impact in the beginning, then after a longer period suddenly the innovation really takes off with a more than linear impact or growth. In the end a growth rate reduces again.

## 4. Conceptual mobility framework

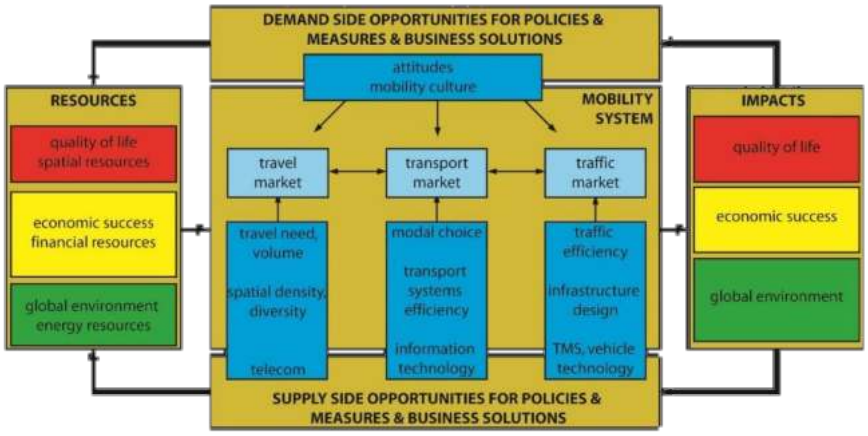

Figure 2: Mobility system approach (Lauwers & Allaert, 2013: based on Egeter and van de Riet, 1998)

In their search for an heuristic framework for transitions of mobility systems, Switzer, Bertolini, and Grin (2013) combine the transport land-use feedback cycle model with the multilevel perspective transition approach. However, we would rather propose the framework of Egeter and van de Riet (1998) since their model is a more elaborated equivalent of the transport land-use feedback cycle. Later, also (Lauwers & Allaert, 2013) further refined this model, by embedding the mobility system in a broader context of inputs and outputs and by indicating feedback loops between the components (see figure 2). The conceptual model divides the mobility system in three connected arenas instead of two; not only land use versus transport is considered, but instead a travel market, a transport market and a traffic market are identified, each time with a supply and demand side. The travel market consists of the demand and supply side of functions and concerns activities that lead to the need for transportation. In this arena people can choose to participate in activities and decide if the trip is necessary/worthwhile. The spatially distributed functions or activities they want to engage in determine the space and time of the displacement. If one decides to make the trip, one comes automatically in the demand side of the transport arena. Here one has to choose the transport modality of the trip: bike, car, public transport, etc The supply side in this arena consists of various transport mode suppliers, e.g. public transport companies, private parties. Then, when the transportation mode is finally chosen, the space (travel route) and chosen travel time slot are decided upon in the traffic market. The actual trips are undertaken and defined in space and time. The outcomes of the generated trips could have impacts: e.g. congestion along the chosen route, negative health impact, environmental impact Thus these arenas are embedded in a broader context of attitudes and culture. All mobility system arenas are connected with each other, direct or indirect via feedback loops. The order of the arenas, as described above, does not imply that the travel market and the traffic market are not connected. The spatial developments or even road construction works have a direct influence on the chosen route, while they have also to do with the travel market and the spatial context.

From transition theory the multilevel perspective is useful. When applying this scheme of arenas, i.e. Travel Transport Traffic Environment (inputs and outputs), from the proposed mobility framework to the multilevel perspective, with the niche regime landscape distinction, we end up with identifying for each of the first arenas the three different types of actors. So that in fact per mobility arena different niche actors, regime actors and landscape actors can be distinguished. However the positive transition curve towards institutionalisation is not necessarily the only way (or may be not the most desirable way) of becoming . Not every innovation is equally successful, or generally app innovations will never leave the niche sphere, and for this will never become institutionalized. For the setup of an analysis framework for the Flemish mobility system we encounter some conceptual challenges here. First, the framework we are looking for should be able to explain the success stories of some actors, while some others fail under the same conditions. Secondly we have to incorporate both actors and structure in the framework, because they have a reciprocal relationship. Actors are influenced by present institutions but at the same time arrange and influence themselves this structure. To overcome

these challenges, we draw upon the contributions of the actor network theory literature for the conceptualization of the becoming of actors. *How do actors organise themselves and their envir Who do they (temporarily) act with?* These are questions that cannot sufficiently be addressed by the institutional (change) theories. This challenge is already addressed by Greener(2002), he proposed to theoretically fine-tune the accounting for behaviour of path-dependent structures in order to gain insights in the means by which structure becomes limiting and to gain insights in overcoming these lock-in situations and break free of them. For this fine-tuning he proposed to take a closer look at the actor network theory contributions (Greener, 2002).

## 5 Actor Networks

### *5.1 Actors or agents with agency? Some definitions*

Actor network theories typically do not differentiate between human and non-human actors; all entities belong to the sole actor category. Actors that have a leading role are called **actants** Latour, 1996). An actor becomes an actant when he acts or when he is granted power or permission to act by others (Latour, 1996, p. 7). However, following Boelens (2010) and later also acknowledged by Latour, non-living (and non-human) entities are not able to negotiate or even communicate themselves. Consequently, they are better served by so-called **intermediaries**, things or actors who speak for those non-human entities, without changing their identity. Non-living things can speak for themselves by their presence for instance. On the other hand they can be represented or impersonated by **mediators,** thus, when another human entity advocates for the non-human one. Giddens (1984, p. 9) distinguishes between agency and action . ***Agency*** *refers not to the intentions people have in doing things but to their capability of doing those thing in the first place (which is why agency implies power)* (Giddens, 1984, p. 9). ***Action*** depends upon the capability of the individual t make a difference *state of a*ffairs or course of events. An agent ceases to be such if he or she loses a difference , that is , to exercise some sort of power (Giddens, 1984, pp. 14-15). The **A duality** is to be seen as an inseparable whole. The actor is then the concrete outcome or crystallization of the actor-network at a specific time and place, while the network is the abstract structure in which the actors are connected on various levels. By this the duality between the individual (actor) and collective (network) has been eliminated (Callon & Law, 1997; Latour, 1996). According to Latour it is not possible to trace where the individual elements stop and from where the collective (network) takes over. Note that following Latour (1996) there is nothing but networks, everything is network (Latour, 1996, pp. 5-10).

### *5.2 Actor-Network Theory*

Callon & Law have been conceptualizing an actor-network theory based on four principles. First, they see the social as heterogeneous in nature. Secondly, they state that all entities are networks of heterogeneous elements. Those networks act unpredictable and are not fixed in form, space or time. Their identity changes while interacting in the network, it is only within and through (re)actions within this network that entities have a meaning. And finally, every stable social arrangement is simultaneously a point (individual) and a network (a collective). By these four rules they overcome the individual/collective and the agent/structure dualism, by stating that this dualism does not really exist, but is only a matter of perspective (Callon & Law, 1997).

> *There is no difference between the person and the network of entities on which it acts. Or (the real point) between the person and the network of entities which acts through the person. Network and person: they are co-extensive (Callon & Law, 1997, p. 169).*

ANT is based on actors and their relations (also called networks), these relations are not only between actors themselves, but also between the human and non-human actors, which could be the more local conditions or the legal framework. ANT stresses that such networks are not necessarily stable or fixed between all heterogeneous actors. In fact, ANT assumes that all actors are continuously reassembling

and organizing their network in a certain way to become more innovative and vigorously (Boelens, 2010, p. 36).

Callon elaborates four phases of translation . Quoting Callon (1999) translation is the process *during which the identity of actors, the possibility of interaction and the margins of manoeuvre are negotiated and delimited* (Callon, 1999, p. 59). Equally translation is in ANT-terms *the possibility equivalence, the possibility that one thing (for example an actor) may stand for another (for example a network)* (Law, 1992, p. 386). Consequently, translation demonstrates how ideas or visions are introduced, framed and taken up in the collective agenda. The translation of ANT similar to the path of the path-dependence theory, only in actor network theory the focus is on the role of (each of the) entities in shaping the path, while in the path-dependency approach there is only the resulting path. Or in Kingdon s case the ANT-translations refer to the three acting streams, as a wh or a resultant force, with no specifics for the shaping (f)actors. Additionally, this translation concept is related to the centrality within social network analysis. We elaborate on the because this enables ANT to incorporate interest and agency into the conceptualisation of actor-network behaviour. And because this allows us to understand why, under the same conditions, some actors or actants are successful while others are failing. The four translation phases in ANT are: 1) problematization; 2) interessement; 3) enrolment; and 4) mobilization of allies. The first phase contains the highlighting of a problem, resulting in a common problem definition. The relevant actors can be identified or representatives can be chosen in order to include all relevant stakeholders into the debate. In a second phase, there is the built up of interest. In this phase one looks first, for ways in which all those actors can become actually interested and engaged in the search for solutions, and secondly, for the terms of commitment in which these actors want to become engaged. A third phase has to align all the interests of the various actors, and rearrange and convert these in order to create potential associations in these interests. Enrolment is about the registration and the li (also with regard to access to resources) on the basis of which their possible role in the whole story can be defined. The last phase contains the mobilization of allies. In this phase one is predominantly looking for support for the chosen actions and solutions. The embedding of the solutions in the wider setting, or the institutionalization is also situated in this fourth phase (Callon, 1999). With the focus on these translation phases within the actor network approach, we have brought interest and agency into our framework.

*5.3 ANT critiques: ARA*

Boelens (2010) criticizes the broad Actor-Network Theory (ANT) discourse of Callon, Law and Latour. In his work he focuses on the useful aspects of ANT, but he also points out the imperfections of ANT. A main objection following Boelens (2010) is that ANT does only say something about how things have become this way, but ANT does not say how or under which conditions the situation can be improved. The translation phases, by which the actor-networks take shape, gain interest and form assemblages and coalitions, stop where planning ought to start (Boelens, 2010, p. 38). Another important shortcoming of ANT can be found in the equalization of humans and non-humans in the actor networks. Boelens divides the non-humans in intermediaries versus mediators, respectively when they adopt a passive role in the first case or are represented by another actor in the latter case. Furthermore, it is important to differentiate between actors and actants , with actants being the more dominant actors defining and/or organizing the network, and with actors as all other associations and acting bodies (Boelens, 2010, p. 37; Latour, 1996). The last objection in respect to spatial planning is that, in the creation of a support base in the last translation phase (Callon, 1999), one has to take into account the effects for actors (entities, people, resources) of future generations, that are not yet but will become part of the network, especially in the context of taking sustainable measures (Boelens, 2010, p. 39).

Therefore he suggests going beyond the ANT onto a more outside-in, instead of inside-out approach, an actor relational approach (ARA) is suggested. Thus not only the actors are important, but also the actions and reactions they provoke (resulting in a network). Boelens sees a role for planners to re-orientate their perspectives profoundly, starting from the outside, from the aims of key stakeholders in civic society and business society. The public society becomes just one of the three types of players, next to the civic

and the business type (Boelens, 2010). The connections actors make, albeit between or within the types, give meaning to the actor-network assemblage. For according to Law (1986) every (social) action is fundamentally relational, it can only occur as a consequence of the specific connection between the heterogeneous material forming the network. It is only within this network that people, entities and resources have meaning (Boelens, 2010, p. 36; Law, 1986). But also the opposite is through it is only within specific action contexts institutions do exist. Indeed because the actors are not only engaging in action within a given institutional framework, but also recursively making and reconstituting the institutional matrix (Jessop, 2001, p. 8).

> *The approach is not about actors as such, in the broad sense of interactive planning (i.e. all affected parties), but about leading actors, who are primarily encountered* in the world of human action. ( ) Here we distinguish between leadir the business society ( ), within the public society ( ) and within ( ) (Boelens, 2010, p. 41).

What we attempt with our analysis, namely the unravelling of the Flemish mobility system, fits within the framework of the ARA-approach. Especially the first and second phase of ARA contain the focus of our research: 1) Interpreting the problem by determining the focal actors and unique core values and 2) Actor identification and actor analysis (Boelens, 2010, p. 43). The key actors and institutions in the broad field of mobility are to be mapped in order to identify possible connections and common aspirations for the transition towards a more sustainable mobility.

## 6. Towards a conceptual framework for the Flemish Mobility System

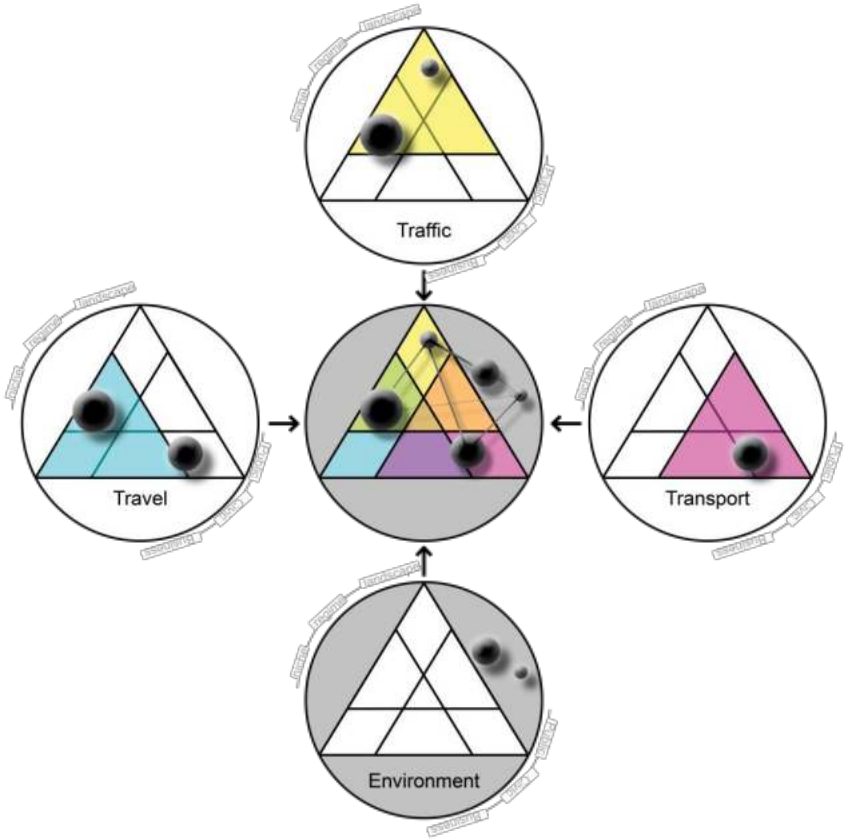

Figure 3: Proposed conceptual framework for analysis (own elaboration)

Figure 3 gives an idea of the conceptual framework we propose for the analysis of the Flemish mobility system s orgware. From actor-network theory and actor relational approach we retain the notion of actors forming actor-networks and becoming assemblages, with actants being the key actors, that have agency. According to the ARA approach we distinguish between civic, business and public types of

actors, typically represented by a triangle scheme (which we retain here). Within the actors, we can also distinguish between niche/regime/landscape, which we retained from the multilevel perspective. For the context or the conditions, in which the shaping of the actor-networks take place at a certain time with certain intentions, we built on the institutionalisation theories of path-dependency. The conceptual model of Egeter and van de Riet (1998) as elaborated by Lauwers and Allaert (2013) provides us three interconnected mobility arena s within a greater system (the interconnection is graphic by overlap of the arenas). This conceptual framework also fulfils the preconditions of a stronger integration or collaboration between land use planning and mobility planning as is strongly put forward by amongst others (Banister, 2008; Bertolini, 2012). The idea of a fourth arena, covering the rest of the indirect influencing actors and factors comes from the institutional theories and the ideas of structuration as well as from the landscape as mentioned in the MLP, to avoid misunderstandings, we called the fourth arena environment . This conceptual scheme enables further research with the actual mapping of the mobility-related actors. By considering the translation phases of ANT, Interest and agency are corrected for. After the mapping, possible windows of opportunity can be identified then, based on Buitelaar et al. (2004); Kingdon (1995).

## 7. Conclusions

To get an idea of how to make the Flemish mobility system more sustainable one has to know the system. In order to reach the sustainability objectives, insights in the governance or orgware of the system are to be attained. Hitherto the focus in the field of mobility was predominantly on (socio-)technical innovations and knowledge (software) and on the infrastructure (hardware). However, the governance component has remained under the radar so far. We believe that the governance of the system can no longer be ignored. Challenging initiatives, like Uber or driverless cars, will threaten present governing strategies and institutions, while they could be considered as innovations with a lot of possibilities. Leaving them out of consideration will expose the system. Therefore we built a research framework that would enabled us to conceptualize the Flemish mobility network. Starting from the institutional theories and perspectives of path dependency, we retained the notion that history matters, but still allows for change. The existence and representation of actors is based on the actor-network theories and the actor relational approach. Business, civic and public actors form dynamic assemblages arrange the context, and are simultaneously influenced themselves by the institutional context. The mobility framework divides the broad field of actors in three (non-exclusive) arenas: the travel market, the transport market and the traffic market. Further, all of these are embedded in a fourth environment arena, hereby representing the reciprocal relation of the mobility arenas with the context (the structure, institutions). With this framework the unravelling of the Flemish mobility system can start. The analysis of the actors and factors of importance and their interconnections in the Flemish mobility system can be carried out after which possible orgware improvements and conditions for change can be identified.

# TRACK 14

# Responsible Economics, Economic Policies and Public Finance of Urban and Regional Interest

## Track description

Co-chairs: **Michael Getzner**, **Francesco Musco**

The globalizing economy and increasing capital flows makes local and regional economic development volatile, with significant social consequences. The economic power of local and regional governments often cannot compete with big private companies. In addition, regions and cities are in a competitive situation with respect to the location of enterprises and (international) institutions. Can the big companies accept their own part of responsibility related to place and space? Is there a different cooperative model among cities and regions to avoid unnecessary and distorting competition, and a race to the bottom regarding social and envi standards? What is the limit for inter-governmental competition for private investments? What are the planning approaches addressing the above issues? How is the public sector, especially planning, limited to or locked-in in existing budgetary policies and what can for a stable, sustainable, and more resilient economic and social development? How do sustainable and resilient local and regional economic and public finance policies look like? Both theoretical and empirical papers are welcome to explore these issues.

# Valuing the appearance of an Alpine landscape: the costs and benefits of underground cabling of high-voltage power lines

## Abstract

High-voltage power lines are crucial for the security of electricity supply, and also necessary for regional renewable electricity production. However, power lines cause damage especially to human health (electric smog, noise), and to sensitive ecosystems.

The fragmentation and impaired appearance of Alpine landscapes has raised major opposition towards the planning of new power lines in Austria. An alternative, though very costly, to the erection of new lines is underground cabling. The current study presents the costs and benefits of underground cabling in a major Austrian tourist resort in the Tyrolean Alps; tourists were asked to value improvements of the appearance of the landscape with two approaches. The first presented respondents with manipulated pictures of the landscape with the existing and without power lines, and asked for the potential change of the frequency of trips to the area. The second ascertained the respondents' willingness-to-pay for a nature conservation fund financing underground cabling.

While 60% of respondents would positively change their travel behavior with an improved appearance of the landscape, and also stated a positive willingness-to-pay for underground cabling (on average about EUR 9 to 13), the additional costs of underground cabling would not be outweighed by the tourists' willingness-to-pay. For the purpose of planning new power lines, it is thus important to explore the full range of benefits of underground cabling including the willingness-to-pay of Austrian residents which might be much higher than that of tourists alone, and not only concentrate on the significance of a pristine Alpine landscape for tourism.

**Keywords:** Alpine Landscape, transformation of landscapes, high-voltage power lines, economic valuation, underground cabling.

## 1. Introduction and background

The Alpine landscape in Austria has been transformed into a cultural landscape over the past centuries. Even the remaining natural areas such as national parks or Natura 2000 areas are affected by human use. For the Austrian Alps, tourism is, of course, one of the major and large-scale land uses. Especially in areas of ski resorts, all kinds of infrastructure (e.g., ski lifts, cable cars, hotels) may impair the typical appearance of the landscape. Besides such infrastructure, high-voltage power lines (transmission lines) are considered to lead to major negative effects on the landscape not only in terms of visual disamenities but also owing to their manifold negative effects on human and ecosystem health. A range of spatial planning instruments (e.g., land use and zoning plans prescribing a certain distance from power lines to residential areas) have thus been

implemented to reduce direct land use conflicts (Kirschner et al., 2007). For instance, high-voltage power lines are subject to a comprehensive environmental impact assessment.

While the negative environmental effects of high-voltage transmission lines are well documented (e.g., Battaglini and Bätjer, 2015; Jorge and Hertwich, 2013), such power lines are also essential for transporting energy from the sites of production to the sites of consumption. Even more so, the current development of producing larger amounts of renewable energy sources (e.g., by means of wind turbines) has led to planning efforts of new transmission lines and energy storage infrastructure in order to connect the locations of production and consumption across Europe (Kishore and Singal, 2014).

An alternative to overhead high-voltage transmission lines is underground cabling. While many negative effects on human or ecosystem health are substantially reduced by underground cabling, this technological option is very costly. Costs of underground cabling depend on the concrete technology and on the necessities given the topography of the landscape and are up to 12 times higher than the costs of overhead cabling (Lang, 2014).

However, public (citizens') opposition to overhead high-voltage power lines is significant in current planning efforts for new transmission lines in Austria (e.g., Österreichisches Parlament, 2012). Often, the demand for underground cabling is reasoned by the negative effects of overhead transmission lines on the appearance of the landscape, and consequently, on (eco-) tourism since tourists expect an unobstructed view on the alpine landscape when visiting Austria.

Against this background, the aim of this paper is to shed more light on the effects of overhead transmission lines on tourists' perception of the landscape, and to ascertain tourists' willingness-to-pay for underground cabling to secure an unobstructed view of the alpine landscape. In particular, the purpose of this paper is to find answers to the following questions:

- How do tourists in the case-study area of the prominent ski resort of St. Anton am Arlberg (Tyrol) perceive overhead transmission lines?
- Were tourists aware of transmission lines crossing the landscape when booking their holidays?
- How would tourists change their travel behavior if overhead transmission lines were removed?
- Do tourists have a willingness-to-pay to fund underground cabling?

To find answers to these questions, an empirical survey was undertaken in the internationally well-known alpine resort of St. Anton am Arlberg (Tyrol). Tourists during the 2014 winter season were surveyed with respect to their preferences for pristine landscapes and their willingness-to-pay for underground cabling of power lines which currently have significant negative effects on the appearance of the landscape. In addition, tourists' potential changes of trip frequency were elicited depending on the hypothetical changes of the landscape if the power lines were put underground.

The structure of the paper is as follows: In Section 2 there is a brief overview of literature on valuing landscape changes, and of studies on the costs and benefits of underground cabling of power lines. In Section 3 the experimental setting and the survey is presented. In Section 4.1 the descriptive results of the study are discussed, while Section 4.2 includes the econometric results of the survey. Section 4.3 presents the costs and benefits of underground cabling in light of the survey results. Finally, in Section 5, the results are summarized, and conclusions are drawn.

## 2. Costs and benefits of high-voltage power lines: a short review

Environmental economics offers a wide range of methods for valuing changes of a natural landscape. Direct valuation approaches such as contingent valuation or choice experiments present respondents (residents, visitors, tourists, general public) different scenarios which may include

management options for developing an area. Presenting such scenarios to respondents is often done by means of pictures that show the original landscape, and are then manipulated to emphasize possible changes, e.g., by inserting new infrastructure or a higher number of visitors. Usually, two measures of benefits are ascertained. One the one hand, respondents may be asked to state their frequency of trips (visits) to an area based on the current and potential future appearance of the landscape, thus combining revealed and stated preferences. The difference between these may then be assessed by differences in consumer surplus based on travel demand models (e.g., Whitehead et al., 2000; Hoyos and Riera, 2013). This approach can value the recreation benefits of different scenarios. On the other hand, non-use values can be ascertained by comparing willingness-to-pay bids of respondents given different development scenarios (e.g., Lienhoop and Ansmann, 2011; Getzner and Svajda, 2015).

Such techniques of presenting respondents development scenarios are, of course, also used in urban and regional planning in order to highlight potential changes of the appearance not only of natural but also residential (urban) environments (cf. Zech, 2013; Tisma et al., 2012).

One of the earlier valuation studies on visual disamenities owing to overhead transmission lines was done by Harrison (2002). He compared costs of overhead and underground power lines; while the costs of the latter were about twice the cost of the first, politicians decided on burying the power line due to the significant impacts on the environment valued, among others, by losses in ecotourism, and residential property values.

With respect to the valuation of power lines, changes to the landscape, and underground cabling, Tempesta et al. (2014) have recently published a study on costs and benefits of underground cables. While there is a majority of respondents who would be in favor of underground cables, willingness-to-pay is only larger than the costs associated with underground cabling in certain specific areas, especially in natural mountainous areas and nature parks. This results points to an important aspect also for this paper since high-voltage power lines might be generally accepted in flat landscapes or intensively used areas, but less in the natural environment.

Another study in Finland by Soini et al. (2011) ascertained preferences of respondents for different types of infrastructure such as high-voltage power lines in comparison to other infrastructure that might impair the visual appearance of the landscape. Respondents in their study stated a diverse spectrum of preferences and perceptions especially emphasizing preference heterogeneity.

Devine-Wright and Batel (2013) tested whether the appearance of the pylons carrying the transmission wires would gain a differentiated acceptance by respondents in their UK study. The authors find that several forms of pylons in fact are preferred to others, but that even the most ‘appealing’ pylon would not be preferred to underground cabling of power lines (cf. for different energy infrastructures also Cohen et al., 2014).

## 3. The study site, and testable hypotheses

In order to answer the basic research questions of the current study, 140 tourists were surveyed during the Easter holidays in 2014. The case-study area chosen for this survey was the surroundings of the village of St. Anton am Arlberg, a prominent and internationally visited prime tourism resort. Especially during the winter season, the resort is fully booked. The village is connected to the Austrian highway network, and the Austrian railway company has a stop of international trains at St. Anton. However, since the village is geographically located along the major East-West corridor of inner-Austrian infrastructure, major high-voltage power lines cross the area. Some of the power lines are very near the village, and also stretch over several ski slopes.

For the purpose of the current study, data was collected on the perception and preferences of tourists in St. Anton am Arlberg with respect to overhead power lines, and the tourists’ trip frequency both in the status quo and in the case one of the scenarios were to become reality. In addition, respondents stated their willingness-to-pay for the improvement of the appearance of the

landscape by means of two scenarios of underground cabling. *Figure 1* presents the status quo (current appearance of the landscape), and two potential scenarios of underground cabling differing in the extent (partial vs. complete underground cabling).

Figure 1: Status quo and potential changes of the appearance of the landscape at the St. Anton ski resort in the Austrian Alps

*Status quo: current appearance of the landscape at St. Anton am Arlberg*

*Scenario 1: Partial underground cabling of one of the high-voltage power lines crossing the area*

*Scenario 2: Complete underground cabling of both high-voltage power lines crossing the area*

Source: Authors' pictures (original and manipulated).

*Table 1* presents an overview and description of all variables used in the empirical estimations of both trip frequency, and willingness-to-pay of respondents for the two scenarios of underground cabling.

Table 1: Variables of the empirical estimation

| *Variable name* | *Description* |
|---|---|
| *Dependent variables* | |
| Travelfrequency | Frequency of travels to the St. Anton skiing area |
| WTP | Willingness-to-pay of respondents for scenario 1 or scenario 2 (EUR, ln) |
| *Explanatory variables* | |
| $T_i$ | |
| Travelcost | Travel costs of respondents for their visits to an alpine pasture landscape (EUR) |
| $G_i$ | |
| Scenario1 | =1 for scenario 1 |
| Scenario2 | =1 for scenario 2 |
| $S_i$ | |
| Income | Income of respondent (net monthly income, per household, EUR, ln) |
| $P_i$ | |
| Disturb | =1 for respondents who perceived overhead high-voltage transmission lines as disturbing |
| Aware | =1 for respondents who were aware that transmission lines would cross the area |
| View | =1 for an unobstructed view of an alpine landscape to be a major motive of repondents to visit the area |
| Alpine | =1 for respondents who came to the area to enjoy a high-alpine landscape |
| Lift | =1 for respondent stating that their major motive to visit the area is a dense lift network |

Our main hypotheses to be tested are:

$H_1$: $Tripfrequency_{i,Status\ quo} < Tripfrequency_{i,Scenario\ 1} < Tripfrequency_{i,Scenario\ 2}$

$H_2$: $WTP_{i,Scenario\ 1} < WTP_{i,Scenario\ 2}$

The two hypotheses are developed based on the research questions of the current paper. First, we hypothesize that tourist in fact have a preference for underground cabling owing to a reduction of visual disamenities given the rather prominently located high-voltage power lines which crosses the ski slopes. Second, we test whether tourists in fact will be willing to pay a higher contribution for a hypothetical landscape conservation fund to finance underground cabling near the tourism resort.

## 4. Empirical results[1]

### 4.1 Descriptive survey results[2]

In order to ascertain preferences of respondents (tourists) for the different scenarios presented above, *Table 2* sums up some details of the descriptive survey results. One important aspect of the choice of the holiday resort is – besides the prices of accommodation, transport, offers for sports and leisure activities – the variety of landscape amenities and attributes of the tourism offers in the region. The upper part of the table shows that one major advantage of the ski resort lies in the extensive lift network and the length of ski slopes. Other landscape amenities such as high-alpine landscapes, or open landscapes with long-distance view, are of minor importance.

As the ski resort is not only a nationally prominent resort but is also visited by international tourists, the duration of transport, as well as the means of transport, are certainly specific to the area. About one fourth of respondents came by plane, and about one fifth of respondents used the intercity railway connection directly to the St. Anton train stop.

Overhead transmission lines do not seem a major disturbance of tourists: While about 13% of respondents already have power lines close to their home, and information levels are not high with respect to potential effects of overhead high-voltage transmission lines, 55% of all respondents were well aware that there would be overhead power lines close to the ski resort. Most respondents knew from the existence of these power lines because of past visits, but some also said that they expected power lines crossing the area based on pictures from the resort prior to their journey.

[1] The entire questionnaire and further descriptions of the experiment, all the data and empirical assessments, including econometric estimations, can be obtained from the authors on request.

[2] Owing to limits of space, only the most important results will be presented. Some more descriptive analysis can be found in Lang (2014).

Table 2: Descriptive survey results: attractiveness of the ski resort, modes of transport, and perception of existing power lines

| *The ski resort of St. Anton am Arlberg (Tyrol) is attractive because of… (mean points on a 5 point Likert scale, 1=most important)* | |
|---|---|
| Number of lifts and extension of the ski slopes networks | 1.36 |
| High-alpine landscapes | 1.44 |
| Appearance of the landscape | 1.60 |
| Transport connections | 1.85 |
| Open landscape with long-distance views | 1.92 |
| Activities and events | 2.13 |
| Local urban center | 2.15 |
| Solitude | 2.79 |

| | *Mean* | *Std. Deviation* |
|---|---|---|
| Duration of traveling to the area (hrs.) | 6.30 | 32.20 |
| Distance to the area (km) | 768.00 | 402.45 |
| Length of stay in the area (days) | 6.58 | 2.69 |

| *Mode of transport (multiple answers, % of respondents)* | |
|---|---|
| Car | 74.30% |
| Air | 25.00% |
| Train | 22.10% |
| Bus | 10.00% |

| | |
|---|---|
| *Transmission lines near the home of the respondent (% of respondents)* | 12.90% |
| *Information level about high-voltage transmission lines (mean on a 5 point Likert scale, 1=very well informed)* | 3.96 |
| *Respondents were aware, that transmission lines are crossing the area (% of respondents)* | 55.00% |
| *… owing to the experience during the last visit (% of respondents)* | 50.00% |

| *Transmission lines are disturbing because of the …* | |
|---|---|
| … pylons | 54.30% |
| … transmission cables | 27.10% |
| … noise | 22.90% |

*Table 3* presents the descriptive survey results with respect to the different scenarios (cf. *Figure 1*). The upper part of the table includes the respondents' perception of the status quo and the two scenarios; in most cases, the scenario 1 with its partial underground cabling does not seem to add much improvement to landscape amenities. For instance, the scenario 1 is not perceived differently in comparison to the status quo with respect to the diversity of the landscape. However, scenario 2 (complete underground cabling) improves the landscape significantly, for instance, with respect to natural landscapes, unimpaired views, or the uniqueness of the view. 93.6% of respondents preferred scenario 2 to the status quo and to scenario 1.

Table 3: Descriptive survey results: Preferences for scenarios, change of travel frequency, and willingness-to-pay

| *Perception and valuation of scenarios (mean on a 5-point Likert scale, 1=best value)* | *Status quo* | *Scenario 1* | *Scenario 2* |
|---|---|---|---|
| Natural landscape | 3.50 | 3.36 | 2.64 |
| Diversity of the landscape | 3.14 | 3.13 | 2.75 |
| Area used | 2.39 | 2.90 | 3.67 |
| Unimpaired view | 3.52 | 3.15 | 2.40 |
| Uniqueness of the view | 3.19 | 3.03 | 2.55 |

| *Will ski lifts still be disturbing after underground cabling?* | |
|---|---|
| Very disturbing | 17.90% |
| Somewhat disturbing | 20.70% |
| Not disturbing | 34.30% |

| *Frequency of vacations in the area during the last five years or in the next five years if scenario 1 (2) were to be realized* | *Mean* | *Std. Deviation* |
|---|---|---|
| Status quo | 5.56 | 6.31 |
| Scenario 1 | 5.42 | 5,22 |
| Scenario 2 | 6.23 | 5,28 |

| *WTP for…* | *Mean* | *Std. Deviation* |
|---|---|---|
| … scenario 1 | 3.54 | 9.34 |
| … scenario 2 | 7,81 | 13,66 |

It is, however, interesting to consider that the pylons of the ski lifts which are still very visible in the pictures (both status quo and scenarios) are not perceived as disturbing by the majority of respondents. Only about 18% of respondents still perceived lift pylons as very disturbing.

*Table 3* also includes the respondents' assessments of the status quo and the scenarios. While travel frequency would not change if scenario 1 were to be realized, there is a significant, though somewhat small, stated increase of trip frequency in scenario 2 (complete underground cabling). This result indicates that respondents do not perceive a partial improvement of the landscape view in scenario 1 to be sufficient to increase trip frequency. However, even in the case of complete underground cabling, trip frequency would not change dramatically.

Finally, the table also presents mean willingness-to-pay figures. Respondents were willing to pay EUR 3.54 per person per stay for the realization of scenario 1 (corresponding to about EUR 0.54 per person per day). For scenario 2, willingness-to-pay is much higher, with about EUR 7.81 per person per day (EUR 1.52 per person per day). These rather low figures suggest that respondents do not hold strong preferences for the removal of transmission lines; in order to explore preferences further, the next section provides econometric evidence regarding recreation benefits and willingness-to-pay.

### 4.2 Travel frequency and willingness-to-pay for removing power lines

In order to answer the hypothesis $H_1$ presented in section 3, travel frequency of visitors (tourists) is estimated econometrically by means of a count data model. Such estimation procedure hypothesizes that trip frequency foremost depends on travel costs associated with travelling to (visiting) an area. In addition, we test whether trip frequency would change in the case if a

scenario were to become reality. Furthermore, additional variables are included in the empirical estimation in order to ascertain potential additional explanatory variables of trip frequency. *Table 4* presents an econometric estimation of the frequency of travels to the area.

Table 4: Determinants of the respondents' travel frequency depending on potential scenarios of landscape changes

| *Variable* | *Coefficient* | *z-Stat* | *Sign.* |
|---|---|---|---|
| Constant | 0.3368 | 1.0584 | |
| Travelcost | -0.0104 | -6.9339 | *** |
| Scenario1 | -0.0524 | -0.9768 | |
| Scenario2 | 0.0972 | 1.8822 | ** |
| Income | 0.0909 | 2.3331 | ** |
| Disturb | 0.1894 | 3.3925 | *** |
| Aware | 0.7928 | 15.598 | *** |

| S.E. of regression | 4.9930 | | |
| Log likelihood | -1,163.742 | | |
| n | 383 | | |

Dependent variable: Travelfrequency
*** p<0.01, ** p<0.05, * p<0.1
Count data model (Poisson).

First, our basic hypothesis that trip frequency depends on travel costs is highly supported with a significantly negative coefficient for the variable 'Travelcost'. Based on the estimation and the coefficient for travel costs (-0.0104), the consumer surplus per trip amounts to over EUR 129 per stay; given the average length of stay in the area (about 6.6 days), consumer surplus measured by travel costs amounts to about EUR 19.5 per person per day.

The coefficient of the variable 'Scenario1' is not significantly different from Zero. This means that respondents would not change their travel frequency if this scenario would be realized. This result can be expected since the change of the landscape is marginal, and there still would remain the other high-voltage power line. However, the coefficient for the variable 'Scenario 2' is highly significant indicating that respondents would in fact be sensitive to major improvements of the visual appearance of the landscape, and would increase the number of trips to the area slightly. Given the coefficient of 0.0972, consumer surplus of the realization of scenario 2 amounts to EUR 138 per person per trip; given the difference between the status quo and the scenario 2, consumer surplus would increase by EUR 9.35 per person per trip. Assuming the average length of stay, respondents value the reduction of visual disamenities of the high-voltage power lines by at least EUR 1.42 per person per day.

While the estimation so far has only included travel costs and the appearance of the landscape as explanatory variables, we also included several other factors influencing trip frequency. As a central socio-economic variable, we assume that trip frequency is directly connected with the income (net of taxes) of the respondent's household. The estimation clearly indicates that trip frequency depends positively on income.

Furthermore, there are a number of variables that additionally determine trip frequency. On the one hand, the variable 'Disturb', denoting the respondents' perception of transmission lines as disturbing, adds to the explanatory power of the model. This variable is closely connected to the variable 'Aware' denoting the awareness of respondents prior to the journey that power lines are

close to the ski resort. Both variables taken together implicitly acknowledge that respondents who were aware of transmission lines exhibit a higher trip frequency than other respondents; they might thus be regular visitors of the area who "got used" to the appearance of the landscape.

Respondents who primarily prefer unobstructed views of the landscape (variable 'View') are less likely to visit the area while respondents seeking a high-alpine mountainous landscape (variable 'Alpine') exhibit a higher trip frequency as especially St. Anton offers such landscapes above the valleys and the potentially disturbing infrastructures. Finally, respondents who enjoy a dense lift infrastructure (variable 'Lift') state a higher trip frequency.

All in all, the model exhibits a rather high explanatory power given the limited number of respondents even if the observations for each respondent [n=140] are pooled resulting in a total number of observations of 383.

Table 5: Determinants of the respondents' willingness to pay to prevent landscape changes considered to be unfavorable

| *Variable* | *Coefficient* | *z-Stat* | *Sign.* |
|---|---|---|---|
| Constant | -2.6617 | -2.6632 | *** |
| Scenario2 | 0.6016 | 3.8281 | *** |
| Income | 0.271 | 2.1738 | ** |
| Disturb | 0.3487 | 1.6008 | * |
| Aware | -0.0474 | -0.2936 | |
| View | 0.3769 | 2.1358 | ** |
| Alpine | -0.2012 | -1.2097 | |
| Lift | -0.3398 | -1.8962 | * |

| S.E. of regression | 0.5414 | | |
| Log likelihood | -421.8708 | | |
| n | 256 | | |

Dependent variable: WTP
*** p<0.01, ** p<0.05, * p<0.1
Baseline is the WTP for preventing scenario 1.
GLM (maximum likelihood) estimation (Poisson distribution assumed, log link).

*Table 5* presents the econometric estimation of the determinants of willingness-to-pay of respondents for the realization of scenario 1 or 2. As discussed above, mean willingness-to-pay amounted to EUR 3.54 per person per stay to promote scenario 1 (partial underground cabling) while scenario 2 attracted a mean willingness-to-pay of EUR 9.34 per person per stay; given the average length of stay, daily willingness-to-pay amounts to EUR 0.54 per person (scenario 1) to EUR 1.52 per person (scenario 2). Interestingly, the latter figure is quite close to the gain of consumer surplus computed above by means of the travel demand model.

The WTP estimation broadly includes – for the purpose of comparability – the same variables as the estimation presented in *Table 4*. Given the WTP for scenario 1 as the baseline, the estimation clearly indicates that willingness-to-pay of respondents is significantly higher for scenario 2. In addition, the income variable is significantly positive indicating that willingness-to-pay of respondents for the improvement of the landscape appearance is positively correlated with income as suggested by economic theory.

Furthermore, we find that willingness-to-pay of respondents who feel disturbed by high-voltage transmission lines is above-average. Moreover, respondents who prefer an unobstructed view of the landscape – as a measure for the strength and intensity of preferences – state a higher willingness-to-pay for underground cabling. Finally, respondents who positively value the density

of ski lifts at the St. Anton ski resort state a lower willingness-to-pay, presumably because they are more used to the impaired view of the landscape.

### 4.3 Costs and benefits of underground power lines

The last section has provided some econometric evidence towards recreation benefits of underground cabling, and the respondents' (tourists') willingness-to-pay for the removal of overhead transmission lines. In order to test whether the benefits of tourists with respect to the removal of power lines is sufficiently high to at least match the costs of underground cabling, a cost-benefit analysis on a (hypothetical) removal project for underground cabling in the village of St. Anton am Arlberg is presented in the following.

For this project, we assume that over a certain stretch, the existing transmission lines are removed from the surface; as there are three major power lines crossing the area with different voltages (110 and 380 kV), we assume that our hypothetical project includes a tunnel for the underground cables. For this purpose, the tunnel to remove the overhead cables is 13,972 meters long; given the costs of removal of about EUR 15,700 per meter, total investment costs sum up to EUR 176 million (for all underlying data and details, see Lang, 2014). Under the assumption that the existing overhead power lines have to be renewed anyway, and that the cost ratio between overhead and underground cabling is 12.4, we arrive at differential costs for the underground cabling of around EUR 161 million.

On the benefit side, we present two options for valuation which are very close to each other. *Table 6* presents the present value of both the valuation of recreation benefits by means of the consumer surplus, as well as willingness-to-pay of respondents for the removal of overhead power lines. Given the average annual number of tourists in the region (in total about 1.2 million overnight stays), and the average consumer surplus and WTP, respectively, we arrive at additional recreation benefits of about EUR 53 million (present value over 40 years, d=1%). As the table shows, the value of recreation benefits is highly sensitive to the discount rate varied from 0% to 5% over a planning period of 40 years which is the usual technical lifespan of high-voltage power lines.

Table 6: Consumer surplus based on trip frequency, and willingness-to-pay for realizing underground cabling

| | | |
|---|---|---|
| Average number of tourists (overnight stays) during the winter season 2012/2013 at St. Anton am Arlberg | 1,013,187 | |
| Average number of tourists (overnight stays) during the summer season 2013 at St. Anton am Arlberg | 123,202 | |
| | *Scenario 1* | *Scenario 2* |
| Consumer surplus per person per stay (difference to the status quo if scenario 2 would be realized)* (EUR) | | 9.350 |
| Consumer surplus per person per day (difference to the status quo if scenario 2 would be realized)* (EUR) | | 1.417 |
| Aggreated annual consumer surplus for visitors (scenario 2) (EUR) | | 1,609,884 |
| Average WTP for the realization of scenario 1 (2) (EUR) | 3.540 | 9.340 |
| Average WTP per person per day (EUR) | 0.536 | 1.415 |
| Aggregated annual WTP of respondents based on total overnight stays (EUR) | 609,518 | 1,608,163 |
| *Discounted benefits of underground cabling* | | |
| Discounted total consumer surplus (d=0%, 40 years) (EUR) | | 64,395,377 |
| Discounted total WTP (d=0%, 40 years) (EUR) | 24,380,709 | 64,326,505 |
| Discounted total consumer surplus (d=1%, 40 years) (EUR) | | 53,388,650 |
| Discounted total WTP (d=1%, 40 years) (EUR) | 20,213,457 | 53,331,550 |
| Discounted total consumer surplus (d=3%, 40 years) (EUR) | | 38,328,475 |
| Discounted total WTP (d=3%, 40 years) (EUR) | 14,511,529 | 38,287,482 |
| Discounted total consumer surplus (d=5%, 40 years) (EUR) | | 29,005,353 |
| Discounted total WTP (d=5%, 40 years) (EUR) | 10,981,706 | 28,974,331 |

* As there is no significant difference between scenario 1 and the status quo in terms of trip frequency, additional consumer surplus is Zero (cf. Table 4).

In addition to recreation benefits (or WTP) of tourists at the ski resort, underground cables avoid some of the external effects of overhead power lines such as noise, electromagnetic fields, and fragmentation of ecosystems owing to the transmission route. Furthermore, underground cables are connected with a reduced loss of voltage (line losses) compared to overhead transmission lines. Valuing the reduced losses of underground cables with reasonable input data (loss per kilometer, valued at electricity costs), we arrive at benefits of underground cables (compared to overhead power lines) of around EUR 11.7 to 27.2 million over the lifespan of the power lines (depending again on the discount rate over the whole period). *Table 7* presents the comparison between costs and benefits of underground cabling.

Table 7: Costs and benefits of underground cabling: results for scenario 2 (complete removal of overhead power lines, construction of underground cabling)

| | *Discount rate* | | | |
|---|---|---|---|---|
| | 0% | 1% | 3% | 5% |
| Additional cost (one-off investment) for underground cabling (EUR) including marginal maintenance costs | 161,810,000 | | | |
| Additonal benefits owing to the reduction of transmission losses (EUR, present value) | 27,165,312 | 22,299,113 | 15,698,000 | 11,653,299 |
| Recreation benefits (consumer surplus) for scenario 2 (present value) (EUR) | 64,326,505 | 53,331,550 | 38,287,482 | 28,974,331 |
| Benefit-cost ratio (consumer surplus) | 0.340 | 0.290 | 0.216 | 0.167 |
| WTP for scenario 2 (present value) (EUR) | 64,395,377 | 53,388,650 | 38,328,475 | 29,005,353 |
| Benefit-cost ratio (WTP) | 0.341 | 0.291 | 0.217 | 0.168 |

The results of the cost-benefit analysis suggest that the costs involved for underground cabling in the case-study region are not offset by the benefits of reduced losses, and by the tourists' willingness-to-pay for removing overhead power lines since the benefit-cost ration is clearly below 1 for all assumptions.

## 5. Discussion, summary and conclusions

The current paper has taken up the discussion on the importance of an unobstructed view on the Alpine landscape for tourism resorts. In order to test whether tourists indeed have a sufficient willingness-to-pay for the removal of overhead high-voltage power lines usually associated with negative effects both on the appearance of the landscape, and on human and ecosystem health, we conducted a survey of tourists visiting the prominent and internationally visited St. Anton holiday resort in the Tyrolean Alps.

In order to value the benefits of removing the overhead transmission lines, we employed two approaches; one approach asked tourists to state the current (status quo) and hypothetical frequency of trips to the holiday resort (for scenarios 1 and 2). If scenario 2 would be realized, about 60% of respondents stated that they would stay slightly longer or visit the region more often. Based on a recreation demand model (travel costs), additional consumer surplus amounts to about EUR 1.417 per person per day if scenario 2 (complete underground cabling) were to be realized. This amount is about the same size as the usual daily tourism tax charged for every overnight stay. Of course, the recreation benefits measured by the consumer surplus crucially depends on assumptions about travel costs (transportation and costs of travel time). The other approach measured benefits of an undisturbed landscape by means of the respondents' willingness-to-pay to finance underground cabling. It turned out that WTP per person per day of EUR 1.415 is almost equal to recreation benefits measured by the travel cost model. This result is interesting since economic theory would suggest that recreation benefits owing to the realization of a certain scenario measured by different methodological approaches should lead to the same order of magnitude which actually took place in this study.

Given the huge cost of underground cabling, however, the willingness-to-pay of visitors for such scenario as a measurement of benefits (either recreation benefits based on the travel cost method or benefits measured by the respondents' willingness-to-pay) does not outweigh these costs over the whole lifespan of transmission lines (40 years). Even if we assume that the discount rate of benefits would be Zero, the benefit-cost ratio is far from unity. The cost-benefit analysis of the overhead transmission lines removal project only includes the substantial reduction of transmission losses as a benefit of underground cabling as a proxy for potentially important other external effects of overhead power lines. These external effects may include noise and ecosystem fragmentation.

The results so far suggest that respondents were well aware that the area around the village of St. Anton am Arlberg is an intensively used area with tourism infrastructure, but that overhead high-voltage power lines are also close to the area. The majority of respondents stated that they knew that there were transmissions crossing the area, and that the disturbance is – on average – not very far-reaching. In addition, respondents thought that even after the removal of the transmission lines, the remaining lift pylons would also not be impairing their view on the landscape.

Of course, underground cabling may have a number of additional benefits; however, if (eco-) tourism is used as an argument in the debate on high-voltage power lines, one has to be aware that the results of this study indicate that the willingness-to-pay of visitors (respondents in a survey) is not sufficient to outweigh these costs. Thus, projects of underground cabling will need more specific argumentation besides (eco-) tourism. Some of these arguments may be:

- Residents and the general public may hold strong preferences for underground cabling in sensitive natural areas. As earlier studies show (see Section 2), however, preferences and willingness-to-pay could be regionally different, and may only be substantial in natural areas. In areas and regions that are already affected by numerous infrastructures (e.g., highways, railroads), underground cabling might not be economically efficient.
- Tourists hold differentiated preferences as well. As the current study shows, many respondents in our survey were well aware of the existence of power lines crossing the area. However, the removal of transmission lines in natural areas might attract new groups of visitors who might have spent their holidays in other resorts.
- If the tourism tax would indeed be increased to at least partially fund a project for underground cabling, demand for holidays in this Alpine region might be reduced as a reaction to higher prices of overnight stays. While this argument is well founded in demand modelling, it may also be assumed that the reduction of demand might not be significant since the additional costs in the form of increases of the tourism tax is only marginal compared to the average spending of tourists in the region (the St. Anton resort is certainly one of the most expensive resorts in the Austrian Alps).

All in all, for the purpose of planning new power lines, it is thus important to explore the full range of benefits of underground cabling including the willingness-to-pay of Austrian residents which might be much higher than that of tourists alone, and not only concentrate on the significance of a pristine Alpine landscape for tourism.

# IDENTITIES OF A PERI-URBAN HABITAT
## The potential for agricultural cluster development in Tirana

Elona Karafili[1], Endrit Marku[2]
[1]POLIS University, Tirana, Albania e.karafili@hotmail.com
[2]POLIS University, Tirana, Albania endrimarku@hotmail.it

*As often the case with the newly formed peri-urban areas in the outskirts of expanding cities, the territories that surround Tirana face the pressure of converting agricultural fields into urbanized land, resulting in identity loss, environmental deterioration, and high unemployment companioned by poverty and ultimately a low quality of life. Besides the challenges, the proximity to the capital city provides also advantages, such as economies of scale and scope deriving from the agglomeration of the activities, good access to labor force, market, infrastructure, as well as educational and research facilities, constituting therefore the basics for cluster development. This paper explores the evolution and present state of one of the first environments, in sequence, encountered by the visitors approaching the capital of Albania, Tirana. Once a carefully planned agricultural landscape, today it s a hybrid urban-rural spatial continuum, a peri-urban habitat searching for a proper identity. We will try to elaborate on the potential of the area to host cluster development, with a specific attention paid to agricultural clusters that would have an important effect not only to its economic performance but also on the preservation of the territory and landscape.*
**Keywords:** Peri-urban identities, agricultural clusters, Tirana

## 1. Introduction

The Tirana valley gives the impression of a natural amphitheater crossed by the homonym river and shaped by the Dajti mountain (east), the hills systems (south and southwest), and the Ishmi (northwest). The main road approaching the capital are Tirana-Durrës axis (with more than 250 businesses and around 15,000-20,000 daily commuters, and a number of Universities adding up to the cluster-formation potential[1]) and the North axis crossing the spontaneous urban settlement of international Airport is found at the edge, in the northwest. The area is also trespassed by the old railroad, heading towards Durrës and the North, and practically no more in use. (Fig1) (Toto, Gjika, Karafili, Shutina, & Ymeri, 2015).

## 2. Methodology

The data presented in this paper was gathered through qualitative methods: desk research on the policies applied thus far and semi-structured interviews with specialists, local farmers and inhabitants.
The desk research focused on literature overview as well as published reports and policy documents on the past and current policies in national and local scale.
The interviewed specialists are experts in agriculture and were asked on the potential of the area to re-activate this activity, the fertility of the soil, the most suitable plants for this kind of soil, etc.
The local farmers and inhabitants were asked on their current economic activities, their needs, the future plans, and their relationship with other farmers and industries in the area, as well as public actors such as governmental agencies and the agricultural university.
The field visit served to map the eventual cluster actors and gather empirical evidence on the current conditions of the area and the activities that take place there.
Porter s clusters map model served as a theoretical framework to introduce the co cluster in the area.

[1] This data are estimated through field surveys (social- economic and visual) carried out by POLIS University in the framework of master workshops and research studies.

## 3. The evolution of the area s identity

Two decades ago, rail convoys were a usual presence in the Albanian landscape. Travelers were mostly using this mean of communication, making the railway itineraries and the train stations, the windows and gates from where the acquaintance with environments, cities and places in general started. The entrance to Tirana, as well, was happening mainly along rails, over passing settings differing a lot from those encountered by the asphalted perspective.

The presence and image of subjectively' gigantic silo s, large industrial compounds and that of the A hospital surrounded only by space, while approaching Tirana, are still a part of the Albanians collective memory. The same can be said for the character of this space made of wide cultivated fields, populated by the frequent presence of large groups of farmers, less frequent Albanian homemade red painted tractors and vineyard or olive grove covered hillsides. That is more or less what was awaiting and accompanying the visitor approaching or leaving the capital, a relatively readable spatial layout with man-made and natural, settings distinctly placed in the landscape

Although heavily mutated under the thick Albanian transition, a lot of evidences have survived in situ , in hand for a watchful eye to discover. The train isn t there anymore, but there s sti more large plantations but the poplar rows in between them still exist; The seasonal noises of the combat jets, now just scrap leftovers, have been replaced by the daily clatter of the passenger planes; Either the former industrial and agricultural ruins, the Tirana river, the place names now melted under the same built

continuum , the indigenous inhabitants along the multitude of new settlers remain today a structural part of this peri-urban triangle.

Soon after the regime swap, buses, light vans and the first private owned automobiles begun to overtake the train service. Time became more precious than some few money spared by the inexpensive ticket. Though, despite the relentless decline, rail convoys resisted as a prime choice for some more years at the beginnings of the Albanian transition. So did the longitudinal section through the railway path that remained the habitual experience for most of the travelers. Transiting, at 40km/h, from the window seat you could notice in a relatively short lapse of time the rapid-changing of the surrounding landscape, itself transiting from an agricultural habitat to an expanding slum.

The definitive fade of the Albanian rail transport interrupted the experiencing from within of this suburban part of the capital. This itinerary, that was penetrating this area, starting at the international airport, has been forgotten gradually, together with the perspectives it was offering from within. The above mentioned set of imagery are now recorded history replaced by the superficial perspectives of the two tangential road transport corridors connecting Tirana to the Adriatic and the Northern regions. The triangle of land on the Tirana s river margins kept developing unnoticed by the many under the general ca area , diverting entirely from the past socialist *climax of ideological anti-urbanism* . (Davis

Action has not been lacking in the last two decades, and even before. This action has changed actors and intensity. At the beginnings it was done by centralized structures, today instead by individual interventions, and the last ones have a more visible impact. Today we see an environment filled by a multitude of spaces, buildings and functions. The Tirana-Durres highway, the first road in the country counting more than two lanes turned in the main place were the change was visible, a transitory space *that loses its architectures as a reptile loses* its skin (Koolhaas & Foster, 2013), a showroom for the Albanian fresh capitalism

Among the new functions hosted by this important infrastructural connection and one of the very first signals that placed Albania within the edges of the global economy, was the transfer of the Coca Cola facilities along the Tirana-Durres corridors. It was 1994 and the factory was located on a strip of land in between the railway and the driveway, with the front marked by a giant coke bottle fac passage from the public transportation, represented by the railway, to the private transportation, associated to the driveways, went in parallel with the ongoing mutation of the Albanian society, from a collective-socialist to consumerist-capitalist stage. It is not by chance that one of the symbols excellence chose the highway, at the time just a narrow strip of asphalt, as the orientation fo headquarters, a farsighted symptom forecasting the times to come.

Eleven years later, another function appears, the first Albanian shopping mall located in the very same area. It was 2005 and the query railway vs highway was meaningless at that point. Any Albanian could experience in first place without having to travel abroad a typical space of the western lifestyle, linked together by the *conditioned air system*. (Koolhaas & Foster, 2013)

The rising profiles of the large structures hosting the principal showrooms of the Albanian capitalism are enclosing any visual vector toward the inner part of this area Beside the agricu many bunkers are still here to remind us of another former character of the area, recalling an era of strong militarization. There are less than before, for the most part just concrete piles disfigured form their steel skeleton. The former rows are still today, visually easy to connect, assembling the spatial fortification wall once there to protect Tirana from any western hazard. It can remind us of what Tirana is in spatial terms, *A Ring City* (Muntoni, 1997). After the 1858, another ring city, Vienna, built its rings, parks, grandiose public buildings and squares by upgrading their urban fabric in a space of similar valence. In its own way Tirana is building here its capitalist inspirations blurred by informality and poor governance. Represented by the large economic agglomerations, on the borderlines, the inner informal sprawls and the barren agricultural land, deserted railway and polluted river.

As for many aspects of the Albanian society, the character of today s built form continuity with the area s past. Among the reasons for this fracture were: the massive migrations from the different parts of the country; the further migrations in the western country and its relative cultural influences; the spineless architectonic heritage leftover from the past decades.

Architecture has its patterns and arrangements, in different compositions as c (Unwin, 2009), and so it is the Tirana s suburban built environment, filled with el can be traced to the regional influences of either the Albanian origin places of the settlers or their later west European emigration destinations. The reasons behind the appearances of the these buildings apparently go beyond simple functional needs and have more ornamental character turning in proper status symb controlled by none other than the economic health of the owner.

The present typologies originated from the first provisional and all alike shelters that later became permanent and customized, passing form one floor structures built with inexpensive concrete blocks to gaudy villas displaying more than sheltering needs. The unfinished basic flat ceilings framed only by the protuberant steel filaments of the underlying columns, turned in richly shaped slopping roofs. Buildings elevated on slender pilotis, inhabited only in the upper floors still populate the flat landscape exposing ambitious objectives juxtaposed to the incapability to achieve them.

The first contact with the local people occurs along the Tirana river banks, after crossing a narrow corridor in between newly build houses that apparently had a granted public passage. The large ridge that dominates any map or satellite photo and that would normally remain unnoticed if you are not searching for it, opens up surprisingly. Going so close to private domains that are usually frequented by familiar faces attracted the attention of the inhabitants allowing unplanned short interviews, often in form of spontaneous chats that would later help in having new clues about this habitat from an inner perspective. Two decades of unnoticed development from the outside was there waiting to be rediscovered in the memories and in the everyday experiencing of the area by its inhabitants.

A man in his forty-s approaches, after noticing us walking close to his house garden along the Tirana River Banks. His home looks at the river and the blurry skyline of Kamza, toward something that must have been quite a picturesque view. Only a thin extruded line, a wooden curtain, separates his carefully planted garden with his fertilized soil and apparently healthy vineyard, from a stretch of the manmade landscape made of construction leftovers, smashed bricks, concrete pieces and plastic waste. You could probably count the years of the Albanian transition by observing the juxtaposition of the layers along the water banks.

Soon the group gets larger and the discussion more animated, revealing more about the way this seemingly continous and homogenous peri-urban area functions. They frequently refer to oblivious concepts as the center of the town, the agricultural establishment, the former factory, etc. Physically they are still there, but whislt once the centralities of the area, at least during the working hours, today they are hardly distinguishable.

The local inhabitants stress their connection to Tirana albeit the closer proximity to another municipality: Kamza (one of the largest in the country). They proclaim themselves citizens of Tirana but the presence of the capital city is nowhere to be found. This makes you think about the high fragmentation of the area and the lack of continuity not only in physical terms about also in terms of a missing identity and sense of belonging.

The industrial identity building elements of the past seem impotent to provide a future projection for these people, whist the only continuity element whom they remain close to, is the land. Agriculture has been and although in a totally different setting, remains the primary activity of the area, now more present in the form of private gardens and self-employing small farms.

Based on this analysis, the revival of agriculture might turn into a mean of collective efforts and a community building instrument, providing not only economic benefits but also a way to preserve the territory and the landscape.

## 4. Theoretical background

Influenced by Porter s work on competitiveness and clusters, but also by the increa and knowledge economy, many countries are developing cluster policies or introducing the concept of cluster promotion in their regional or economic and business development policies. Besides the measures taken in national level, the European Union has played an important role to encourage and foster cluster policies. However, cluster policy remains a new phenomenon, varying noticeably among the different countries within EU, and recently also emerging in other Eastern European countries.

The development of cluster policy is still at an early stage in most countries. There a differences among the countries of Eastern and Western Europe. Among those countries that have adopted the policy of the cluster after 2000, are mostly small countries in terms of population and/or geographical size of countries in Eastern Europe. (Obadic, 2013)

Albania is still new to the concept of clusters, and albeit the increasing and explicit use of the term in the objectives of several agencies, an articulated cluster policy is lacking. It is also impossible to find any official figures on cluster activity in Albania, neither in national/regional data, nor in the European level. The European Cluster Observatory (2014) also provides no reports on clusters in Albania. Nevertheless clusters constitute a real potential. In order to face competition, Albanian firms are becoming more and more aware that cost-efficiency is not enough. There is a need for qualitative products, which require the adequate technology, human capital and knowledge. Achieving such factors individually is very hard if not impossible. Positive externalities deriving from economies of scale and scope provide better chances to lay the ground for joining forces in otherwise too costly investments, especially in technology and R&D.

Some of the early clusters that already started to emerge are in the meat processing industry, medicinal and aromatic herbs industry, leather good production industry and tourism industry. Not surprisingly the major part of the actors pertaining to these tentative clusters are located in Tirana constitutes the pulsing heart of the Albanian economy, as well as the concentration of the labor force and with a population of nearly 1/3 of the national one, it also represents the largest market in the country.

However, Tirana Durres region constitute an entity that comprises more than just the two cities and the highway that connects them, which is also the business corridor that hosts many industries operating in the country. Both cities, especially Tirana are surrounded by a peri-urban fringe that has been under constant development pressure, resulting in the rapid conversion of agricultural fields into urban land.

The area laying between Tirana and the Rinas airport, has been transformed from a vast land dedicated entirely to agriculture, especially fertile for crops and orchards, into an urbanizing territory facing the typical challenges of the peri-urban areas: identity loss, environmental deterioration, high unemployment companioned by poverty and ultimately low quality of life.

Nevertheless, after 2 decades of massive immigration fluxes settled in the region t surface and tripled its population, there is a certain saturation that has decreased significantly the pace of this growth. Moreover, the construction sector is no longer thriving under high housing demand, but with a considerable vacant housing stock, the development pressure in these peri-urban areas is no longer as strong as it used to be.

The actual condition is a highly fragmented area, with developed plots spread throughout the territory, but also a considerable amount of vacant land that still possesses a strong potential to be exploited for

agricultural purposes. Such potential is currently underestimated and the promotion of an agricultural cluster would provide a vital instrument for the local economic development and reduction of poverty.

The current agricultural situation of the area is shown at Figure 2.

Figure 2: Synthesis of the Agricultural System in the Area
Source: (Toto, Gjika, Karafili, Shutina, & Ymeri, 2015)

The current businesses present in the perimeter of the area employ primarily people from outside the area, failing to have an impact in the economic reality of the inhabitants. (Metro_POLIS, 2013)

In the past the main employers of these people were industry (the coal mine of Valias and the brick factory) and agriculture. In the current conditions none of the above is active, but whist the reactivation of the industry requires major investments that must be initiated by the government being a public property, agriculture constitutes the highest potential of the area for its future development.

In many developing countries, the greatest potential for sustainable growth lies Yet ironically, it is this sector where poverty is most widespread and found in its worst forms. Small-scale farmers, and the rural communities in which they live, are imprisoned within a c low margins, resulting in low risk-taking ability and low investment, which leads to low productivity, low market orientation and low value addition which, in turn, nets low margins (GÆlvez-Noga

Indeed the eventual impact of agricultural clusters in developing countries has been little discussed in the current body of literature, but is recently receiving increasing attention.

Eastern Europe is, in comparison with Western Europe, less developed, there is a l
cost (agricultural) labor, there is a high geographical proximity of clients and the amount of land and natural resources are also present as their comparative advantages. (Looijen&Heijman, 2013)

## 5. The Agricultural Cluster Concept

Building on Porter s (1998) definition of clusters as geographically proximate g
companies and associated institutions in a particular field, linked by commonalities and complementarities, Gálvez-Nogales ( 2010) defines the agricultural clusters as simply a concentration of produ
institutions that are engaged in the food and agricultural sector and that inter-connect and build value networks, either formally or informally, when addressing common challenges and pursing common opportunities.

In the selected area many of the prerequisites for initiating a cluster are met.
There is vacant land especially qualitative for crops and orchards. Specialists say that land suitability analysis indicate that the area is appropriate to cultivate vegetables, fruits, vineyards as well as flowers. In 1990 the peri-urban areas covered 16% of the agricultural land and were responsible for 28% of the overall domestic agricultural products. (Lushaj, 2014)

There is a tradition in agriculture, but more importantly considering the previous agricultural use of the area, the eventual new farmers can make use of the existing irrigation channels and through joint action mobilize the investments to upgrade the former farming facilities, invest in new technologies and in research aiming at an increased productivity.

The contact with the research is facilitated by the presence of governmental bodies, universities and research institutes such as the Ministry of Agriculture, Rural Development and Water Management; The Rural Agricultural Development Agency, The National Food Authority; The Center for Agricultural Technology Transfer; the Agricultural University of Tirana, but also private institutions with expertise in territorial and environmental issues such as POLIS University, Co-PLAN institute.

Indeed the lacking communication among the business and academia is a missed opportunity for both parties as well as for the country in general. Industry-university collaboration in Albania lowest in the world. In 2012, Albania ranked 139 out of 144 countries. This constrains opportunities for growth and represents an untapped knowledge potential for innovation. (World Bank,

There is a new logistic park and multimodal station being built in the area that together with the Tirana Durres corridor ensure good accessibility and lower the transportation costs.
Many of the businesses in the food processing industry are located in close proximity and so are the labor force and the market.

There is an increasing interest in agriculture and greenhouses highlighted by the willingness to invest by the government and the private investors alike. A number of NGO-s supported by international donors (i.e GIZ; Partners Albania and Rockefeller Brothers) has been quite active lately to promote agricultural and green start-ups.

Moreover the agricultural cluster may positively influence the performance of other industries such as the food industry, wine industry, but also agri-tourism. In the center of this area, there is a family business Uka
Farm that is currently functioning as a farm but also as a winery as well as a re
from farm to fork concept. Such complementary activities and others as food festi
tasting tours can mitigate joint action among the players of the eventual cluster.

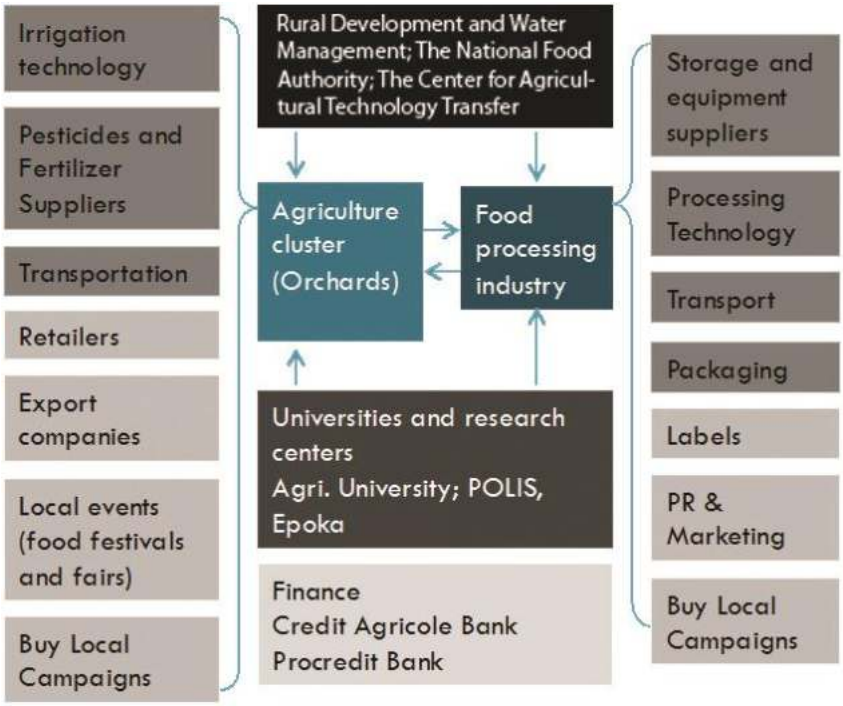

Figure 3: The agricultural cluster model

However, albeit the potential, there are several constrains that prevent the development of an agricultural cluster in the area.

Albania can be categorized in countries that lack a conducive enabling environme agricultural lending. Although climate and soils are excellent for farming, in combination with the fragmentation of farm land into plots of little more than 1 ha, it is clear that Albania is not well prepared to compete on international markets. That said, it is exporting particularly vegetables and fruits to some of its neighboring countries and herbs/aromatic plants to the EU and the US. Low labor costs and aforementioned excellent natural conditions are key drivers behind these exports. (Rabo Developm

The territory is highly fragmented and sometimes for specific plots there is no clear ownership of the land or overlapping property rights. Even though the development pressure on the area has decreased, the alternative use as urban land is still retained more profitable by the land owners, who prefer to keep it vacant or sell with the market value as urban land.

The peri-urban model has allowed agricultural land use to remain sufficiently profitable vis-à-vis urban land use and is due to the existence of a mono-cultural society which has prevailed despite immigration. A second important aspect is the predominance of small properties rather than the large areas of cultivation characteristic of the conventional rural sector. This is associated with the potential use of the land for urbanization and with the preoccupation of individual producer activity over the communal activities of the past (H. Losada, 1998)

Additionally there is a high mistrust among the actors that might eventually engage in the potential agricultural cluster. As recent studies show, the level of mistrust is even higher in the Albanian context.

The barriers faced by small- and medium-sized firms in transition economies are different from the barriers identified in other developing and developed countries. Cultural issues, especially, national culture plays

an important role in knowledge sharing in firms. Transition economies have unique social and cultural conditions, partly influenced by decades of harsh a repressive communism. Some of the transition economies with the harshest and repressive regimes face issues such as lack of trust that have significantly influenced the cultural fabric of the society in these transition economies. (Vajjhala

Moreover they face the typical communication bottleneck present in almost every cluster initiative.
In real clusters, communication between different kinds of agents is massively flawed. S
believe they have something new exciting to offer, have a hard time even to be allowed to meet with the right people at a large enterprise. Large enterprises searching for a new supplier are more likely to look for an established international supplier than to go searching among innovative SMEs located right under their nose. Policy makers have only vague ideas about what business really needs. Researchers are more interested in academic publishing than commercializing their new findings or talking to business people. Schools formulate their curricula oblivious to what skills the industry is calling for. Entrepreneurs find it difficult to persuade banks to invest in new innovative businesses. It is not difficult to understand that these connections will not just happen spontaneously. (Ketels, Lindqvist, &S lvell, 201

Indeed considering the stage of the Albanian economy and the general and specific challenges faced by an eventual agricultural cluster initiative, it is important that the public authorities (in national or regional level) adopt and implement cluster policies able to understand and address the particular needs of the industry.

Sometimes the development of such policies is challenging itself as the cluster c
and therefore does not offer a practical guide for policy-makers in their efforts to design and implement policies. A key limitation is a lack of clear cluster boundaries. The majority of the countries have not developed a strategic approach on cluster-form organizations . (Obadic, 2013)

According to IRE Subgroup, the following is needed: (IRE, 2003)
- plan to carry out mapping studies on clusters, identify regions, sectors of activity, technologies that would benefit from cluster-form organizations and integrate them in their overall strategy on economic and social growth;
- identify barriers and limiting factors to cluster development and organize regular revision of their existing policy measures;
- obtain their governments long-term commitment; and
- raise awareness on the potential benefits of clusters among the players concerned

Some examples of government support to agro-based clusters are provided by Gálvez-Nogales (2010):
- Information collection and diffusion
- Promotion of associations and networks and development of PPPs
- Support to export activities and collective marketing initiatives
- Provision of training and technical assistance to cluster stakeholders
- Improvement of access to finance
- Policy support and regulatory function
- Creation of an enabling environment, including public investment in infrastructure
- Research and development

However besides the top-down approach, there are other forms of cluster organizations that might apply to the Albanian conditions.

Cluster initiatives typically are organized through small and nimble organizat
entrepreneurial spirit driving the organization, walking across the gaps between actors inside clusters, and

receiving financial support from a range of both public and private sources. Half of the organizations have 3 or fewer employees (Ketels, Lindqvist, &S lvell, 2012)

If applied in cluster scale the policies that intend to promote local production can be much more effective than the current flat policies such as exemption from the petroleum tax of all farmers regardless of their sector or productivity. This is basically subsidizing the inefficiency, while on the other hand cluster support together with campaigns that rise awareness on the consumption of Made in Albania products woul increase the chances of local products to sustain competitiveness.

The new territorial and administrative division of the country foresees that the peri-urban areas surrounding Tirana will be part and under the jurisdiction of the Municipality of Tirana, therefore local policies can play a role, besides the national one.

Such policies must aim the land consolidation and put a greater focus on the organic products, as well as products with potential for exports. Encouraging the local production to obtain quality certificates will improve their competitiveness and trigger their exportation.

## 6. Conclusions

Albania is still new to the concept of clusters, but there is a potential for cluster development in the current Albanian economy and some early initiatives are emerging, especially in the Tirana-Durres region.

Both cities, especially Tirana are surrounded by a peri-urban fringe that has been under constant development pressure, resulting in the rapid conversion of agricultural fields into urban land, resulting in an identity loss, environmental deterioration, and high unemployment companioned by poverty and ultimately low quality of life.

This paper explored the idea of an agricultural cluster that would be instrumental for the local economic development and reduction of poverty. Besides the crop and orchard production, the agricultural cluster may positively influence the performance of other industries such as the food industry, wine industry, but also agro-tourism. The development of an agricultural cluster would also help preserve the territory, environment and landscape of the area from ulterior deterioration.

There are however constrains that prevent these initiatives, among which the most important the high mistrust among the actors and lack of communication among the stakeholders.

One of the findings is that the local inhabitants remain close to the land and see agricultural a natural activity and a way of living. Clusters can turn these activities from family-scaled to market players.

Such bottlenecks can be overcome through tailor made strategies that engage both the public and the private sector. Small and operational cluster organizations can be effective in facilitating the communication and mitigate joint action among the players in a cluster.

The role of the government however is much needed in providing basic infrastructure, easing the access to finance and executing its regulatory function.

The policies aiming to promote the economic development of these areas and the consumption of local products can be much more effective if designed and applied in cluster level.

# STRUCTURAL TRANSFORMATION AND SPATIAL INEQUALITY BETWEEN NORTH AND SOUTH CORRIDORS OF CENTRAL JAVA AND YOGYAKARTA

Rahadini Ari[1]

[1]Institute of Regional Science, Karlsruhe Institute of Technology, Germany, ari.rahadini@kit.edu
Architecture Study Program, Department of Civil Engineering, Semarang State University, Indonesia

Keywords : transformation, inequality, spatial.

***Abstract:*** This study is the preliminary research of spatial inequality in Central Java and Yogyakarta. Inequality within the same country occurred because of the differences in structural transformation at the same time in different regions. Java has two centers of growth, Jakarta and Surabaya. This two centers create an axis from west to east. This axis was started in 1808-1811 when the Dutch build the `Grote post weg´ connecting west Java (Anyer) to east Java (Panarukan) in the north coastal region of Java, later it was built until Banyuwangi. Among this two centers, Central Java plays as the `transit´ region.

This study analyzes structural transformation using Location Quotient, to identify the shift away from agriculture to non-agriculture over the time intervals 1990 until 2000, 10 years before the decentralization policy was implemented and 10 years after it. Williamson Index is used to show the inequality trend between north and south corridors of Central Java and Yogyakarta provinces.

This study shows that the transformation from agriculture to non-agriculture in north corridor implies a decline in the inequality trends. Many regions in south corridor are in primary sectors especially in agriculture and at the same time, the inequality goes up.

## 1. Introduction

### *1.1 Indonesian Issues*

Thus far, Java has always been the most important island in Indonesia. It is the center of political, economic and cultural in Indonesia. Based on national census, the population shares 64 % (1970), 62% (1980), 60% (1995), 59% (2000), 58% (2010) of the national population (Statistics Indonesia, 2014b). From 1990-2010, Java has contributed 59,03 % of total Indonesia GDP[1] with DKI Jakarta (15,98%) as highest contribution and shared around 60 % of total employee in Indonesia with the highest absorption in East Java.

The major issues of economic dispersion in Indonesia is always concerning about Java and outside Java. Java hosts more than 83% of medium and large manufacture industries in Indonesia (Statistics Indonesia, 2014a). The major non-oil industries are mostly concentrated in the capital of provinces due to the infrastructure accessibility. Those are Greater Jakarta (Jabotabek[2]), Bandung (west Java), Greater Surabaya (East Java) (Hill, 1990; Resosudarmo et al., 2002). This spatial concentration has induced the agglomeration in west part (greater Jakarta) and east part of Java (greater Surabaya) (Kuncoro, 2002). Both provinces has been recorded as the most dense population in Java (Statistics Indonesia, 2014b). Some of manufacturing are also found in Semarang and few regions in Central Java (Henderson, J. Vernon and Ari Kuncoro, 1996). The rapid economic growth of Java has always attracted people from outside Java to migrate and overcrowd Java.

[1] GDP (Gross Domestic Product) refers to national and province level.
[2] Jabotabek is abbreviation from Jakarta, Bogor, Tangerang, and Bekasi. (Jakarta and the adjacent regencies as the hinterland). Nowadays Depok Regency has been included in Greater Jakarta known as Jabodetabek.

*1.2 Central Java Issues*

Jakarta, West Java and East Java provinces have been contributing approximately 65 % of total employment and 71 % of total production in Java. Those regions are an evident as a substantial industrial spill over. The differences in the employment share of manufacturing industries can mainly cause spatial disparities within regions (Kuncoro, 2002)

As main cities, Jakarta and Surabaya has created an axis from west to east Java in north coastal region. It is a bipolar pattern of urban growth. It can be said that this pattern has been found as the manifestation of De Grote Post Weg[3] (known also as PANTURA[4] road) built by Daendels in north Java. This road takes a significant part in distribution of goods and services from West to East Java (Nas and Pratiwo, 2002). From East Java, the goods later will be distributed to East Indonesia. By the goods and services distribution flows from west to east, Central Java is only a traversed region.

The area of this study consists of two provinces, Central Java and Yogyakarta Provinces[5]. The land slope in both provinces is identified as flat land in coastal region and mountainous region with many active volcanoes in interior region. Based on the natural characteristic as one of the influence factors in spatial development strategies, the spatial as the geographical unit in this study refers to the north, mid and south region[6]. North and South regions development are clearly explained as the priority in national and regional spatial plan development strategy especially in infrastructure development (Central Java Province, 2011; Coordinating Ministry for Economic Affairs, 2011). The regions that crossed by De Grote Post Weg and adjacent to Java Sea are known as the north regions. The south regions are the regions that adjacent to the Indian Ocean. Yogyakarta province lies in mid corridor and south corridor of Java.

In this study, the location quotient (LQ) analysis identifies the structural transformation. Then the transformation is compared to the Williamson Index as an inequality trend index. At the end, the inequality index will be equated to the inverted U-shaped curve from Kuznets.

**2. Economic Dualism and Structural Transformation**

*2.1. Economic Dualism*

The economic growth focuses on only three key sectors: agriculture, industry, and services (Kuznets, 1973). The economic dualism theory divides the economic sector into two sectors: the agriculture sector as the traditional sector and the industrial sector as representing of the modern sectors (Boeke, 1978). Economic development implies the agriculture s share of gross economic product decr industry s share increased. The structural transformation later will cause the shift of employment structure and of the education degree required of the occupation. Also, it will enlarge a new employment opportunity and increase the population in urban areas.

Most of the regions in Central Java and Yogyakarta are still on the first stage of development that refer to agriculture, mining and quarrying which are the primary sector. The secondary sectors are manufacturing industry; electricity, gas and water supply and construction. From 1990-2010, the contribution of the primary sectors to GDP and employment in Central Java and Yogyakarta provinces tend to decline. Figure 1 indicates that since early 1990s, the position of the primary sectors in Central Java and Yogyakarta have been gradually replaced by the secondary sectors as the main contribution of GDP. Though the growth and the transformation is not as aggressive as in Central Java, the secondary sector has been growing continuously in Yogyakarta.

[3] Grote Post Weg come from the Dutch language which means the great post road.
[4] PANTURA is abbreviation from Pantai Utara Jawa (the north coast of Java, Indonesian, red)
[5] Central Java Province consists of 29 regencies and 6 cities. Yogyakarta Province consists of 4 regencies and 1 cities.
[6] North, mid and south regions lie as the corridors.

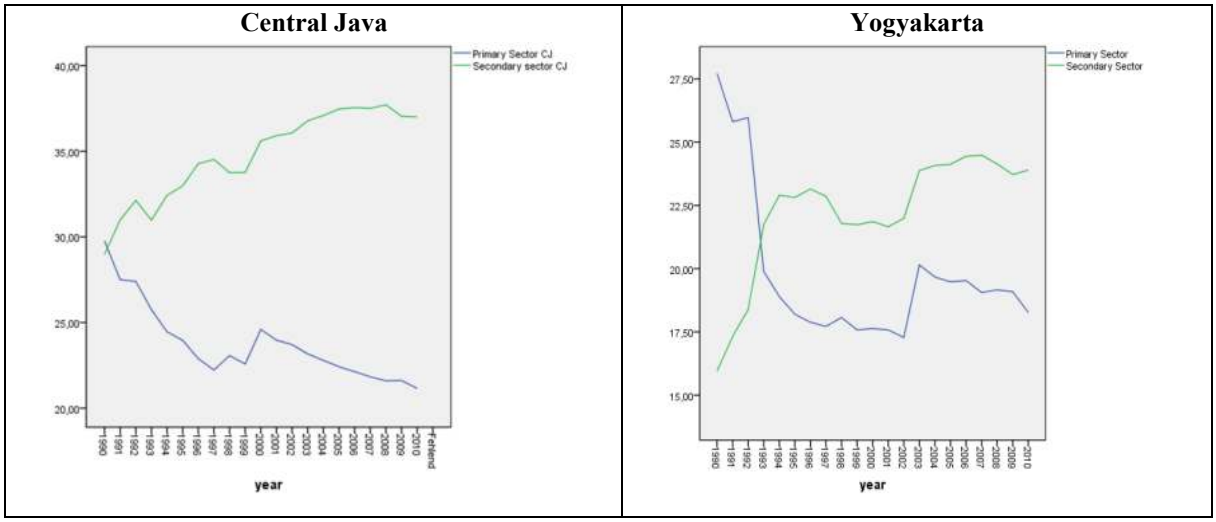

Figure 1. The Primary sectors and the secondary sectors in Central Java and Yogyakarta provinces from 1990-2010.

*2.2. Structural Transformation and Regional Specialization*

The structural transformation will be measured by the simple Location Question ( ) indicator. is used to rate the regional specialization in certain economic sector and in particular time[7]. This formula will identify the shift of the employment[8] structure in each region and corridor. The specialization index is defined as follows,

$$\frac{}{}^{1} \quad \text{or} \quad \frac{}{}$$

Where is the employment in sector in given city/ regency is the employment in industry in the region; is the total employment in state *J* and is the total employment of region. The result from this formula if > , it means that the ratio of certain employment in particular industry in given state at year is bigger than the ratio of region in the same item comparison. The city/ regency is more concentrated in that certain sector compared to the region. And if < , it means that the ratio of the certain sector in GDP and employment in particular industry in given city/ regency at year smaller than the ratio of the reference region.

Figure 2 indicates that the agriculture is concentrated and specialized in south corridor. The trend line in fact fluctuated but it tends to decrease ( $_{995}$ = 1,29; $_{2000}$ = 1,23; $_{2005}$ = 1,35; $_{20\ 0}$ = 1,29). The south corridor, precisely in Cilacap[9], has natural endowment especially in oil and gas. Thereby at early 1990 s, the manufacture industry (non-oil and oil industry) contribution[10] to GDRP corridor could surpass the manufacture industry contribution to GDRP in north corridor. But after 2005, it has slightly decreased due to the fluctuation world oil-gas price and productivity.

[7] Concept ( Bendavid-Val, 1991; Isard, 1998) in general is a comparison of two levels relationships between certain region in selected variable and the reference variable in reference area in higher level (national level) during in particular time.

[8] The data is not included the informal sector

[9] The Refinery Unit (RU) IV Cilacap is the major Refinery Unit in Java. It supplies 34 percent of the national fuel or 60 percent of the fuel needs in Java. Currently Cilacap refinery capacity has reached 348 thousand barrels per day (BPSD). In 2015 the capacity processing will increases 17,8 % barrels per day. It is the largest among the five other oil refinery run by PERTAMINA as RU II Dumai, RU III Plaju, RU V Balikpapan, RU VI and RU VII Balongan, Sorong.

[10] GDRP (Gross Domestic Regional Product) refers to cities and regencies level

The non-oil gas industries have been progressed in north corridor. The industry in north corridor is the highest among other corridors. Although some regions in north corridor remain as agriculture but the agriculture is the lowest level among other corridors.

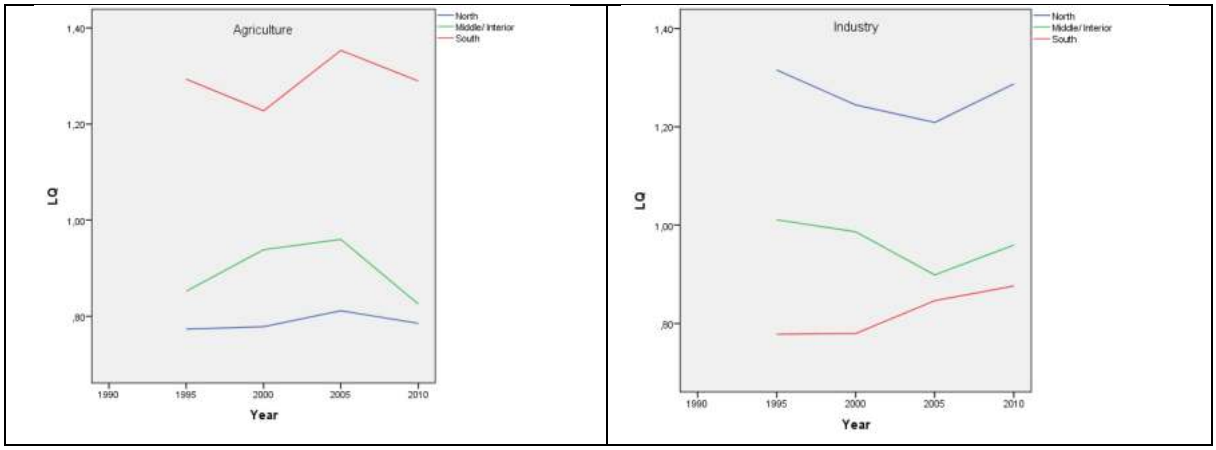

Figure 2. LQ Agriculture and non-oil Industry by employment[11] in north, mid and south corridors.

In 1995, the industry gap between mid and south corridors was relatively wide but later the south corridor ( $_{995}$ = 0,78; $_{2000}$ = 0,78; $_{2005}$ = 0,85 and $_{20\ 0}$ = 0,88) could catch up the mid corridor ( $_{995}$ = 1,01; $_{2000}$ = 0,97; $_{2005}$ = 0,90 and $_{20\ 0}$ = 0,96). These numbers are an evidence that the government policy to build up the manufacturing industry encourages the growth of manufacture in south corridor.

### 3. Patterns of Structural Transformation and Spatial Inequality

The major aspect of structural transformation will include the transformation from agriculture to non-agriculture and later from industry to service that also corresponding to labor occupation change (Kuznets, 1973). In early stage of development, the inequality will increase but later decrease, as the transformation of economic based occurred ( Lewis, 1954; Kuznets, 1955). The inverted U-shaped curve from Kuznets shows that in the early stage of economic growth, all the regions were equal then become increasingly unequal but it will improve in the final stage of economic growth.

Spatial inequality refers to the level differences on some particularly variable (usually income) at the different spatial or geographical units (Lall and Chakravorty, 2005). It also describes that history, natural resources, human capital, local political economy, and cultural are the contributory factors of the spatial inequality within regions.

The inequality index will be measured by the Williamson Index. There are two ways to measure the Williamson Inequality Index (Hassan, 2004): a weighted coefficient of variation by region share of the population ( ) and unweighted coefficient of variation ( ) by region share of the population but weighted by number of regions. The Williamson Index is defines as follows:

$$= \{ \overline{[ \quad ( \quad ^2 ) / \ ]} \} /$$

$$= \{ \overline{[ \quad ( \quad ^2 / ) \ ]} \} /$$

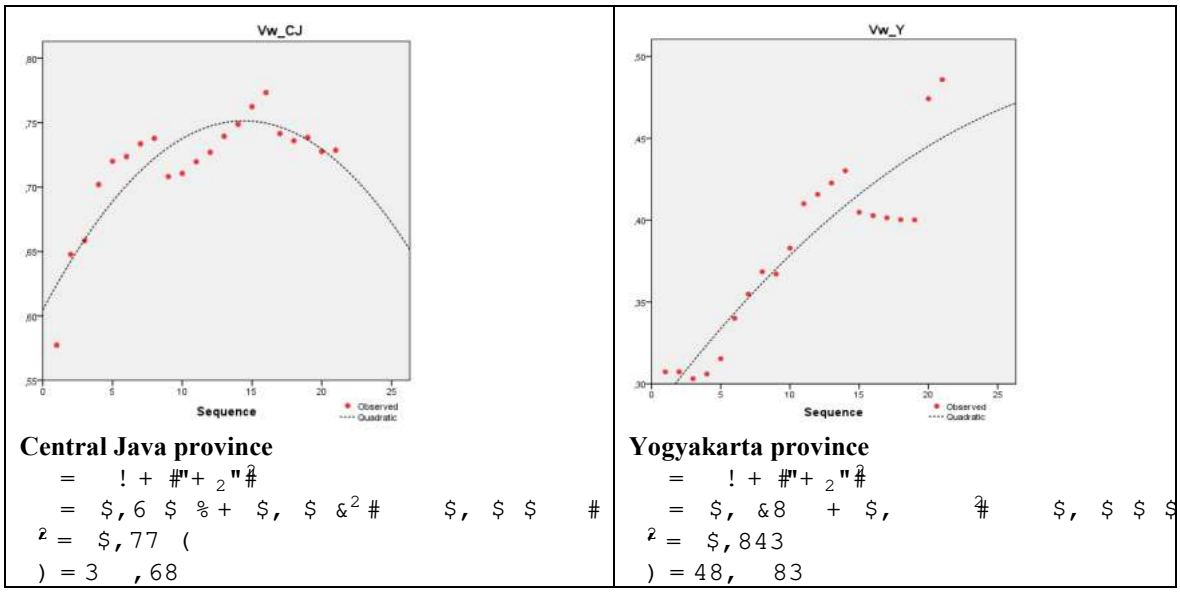
Where is weighted coefficient of variation and is unweighted coefficient of variation; is income per capita of region and is national per capita income; is population in region and is

[11] The data for the employment structure is available since 1993 in all regencies and cities in Indonesia, but in 2000, the employment structure data in Yogyakarta provinces is not available.

national population; is number of region. In this study, will be used. Kuznets has explained that population has the significant role in economic growth. The high rate of growth of per capita product and of population is one of six characteristic of Modern Economic Growth. Therefore weighted coefficient by population share is more realistic. Based on the R square, the polynomial (quadratic) is a better model to assess the trend of the Williamson Index. The equation will be used:

$$= \; ! + \#" + {}_2"\#$$

Where is the year and # is the Williamson Index.



**Central Java province**

= ! + #" + 2"#

= $,6 $ % + $, $ &2 # $, $ $ #

2 = $,77 (

) = 3 ,68

**Yogyakarta province**

= ! + #" + 2"#

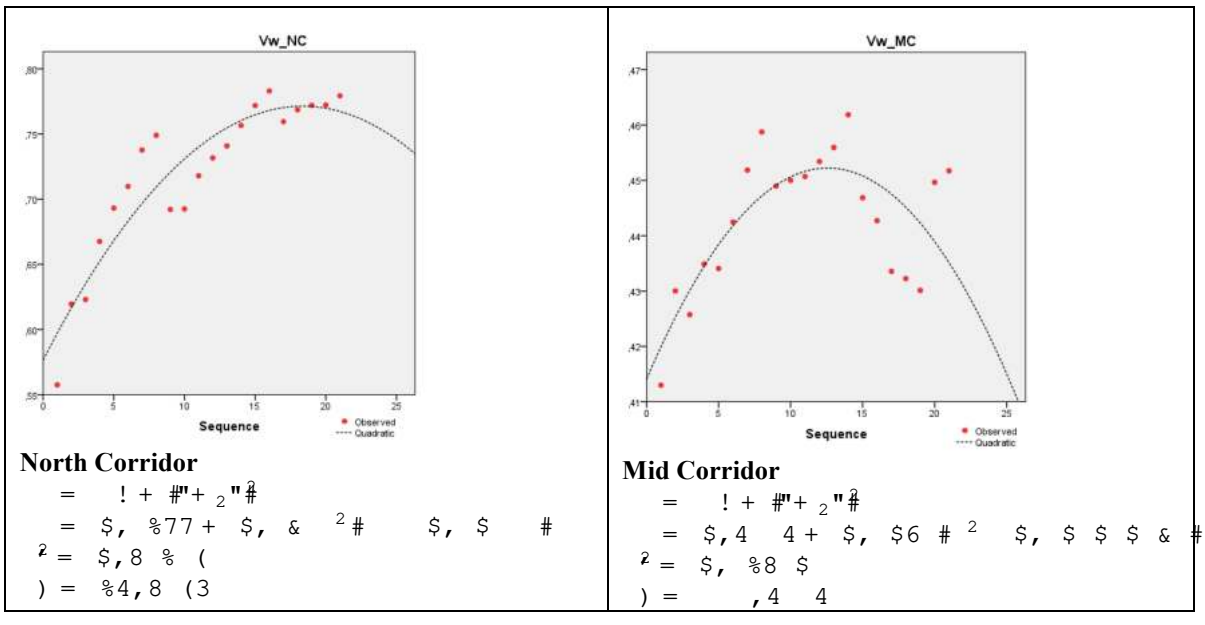
= $, &8 + $, 2# $, $ $ $ & #

2 = $,843

) = 48, 83

Figure 3. Williamson Index Estimate and Observed Curve for Central Java and Yogyakarta Provinces

Based on the inverted U-shaped curve, the inequality trend in Central Java has reached the critical point in 2005 later it tends to decrease. By contrast, Yogyakarta has not yet reached the critical point. It signifies that the inequality trends in Yogyakarta continue to increase (Figure 3). The highest index so far in Central Java 0,77 reached in 2005 and in Yogyakarta 0,49 reached in 2010.



**North Corridor**

= ! + #" + 2"#

= $, %77 + $, & 2# $, $ #

2 = $,8 % (

) = %4,8 (3

**Mid Corridor**

= ! + #" + 2"#

= $,4 4 + $, $6 # 2 $, $ $ $ & #

2 = $, %8 $

) = ,4 4

Figure 4. Williamson Index Estimate and Observed Curve for North and Mid Corridors.

Although the inequality trends in north and mid corridors fluctuated, figure 4 shows that both corridors have already experienced the inverted U-shaped curve and reached the critical point in 2005-2006. In south corridor (figure 5), the inequality index increases and it has not yet reached the critical point. So far, the highest inequality index ( ) in north corridor was 0,76 in 2006 and in south corridor was 0,85 in 2008.

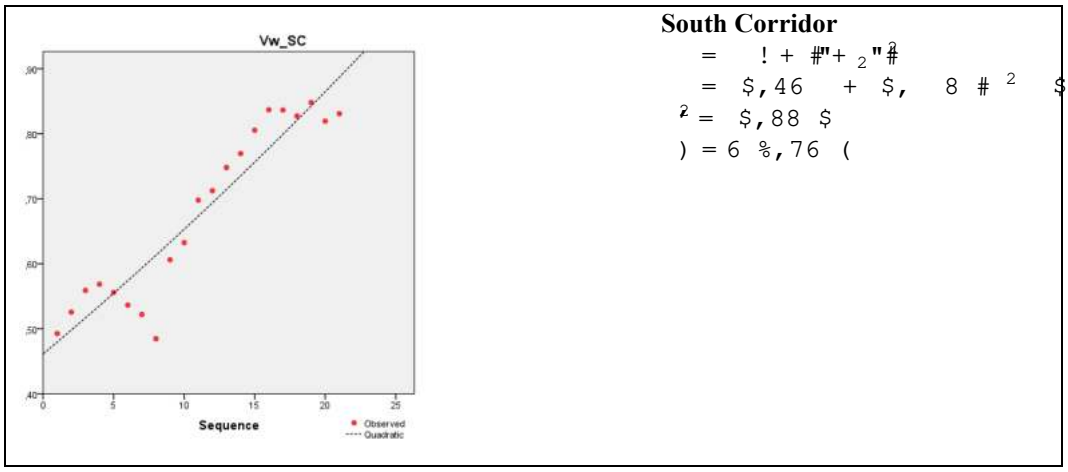


Figure 5. Williamson Index Estimate and Observed Curve for South Corridor.

The pattern of the structural transformation and the spatial inequality can be defined as an inverse relationship. The industry trend line in regional specialization (figure 2) has the opposite direction to the inequality trend line (figure 4). In north and mid corridors, the $_{2005}$ in industry significantly decreased that implied an increase of inequality trend. After 2005, the industry in both corridors have consistently increased and contrary, the inequality trends have gradually declined. In south corridor, the industry has been unspecialized ( <1) and the inequality trend slightly goes up.

## 4. Conclusions

Structural transformation from agriculture to non-agriculture as the creation of the modern economy and of employment opportunity has led to the rapid growth of Central Java and Yogyakarta province. Although most of the regions in both provinces are agriculture but the contribution of agriculture to GDRP and employment tend to decrease. The secondary sectors have replaced the primary sectors as the contribution to GDP in Central Java and Yogyakarta provinces.

The spatial differences between north, mid and south corridors have carried the divergence of spatial development. The north and mid corridors, where cities and manufactures are located, have been generating higher economic growth than south corridors. The spread effect from the cities to the surrounding regencies were not as massive as the government expected especially during the centralized system before 2000. The economic dualism and the regional specialization between agriculture in south and manufacturing as the modern capitalist in north are consistently occurred. Consequently, the inequality between north and south corridors increases. The manufacture location has affected the spatial inequality

Kuznets curve shows that in early stage of development, the inequality will increase but later will decrease, as the growth and development occurred. Manufacture industry is applied as the engine of economic growth. The transformation from agriculture to manufacture industry has provoked a decline in spatial inequality.

# ACTUALLY VARYING NEOLIBERALISM IN A GLOBAL ZONE: DEVELOPMENT PHASES IN SYDNEY S DARLING HARBOUR

Glen Searle

University of Queensland, g.searle@uq.edu.au

Key words: neoliberal urbanisation; neoliberal policy path dependence; neolibera

## Abstract

This paper traces the successive phases of the redevelopment of the Darling Harb as a central focus of the city s transformation into a global city since the 198 the paper is to identify the different versions of neoliberalism employed in eac the institutional and politico-economic factors that have generated varying vers in the same zone. The paper takes the premise of Peck, Theodore and Brenner (200 neoliberalism in practice is an imperfect vehicle that has to accommodate existi institutions and political structures as a starting point. The distinctive contr demonstrate how neoliberal outcomes in a given area draw selectively on such con consequentially to show how the place-specific practices of neoliberalism can va time as different factors are drawn on at different times according to micro-pol changing development objectives. The paper analyses four stages of redevelopment Harbour area, using primary and secondary sources, to develop its argument: the Authority scheme of the 1980s; the City West Development Corporation redevelopme area in the 1990s; the post-2000 redevelopment of remaining old port land by the Delivery Authority; and the current redevelopment of convention and entertainmen private Lend Lease Corporation.

## 1. Introduction

This paper traces the successive phases of the redevelopment of the Darling Harbo a central focus of the city s transformation into a global city since the 1980s. paper is to identify the different versions of neoliberalism employed in each ph institutional and politico-economic factors that have generated varying versions same zone. As part of this objective, the paper uses this analysis to assess the evolution of neoliberal policies in Darling Harbour indicates some of the basic al (2009) about the nature of neoliberal urbanisation including the role of loca the potentially contradictory notion of policy congruence.

The paper analyses four stages of redevelopment of the Darling Harbour area, usi secondary sources, to develop its argument: the Darling Harbour Authority scheme City West Development Corporation redevelopment of the western area in the 1990s redevelopment of remaining old port land by the Barangaroo Delivery Authority; a redevelopment of convention and entertainment centre land by the private Lend Le

## 2. Neoliberalism and urban development

Neoliberal policies underlying contemporary urban development took root in the 1 entrepreneurialism became the leitmotif of urban governance (Harvey, 1989). Nev urban policies cannot be seen as a hegemonic, unvarying entity applied unvarying

cities (Connell and Dados, 2014). Instead, Brenner and Theodore (2002) have argu
policies are contextually embedded through their production within legacies of i
frameworks, policy regimes, regulatory practices, and political struggles. They
resulting process and outcomes as actually existing neoliberalism . This means
narratives have a disconnect with micro-level accounts of local urban policies a
al, 2014). Paradoxically, as Jessop (2002) notes, there might be an increase in
neoliberalism. Thus there is a combination of rollback neoliberalism of opposi
forms and rollout neoliberalism of new modes of regulation and new forms of st
(Peck and Tickell, 2002). Peck et al (2009, p.52) see these processes as operati
error experimentation, more often than not under a situation of crisis that can
dysfunctional consequences.

Given the locally and transiently embedded nature of urban neoliberal policies,
whether it is possible to discern underlying influences and communalities in suc
which we can make connections between neoliberalist policies in one city and pol
or indeed between policies over time in a given city, and thus gain deeper under
(2009, p.61) have produced a table that summarizes key features of mechanisms of
urbanism. The key outcomes of rollout mechanisms they list are a checklist that h
comparative analysis, and that describes significant aspects of the case study i
outcomes include:

- Creation of mega projects to attract corporate investment (in Darling Harb
phases 1,3 and 4)
- Creation of privatised spaces of elite/corporate consumption (casinos in p
convention and exhibition centres in phases 1 and 4)
- Rolling forward of the gentrification frontier and the intensification o
polarization (high income apartments in phases 2, 3 and 4)
- Adoption of principles of highest and best use as the basis for major la
decisions (phases 2, 3 and 4)
- Imposition of decontextualized best practice models derived from extra-j
(phase 1)

However, the re-organisation of regulations and institutional structures that pr
not have a similar checklist. Such re-organisation must be contextually generate
and will thus be the product of that context and less amenable to comparative an
(2014) argues that the current urban governance environment of starved resources
returns is producing policy imitation rather than innovation. Peck et al (2009)
similar view, that neoliberalism was producing heightened congruence and increas
of reforms. Jones and Ward (2002) reach a similar conclusion drawing on Offe s (
conceptualisation that there has been a crisis of rationality, an objective inab
the socio-economic system, and that this has generated unintended consequences t
contradictions of accumulation producing a crisis of crisis management (Jones an
133). Jones and Ward (2002, p.134) suggest that one implication of this schema
repertories become exhausted, with old policies being recycled and new ones borr
elsewhere via speeded up policy transfer. But the notion of policy congruence rem
in contradiction of Peck et al s emphasis on the path-dependent nature of neolib
which locally contextual paths are surely dominant. The importance of the latter
changes responding to crises is emphasised by Jessop (1990), with changes select
effectiveness, which in turn depends on path-dependent specific structures of op
1990; Gualini 2006, pp.886-887).

A central purpose of this paper is to take up this issue of emerging policy cong
the extent to which the four phases of neoliberal policies in Darling Harbour ha
more congruent over time between themselves and/or with wider neoliberal tendenc
is to explore the micro-politics of policy in each phase to help understand the
neoliberal policies over time in Darling Harbour. The following sections describ
phases of Darling Harbour s redevelopment, and are followed by an overview of th
they help to answer the paper s central questions.

## 3. Phase 1: Darling Harbour Authority (1984)

Darling Harbour has been a port area since the early days of the city. The cons
to the south at Botany Bay in the late 1970s, to relieve congestion in port acti
generally, caused an extensive area of land at the southern end of Darling Harbo
for redevelopment. By 1983 a government study had identified preferred developm
educational-entertainment park, Chinese garden, major residential complex, fores
maritime museum (Young 1988, p.193). In 1984 the New South Wales (NSW) state Pr
announced that Darling Harbour would be developed as the state s major contribut
Australian bicentennial program for 1988. This came as NSW was emerging from it
in fifty years. The project would be part of a Keynesian program of major works
motorways and rail lines to stimulate the economy. The Darling Harbour developm
firmly oriented at capturing more of the already expanding global tourism number
one of three economic development foci of the Premier. The project would have m
convention buildings, a harbourside market and a hotel along the foreshore, as w
garden and maritime museum. A casino would be developed, with the state licence
recoup much of the project s development costs.

With a deadline of only three and a half years to demolish and rebuild over 50 h
land, a strongly pro-development institutional framework was established. In Se
Darling Harbour Authority (DHA) was set up by an Act of state parliament (Table
Authority s board contained appointees of the government, including several from
The Authority itself had sweeping powers, able to make its own planning controls
state planning act (the Environmental Planning and Assessment Act) and outside t
proceeded to produce its own development strategy by the end of 1984. The desig
responsibilities of the Authority were given to private companies which reported
executive. A Quality Review Committee was appointed to monitor the quality of t
process (Young 1988, p.195).

Table 1. Institutional arrangements in each phase of Darling Harbour redev

The DHA was an example of UK-inspired path dependency. Its inspiration was the Docklands Development Corporation, recently established. The LDDC had similar p planning and development, and had a similar goal of revalorising obsolete public end, Darling Harbour was not the electoral success that the government had hoped design was criticised by leading commentators such as Deyan Sujic (1992): the te Rouse-led redevelopment of Baltimore s waterfront, and Rouse himself was employe in early planning stages by the DHA. The promised people mover became a priva that required special state legislation because of major public and city council destructive visual impact at the city end. The first licence for the casino was operators were suspected of mob connections in the US, and a casino was not buil Searle and Bounds 1999).

## 4. Phase 2: Pyrmont-Ultimo (1992)

The redevelopment of the Pyrmont-Ultimo peninsula to the west of Darling Harbour under the City West Development Corporation which was established for that purpo Byrne 2002; Searle 2005). This had its genesis in 1988, when the Central Sydney the peninsula s development potential. The new Liberal-National State governmen potential for several reasons. Pyrmont contained a number of major government s soon were to) become surplus, and redevelopment of these sites could generate fu state debt which soon emerged as a major ideological concern for the government. surplus government sites (especially port areas after the construction of Port B increasingly obsolete industrial sites on the peninsula such as the wool stores, help the government s main urban policy, urban consolidation, promulgated princi infrastructure costs arising from a welfare state fiscal crisis. It would also boom-time pressure on central city office accommodation.

Accordingly the government prepared a City West regional strategy for the penins west areas with large surplus government land holdings. A draft City West Regio Plan (REP) to provide for a large increase in population and jobs was exhibited adopted (gazetted) in 1992 (Table 1). The population would increase to 16 500 ( in 1986), and employment would increase from 14 000 to 54 000, complementing CBD The strategy became financially feasible when the Commonwealth government signed agreement with the State government to provide it with $117m of Building Better funds for redevelopment. An Urban Development Plan (UDP) containing development Pyrmont and Ultimo was produced by the government in 1993.

To fast track development in Pyrmont-Ultimo, the REP contained several key mea
the area for redevelopment, bypassing local council powers to do this under the
Planning and Assessment Act (EPA Act). In addition, it laid down the development
council or the Minister for Planning was required to consider before allowing dev
under the REP, the UDP would replace the standard local government development c
EPA Act. Finally, the REP contained a new planning instrument, Master Plans.
applicable to key sites in Pyrmont-Ultimo mainly located on the waterfront, and
preferred type of development. The Minister for Planning would approve developm
areas, thus eliminating developer concerns about local government approval. The
Master Plans to be prepared by site owners or lessees, which delivered a high de
control to owners and developers. The largest master plan site was an old sugar
bought by major developer Lend Lease prior to promulgation of the REP. With the
Lease produced a master plan that allowed development well above the limits set
area it increased allowable development from a single 21storey tower to four tow
that was 30 storeys, to maximise profits from providing harbour views (Searle an
These and other apartment blocks would be sold to incoming professionals, drivin
population out as rents rose.

Accompanying the new plans and planning procedures for Pyrmont-Ultimo was a new
City West Development Corporation. This did not require new legislation that mi
difficult for the government to pass in a now hung parliament: instead, the corp
set up under the provisions of the 1970s Growth Centres Act that was intended to
cities beyond the metropolitan area. The Corporation became the development agen
peninsula. It would administer development of the government sites and the coord
major infrastructure, as well as be responsible for the general implementation o
plans. This included responsibility for public participation programs, which we
perfunctory and increasingly biased over time.

Community opposition to the government s plans for the peninsula steadily grew.
continued apace, with few concessions to local concerns. In sum, the Developmen
the central agency in achieving fast track development on the peninsula, making
by-passed normal planning processes, and paying scant regard to the community s
existing distinctive working class character of the area.

## 5. Phase 3: Barangaroo 2005

The Barangaroo project has involved the redevelopment of the last shipping wharf
dockside land in Darling Harbour, totalling 22 ha, located north-east of the Dar
Authority s area. Value capture from development of the southern part of the sit
necessary infrastructure and construction of a large harbourside park across the
site. The initiative responded to a crisis in the form of a downturn in the loca
stagnant construction sector, in the years immediately following the 2000 Olympi
2013). The state government saw redevelopment of the site as a major office prec
construction in the short term and enhancing longer term economic development by
Sydney s role as a global financial services hub in the Asia Pacific region (Ba
Authority 2010a). Following the success of the Olympic Games delivery authority
projects of the Olympics delivered to a tight time schedule, another version, the
Authority, was set up to ensure timely and efficient development of the site.

An international design competition for the site was held in 2005. The governmen
space levels and a condition for half the site to be public parkland ( Headland
consortium won the competition. The winning entry generated a concept plan that
the government in early 2007, using new Part 3A powers under the Environmental P
Assessment Act whereby the Minister could approve major projects and bypass the
(Table 1). The land was rezoned by the government in late 2007. The maximum fl
would be approved was set at 388,000sm. Development rights and a 99 year lease w
Lend Lease, in return for providing waterfront plaza infrastructure and funding
Headland Park, building a pedestrian tunnel from the nearest rail station, and r
cruise terminal, at a total cost of $A521m (Barangaroo Delivery Authority 2010b)

Almost immediately the concept plan became deeply contested. Land Lease lobbied
extra 120,000sm of floor space. The state s planning system allowed developers t
after approval of initial project parameters at the Master Plan stage, and the P
was being played out again by the same developer. Then the design excellence rev
by former Prime Minister Paul Keating, altered the concept plan to reinstate t
more natural physical form that would be more akin to the landscape as it was
in the early eighteenth century. The extra costs of $A150m required to construct
elements (Lenaghan, 2010) were traded off against increased maximum heights for
Accordingly, Lend Lease applied in 2010 to increase office space by another 60,0
the height of the towers to a maximum of 209m which would create valuable new co
views.

Much of the extra floor space was allocated to a new high rise hotel that would
jutting out into the harbour. There was intense opposition from at least three c
saw the iconic status of the harbour as being under threat (Searle, 2013). In re
approved a reduction in the office towers from four to three but keeping the tot

Liberal–National state government, elected in March 2011, bowed to this oppositi
hotel and pier proposal. Nevertheless, the demands by Lend Lease after 2007 to e
had led by early 2015 to a total approved floor space that was 70 per cent greate
concept plan (Ruehl, 2015).

Following this, an unsolicited proposal for a casino for international players,
accommodation, was put to the government by Sydney mogul James Packer. It would h
site designated for foreshore parkland in the concept plan. This would require a
be awarded after the expiration of the competition-free period that went with th
licence in the 1990s for the Star City casino on the other side of Darling Harbo
was invited to submit an alternative casino expansion plan, but was unsuccessful
company winning the right to the new licence. The Packer bid came with a full de
involving an iconic building prepared by a leading UK architect that would be
(except for an observation tower). Most of the upper floors would be luxury apar
higher ones being able to see over the ridge at Observatory Hill to the panorama
the harbour, including the Opera House. The proposal is now with the government
is doubtful that the state will require significant reductions given that it has
principle, despite the City Council s opinion that the increase in public benefi

## 6. Phase 4: South Darling Harbour

The fourth and latest phase in Darling Harbour s redevelopment has involved the building of the 1980s Sydney Convention and Exhibition Centre (SCEC). To this ha redevelopment of remaining government land south of the original 1980s Darling H construction area, including rebuilding of the state government s 10,000 seat En that opened in 1983.

. The initial stimulus was provided by private sector lobby groups, the Property and the Tourism and Transport Forum, which commissioned a study of deficiencies convention and exhibition industry capacity. The study, published in early 2007 2007), concluded that SCEC capacity constraints were causing 40 events a year to $A218m p.a.), and that expanded capacity would increase exhibit use by 16 to 32 government then commissioned its own review, the O Neill Report by the head of i agency, published in early 2008. It supported the PCA–TTF report, finding that a and exhibition space was costing Sydney s economy $A477m a year (Hall, 2010), bu expansion of facilities at Olympic Park in addition to expansion of the SCEC (Ci The latter component was challenged by the Exhibition Organiser s Coalition, who relegated far from the city centre at Olympic Park (City of Sydney, 2013a). From government requested the Sydney Harbour Foreshore Authority, the successor to th Authority, to develop design proposals to rework and upgrade the existing SCEC f entertainment centre. Master plan proposals were developed centering on expansio government commitment to expansion stalled.

. However, Sydney s slowing economic growth, especially relative to its great riv significant state political issue. Expansion of SCEC facilities was seen by the right–wing Liberal–National Coalition opposition, Barry O Farrell, as an opportun initiative here. In March 2010, a year before the next election, he promised to private partnership development of a new convention and exhibition centre if the elected (Hall, 2010). The infrastructure lobby group Infrastructure Partnerships a pre–feasibility consultant study of a new centre that was presented to O Farre (Infrastructure Partnerships Australia, 2010). The consultant s report concluded was the best location for either new or expanded facilities due to the generatio revenues from higher levels of established foot traffic, and ability to integrate surrounding Darling Harbour including the CBD, major hotels and transport networ entertainment facility should be included for up to 10,000 people. The cost of re convention and exhibition facilities was estimated to be $A630m. The Coalition w with proposals that were largely consistent with the IPA recommendations.

.

. The Liberal–National Coalition won the state election in March 2011, and almost announced that the size of the project would be increased by two–thirds, includin (containing a car park and the existing Entertainment Centre) in the monorail co the SCEC where redevelopment potential would increase when the monorail was shor This southern area the Haymarket precinct – would be redeveloped for mixed use SCEC developer via a direct project agreement with the government involving a fee develop, and not as a PPP (Table 1). This arrangement would also apply for a new at the northern end. It is unclear why the winning developer of the SCEC was all blanche for the southern redevelopment. But it is probably significant that the Infrastructure NSW agency, set up by the new government to recommend infrastruct given responsibility for managing the redevelopment, was headed by Nick Greiner in a neo–liberal government ideology to the state when he became state Premier i

The SCEC requirements for redevelopment set out by Infrastructure NSW for biddin specific in terms of size  principally an exhibition centre of 40,000sm, a conv accommodate 10,000 people, a meeting room space of 8,000sm between the two centr premium entertainment centre holding up to 8,000 people. Urban design guidelines were also set out. These covered  reorientation , connectivity, activity, and op realm (Sydney Harbour Foreshore Authority and Infrastructure NSW, c2012). These general, such as  Building a place that invites tourists, visitors and locals to were a little more specific such as requiring new east–west and north–south conn reduction of open space. These requirements allowed bid consortia considerable f planning and design, especially in the Haymarket precinct where building size an very much developer-determined. This resulted in a virtually privatised planning successful bid was selected mainly on financial criteria and to some extent the the new convention and exhibition facilities.

The winning consortium was headed by Lend Lease, who thus had carriage of anothe Darling Harbour redevelopment stage. The consortium s proposed development was a professionals and the City Council (which was excluded from the planning process designated as a state significant project). The demolition of the existing exhib won a Sulman Medal, the highest award in Australian architecture, was criticized and relocation to serve unmet state needs was proposed as a priority (City of Sy 2013). ICOMOS considered that the scale of the redeveloped SCEC would  overwhelm century historic buildings  and significantly compromise and reduce the harbour setting  (ICOMOS International Scientific Committee on 20th Century Heritage, 2013). The consortium s proposals for Haymarket found some support from the City Council, i of new connections as per the urban design brief, but were criticized for over-d of critiques of previous Lend Lease developments in Darling Harbour:

 There is one too many residential towers that block views and generate overshad and cores have no setbacks from the street alignment to ameliorate wind downdraf housing is too high in its context and overshadows the Powerhouse Museum forecou Sydney, 2013b)

More generally, professionals were critical of the covert non-public planning pr Sydney University architecture professor said that a separate master plan should taking public opinion into account. Instead, the government had  wrapp[ed] the m tender process  (Hasham and McKenny, 2012).

## 7. Overview and conclusion

The Darling Harbour case studies support several key contentions made by leading commentators about the nature of contemporary neoliberal processes in city devel rationale for a new round of neoliberal projects usually has a context of crisis cases above, these include the perceived need for major projects/redevelopment i growth (phases 1 and 3), a state fiscal crisis (phase 2), and a competitive cris sector (phase 4). The contention that neoliberal responses are path dependent on finds support. The development corporation structure used in phase 2 derived fro enacted for a very different kind of development, which was required because of situation of the time. The delivery authority used in phase 3 probably owes much similar authority used for the Olympic Games. There is probably an element of pa

involvement of Lend Lease as the major developer in phases 2, 3 and 4, although
knowledge about linkages between its successes.

On the other hand, there is also ample evidence of using approaches and solution
common internationally. The use of a UK-style development corporation to produce
development in phase 1 is the standout here. The output mix of convention and ex
casinos and up-market high rise apartments is a standard one in global terms. But
neoliberal processes and outcomes in Darling Harbour does not point to policy co
first phase was the most derivative of international policy practice and, arguab
its framing of development behind the deeply contextualised Headland Park is the
fourth phase essentially revisits outcomes from the first phase and updates them
locally path dependent. Finally, the way in which Lend Lease is paying for the r
and apartments in the last two phases and was or has been given the power to mak
plans in phases 2 and 4 (with fewer constraints in the latter) suggests that the
policies are becoming less harshly pro-market (Peck et al, 2009) is dubious in t
context.

Keywords: Urban Renewal Area, Evaluation Criteria, Economic evaluation criteria

## 1. Introduction

Since the 921 earthquake struck Taiwan in 1999, Disaster-Prevention Urba (DPUR) become one of the major considerations in disaster-prevention policy. T DPUR projects by the Ministry of the Interior in 2013 aims to introduce an inte for urban areas with higher disaster risks. However, the need for clear and it criteria for DPUR area selection is crucial. Controversial debates regardi designating the renewal area might result in high-risk area being undervalue low-risk area could be overvalued and stigmatized. Therefore, this research is proper evaluation criteria for DPUR areas in order to balance the possible nega on the renewal area.

This research will be based on the second phase of the DPUR Research Project District, Tainan City, which was brought up by the Ministry of the Interior. buildings risk map, blocks with higher ratio of high-risk buildings per block the potential DPUR areas. Secondly, cost-benefit analysis will be contacted fo different ratio of the high-risk buildings. If benefit exceeds cost then it ma further invest in reducing the risk of disasters. Renewal cost will consider buildings, construction cost and land expropriation cost, etc. Renewal benefit potential disaster loss. This research is expecting to establish a better ev facilitate the designation of DPUR area that could consider both the moral conc feasibility.

### 1.1 Delivering Concept of Disaster-Prevention Urban Renewal

Taiwan is located at the Circum-Pacific Seismic Zone, which has earthquakes a more than 200 times per year. The earthquake in Chiayi in 1906 caused 1,258 deaths, an buildings were completely destroyed; the earthquake in Hsinchu in 1935 caused 3 17,907 buildings were completely destroyed; the earthquake in Tainan in 1964 ca and 10,924 buildings were completely destroyed. On 21, September 1999, the earthquake on record in Taiwan in the 20th century struck Taiwan and took 2,415 buildings were completely destroyed, which also impacted the industry and econom of Taiwan. This fatal earthquake awakened the consciousness of urban disaster forced the government to face the necessity and exigency to review the urban st disaster impact.

In 2013, the Ministry of Interior of Taiwan proposed a new idea Disaster-p Renewal (DPUR), which is an attempt to review the existing urban renewal area consideration of criteria related to the impact of seismic disasters in order to

and increase the resilience these areas via building renovation or reconstructi
the Interior of Taiwan, 2013) Therefore, the primary concern of DPUR is to po
where there are high seismic disaster risks that urgently need to be evalu
However, the existing designation criteria for urban renewal areas in Taiwan ar
enough to clearly identify the DPUR areas.

## 1.2 Urban Renewal Designation Criteria in Taiwan

The urban renewal designation criteria in Taiwan are according to Articles 6 a
Renewal Act. According to Article 6, the areas with buildings that are deterior
to public safety are prioritized to be designated as urban renewal areas. Arti
that the areas with high possibility of being impacted by serious disasters sho
be designated as urban renewal areas. However, the completeness and specificati
mentioned above have recently been widely discussed.

First, the designation criteria for urban renewal areas in the Urban Renew
fundamental and indistinct to give specific and equal handling (Shih, 2008; Sun
The existing designation criteria also fail to deliver a comprehensive consid
prevention for the DPUR area (Cheng, 2011). Second, the designation criteria put
the deterioration of the physical environment but ignore the other local is
development potential. Therefore, although urban renewal improves the condition
environment, it doesn t help the local economic development or the disaster resi
so the public benefit of urban renewal cannot be wide spread (Sun, 2013; Lin,
existing urban renewal area designation lacks a consideration of an area-base
publicly-driven urban renewal areas in Taiwan are determined by an evaluation of
environment and the operability of the plan, and the privately-driven urban re
determined by the market value potential, which therefore tends to be more like
plan. The consequences of both of these approaches for urban renewal lead to dif
improving the disaster resilience and stimulating the economic development of
2008; Sun, 2013).

Therefore, lacking specific designation criteria and a consideration of an area
designated urban renewal areas will not only fail to improve disaster resili
undervalue or overvalue the risk of the areas under consideration. Once high-ris
undervalued, it is possible to misestimate the building tolerances for seismic
will be impossible to lower earthquake casualties when the next earthquake
contrary, once the low-risk areas are overvalued, it is possible to stigmatize
the local development. Hence, this research is an attempt to explore proper eva
DPUR areas in order to balance the possible negative consequences on renewal are

## 2. Literature Review

### 2.1 Urban Renewal vs. Disaster Prevention

In areas with a compact urban fabric, the high-density of old buildings and t
roads threaten the residents life and property safety. Urban renewal seems to
by which to change the urban fabric and improve living quality and safety by
buildings structure, relocating the living infrastructure and redevelopment tar
resilience.

Urban disaster prevention can be gradually created and improved by urban reconstruction, renovation and community planning for disaster resilience, the can be strengthened, and urban renewal areas can be built as the disaster preve surrounding areas. The urban renewal area together with the surrounding blocks, villages can be an urban living circle used to plan for disaster prevention and earthquake (Chou, 2010; Cheng, 2011).

Therefore, in order to reach the goals mentioned above and to maximize the pu urban renewal, we have to clearly evaluate the building conditions and disaster-prevention ability in the process of urban renewal area designation. worse building conditions and disaster-prevention ability should be prioritized DPUR areas in order to decrease the social and economic impacts of earthquakes However, determining the designation criteria that should be used to avoid overvaluing errors that may result in unnecessary impact to these areas require on optimizing evaluation criteria for DPUR areas.

## 2.2 From Renewal to Disaster Resilient: A Case Study of Japan

The concept of urban planning in Taiwan was originated during the Japanese occ had a great influence on the urban development of Taiwan. As a result, these tw similar urban fabric and also have acquired similar urban issues as time has high-density of deteriorated houses in urban centers, narrow and winding a subdivisions. Moreover, Taiwan and Japan are both located in the Circum-Pacifi and are bothered by frequent earthquakes. As the two countries have a similar issues and similar urban disasters, Japan will be used as a case study to compare its designation criteria with that of Taiwan.

The origin of urban renewal in Japan has a close relationship with disaster p Japan, the compact wooden houses frequently caught fire. The great Kanto eart World War II (1937-1945) and the Osaka-Kobe Earthquake (1995) not only serious city but also triggered disastrous city fires that increased the already huge d disasters accelerated the development of urban renewal in Japan and even brought urban disaster prevention. The earliest legislation of urban renewal in Japan c 1924 with the Agriculture Land Consolidation Act, which regulated the mechanism o readjustment. After WW II, the Special City Planning Act was enacted, and in Readjustment Act was revised. It was revised again in 1961 and became the U Remodelling Law.

In 1969, the Urban Renewal Act integrated the Urban District Remodelling L Disaster Countermeasures Basic Act which were attempts to try to combine the re of land with buildings. In the 1990 s, the government enacted the Urban Renaissan Measure Law, which was expected to improve living quality and the urban functi solve the vacancy problems caused by the economic crisis in Japan. In additi focused on the renewal priority of the Urban Renaissance Urgent Development encouragement of private investment initiatives. Lu, 2007;
Regeneration Cases in Japan, 2006

Compared to Japan, the earliest urban renewal plan in Taiwan can be traced back occupation period (1895-1945) when the city fabric was remodelled by the Japanes order to improve sanitation and consolidate the city landscape. In 1964, as the

moved to Taiwan from China, lots of immigrants living together in messy tempo
forced the government to promulgate a new chapter triggering "the reform of the
and development of the new city district" in the Urban Planning Act, which was
1973 to promulgate a new chapter of the urban renewal of the old city district
renewal legislation in Taiwan.

In 1976, as the Public Housing Act was enacted, the government began to colla
military to rebuild the military villages into public housing in order to impro
the city and the urban living quality. In this period, Taipei City experi
development than other cities in Taiwan, so it met the need of urban renewal
cities. In 1983, Taipei initially enacted the local act for urban renewal, but
government enact the Urban Renewal Act for the nation as a whole. The following
921 earthquake struck Taiwan and caused huge casualties. The Urban Renewal Act g
be reviewed and revised in the post-disaster recovery and rebuilding process and
completed after this disaster (Urban Regeneration R&D Foundation, 2011; Zeng, 20

When comparing the urban renewal development history of Japan with Taiwan s, i
that they had different motivations to get involved in urban renewal that led
The motivation of urban renewal in Japan was a result of the post-disaster and p
With economic and social development, urban renewal gradually transformed to la
that took the local economic and social development into consideration. Urban d
also became an important issue in urban renewal. Compared to Taiwan, which was m
on the consolidation of city appearances and the retrofitting of old buildings,
renewal in Japan was transferred from site development to urban redevelopment pl
attention was placed on the integration of urban functions. The Urban Developmen
is taken as another case study.

## 2.3 The Urban Development Plan in Tokyo, Japan

Except for the city downtown areas and commercial centers, Tokyo has a high-
wooden housing communities, most of which are deteriorated and have complex la
Most of these areas lack open spaces and always have narrow and winding alleys,
disaster-prevention issues. As a result, determining how to renew these high-d
communities to strengthen local disaster-prevention seems to be a big challenge
government of Tokyo.

In Tokyo s Urban Development Plan, the urban renaissance areas are classified ac
level, and the areas with higher hazard risks are given priority to be desig
renaissance areas. The Urban Renaissance Urgent Development Areas (URUDAs) are
that are more hazardous in the city that are targeted for urgent renewal. T
Renaissance Urgent Development Areas (SURUDAs) are the areas that are designat
URUDAs. These locations can widely spread the benefits of disaster prevention to
areas and prioritize the building of basic infrastructures.

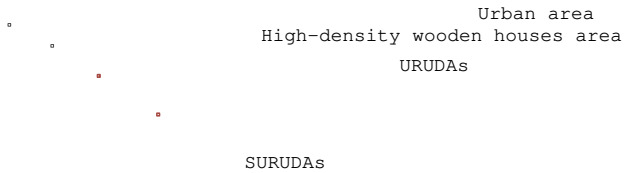

Figure 1 The classification of urgent urban renewal areas in Japan (Chen & Chang, 2005)

The URUDAs and SURUDAs both have time frame limitations related to reaching th the urban renaissance project as shown in the following table. The evaluation cr are made according to the Seismic-risk Area Hazard Investigation Report (the 5th version) by the Bureau of Urban Development in Tokyo. This investigation considers seismic-ris the number of wooden buildings and inflammable areas to create the evaluation cr Chang, 2005

Table 1 A comparison between renewal area and advanced renewal area in Ja Chang, 2005)

| | URUDAs | SURUDAs |
|---|---|---|
| Time frame | 2025 | 2015 |
| Goal | 70% inflammable buildings | 70% inflammable buildings |
| Purpose | Besides renovation, reconstruction and land redevelopment is also encouraged to be promoted by the residents in order to improve disaster-prevention ability in communities. | Besides encouraging renovation, an infrastructure development plan is also promoted in order to improve disaster-prevention abilty. |
| Assessment standards | 1. Evaluate the possible number of the buildings that will be destroyed by an earthquake. The index refers to the Seismic-risk Area Hazard Investigation Report (the 5th version) by the Bureau of Urban Development in Tokyo for which the data is more than 5 points.<br>2. Evaluate the fire hazard index and fire-spread hazard index. The index refers to the Seismic-risk Area Hazard Investigation Report (the 5th version) by the Bureau of Urban Development in Tokyo for which the data is more than 5 points.<br>3. The SURUDAs have to be redeveloped as soon as possible in order to spread the benefit of disaster prevention to the surrounding areas. |

| | | |
|---|---|---|
| | 4. The area which can reach the index below,<br>+ (1 ) 100% 100%<br>osr = open space ratio (%) | |

When comparing Taiwan s and Japan s urban renewal area designation criteri designation criteria has more principle criteria such as deteriorated , la structure and threat public safety, which provides a big framework but lacks follow. In contrast, Japan s designation criteria have more specific indexes such proportion of the household (Shih, 2008). The disaster-prevention criteria and t of Japan are both a good case for Taiwan to learn.

## 2.4 Area-based Urban Regeneration

The case study mentioned above obviously shows that the main purpose of urban re was urban inflammability, which is used as a tool to solve the problem of wooden houses in the city center of Tokyo. With the transformation of the con renewal to urban renaissance, Japan s government raised the level of the urban a higher level, regarding it as a special area of focus with an expectat multidisciplinary collaboration including urban planning, industry and disa Although Taiwan has a similar urban development history and urban fabric with Taiwan does not have high-density wooden houses in its city centers, nor do flammability issues. As a consequence, the urban renewal of Taiwan should be m the issue of comprehensive urban disaster prevention. Learning from the concept urban regeneration, renewal areas should have the ability to improve the condit environment while simultaneously reviewing the condition of the basic local infr degree of disaster preparedness. The purpose of DPUR is not only to strength structures through renovation or reconstruction, but also to improve disaster- entire area using urban renewal as a tool.

The original concept of the area-based approach is from the UK. It was used in policy in the 1970 s, but it was not until the 1990 s that this concept bec popular and was used as a policy by which to improve urban spaces. The ur experiences of Europe in the past 20 years taught that the combination of techni physical environmental with social and legal factors is essential. Although urb can clearly and successfully improve the physical environment, social and econom as unemployment, crime rates and poor education continue in some areas. Area regeneration will not only consider the retrofitting of buildings and the commu also solve the fundamental issues of these local areas, such as crime, unemployment basic infrastructure (Edwards, 2009).

In the process of area-based urban regeneration tries to break the geographic involve not only stakeholders but also other interest groups, as well as tho involvement of future stakeholders. Expecting to together discover local is development potential while improving the physical environment also includes the social and economic development, and even education, housing and transportation Plessis, 2013). Compared to the concept of area-based regeneration, which redevelopment and tends to be small in scale and pays more attention to the im physical environment and increases in market value while contributing very surrounding area, area-based regeneration considers more factors, such as biolog

social contributions. A comparison between these two concepts is shown in the
(Sag, 2010; Sun, 2013):

Table 2 Objectives, methods and evaluation criteria for site-specific and area
efforts (Meyer, 1998; Sun, 2013)

| | Site-specific redevelopment | Area-based regeneration |
|---|---|---|
| Objectives | | |
| Environmental objectives | Reduced human health risks and liabilities | Better regional environmental condition |
| Economic objectives | Tax base increase; job creation on-site | Reduced community drawbacks and specific economic improvements |
| Actual consultation on local community obectives | Minimal; as required by law with respect to community notice and consultation | Potentially extensive; (although development agencies may listen but not act on local concerns) |
| Evaluation criteria | | |
| Time horizon | Short-term completion of onsite development | Long time allowed for expected spill over effects |
| Policy efficacy | Sales for clean up and reuse generated, impact on site values and tax revenues. | New capital flows into area; increase in area economic activity, incomes and property values |
| Public efficiency | Minimum public sector expenditure | Maximum leverage on public funds |
| Public effectiveness | Rate at which private landowners successfully market contaminated sites for reuse | Increase in area economic activity, household incomes; reduction in area drawbacks |

The existing urban renewal in Taiwan is site-specific redevelopment, which emp
physical environmental improvements and increases in market values but ignores
and the development of the entire area under consideration. Lacking a considera
regeneration results in the urban renewal in Taiwan being generally limited t
improvements and a failure to use urban renewal as a tool by which to solve
stimulate economic development. The concept of area-based urban regeneration
more appropriate strategy to respond to local poverty and social-cohesion issue
regeneration will not only emphasize n the renewal of the physical environme
regeneration of the economy. Determining a method by which to attract the inter
and the private sector in investing into these areas has been widely discusse
2009).

Unlike general urban renewal areas, DPUR areas exhibit more investment uncerta
the high-disaster risk and the deterioration in these areas. Although the public
the private sector the successes of the project and provide subsidy assistance, inves
the market profit is still the dominant consideration of the private sector. Th
private sector investment is to show them that this project will be profita
research considers in addition to evaluation of disaster risk and area develop
necessary to add a cost/benefit evaluation of urban renewal. Adding the conside

renewal cost and benefits may increase investment interest and the confidence of
and also raise the proportion of stakeholders, which has the benefit of avoidi
urban renewal area development. The issues mentioned above all reveal the signi
of a cost and benefit analysis in urban renewal designation criteria.

## 3. Methodology

### 3.1 Conceptual framework

This research gives a suggestion of the DPUR area designation criteria for Tai

benefits in order to increase the proportion of the resident involvement a
investment interest. In addition, renewal efficiency in urban renewal areas can b
the visible benefits of DPUR can be seen, such as decreases in disaster losses.

This research is expected to build comprehensive designation criteria for a DPU
of physical environment factors refers to the urban renewal area designation cr
the Urban Renewal Act in Taiwan. In addition, this research refers to the conc
regeneration to take the economic index into consideration. Besides visible
increases in market value, other benefit brought about by the DPUR should also
such as improvements in property safety and decreases in disaster-risk and loss
research follows these two factors to review the existing urban renewal area in Taina
find the optimal evaluation criteria suggestions for the DPUR area. The concept
this research is as follows:

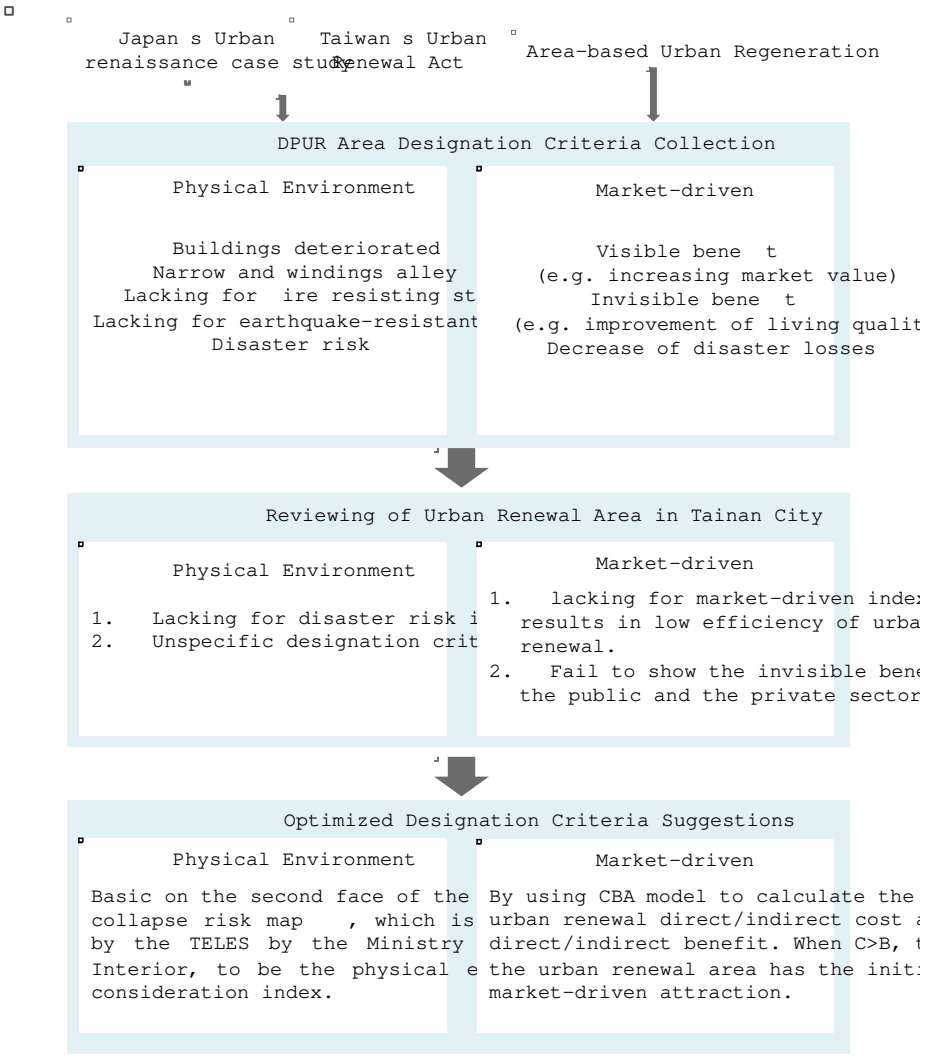

Figure 2 Conceptual framework

## 3.2 Study Area: Yongkang District, Tainan City

Yongkang District and Huweiliao in the East District in Tainan City were chos
areas. There are a total of six faults passing through Tainan City, but only
passes through the urban center and the compact development area in such as way
serious casualties when it triggers an earthquake. Consequently, the area that
passes through was selected as the study area for this research.
Yongkang District is located in the southwest part of Tainan City, which
developmental history that caused there to be a large number of deteriorated bu
the quick development of its transportation, industry and its rapid business
population and urban scale are quickly growing, so the Houchiali Fault may have
this district.

Tainan does not have the local legislation for urban renewal area designation
central legislation spelled out in the Urban Renewal Act. According to Articl
Urban Renewal Act, the areas with buildings that are deteriorated and hazardous

or the areas with high possibility of being impacted by a serious disaster shoul
designated as urban renewal areas. However, the designation criteria in the
principle guidance that not only lacks specific and objective guidance but also
of area-based urban regeneration that emphasizes physical improvements but
economic, social and disaster-prevention issues.

Moreover, the execution of the existing Taiwan urban renewal policies mostly
sectors investment and resident self-renewal, where the purposes of urban ren
misunderstood as market-driven development. This market-driven force becomes th
to whether an area appropriate for urban renewal can be renewed or not. In or
private sector-driven urban renewal projects, lots of incentives, such as tax re
ratio preference have been considered. However, these incentives encourage priv
urban renewal project investments that are mostly located in areas that have
potential. The areas that are deteriorated and hazardous don t tend to attract
resident-driven renewal projects. The renewal project are more focused on actual
on public benefits. Benefits that are not readily apparent, such as decreases i
renewal and increases of property safety and living quality, are ignored.

The following table showing urban renewal area execution obviously illustrates
urban renewal projects have mostly been outside of the statutory urban renewal
representative counties in Taiwan. Especially in Taipei City, New Taipei City a
where the market value in the city is gradually rising, the number of urban ren
the statutory urban renewal area is much greater than the urban renewal projec
urban renewal area. This research s study area is in Tainan City, which has 18 u
but as of 2014, there are only 8 places where urban renewal is actually being
efficiency of the urban renewal is quite low.

Table 3 Urban renewal project statistics for five representative counties in
2014)( Ministry of The Interior, 2014)

| County | The statutory urban renewal area | Urban renewal project in the statutory urban renewal area | Urban renewal project out of the statutory urban renewal area |
|---|---|---|---|
| Taipei City | 235 | 11 | 820 |
| Xinbei City | 67 | 11 | 225 |
| Taichung City | 54 | 1 | 75 |
| Tainan City | 18 | 8 | 0 |
| Kaohsiung City | 12 | 5 | 4 |

This research is based on the second phase of the analysis of the building co
Yongkang District, which was delivered by the Ministry of the Interior in 201
divided into four levels as evaluated by the Taiwan Earthquake Loss Estimation
and the structure, story and the ages of the buildings were comprehensively eva
the building collapse risk map with the existing primary urban renewal area in
shows that the area includes the Feyang military village, the surrounding area
supply depot and the area surrounding the Yongkang Veteran General Hospital.

After overlaying the two maps, the results indicated that the buildings in these areas mostly are low-collapse-risk; the urban renewal area surrounding the sou depot is vacant, and the buildings in the other two urban renewal areas are extremely low-collapse-risk buildings. The following figure also shows that t high-collapse-risk are mostly not in the primary urban renewal area. Consequen primary urban renewal designation criteria in Tainan cannot efficiently respon disaster risk, and the physical environment deterioration for the designation areas in the future need to be carefully evaluated.

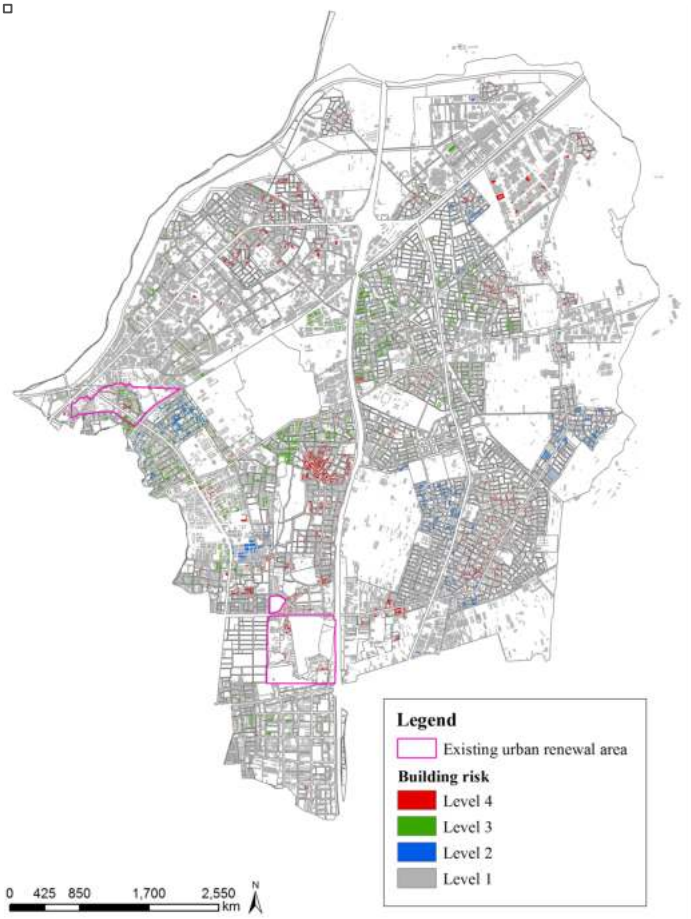

Figure 4 Overlay of existing primary urban renewal area and the building coll Yongkang District
(Ministry of The Interior, 2013)

Table 4 The proportions of building collapse risk in the existing primary urba Yongkang District, Tainan City

| Primary Urban Renewal Area | The Feyang military vi | Surroundin area of sou military su depot | Surroundin area of Yongkang Veteran General Hospital. |
|---|---|---|---|

| | | | | |
|---|---|---|---|---|
| Total buildings | | 3,028 | 0 | 1,950 |
| High-collapse-risk | Buildings | 73 | 0 | 96 |
| | Proportion of the total buildings | 2.41% | 0.00% | 4.92% |
| Medium-collapse-risk | Buildings | 251 | 0 | 1 |
| | Proportion of the total buildings | 8.29% | 0.00% | 0.05% |
| Low-collapse-risk | Buildings | 0 | 0 | 0 |
| | Proportion of the total buildings | 0.00% | 0.00% | 0.00% |
| Extremely low-collapse-risk | Buildings | 2,704 | 0 | 1,853 |
| | Proportion of the total buildings | 89.30% | 0.00% | 95.03% |

The initial designation for the existing primary urban renewal area in Yongkang comprehensively consider the deterioration and hazards in the area and ignored factor for the residents and private sector, which caused low efficiency in reg that is an obstacle to lowering disaster risk, improving quality of life and dis opinion of this researcher, the designation criteria for the physical enviro specific as Japan s urban renewal designation criteria and should involve consi risk. Besides the criteria related to the physical environment and disaster r criteria also should consider the benefits spreading to the surrounding areas, the ability the entire area to prevent disasters and the stimulation of economi can be based on the area-based approach. This research adds the economic evalu consideration, which examines the potential of market-driven approaches by renewal costs and benefits. It is believed that the intent of DPUR can be a designation criteria of the DPUR area take into account a consideration of b environment and the market, so that resident and the private sector alike wi helping DPUR area renewal efforts.

## 3.3 Quantity Framework for Creating Evaluation Criteria of DPUR Area

This research re-designates the primary urban renewal area by adding new desi from the perspective of the DPUR by evaluating the area s deteriorated buildings other physical environment factors in addition to adding the potential economic ben consideration of the DPUR area designation.

This research is based on the second phase of the analysis of the building co Yongkang District, which was delivered by the Ministry of the Interior in 2014 by the Taiwan Earthquake Loss Estimation System to simulate earthquake losses collapse risk can be divided into four levels after overlaying the PGA and bu which are high-collapse-risk (A), medium-collapse-risk (B), low-collapse-risk low-collapse-risk. In the criteria for physical environment, the research bas high-collapse-risk and medium-collapse-risk buildings in the map, but the medi buildings still have to overlay with the other disaster indexes, such as flood, of road blockages and soil liquefaction. If the medium-collapse-risk buildings the other high-risk disaster indexes (B4), then they may belong to the high-col (A).

The evaluation process is in accordance with the Urban Renewal Act to use a bloc
unit. Each hazardous block is evaluated by calculating the percentage of dan
(A+B4) in relationship to the total number of buildings on a block. Therefore
defines the block will result in designation as a DPUR area, which is the m
research.

The research uses the CBA model to evaluate the optimization of the percent
mentioned above. The cost is defined as the the direct/ indirect cost in the ur
and the benefit is defined as the the direct/indirect cost if not doing the u
After listing the cost and the benefit in the process, the total cost and benef
compared by additionally considering the earthquake probability, risk premium
interest rate. As a result, when the benefit exceeds the cost, it means that
hazard percentage has market-driven potential and also a physical environmenta
renewed. In short, this research is an attempt to use the CBA model to find most
percentage of a block to be designated as a DPUR area.

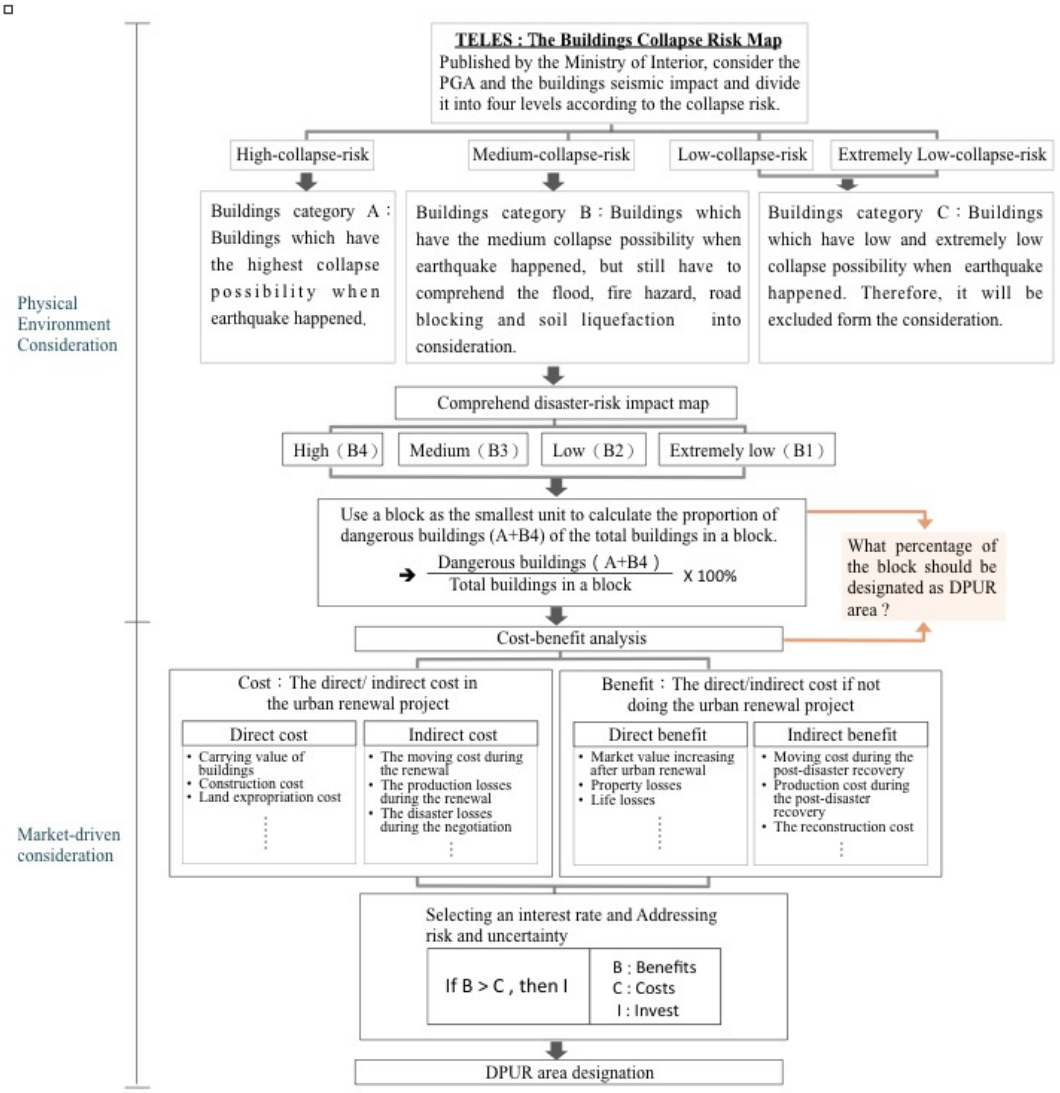

Figure 5 Future research process

## 4. Conclusions

Taiwan is located at the Circum-Pacific Seismic Zone, which is seriously impac
earthquakes. The huge casualties and losses in the 921 earthquake created
disaster-prevention in the Taiwanese government. As a result, the Ministry of
brought up the idea of Disaster-prevention Urban Renewal in 2013, which is in
the existing urban renewal areas by adding a consideration criteria for seismi
order to decrease vulnerability and increase the resilience of such areas via b
reconstruction. Nevertheless, the DPUR area designations still face lots of ch
existing urban renewal area designated criteria according to the Urban Renewal
and fail to consider market-driven factors related to renewal areas where the f
urban renewal is low. By reviewing the existing urban renewal area in the Yo
Tainan City study area, it was found that the prioritized urban renewal areas
seismic disaster risk but rather focused on market-driven factors for the purp
which may have resulted in failing to reach the goal of DPUR and may be the rea
efficiency of the renewal project.

Under the threats of unpredictable earthquakes, it is urgent that the DPUR are
that the disaster resilience of the area is improved. However, the existing de
Taiwan are more focused on improvements to the physical environment and lack a
consideration, which makes it hard to relocate the disaster prevention facili
attract the private sector to join in the project. Most of the private sectors,
stakeholders and enterprises that are interested in the renewal project, decid
project or not according to the investment risk and the market value. However,
benefits that are not immediately apparent such as quality of life, safety and
The complete benefits of disaster-prevention urban renewal may be underval
considering the visible benefits such as the appreciation market value of buildi

Therefore, this research is an attempt to explore proper evaluation criteria for
case study of urban renewal area designation in Japan and the area-based appro
takes the physical environment into account and also economic factors including both
invisible benefits. The main purpose of this research is to make an attempt
efficiency renewal problem, to arouse consciousness related to community disast
also to compare the benefits and cost of DPUR for the government and private se
the costs and the benefits in the CBA, which is also expected to give suggestio
renewal designations Taiwan.

# Inter-urban Competition and Urban Entrepreneurialism ——A Perspective of China s Urban and Rural Space Rescaling Process since 1978

Zhan Cao[1], Zhenwei Peng[2], and Sheng Bi [2]

[1] College of Architecture and Urban Planning/Tongji University, 1989caozhan@tongji.edu.cn
[2] College of Architecture and Urban Planning/Tongji University, pengzhw@tongji.edu.cn

**Abstract:**
Since the Reform and Opening-up of China in 1978 the comprehensive effect of marketization, globalization, decentralization has created an economic miracle and unique urban and rural spatial phenomenon. In this process, the growing extensive Inter-city Competition environment has become the institutional foundation of local development. The behavior of Urban Entrepreneurialism has been played a principle role as well. To some extent, the growth machine formed by local government and enterprise dominated the urban and rural space rescaling process.

Specifically, this process can be summarized into four phases: (1)1978~1980 township government in cooperation with the TVEs which lead to the thrive of small towns. (2)1980~2000, urban government work with State-owned Enterprises and few private enterprises which promoted the urban development gradually. (3)2000~2008, local government deeply cooperated with diverse enterprises both for profit and cause the savage growth of urban area.(4)Since 2008, local government turned to smart growth because of the economic crisis and lack of resources.

From the perspective of institutional change, and growing factors mobility, we constructed the basic analysis frame of institutional system and elements of change the formation of Inter-city Competition Urban Entrepreneurialism space changes , trying to explain the mechanism of China's urban and rural space evolution since the Reform and Opening-up policy from a historical-geographical-social view.

**Keywords:** Inter-urban Competition, Urban Entrepreneurialism, Rescaling of China's Urban and Rural Space

## 1. Introduction

Born in the west, the conception of Urban Entrepreneurialism has its specific historical, political, and economic background. Urban development more or less takes on some manifestations of Urban Entrepreneurialism in the process of china s urban development since the implement of the policy o the Reform and Opening-up. However, numerous difference among China and the western in specific background, goal, content, and behavior and so on, can also been easily seen (Yin *et al.*, 2006). To some extents, changes from macroscopic institutional systems, are the inductive factors that leading China s Urban Entrepreneurialism . During the process, local governments not only display strong

profit-driven, but also track out some diversified innovational institution system and practical path, which radically transforms the dynamic Chinese urban development and enormously contributes to the reconstruction process of urban space (Wu *et al.*, 2002; Zhang *et al.*, 2006, 2008). Any participants in competition in the market are Entrepreneur Talent[1], and the key to the success of reform, to a large extent, lies in how to take advantage of these entrepreneur talents and regulate their behaviors (Zhang *et al.*, 2010). At this point, logically speaking, there are no fundamental differences between China and the western in terms of Urban Entrepreneurialism , based on which, this dissertation, regarding the changes of macroscopic institutional system and urban space interaction as the logic start, is going to attempt to build a basic analytical framework: institutional system and elements of change the formation of Inter-city Competition Urban Entrepreneurialism space changes, and also is devoted to the overall interpretation of the dynamic mechanism of urban development and spatial evolution since the Reform and Opening-up, and the dialectical cognition of Urban Entrepreneurialism under the New Normal in the context of the current economic development.

## 2. Urban Entrepreneurialism s origin and the Practice of Western experience

### *2.1 The Macro-Political and Economic Background: the Failure of Keynesian and the Restart of Neo-Liberalism*

In the early 1970s, the impacts of Oil Crisis on the western, gave rise to the interruption of the rhythm of economic development, and then set back the entire economy in the west as a whole: deindustrialization, the collapse of the financial system, the structural unemployment and fiscal austerity. To some extent, this recession contributed to western capitalist economy a long period of time Stagflation (economic growth accompanied by stagnation and inflation). In the face of this unprecedented crisis, the Keynesianism, regarding the inflation as the main stimulus of the growth, fell into mal-function. In that case, western countries began to turn to the free market mechanism, and gradually from the Keynesian intrusive expansion and tightening policy shift toward the Neo-Liberalism type. Besides, they also relaxed restrictions on market, cultivated market free competition mechanism, and enhanced the mobility of factor resources. Free market mechanisms, privatization, the dispersion of national centralization as well as the flattening (Neo-conservatism) tend to make similar response countermeasure among different city government: by fierce competition, making cities as much attractive as possible so as to anchor mobile factors. Such a Inter-city Competition phenomenon is defined as Urban Entrepreneurialism (Gentler, 1988; Harvey, 1989), whose emergence manifestation of crucial transformation, that is, from Keynesian mode of circulation of capital accumulation to the Neo-Liberalism of elasticity of capital accumulation paradigm (Sayer, 1989; Schoenberger, 1988; Harvey, 1990).

[1] Entrepreneurial Talents (Zhang *et al.*, 2010 ) ) is one of the most important basic factors in the development of economy. Specifically, refers to the individual who owns relatively higher ability of the foresight and judgment to the unknown world (similar to hayek's tacit knowledge ). And have a strong innovation and enterprising spirit.

### *2.2 The Exploration of Governing Mode: From Urban Managerialism to Urban Entrepreneurialism*

There are mainly three types about the participants of market: one is authority, such as national and local administrative jurisdiction at all levels of administrative department; The second is the main body, private entrepreneurs, such as company earnings organization; Three is the various types of social organizations, such as non-profit organizations, social groups, and the official association and so on. The three main players form a Growth Coalition (or Growth Machine), and become the Urban Entrepreneurialism subject (Molotch, 1976).

Though the interactive process is different among cities, its specific behavior patterns can be abstracted for three characteristics: Firstly, the core of Urban Entrepreneurialism lies in the fact that the local government is in charge, under the leadership of the public-private partnership (PPP) mode, with the intention of drawing external mobile factors, direct investment or new labor resources. Secondly, the Urban Entrepreneurialism s turning toward has the characteristics of speculation and profit-driven, therefore is often accompanied by risks, but in most cases the digestion of these risks can be borne by local government. Again, Urban Entrepreneurialism , relying on the model of PPP mode, is engaged in a specific political objectives and economic performance of place construction (Harvey, 1989).

### *2.3 The Space Practice of Western Urban Entrepreneurialism*

With lower transportation costs, the development of information technology, market segmentation and spatial barriers gradually decline, the Inter-city Competition surfaces, and is more strengthened by Urban Entrepreneurialism . To some extent, more and more cities are involve Competition , with the intention of scrambling for the mobile elements, an practices of place construction anchoring mobile factors Then what are th manifestations of place to construct which Urban Entrepreneurialism focuses Harvey s research (1989) on some success stories, summed up the five types of Urban Entrepreneurialism in general practice space path selection (Table 1). These five are not mutually exclusive path. The results often depend on the selected city endowment factors, fluctuations in market supply and demand and the Growth Coalition s manner and timing.

Table 1. The Type of Space Practice

| The type of spatial practice | Offer the support of policy and infrastructure, and strengthen the comparative advantage including the geographical and resource superiority and public and private sector in alliance | Actively construct the various consumption space in order to prompt the consumption of | Build the center-city within the global city network | Actively support the traditional competitive industries and | The big event marketing of city, Actively strengthen the urban |

*2.4 The Dialectical Cognition*

Urban Entrepreneurialism has contributed a lot to the resolution of the problem of the decline among western cities. However, the inclination of profit-oriented growth should be taken into consideration for its side effects: a seemingly successful place construction is often accompanied by social polarization and impoverishment phenomena, such as the center of the city gentrification movement further curing of class stratification and spatial segregation; in addition, the intense Inter-city Competition will intensify the expansion of the uneven development of the region as well as the gap between rich and poor citizens. Faced with these problems exposed, since the 1990s, the British Communist Party leader Tony Blair has proposed a Third Way policy to seek compromise and balance between left and right consciousness. In a way of Fuzzing the Neo-Liberalism and the Keynesian position boundaries, beyond the value conscious opposition, concern equity and efficiency, balance power and responsibility, in order to adapt to changes in the class structure of the UK and the various aspects of global economic, technological and political changes.

## 3. The Paradigm of the Urban Entrepreneurialism of China

The process of institutional changes with China s characteristics is referre
Paradigm , in which the marketization, decentralization and globalization is the
reform (Wu *et al.*, 2002; Yin *et al.*, 2006). In the course of dramatic transformation, Chinese local government shows an evident inclination for Urban Entrepreneurialism , in a sense, which inevitable outcome and important impetus of the Reform and Opening-up. In the face of a more complex macro-economic context, the Chinese paradigm of Urban Entrepreneurialism has its own uniqueness.

*3.1The Transformation of Local Government: From All-round Contract System to TVEs*

**(1)The Start of Entrepreneurialism among Township and Village Government**

In the late 1970s, the establishment of All-round Contract System[2] in rural area, is the historical starting point of China's comprehensive reform, laid a separation of rights (proprietorship right, management right, contract right) to land on the basis of a series of system innovation to promote the development of small cities and towns (Zou, 2000). With rural All-round Contract System success and promotion practices, coupled with the central and local s vertical decentralization, rural economic development gained autonomy. Established on the basis of ambiguous property rights of rural industrialization, Township and Village Enterprises (TVEs) have become the fundamental driving force of urban spatial development. In this process, the villages and towns thirst for fiscal revenues, the pressure of the community development and traditional geographical-kinship concept makes their behavior consistent with the local TVEs. The strong sense of traditional collective attributes in the villages and towns government become the actual controller of the TVEs, and to a great extent, bear the risks of the externalities of market which is not perfectly regulated. The Entrepreneurialism is referred to as the local state corporatism under this circumstance (Oi, 1989). TVEs under the auspices of the local government achieve a low-cost resource allocation, which helps to create favorable conditions for the prosperity and development of TVEs (Figure 1).

[2] All-round Contract System is the main form of China's rural household contract responsibility system. Before 1970s, under the communist collective management, which lack of effective incentive mechanism due to the land property rights legally belong to the collective party, the economic development of rural area was in stagnation, farmers life quality were in a very low level. In Anhui province, some farmers began to secretly undertake the All-round Contract System within their own community by dividing the collective land to each household. By this way, this community achieved huge productive success. Strictly speaking, according to the socialism ideology, it was illegal. However, since it can strongly stimulate the farmers initiative, the All-round Contract System then legalized across the nation. Theoretically, the vague property right of the collective land can be divided into three different rights: proprietorship right, management right and contract right.

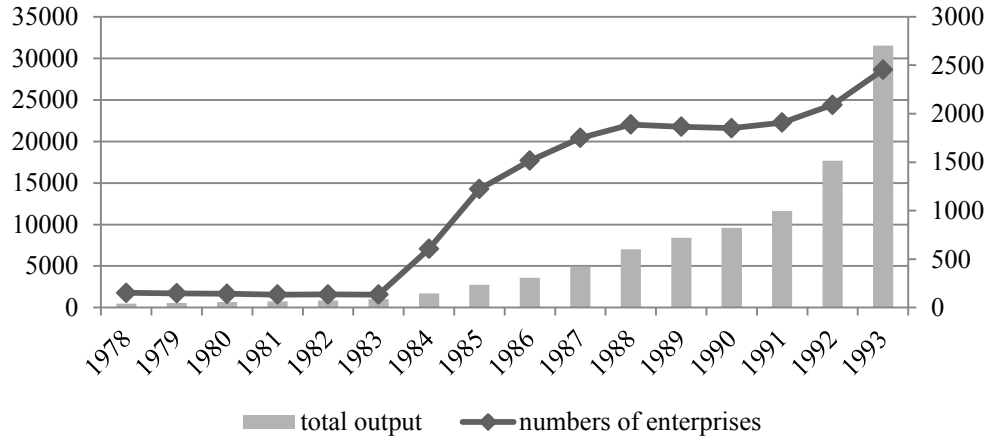

Figure 1. The Total Output Value and Number of TVEs (1978 - 1992)
Data Source: Chinese Year Book

**(2)The Spatial Shift under the Domination of the Alliance of Government and Enterprise**

In the early1980s, in case of the finite element resources, the township Government-Enterprise Alliance went to great length to squeeze the industrialization costs as much as possible, with the characteristics, in terms of space, of small, scattered, chaotic and poor (Zou, 2000). In the early stage of the development of TVEs, villagers not only do farming but also do industrial work in TVEs. These hybrid activities embedded in the villages and towns community, thus it shows the characteristics of blossoming scattered layout. Under the guidelines of encouraged farmers jumping into the local factory instead of going to big cities [3], TVEs shows the characteristic of undertaking industrial production in the rural township, in the village, household do at home . It was disorderly inefficient, diversified, fragmented.

By the end of 1996, China's economy succeeded to achieve a soft landing[4], but the main contradiction of social and economic development turned from the constraint of supply to that of demand. In addition, the Asian financial crisis led to the reduction of international investment, and the shrinking of export market. For this reason, the acceleration of urbanization has become an important means of stimulating economic growth and further development of small towns has become a way to restart consumer market (Zou, 2000). Thus there appeared two kinds of spatial evolution path: one is the villages and towns economy of Sunan area (Southern Jiangsu province), relying on high-tech park

[3] In early stage of China s industrialization process, urban development depends on the price gap between industrial products and agricultural products. In that case, the price of industrial products was much higher due to the high cost of urban industrialization. So at that time, the migration from rural to cities was strictly limited. (Hukou system was invented then )

[4] During 1990s, China s economy suffered from a high inflation. With continuous policy implemented in a relatively long period, the inflation rate came down gradually.

construction and supporting policies, to attract international capital; the other is the villages and towns in Zhejiang area around local key enterprises, small and medium-sized enterprises to build characteristic economy (Tang *et al.*, 2013). Along with the intensifying of the globalization process, the continuous perfection of domestic market economy system and the advance of standardization of TVEs, township government gradually withdrew from direct intervention in these enterprises and turned to mainly focus on the park construction and preferential policies. What s more, with a clearer property rights, the limit of boundary constraint to the township enterprise greatly abated, which was in favor of creating conditions for enterprises concentrate to industrial park .

Although the implementation of the enterprises concentrate to industrial park policy, to some extent, improved the situation, the traditional pattern of township enterprises, namely, the situation of greatly scattered, little centered did not radically improve. Because of the serious administrative division, the development of TVEs crumbled in homogeneous competition. Since the beginning of 2000, by the institutional innovation of merging townships and small villages, TVEs has been in the transformation into large-scale, intensification, and modernization.

### *3.2 The Spatial Expansion of Local Government under the Driven-profit: From the Enterprise Finance to Land Finance*

TVEs have sprung up everywhere and detonated the development of small towns. Besides, the era of the planned economy of urban and rural balance is broken. The countryside through the integration of land and capital has not only achieved the rapid development of industrialization and urbanization, but also set an example for the future growth of a massive expansion of urban areas (Wu *et al.*, 2014). Rural industrialization and urbanization has fully demonstrated the strategic value of the land as an fundamental element of space. In addition, the experience of development of small towns began to be consciously adopted by urban area since 1984. Among these, institutional system of Compensated Use of Land , the Commodification of Housing[5] and other innovative systems, greatly promoted the rapid reconstruction process of urban space. At the same time, the local government turning from Enterprise Finance to Land Finance showed obvious characteristics of Urban Entrepreneurialism .

**(1) From Enterprise Finance to Land Finance**

Since the 1980s and the early 1990s, with the implementation of Fiscal responsibility system[6], State-owned Enterprises were in the control of local government, which played a dual role of economic and politic incentives to local government (Tao, 2011). At this point, the state-owned

[5] Before these policy enacted, the State-owned land can only distributed by government and exchange behavior was strictly limited.

[6] Local government manage the local State-owned Enterprises due to the over concentrated management system turned to be inefficient.

enterprises are still the absolute dominant national economy, and local government revenue depends on the state-owned enterprises rather than profits tax, which is the Enterprise Finance .

Since the mid1990s, under the pressure of the tax reform, the stimulus of housing commercialization and the increasing mobility of global factors, there were two means for the local government to participate in the Inter-city Competition , including reducing the production elements' price and expanding the expenditures. And then Land Finance emerged at the historic moment: the government firstly purchased the collective agricultural land in a very low price, then by the rolling development mode of land mortgage - access to commercial loan - construction of a complete infrastructure - attracting investment - getting tax , in order to attract industrial enterprise to invest on construction; On the other hand, through the mode of land reservation- auction - ready land for sale - get high transfer pay , to advance the residential and commercial construction. Additionally, the special land binary institutional system, caused the differential land price gap between urban and rural areas. This part of interests in public sphere becomes the direct stimulus to the local government s Urban Entrepreneurialism[7]. Furthermore, the lag of unified land market construction and the tacit approval of the monopoly of land in legal system, make the Land Finance become the shortcut for the urban development, even become the main part of the local government s revenue (Figure 2).

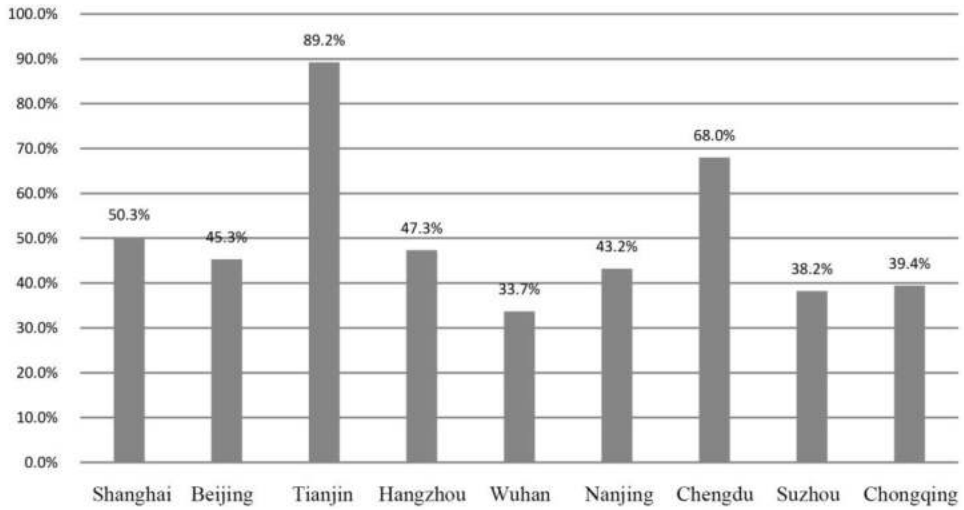

Figure 2. 2013 top ten cities accounts for payment of land revenue rati
Data source: Citic construction of research and development department

**(2)The Spatial Shift of China in the Logic of Land Finance**

In the logic of Land Finance , the initial establishment of the institutional system of Compensated Use of Land , incorporate the supply of industrial space into the circulation of capital market. The

[7] Urban government can always purchase the suburb collective land with very low price, and the collective community has no chance to bargain. In another word, the government has absolute monopoly in controlling land.

System of Land Reserve and Bid, Auction and Listing will further transform residential and commercial space into tradable goods , the gradual transformation of space as a real estate into chattel, and the deeply nesting of space production and capital circulation, create the unique changes of urban space in China.

**a.** New Towns Space of Development by Leaps and Bounds

China new towns spawned with the construction of Development Zone in 1984, in the past 30 years, the number of large, widely distributed, different spatial scale, and different strategic target of Development Zone has become a focus of local government competition. The approval of the project Development zone not only means getting enough space for development and the spill over effect of industrial agglomeration, but also means getting a series of the central financial support and preferential policies (Wu *et al.*, 2011). Because of the excess supply of Development Zone , the central government began to halt Development Zone fever at the beginning of this century. Then, as the pilot experiment of the Reform and Opening-up, Development zone has evolved into a vari politically correct and profit-oriented variants: university town, science and technology town, high-tech industrial park, new city, eco-city, bonded area, etc., which are out of the framework of the construction of original city and shows a tendency of transition of development. (Figure 3).

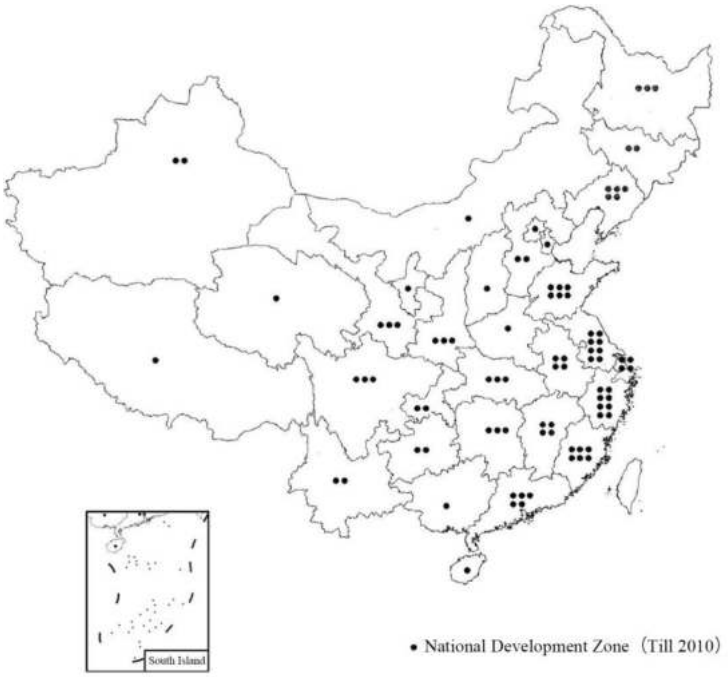

Figure 3. 2012 The Distribution of The National Economic and Technological Development Zone

**b. The Construction of Gated Community Space**

With the implementation of the reform of the commercialization of urban housing in 1998[8], the newly increased demand of the urban housing was introduced into commercial housing market, and then the explosive development in the real estate industry appeared (Figure 4). Of these, more than 80 percent of urban residential communities have adopted a new type of gated community (Yang, 2011). After the implementation of the Bid Auction and Listing[9], and in the face of huge profits, local governments and property developers as well as financial institutions form an alliance for the mutual profit. A large number of gated communities sprang up. Besides due to the genetic transmission of culture of unit compound[10], because of the complete and clear land property right, overall planned gated communities has the advantage of making good use of the land and providing better security management, and offering a better living environment (Zhu, 2011). On the other hand, under the background of rapid urbanization of Chinese cities, the public infrastructure and the supply and management of public space is lagging behind, the gated community to some extent, realize the compensation in private sphere. For example, Beijing's Wangjing area is made up of numerous gated communities, covering an area of 16,000km², and the resident population of 600,000, including schools, hospitals, public transportation. Additionally, the residents are mostly middle-class. Although gated communities have effectively curbed the loss of land rent and the degradation of the environment, and provided a large amount of living space, but also have strengthened the segregation of social class.

[8] Before 1998, the urban housing was distributed free by government or State-owned Enterprises because of the ideology of the socialism. However the housing quality is mismatched.

[9] Bid Auction and Listing is a creative land exchange system, which regulate the land market in an effective way and avoid rant-seeking or free-rider behavior.

[10] Before 1998, the urban fabrication was consisted of Units, which was an unique social-space form. The residents, which often were colleagues or co-workers, dwelled next to the State-owned Enterprises, and the housing with clear wall-type boundary was supplied by the enterprises. It s a social-space form of concentrated power system.

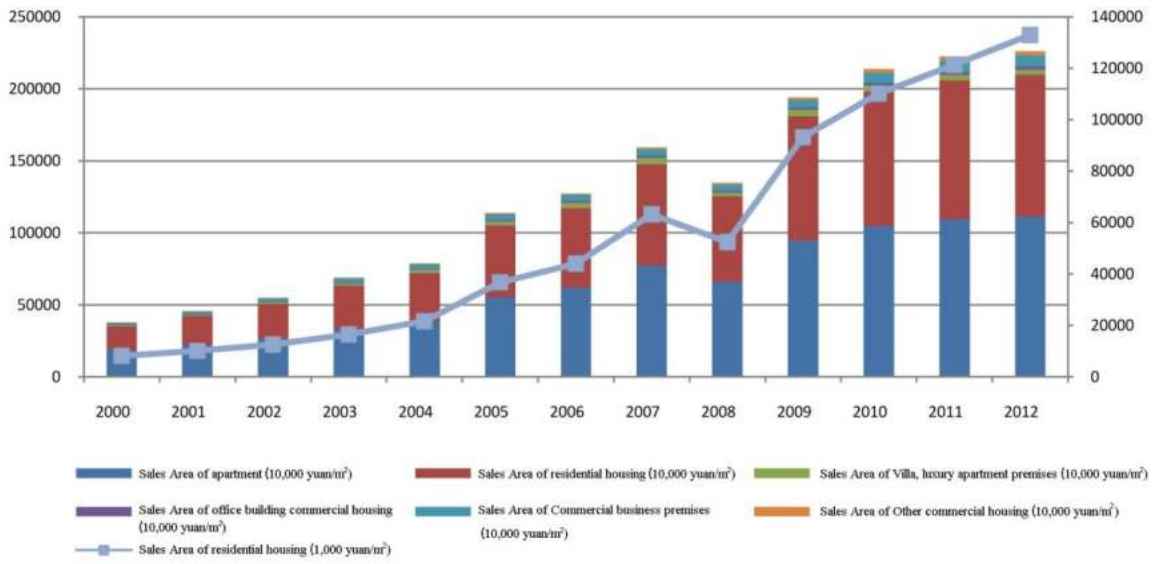

Figure 4. National Commercial Housing Sales Area and Sales 2000-2012

Data Source: Chinese Year Book

**c. The Jigsaw-like Redevelopment Consumption Space**

The redevelopment of the old city area is carried out with the construction of the peripheral new town in China. The center of the city, has great economic potential and cultural value, but because of the rise of land price, depreciation of building, functional aging, and is in great need of renewal. However, the redevelopment of China s old city, deviates from that of Western countries, with the core values of public benefit maximization as the basic goal, and demonstrated a strong tendency to pursue profit, which is also the behavior of Urban Entrepreneurialism the threshold of huge investment, and the high costs of transaction, made the local government introduce the market-oriented mode of operation into the practice and cooperate with the property developers and they were always profit-oriented, which formed the compounding consumption space like jigsaws in the center of cities. The profit-oriented commercial led to the fracture of the traditional culture, and its unbalanced benefit tendency has increased the unstable factors of society.

**d. The Grand Space of Big Event Marketing**

In the competition of globalization, big event marketing becomes a kind of typical behavior of Urban Entrepreneurialism of local government. Big event marketing as the engine of leapfrog develop of the new district and the renewal of old city is attached great importance by local government. Especially the big event marketing with great attraction, the support of central government, the high exposure in short time, and promoting the image of the city, becomes the plundered object of local government (Yu *et al.*, 2011). Such as the integrated marketing and site construction of the Beijing 2008 Olympic Games, the site construction of 2010 Shanghai World Expo, sports new town of Nanjing 2014 youth Olympic Games Olympic and so on. These projects of urban spatial development

and the improvement of urban competitiveness have tremendous impetus to the development of urban space and advance of competition. But because this kind of project, with obvious external political tendency, often ignores the social, economic, and space effect in the process of planning and construction of the urban and many of the reasonable natural evolution of urban space gave way to the project of big event. At the same time, the excess supply of the space and economic investment tend to be inefficient, and the plunging deeper into indebt as well.

**e. The Restricted Property Housing and Urban Villages**

The Restricted Property Housing[11] and Urban Village , existing extensively, has no direct relation to the Urban Entrepreneurialism and is the consequence of the rational bottom rural to the Urban Entrepreneurialism . Because of the existence of land binary institutional system, farmers can't share land benefit from existing one-sided system. In the face of the local government s monopoly on land market and radical Land Finance behavior, rural villagers can game against city for the rights and interests of collective land. To some extent, the Urban Village and Restricted Property Housing , under the mismatch of the market economy system, is a rational strategy of the rural to fight against Urban Entrepreneurialism .

*3.3The Transformation into Elaborating Management of Local Government: From the Urban and Rural integration to the Stock Land Optimization*

The first decade of the new century, the incremental expansion of the city, under the maintenance of the Land Finance mode, strongly promote the urbanization process in China. By the end of 2011, the rate of national urbanization surpass 50% to 51.27% for the very first time, which means China has entered the internationally recognized curve of urbanization turning interval, and the rate of many big cities even surpasses 80%. On the one hand, because of the constraint from the red line of the national 1.8 billion mu of arable land, the supply of massive new construction land has become the past, and the growth of the urban construction land meets its bottleneck. On the other hand, a lot of extensive stock land, with disorderly and low economic efficiency in the rural and urban areas is in desperate need of promotion. Both inside and outside pressure forced local government to improve the paradigm of elaborating management

[11] Restricted Property Housing refers to the housing construction in the rural collective land, did not pay the land grant fee and other fees, its property right card is not issued by the national housing agency, but by the township or village government. The reasons of the widespread of can be summarized in three aspects: (1) Commercialized urban housing price is much higher than Restricted Property Housing . (2)Farmers can build their own house and operate it on their collective land according the current Land Management Law. (3)Building a Restricted Property Housing is need not to pay for any property transfer fee. Also the profit of operating or selling the Restricted Property Housing is much higher than the compensation fee by the urban government who always willing to purchase rural land at very low price.

**(1)The Practice of Urban and Rural Integration**

In the process of urbanization in China, the floating population, especially the rural migrant workers are the main force of population growth of the urbanization, and it is true that the growth of towns is accompanied with rural shrinking. Because a large number of migrant workers go to the cities for jobs, the phenomenon of hollow village become increasingly serious (Long *et al.*, 2009). However, the barriers of current land institutional system to strictly restricting the circulation of rural collective land, the constraint of collective construction land into land market, land-lost farmers getting no expected earnings, the high exchange cost of land circulation, lead to the shortage of land use for urban construction and the contradiction of collective construction land inefficient idle situation. In 2007, Chongqing and Chengdu is known as Urban and Rural Integration Experimental Reform , actively explored the innovational circulation system of collective land. Chongqing's experiment of urban and rural integration, that is, farmers with land at a discount buy a share of the enterprise, and jointly establish company to enjoy share out of bonus; The suburban rural homestead are transformed into urban housing and social security; Under the local government s leading, towns a unified, standardized market of rural land circulation (Land-Stock Experiment[12]), to promote the circulation of the idle collective land (Xie *et al.*, 2010). Through this way, by the end of 2013, Chongqing has realized the circulation of 131500 acres of collective land with the volume of 26.726 billion Yuan, clinching a deal on the average by the price 202,000 Yuan/acre, which greatly activate the resources of rural land, and realize the smart growth of the city and the smart shrinking of the countryside.

**(2) Planning Practice of the Stock Land**

In the process of the spread of the rapid growth of China s big cities, there are a large number of inefficient extensive stock lands. Under the constraint of the land supply, Reining the Increment Land and at the same time Revitalizing the Stock Land has become the only way for the development of big cities which is in need of transformation. In 2005, Shenzhen began to recognize the dilemma of urban development, that is, the limited land space, the shortage of water and energy, the overburdened population, the serious overdraft of environmental bearing capacity. In the new round of master plan, the local government formulated the guideline of Balance Increment and Stock land, Focus on Optimize Inventory . A lot of innovational exploration from planning techniques to the top institutional arrangement had done. They also put forward the concept of the Increment and Stock Land as A Whole . In terms of spatial strategies, they put forward optimization guidelines of spatial structure, that is, outsourcing and inter-linking, pre-control restructuring, creating sub-center and

[12] Land-Stock Experiment means rebalance the volume of urban land and rural land. The quantity of the reclamation rural construction land, including rural homestead and affiliated facilities land, township enterprises land, rural public facilities land, can be exchanged in land market to turn into urban construction land. The increase volume of urban construction must be equal with the rural reclamation land.

density (Zou, 2013). At the same time, along with the Code of Shenzhen Redevelopment in 2008, Shenzhen will take the redevelopment as countermeasures to crack resource bottleneck, promote the stock land optimization, including comprehensive improvement, functional change, demolishing and rebuilding. Also the PPP mode is introduced to these special practices. Shenzhen Land Finance in 2013, was less than ten percent of the total revenue, and the success of Shenzhen s mode is a demonstration which shows the possibility of an alternative way of urban development without Land Finance . Besides Shenzhen, Guangzhou-Foshan metropolitan area of the Three Old Reform and Countryside Unit Planning in Shanghai are the transformation into the elaborating management, in the case of the crunch of resource to deal with[13].

*3.4 Conclusion*

From the above analysis, we can see the change of the external system, including the leading to the deepening of China's Reform and Opening-up by the common role of marketization, decentralization, globalization, in the process of which, the mobility of capital factors constantly enhanced. In order to anchor capital factors to realize the economic growth, the Inter-city Competition also intensifies. The spatial development of small town, starting with TVEs, is a testing ground for the Urban Entrepreneurialism , whose strategic value of space elements becomes important and extends to the urban areas. As the rational choice of the local government involved in Inter-city Competition , Land Finance with strong growth impulse, has created a radical reconstruction of the urban space, also has brought many serious problems. With the end of the radical growth, Urban Entrepreneurialism began to undergo the shift to the paradigm of elaborating refinement. Space optimization, stock land optimization, has become a new trend of development mode within China s urban and rural space. The basic logic framework, that is, institutional system and elements of change the formation of Inter-city Competition Urban Entrepreneurialism space changes , to some extent, can explain the unique phenomena of China since the Reform and Opening-up (Figure 5, Figure 6).

[13] These different kinds of land management method are logically the same, which all aim to realize the smart growth: expanding the efficient high density urban functional land while reducing the inefficient rural land.

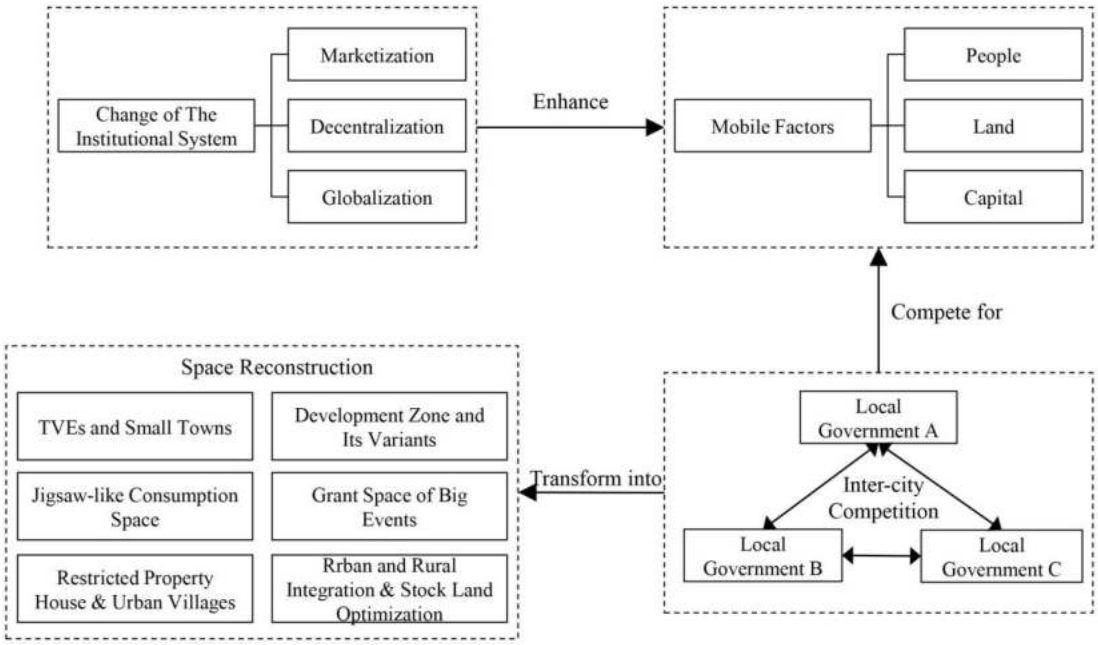

Figure 5. The Logical Frame of Urban and Rural Spatial Transition of Urban Entrepreneurialism

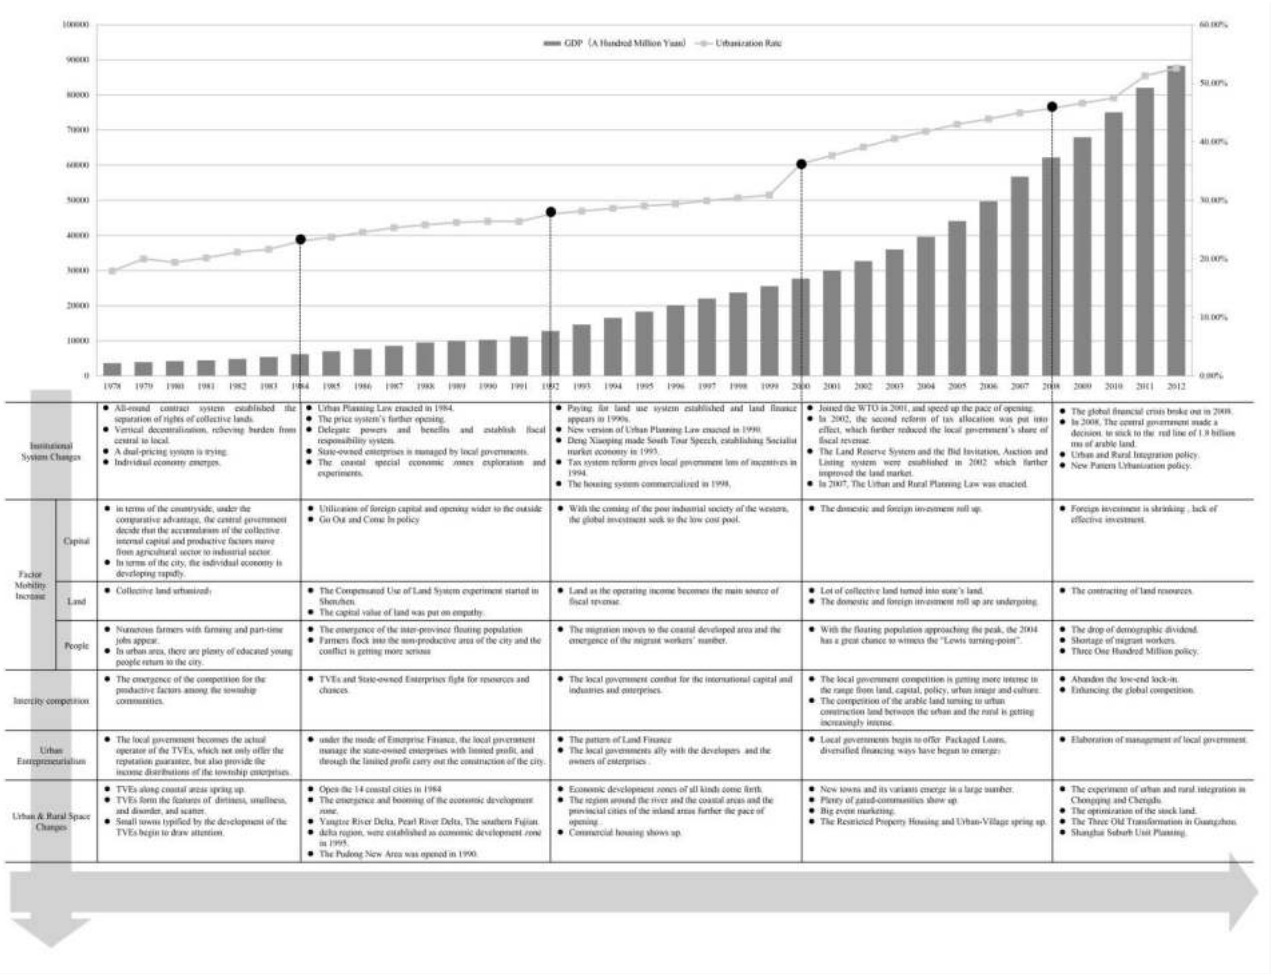

Figure 6. The Logical Process and Timeline of Urban and Rural Spatial Transition of Urban Entrepreneurialism

## 4. Rethinking of the Urban Entrepreneurialism Under the New Normal

### *4.1 Abandoning or Improving?*

The Urban Entrepreneurialism of the local government in China is the product of institutional change in transition, historically and rationally speaking. While from the perspective of the analysis of the Urban Entrepreneurialism we can partly explain the universal phenomenon of the urban and rural space in China, but urban development is a complex accumulation of the action of multiple factors. The only analysis of the Urban Entrepreneurialism has many limitations. A phenomenon of the rapid process of the urbanization process under the growth-oriented context for over 30 years, is worth our reflection. With the approaching of pressure caused by many of internal and external constraints, such as the global financial crisis, the constraint of resources, environmental degradation, the sharp social contradictions, the widening gap between the rich and poor, the phenomenon of rant-seeking government, the growth-oriented concept comes to an end (Zhang *et al.*,

2013). Urban Entrepreneurialism turns from the power of growth in the past into the disorder o re-increase, but that doesn't mean the failure of the Urban Entrepreneurialism . Considered the economic development in the New Normal context at present, the market as the dominant role of factor resources will be more prominent, Inter-city Competition will be increasingly fierce. Under this background, the local government still needs to play the enterprising spirit of entrepreneurs. We thinks that, the abandonment or the maintenance of Urban Entrepreneurialism should adjust measures to local conditions: in the eastern developed regions, local government shall make the economy grow from extensive management into intensive management, and replace the quantity expansion with quality improvement of urbanization, control city stock land, promote economic development and at the same time pay attention to fairness and justice, narrow the gap between the urban and rural, promote rural hematopoiesis mechanism, etc.; In less developed areas in the Middle and West, local governments need to follow and expand the regional preferential policy on the one hand, on the other hand discover and strengthen their own endowment advantages, and vigorously develop differentiated competitive advantage, protect the ecological environment, improve the infrastructure, refine the living conditions in order to promote local urbanization and the backflow of urbanization of the population

*4.2 How Urban Planning as A Technical Tool Deal with the Urban Development*

The development of China s urban planning is accompanied by the mainline of deepening of the Reform and Opening-up (Yang, 2010). Under the framework of the Urban Entrepreneurialism , urban planning and its planners are given a new role, to some extent, marketization is unavoidable and which seeks to maximize the benefit of the client (the local government) in holding certain principles (Zhao, 2013). Over the 30 years of the Reform and Opening-up in China, urban planning, as a technical tool, to a large extent, has become the blueprint of the implement of the space of the Urban Entrepreneurialism . and be bound in the space of Land Finance as the clue to production logically, various types of planning product has obvious growth brand and ambitious political agenda , moreover, became line manufactured products, gradually deviated from its value essence as a coordinator for interests and justice. In the New normal context, rigid constraints, such as resource crunch will force the shift of the mode of urban space development the to the intensive and efficient paradigm, which means that the city planning, in terms of content, methods, management and implementation, is necessary to undergo the shift of intensive and elaborative paradigm. On the other hand, the increase of the market dominance will largely inhibit the discretion of the local government, and the top-down type planning then will be gradually replaced by bottom-up type planning. The demands of the public for the justice also be a bigger challenge to the technical tool of urban planning in the future.

# TRACK 15

# Culture, Entertainment, Tourism and Planning: Panacea or Threat?

## Track description

Co-chairs: **Jan Schreurs**, **Piotr Lorens**

Global entertainment and tourism industry brought many undisputable economic benefits to many regions. In some cases, this is the only opportunity how to increase the living standard of their inhabitants. Conflicts of values, cultures, life styles of local communities, departure from their authentic evolution process and number of related ethical issues may be the dark side of an orientation on commercialisation of culture, and entertainment and related tourism as an engine for economy. The environmental and cultural resources that were used for establishing the entertainment and tourist industry may be consumed by the same industry, without sustainable positive effects on local population. If this could be the case, what should be the role and responsibility of planners?

# THE COMMERCIAL PRESERVATION OF CHINESE HERITAGE: A POISONED PANACEA FOR CITY MODERNISATION

Giuseppe Cinà

Politecnico di Torino, DIST Department, giuseppe.cina@polito.it

Keywords: heritage preservation in China, demolitions in China, urban planning in China

**Abstract**

*In China the entertainment and tourism industry, united to heritage preservation, offers today an unmissable opportunity to increase the living standard of cities. To this end a systematic use of the demolition and reconstruction of vast historical areas became both the keystone of a development policy and the paradigm of a rudimentary culture of conservation at political and technical level. This paper proposes a reflection on the multiple causes of this phenomenon, from the most obvious (the strength of the housing market, the collusion between private and public interests) to the less evident: the opaqueness of land market, the subordination to political power, the conceptualization of heritage in the Chinese tradition.*

*To properly focus on the operational context of the demolition and reconstruction works in historic districts, the text compares some relevant aspects of the political system, the existing legislative framework and the technical tools adopted. Also, with reference to some significant operations the paper highlights how the demolition remains totally controlled by the real estate market and needs to be rethought as a political tool in order to target effective strategies of rehabilitation. In conclusion, the text highlights as in the process of preservation the field of action of the planners is extremely reduced, as operating within public boards strongly affected by a marked oriented policy and scarcely interacting with stakeholders external to the institutional power.*

## 1. To be or to seem, a difficult identity

Nowadays we are used to the everyday chronicle offering a vision of China as a place of great contradictions. A place where the huge scale of urban phenomena shows expressive codes that appear among the banality of the images that we think we understand and the complexity of their content. When observing the new developments we are bewildered as we are unable to understand the different meanings and values of the unvarying architecture marked by a played down post-modern style, which replaces a never achieved modern style. In fact it is not post-modern, but what the Chinese generically call the European style (*oulu feng*). We find it on the advertising towers of the headquarters of large companies where it attains its main expression as well as in the singular hybridizations with the local style and in the endless construction of 'modern houses with Chinese roofs', where the vernacular poetic is often reduced to being a faded crown that clashes with the rest of the building.

In historic areas, equally disconcerting are the vast *hutong* which appear perfectly refurbished with all the figurative stock of historical architecture. In fact, in almost all cases, it is not simply a matter of restoring or recovering historical buildings in various forms, but of new buildings reconstructed ‘in style', which produce urban fabrics that do not constitute evolutionary stages of previous types but just their replacement with 'other' urban organisms.

Evidently in the two contexts of intervention, new and historic cities, various policies are implemented, corresponding to two different systems of intervention (in terms of legal framework, technical and managerial tools, actors involved). However, there are strong similarities of important aspects concerning the planning, management and implementation in the two systems (Abramson, 1997; Zhang and Fang, 2004). This is so evident that it seems that the same political and productive machine

is mastering the two processes of city transformation so that they are mainly distinguishable for their figurative outcomes rather than for their specific social and spatial contexts: in the first case the buildings are made in global style and in the second they are in Chinese style. On one hand the buildings are competing at the level of international poetics, while on the other hand they perform the figurative repertoire of historical identity which is seldom truthful. Paradoxically, the use of identity takes place according to a procedure that is similar to the construction of the Florentia Village in Wuqing, Pudong-Shanghai and Foshan-Guangzhou, the largest village-malls of China, where the historic city, stripped of all pretense of identity, assumes brazen connotations.
The condemnation of the destructive fury that wiped out most of the witnesses of a millennial history in less than half a century, by replacing it with a simplified interpretation in many cases, is now widespread at global level. Yet how can such a deep manipulation of the reality of ancient cities be possible, despite the complaints of such a large number of Chinese and foreign professionals and intellectuals?[1] Are only politics responsible for it or are there other reasons? It is hard to find an answer to such a complex question. Certainly a better understanding of the phenomenon could help to correct its distortions. To this end, I think it is useful, with reference to the historic city, to carry out an indepth analysis of a crucial aspect which better understanding could help us to address preservation policies more effectively: the practice of demolition.
Once carried out on a large scale and with surgical rigor, demolition allowed for the systematic deletion of vast historic areas paving the way to the epic of the forced modernization of last decades. It is obvious that its meaning goes beyond mere instrumental function. As observed in countless cases of major urban transformation, from the Pruitt–Igoe housing in St. Louis (mid 1970s) to the Bijlmermeer district of Amsterdam (1990s), demolition is at the heart of the most complex urban strategies where destruction and demolition can be considered as a 'natural process', as something creative" that contributes to urban construction (Thomsen, Schultmann, Kohler, 2011, p.328). Therefore it is worth asking oneself, even in the case of the historical city of China: How can public policies (financial and legislative) be designed to support the practices of deconstruction and recycling as a public 'good' without negatively impacting on the loss of building stock (Thomsen, Schultmann, Kohler, 2011, p. 329) and its cultural value?.

## 2. Marketing the past

The practice of demolition with reconstruction can be considered the paradigm of the immature conservative practice now present in China at political, cultural and technical level.
As a matter of fact demolitions have never been a shocking problem. Only in Beijing, in the second half of the last century, 22.5 km of city walls, 22 towers, dozens of residences and imperial parks were demolished. More than 2,000 temples, which were used as public spaces other than religious sanctuaries, were used for other purposes or demolished (China Heritage Project, 2005). In the same period the *hutong*, an outstanding embodiment of the road network defined during the Yuan Dynasty (XIII-XIV sec.), passed from 3,250 in 1949 to 1,400 in 2004 (Urban Planning Society of Beijing, 2005, p. 80), with many others condemned to demolition; in the two-year period from 2000 to 2002 more than 4.4 million square meters of historic homes were demolished (Cui, 2004). Yet again in 2002, 40% of the urban area included in the second belt of the historical walls (62.5 sq km) was demolished (China Heritage Project, 2005). This relentless process originated in the early years of the People's Republic foundation, when private property was confiscated and the related ownership regime was lost within an indefinite regulatory framework, which has remained the same in many cases.

[1] One of the many battles against the demolition had as protagonists 24,000 homeholders joined under the leadership of the architect Fang Ke and the lawyer Wu Jianzhong. The latter was not afraid to tell to political leaders of his city: "Not even the Japanese invaders ravaged Beijing as you did" (Rampini, 2005, p. 61).

Demolitions are legal. They are empowered by the Constitution and ruled by several legislative acts[2]. In terms of planning tools, since the1990s the most threatening legal mechanism which helps to justify large-scale looting for the historic city is the *Weigai*, i.e. the *Old and Dilapidated Housing Redevelopment Plans*.

These plans focus on interventions of urban regeneration that are not particularly related to historic centers but are suitable for the purposes of preservation. Indeed, thanks to their character of urgency it is easy to bypass the laws and the protection regulations.

As a consequence, the total area of traditional houses in the old Beijng decreased from 1,160 hectares in 1949 to approximately 500 hectares in 2005 (Whitehand and Gu, 2007, p. 650). It is estimated that in Beijing 221 *Weigai* plans involving nearly 1 million inhabitants were approved from 1993 to 2000 , and that between 1990 and 1998 more than 4.2 million square meters of residences in the historic areas were demolished and reconstructed (Zhang and Fang 2004, p. 289).

The inhabitants are usually warned only a month before the arrival of the bulldozers by the inscription 'demolition' (*chai*) painted on the walls of the *hutong.* Theoretically, a part of the residents, established in the plans, are given the opportunity to return to the rehabilitated houses; but since displacements are mainly due to real estate development whose implementation is not subject to specific checks, people have to settle for meager compensation and seek alternative accommodation which is even more precarious than where they lived before (Cui, 2005; Sui, 2006).

In the case of Shanghai the side-effects of *Weigai* are even more relevant. It is estimated that from 1991 to 1997 22.5 million square meters of housing were demolished and over 1.5 million residents were transferred (Zhang, 2002).

These projects led to the replacement of entire neighborhoods, which affected both buildings deemed to be of little historic interest and buildings with considerable historic interest which are carefully reconstructed in order to reproduce their historic characteristics (Figure 1, 2). The few projects that attempt to implement a gradual redevelopment on demarcated areas succumb to the prevalence of major interventions supported by institutions. Basically, among the four building categories identified by Lv Zhou (2005, pp. 170-171) in the *hutong* of Beijing – i.e. (i) buildings under protection, (ii) buildings restored by private owners, (iii) traditional multifamily buildings, and (iv) new residential buildings - only to the third, which is the most widespread, conservation policies do not acknowledge any value.

Among the most negative cases it is important to mention the major commercial areas of Liulichang (1980-85) and Wangfujing (1993-99), whose 'conservation' led to the widening of historic axes and the destruction and redesign of most of the building fabric. However the worst example of the last decade is the demolition and reconstruction of the Qianmen area south of Tiananmen Square (one of the 25 historical and cultural conservation areas identified in the master plan of 1991), which occurred during the preparation of the 2008 Olympic Games (Zhang and Zhao, 2009). This example demonstrates how at the top of the official recognition of the value of the historic city corresponds the greatest degree of destruction, even more than the anti-historical fury of the Cultural Revolution (Layton, 2007).

[2] Rules on the right to land use, expropriation, compensation and demolitions are contained in the following acts: Law on soil Management, amended in 1998, Art. 58: "... the right to use land owned by the State can be revoked if one of the following circumstances is occurring: for public interest and to rebuild old neighborhoods in order to implement plans of urban construction ....."; Fourth Amendment to the Constitution of the PRC, in 2004: "For reasons of public interest, the government can expropriate (revoke) the right to the use of urban land and offer the right compensation according to the current laws and regulations"; Property Act, 2007, art. 42: "... the government can expropriate collectively owned land, the houses owned by entities or individuals on state-owned land and other immovable property"; Regulations on expropriation and compensation of housing on land owned by the State, three versions issued from 2010 to 2011.

In all cases demolition is considered to be an almost inescapable way of establishing a building site[3]. Consequently, 'urban demolition' (*cheng shi chai qian*) becomes a way of increase the stock of urban land, which is not available for development policies as long as it is occupied by dwellings for which people pay only a nominal rent.
The following 'conservative reconstruction' combines all possible images and styles of historic architecture, subjecting it to the purposes of the real estate market rather than to the issues of the true physical and social context. The result is a largely false housing, in which even in the rare cases where all the existing fabric is not demolished, you can not distinguish the original from imitation; furthermore, thanks to aggressive accreditation campaigns, this result is presented as a compensation in terms of public welfare compared to past conditions of backwardness. Therefore it is not by chance that the unfortunate affair of the *hutong* and *siheyuan*[4] (Figure 3, 4, 5) is one of the most popular themes in Chinese conservation literature (Geffroy, 2004).
In fact, here we are faced with the *invention of the memory* and the construction of a past that the country has never come to terms with after the trauma of the Cultural Revolution. It was not possible for China because it passed from that original trauma to the other triggered by the reforms of Deng in 1978. , Therefore one of China's biggest problems today is not having yet embarked on a path of reconciliation with its memory, the same path which once enabled Germany and South Africa to emerge from a tunnel of torn identity.

**3. Demolition: many reasons, any project**

At this point it is worth considering the genesis and forms that produce such an abnormal mystification of the concept and practice of conservation. There are many reasons behind this phenomenon of uncontrollable aggression but not all of them are referable to the most obvious such as the current political economic system, the strength of the real estate market and the collusion between private and public interests. Other reasons are associated to them which can be summarized as follows: (i) the need of local authorities to 'make money' by means of land value; (ii) the subordination of people to political power; (iii) the weak attachment of the inhabitants of the city centres to the place; (iv) the peculiar conceptualization of heritage in Chinese tradition.
The first reason depends on the chronic lack of resources from the State coffers and local authorities due to the huge amount of public works carried out since the advent of the People's Republic in 1949. In those years, the demolition of the historic walls, as well as a distorted political vision, was accelerated by the shortage of building materials: the walls were actually a mine of building materials (Lu, 2011). With the reforms of Deng and the introduction of the dual land regime – relating to the ownership (of State or rural communities) and use (private, public or mixed) - the value of land increased enormously and land marketing became one of the most lucrative segments of the economic cycle of the present socialist market (Shin, 2009)[5]. Today the sale of land, made possible by the forced

[3] The same method concerned modern housing districts to a greater extent as they became quickly obsolete and free from the restrictions for historic areas. Rehabilitation hardly ever matters but demolition and reconstruction are now in the third generation (1950s, 1980s, 2010s).
[4] A *hutong* is a road or alleyway mostly present in Bejing and northern Chinese cities,that gives the name to the urban district it serves. A *siheyuan* is a traditional courtyard house with one or two-elevations which opens onto a *hutong*.
[5] The Constitution of the Republic of China states (art. 10): «The urban land belongs to the State. The rural and suburban land belongs to the rural communities, except the parts of national interest belonging to the State. The houses and agricultural land relating to private use belong to the rural communities. The State can expropriate land for public interest according the laws, giving a compensation to the owners. To any institution or person is forbidden to occupy, sell, buy or transfer

expulsion of the inhabitants, has become the main source of revenue of local authorities. Its high income potential and the fact that the managers of local authorities can earn money in both a legitimate (by benefits linked to productive operations) or an illegal (by collusion) way, results in a land market that does not meet obstacles even in historic areas, where entrepreneurs can demolish everything except for a limited number of listed monuments.

The second reason is due to the relationship between people and power and the civic culture that corresponds to it. The inhabitants put up with the the decisions of the policy makers with resigned acceptance and do not have the strength to oppose such a threatening and unimpeachable power. Some regulations require that plans are subject to publication and public consultations before approval, such as the Law concerning urban and rural planning (arts. 26 and 46, 2007) and the Ordinance for the preservation of historic cities and towns (2008), yet they have no real cogency (Li, 2013).

However, the conflict over the right of residents to stay in their own home is the issue that mostly affects the inhabitants and power[6]. Although this topic is under a specific legislation, reported by the media and the subject of a number of studies (Davis, 2004; Li, 2013), it always ends up in the same way: in front of a solid cross-alliance between local authorities and real estate developers for managing and implementing new developments, the inhabitants are isolated and without bargaining power (Wu, 2012).

Even the 'Community of the inhabitants', an administrative body working at the level of individual municipal districts helps to bridge this gap. Instead of representing the civil society or social groups involved in a bottom-up process, it is indeed limited to functions that are fully dependent on local government and plays an administrative role of social control (Bray, 2006).

There are some proposals to put an end to this situation as to increase the compensation rate for the evicted inhabitants and to promote citizen participation through an effective application of laws. Meanwhile there are more and more protests and some people, like John Friedman, even see a significant growth of civil society (Walcott, 2007). Nevertheless, the silence of the inhabitants finally prevails, unable to stem the disruptive mercantilism of urban policies (Cui, 2005).

The third reason is related to the phenomenon of the weak social roots of the inhabitants. If urban growth has not fully spread out into the endless suburbs and since the advent of the People's Republic has been overflowing in the heart of the city, it is due to the fact that the city had to act as a clearing house in order to cope with the large migrations from and to the countryside caused by the traumatic development policies of the last fifty years. This has meant that different and unstable populations have significantly changed the cities without maturing a strong sense of belonging. Two other factors are responsible for this incomplete maturation: the inhabitants' uncertainty regarding the workplace and the future of work itself. Moreover, the fact that the most of the housing is still owned by the State, which permits people to inhabit the houses but may want them back (for example for the implementation of a *Weigai*), has discouraged people from investing in them both materially and emotionally.

In this vacuum of stakeholders and identities the nouveau riche have an easy game to play in occupying the valuable areas of the center, flanked by disinformation campaigns that convey a narrative of the protection in a purely commercial way.

Apart from the three well recognizable reasons above mentioned, and as such subject to quite strong social conflicts, there is a fourth less evident but not less important: the reason linked to the particular conceptualization of heritage buildings according to Chinese tradition. In order to discuss this point it is important to note that the idea of cultural property established in the World Heritage Convention

---

illegally the possession of the land. The land right of use may be transferred according to the laws. Any institution or person is required to use the land in a rational way».

[6] Forced evictions are common in rural areas and are a great source of conflict and public protest. According to some projections, up to 65 percent of the 180,000 annual 'mass incidents' in China derive from the opposition to forced evictions (*Forced evictions in China*, Wikipedia).

(WHC, insofar) (UNESCO, 1972) cannot have a universal consensus. In fact the concepts of historical heritage and identity that are stated in the WHL, are differently conceived in the various cultural basins and this leads to significant consequences.
Europeans, as Augustin Berque (2007) underlines, are in favour of protecting historical assets in their materiality, while China prefers the conservation of witnessing aspects: in fact, it is argued that these latter are able to objectify the contents of a historical asset rather than the historical asset in its original physicality. In this sense, paradoxically from a western point of view, a painting of the Qing Dynasty has more value if it is endowed with a comment by a famous intellectual or important politician written on it.
In particular, in China «… the preservation of material forms is not important. It is for that reason that the Chinese can destroy so easily those built forms which, in Europe, would be preciously preserved, or, by the same token, can build new ones with no consideration for what the Europeans would call authenticity», i.e. that of the original matter (Berque, 2007, p. 7).
Having said that, we do not want to affirm that the different conceptualization of cultural heritage in China explains and justifies the current destructive tendencies, but just that a certain habit to the ordinariness of the demolition and reconstruction of historic buildings, associated with traditional practices and rituals, it might have made it less reprehensible. Demolition cannot have appeared to be in sharp contradiction with the culture of conservation especially in the case of small-scale interventions and ordinary urban fabric,.
Moreover, it is worth noting that in China the cultural value of a historic asset is recognised primarily at institutional level. In China the process of application for admitting a cultural heritage to the WHL is certainly not managed by local players, as recently occurred for the Vineyard Landscape of Piedmont: Langhe-Roero and Monferrato (Italy), but originates from a central government policy which is strongly related to turistic development. Therefore when the inhabitants of the historic town demand a best quality of life in the *hutong* and the functional improvement of the courtyard houses, instead of their reconstruction, they make a request concerning a cultural value without official recognition and succumb to the market forces: an example of this is represented by the case of the Plan of Conservation and Development of Nanluoguxiang in Beijing (2006-2020) (Shin, 2010).

## 4. Aporias and practices of reconstruction

At this point, if the lens of cultural relativism acknowledges some kind of historical foundation to the practice of demolition and reconstruction, under what conditions is it still admissible? In order to approach this question let us start by referring to two temporal levels, the past and the present: in other words, before and after the official designation of the buildings and properties of cultural value as heritage to be protected.
In the past, when referring to buildings of recognized cultural value and public interest, whether they were civil or religious, with a stable typology and function over time, demolition-reconstruction was ensuring the transmission of the property (or asset) and its meanings at two levels: by fully restoring it returning to its physical constitution (as a no longer original building yet identical to the original) and by the permanence of its function. The operation was meaningful for the intimate coexistence of form and function, of a stable form over time associated to an immanent and historical function which is considered as the primary content legitimizing the meaning and value of the property (or asset). The buildings affected by these practices were not identified according to selective criteria but simply inherited by tradition. What today appears to be an ambiguous form of conservation / modification was then justified by a common feeling entirely coherent with the maintenance of that tradition.
If we come to the present, with the advent of legislation on this matter, we can schematically distinguish two levels: formally recognized assets of historical and cultural value and assets with less or no official recognition.

With the exception of few cases, the first level includes buildings whose modes and objectives of conservation assume that the physical constitution of the buildings is restored or reproduced by imitating the original (but with typology, materials and technologies that may differ from the original) and that the existing functions can be changed.
This is the case of the buildings in the Forbidden City in Beijing. There the process of reconstruction loses any ritual/traditional meaning since the function, the primary expression of the continuity of their value over time, is now a touristic function: in fact, a profound and objective transformation took place. Once the functions of the buildings 'recovered' by reconstruction changed, their testimonial character was merely allusive. Moreover, reconstruction is often no longer philological but falsified – by new materials and techniques – and is oriented towards reproducing a vision of national identity subject to tourism interests.
Another problematic case was the reconstruction of the gate (and tower) of Yongdingmen in Beijing in 2004, situated to the south of the historical axis of the Ming dynasty. The gate, which was the largest gate in ancient Beijing, was erected in 1553 and then demolished in 1957 under Maoist urban modernization. Its recent reconstruction is supposed to follow the principle of the replica of the original, by using the same materials and techniques. Yet, with the aim of reviving the 7.8 km of the long city axis, which has been freed of the structures that were interrupting its perspective, the gate was not rebuilt in its original place!
An even more striking and common example is the Yellow Crane Tower in Wuhan. The building is one of the four Great Towers of China, built in 223 (Three Kingdoms period), and has been restored or rebuilt 10 times. The last time it was rebuilt using modern materials and with the addition of a lift in 1985, but on a hill situated in the city center one kilometer from its original site. Today it is 15 meters wider, it has 2 floors more than the original 3 and offers visitors an amazing view of the city and the Yangtze River. Nevertheless, regardless of its authenticity, it is considered the same tower which was sung in the poems written by the poet Cui Hao in the eighth century.
Did its reconstruction follow the principles of tradition or not? I think we can answer yes up to the penultimate reconstruction, while concerning the last reconstruction (1985), which was unacceptable from a western point of view, I think that the case is more complex even from a Chinese point of view. In order to evaluate the matter we should better understand many aspects of cultural context which is not an easy task for a foreigner. In fact identity is an issue that affects not only the property (or asset) in itself but also the ways in which it is identified and recognized by various social bodies, by the various representatives and groups with political and institutional power; but unfortunately little is known about this aspect.
However, it is reasonable to state that in order to be deemed conservative or not, an intervention must comply with at least two criteria: that it does not modify the cultural and historical values of the property, and that the economic management of the operation is carried out firstly according to public interest. In the past the traditional practices of reconstruction were controlled by those who were entitled to ensure the continuity of functions, whether they were monks or government officials; and the same techniques and materials of construction were adopted. On the contrary today's practices lead to the erection of buildings which are dissimilar in their physical components and functions, therefore how can they be considered as being conservative?
There is much debate on this issue and the Principles for the Conservation of Heritage Sites in China (China ICOMOS, 2002) could represent a basic reference for it. Yet there is a problem, the ICOMOS China is managed by the State Administration of Cultural Heritage (*guojia wenwu ju*), which reports to the Ministry of Culture. Consequently, unlike the Burra Charter (on which these Principles are based), which was developed by a NGO and is open to the debate among individual or associated experts, in this case the principles are defined by an institutional body and experts who are not

employed by the administration are not allowed to participate: it turns out the dominant role of the State in the decision-making procedures of conservation (Qian, 2007)[7].
It follows that a reflection on this matter is lacking (few people know of the existence of the Principles of ICOMOS China) and that the debate on conservation prefers to deal with other issues as those cultural tourism (Leah et al., 2008; Li and Hou, 2011; Wang and Bramwell, 2012).
On observing the second level, that is the buildings whose value is approximately or not at all recognized (the most prevalent category in historic areas), we find that interventions that affect them are not defined according to their objective attributes of quality, which are actually overlooked, but on the economic return that they can provide. This attitude leads to the modification of those parts, whether they are big or small, built or un-built, that contrast with this goal. The traditional market streets belong to this category, as they are usually widened to build more attractive shopping malls and private residences.
The transformation of the latter is facilitated by a particular condition: the interventions required to provide a functional updating of the dwellings according to new living standards has become the Trojan horse of reconstruction.
This fact goes against the *siheyuan*, i.e. that architectural unit that straddles between noble and ordinary architecture, thus marking out the building fabric of the Chinese city. In its buildings as in its gardens calligraphic compositions, decorations, floral elements and furniture are distributed, through which the owners passed down family anecdotes and traditional Chinese stories. They are narratives and metaphors whose meanings can only be fully understood by an increasingly smaller number of people. These narratives should be preserved together with the built asset but unfortunately they are deleted in the context of fast reconstruction. Therefore in this case, despite the maintenance of the residential function, the delicate complexity of signs and meanings of memory disappear. (Lev, 2005).
However, there are significant experiences that have attempted to reverse this approach, by assigning a key role to the maintenance of existing historic fabric within the cultural and social sustainability of preservation: they all refer to projects and actions supported at international level. Among these the intervention for the rehabilitation of the sector of Wenhuali in the historic center of Yangzhou can be cited as an exemplary case, which was implemented by GTZ (Deutsche Gesellschaft für Technische Zusammenarbeit). The project, funded by GTZ and based on a participatory implementation which overcame significant initial resistance, proved to be very successful, thus establishing itself as a widely repeatable process and method (GTZ, YMG, 2007). Regrettably, the same administration of Yangzhou, which continued the work on the area of Dongguan, betrayed this approach by using renewal measures based on tourism and real estate development, resulting in a commercial, completely rebuilt building fabric and in the displacement of the original inhabitants and traders: once again a top-down process planned and managed by the government and implemented by a real estate company owned by the same government (Li, 2013).

## 5. Conclusions

The reflection presented in this study was carried out in respect to certain aspects that appear relevant in relation to the political context, the regulatory system and the technical tools as well as to certain operations implemented in the historic city. The main issues observed can be summarized as follows:
• In China, the policy of conservation is based on the initiatives of only institutional bodies. It is established on a rigid yet adaptable legal framework, in which it is difficult to distinguish between declarations of principles, objectives, permissions and prohibitions. As such, it does not unequivocally

[7] These limits are worsened by a conservation conceived only in relation to monuments and monumental sites, nonetheless moveable if required by important national developments: "... when a major development project of National importance is undertaken and relocation is the sun of means of-saving elements of a site may they be moved in their historic condition " (Principles ..., art. 18).

address the various components of the protection system (i.e. political, administrative, social, real estate-oriented and so on), and it paves the way to error and manipulation legitimating a not transparent governance of the preservation policy.
• The backwardness of the intervention modes proposed in the various recovery tools corresponds to an insufficient maturation of a specific technical culture. Analysis describing the context to preserve with adequate cognitive frameworks concerning the physical, functional, economic and social aspects is lacking and a theory that puts land use and urban fabrics in accordance with the conditions of their transformation is required. The usual methodology of intervention, bare-bones, gives way to the reconstruction of a historical urban set where it is difficult to distinguish true from false.
• In a cultural context where traditionally the historical properties are recovered by means of the reconstruction method, neither a restoration theory nor a method of recovering at urban scale have been developed. However, in the light of current conditions, the traditional approach is no longer valid. The country is therefore encouraged to update the meaning and vision of cultural heritage together with the relative policies.
• At various levels of government there is little intention to involve the local social forces in the conservation plans. This is reflected by the low consideration of both the players in the field and the conditions of transformation, which gives a huge operational power to demolition with reconstruction and results in the space being used in rough and speculative ways. Therefore it comes a political short-circuit: if there is no increase in the bottom up dynamics, it will not be possible to stimulate a review of government preservation policy; on the other hand, if there is not a significant development of bottom up initiatives there will not be openness in government policies.
• The widespread practice of demolition is also the result of an incomplete maturation of the complexity of history and forms of identity: China still has to come to terms with its history, which was denied during the Maoist era and left on the shelf during the decades that followed.
In conclusion, a revision of the current destructive approach is not sufficient for addressing the main issues of providing new meanings and functions for Chinese historic cities. A more comprehensive discipline of conservation as well as a more far-sighted vision of the future of the cities is required. A vision that is able to properly legitimate the reasons, objectives, forms and contexts of demolition, ranging from urban restructuring, such as that of the *artiste démolisseur* Haussmann, to the removal of accretions in the plans of Cervellati in Italy. In fact the issue of demolition is so multifaceted that the relative problems can be only solved by means of an interdisciplinary approach. In other words, demolition must be conceived as an instrument of a political action, which is able to address specific strategies for the enhancement and development of historic assets, which must be saved from political ideology and pure real estate market.

# CONSERVATION AND DEVELOPMENT METHODS OF HISTORIC VILLAGES: A CASE STUDY IN CHINA *

Wenjun Hou[1], Tianyang Ge[2]

[1] First Author: PhD Candidate, School of Architecture, Southeast University, hwjseu@qq.com
[2] Corresponding Author: PhD Candidate, School of Architecture, Southeast University, getianyang@qq.com

**Abstract:** *At the early stage of the conservation of historic towns and villages in China, government basically focused on protecting the material space. At that time, tourist industry did great effect to help the historic towns and villages to survive. But, in the process of the rapid urbanization in China, Some of them are turned into tourist attractions without control. The contradiction between protection and development become more and more significant. They are facing the problem: how to balance all the factors? This paper studied a typical case in Jiangsu province, China.*

*Frist the paper summarized the general planning methods during the main stage of conservation development in China. Secondly, the paper studied the current status of the typical case, and generalized the problems under the current conservation planning system, such as lack of safeguard mechanism to carry out planning, stress of land-use transformation, excessive tourism economy, and losing of the traditional lifestyle. Thirdly, the paper analysed the need and effect of different members involved in this case. At last, to solve these problems and balance different kinds of need, the paper presented three planning methods: first, put tourism land-use outside the core protection area. Second, set up the environment protection area, to avoid the stress of sprawling of urban area. Third, develop suitable and small-scale commercial activities. And the paper put forward two strategies: firstly, government should pay more attention on the carrying out of the planning, and give more rights to the local groups. Secondly, carry out dynamic planning.*

**Keywords:** conservation and development methods, historic villages, China

## 1 Research background

The conservation of historic villages of China started at the end of 1980s. Investigating the material space was the core work of the protection that time, which only some scholars took part in. Not until the beginning of 21st century, Ministry of Construction and State Administration of Cultural Heritage carried out the evaluation of the historic towns and villages (Qiu, 2014). Since then, 276 villages have been given the title of Historic Villages of China. This makes all levels of government and departments pay attention to the conservation of historic villages.

* This work was financially supported by National Natural Science Foundation of China No.51278113

In 2013, the Ministry of Construction issued The Conservation Planning Requirements of Historic Towns and Villages, which include planning content, result request, investigation and evaluation. This realized the legalization and standardization of the conservation planning of historic villages. But how to make the historic villages develop sustainably is still a problem. And this problem becomes more serious nowadays. Both government and planners are searching for the efficient methods.

## 2 Conservation planning methods review

### *2.1 First stage*

This stage is the sprout period , which started from the early 1980s to 1994. At the beginning, some scholars brought forward the thought of conservation planning of historic villages. The studies almost focused on the forming process of the whole village, characteristic of the material space and cultural heritage(Liu, 1998). For a long time, the conservation planning was confines to the investigation of present situation.

Near the end of this stage, multilevel conservation method was proposed by Yisan Ruan (Huang, 2014). Based on the investigation of architecture heritage, historic village was divided into three conservation areas in this method, which were core conservation area, general conservation area and environmental coordination area. Each of them had different protection intensity and contents. This kind of method helped to protect the historic villages in good condition.

### *2.2 Second stage*

This stage is the foundation period , which started from 1994 to 2003. In this stage, the central government put more emphasis on the conservation of historic villages. And they started to study how to formulate the standard for it. In 1994, The Specification of Conservation Planning of Historic City was issued, which the conservation of historic villages was included. And the conservation planning of historic villages adopted the conservation pattern of historic cities(Yang, 2009b).

During this stage, the conservation planning method was further improved. Conservation framework was formed, which were conservation elements, conservation theme and conservation structure. This method was derived from the conservation of historic cities. It further improved the multilevel conservation method. And it became more comprehensive. It also influenced the formulation of planning standard.

### *2.3 The third stage*

This stage is the development period , which started from 2003 to 2013. Since 2003, Ministry of Construction and State Administration of Cultural Heritage have carried out the evaluation of the historic towns and villages of China. This symbolized the conservation of historic villages entered a

new stage. In another word, the central government used this method to encourage the society to recognize the importance of conservation of historic villages. In 2008, the Conservation Regulation of Historic Cities, Towns and Villages were promulgated, which stipulated that historic villages can t get the title without the conservation planning finished (Huang, 2014). This helped to encourage the local government to carry out the conservation planning.

In this stage, the central government integrated the core content of conservation planning of historic villages. At the same time, China entered a phase of rapid urbanization. The contradiction between protection and development become more and more significant. Because of this, a lot of scholars began to looking for new approaches. According to the research data, the research mainly focused on building science, culture and tourism (Huang, 2014). Tourism has become an economic method to help the historic villages to survive. But this economic method created problems, such as environmental pollution, recession of local culture and so on(Yang, 2009a).

### *2.4 The fourth stage*

This stage is the adjustment period , which started from 2013. In 2013, the Conservation Planning Requirements of Historic Towns and Villages were enacted. It standardized the conservation planning of historic villages. At the same time, planners started to try new methods to solve the new problems, such as establishing GIS conservation database, using eco-technology and so on.

## 3 Typical case study

The paper studied the Dou villages in Nanjing, which is located in the southeast coast of China. Because of the rapid urbanization, this historic village is at the edge of destroy. And many factors clash and work together in it.

### *3.1 Location*

Dou village is located at the southeast of the main city, which is one of the economic prosperous cities in China. It is populated by descendants of the workers who built the Nanjing city from Ming Dynasty. The history of the village is connected with the city (Figure 1). Because of the spread of cities, it is facing the stress of land-use transformation. At the same time, it is facing the tendency to become a tourist attraction, because the will of the local government, who has made some of the historic villages tourist attractions.

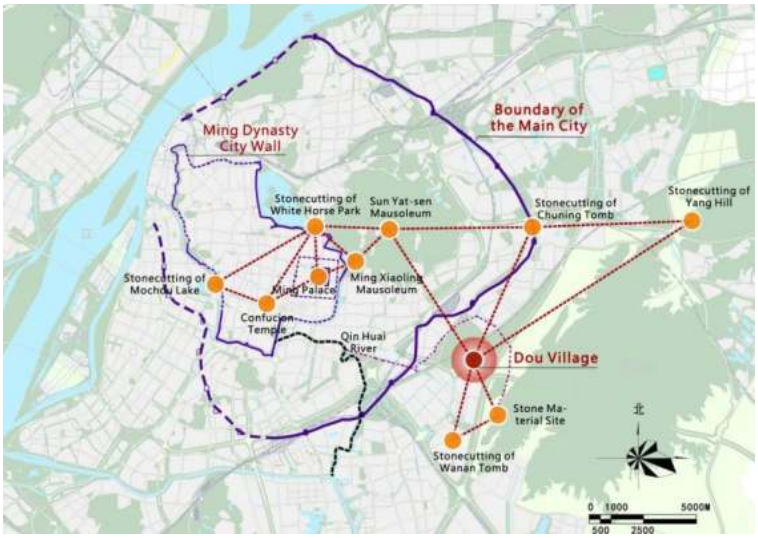

Figure 1 Location of Dou Village and Heritages Built by Natives of Dou Village

### *3.2 Historic factors*

Historic factors include historic buildings, historic streets and alleys, historic environment factors and ancient trees. According to the investigation, there are 835 buildings in this village, which include 81 historic buildings and 754 normal buildings. All the historic buildings were built before 1980. Because of lack of money, some of them are at the edge of damage, which were made of stones. And they scattered among the normal buildings (Figure 2). For this sake, it s very difficult to get the title of historic villages of China. In other word, it can t get special conservation funds from the central government.

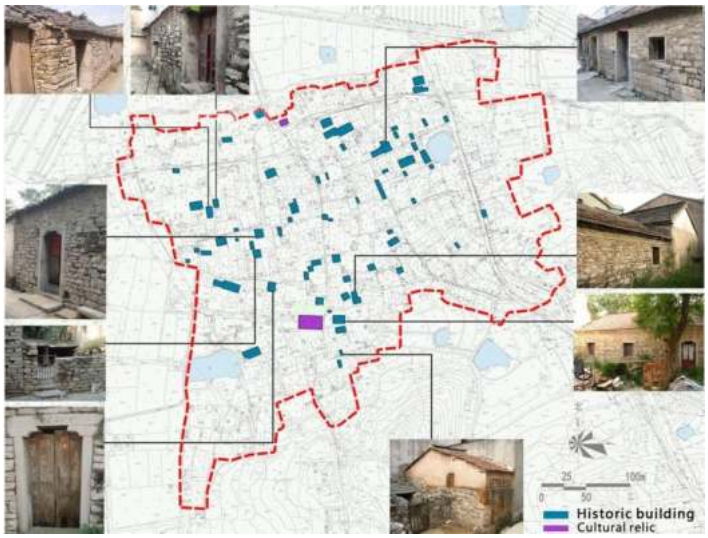

Figure 2 Distribution of Historic Buildings

Unlike the historic buildings, most of the historic streets and alleys are kept in the old way. And this village still is surrounded by farmland and small hills, which helped to avoid being invaded by the city. The other historic environment factors locate in the middle of the village, which include two Cultural Relics of China.

### *3.3 Land-use and economic condition*

According to the survey, 80.92% land of this village is Residential Land, which is 11.24ha (Figure 3). The second-largest land is Road and square land, which is about 11.45% of all. And this village has a small amount of Industrial land, about 2.45%. The others are Municipal utilities land, Cultural relics land and Commercial land. According to further investigation, the stress of land-use transformation is from the outside influence. Because of urban expansion, the land values of the other villages around Dou village increased rapidly. Most of them were turned into high density urban residential land. So the local government and some of residents want to get economic benefits from the land, which is quite attractive.

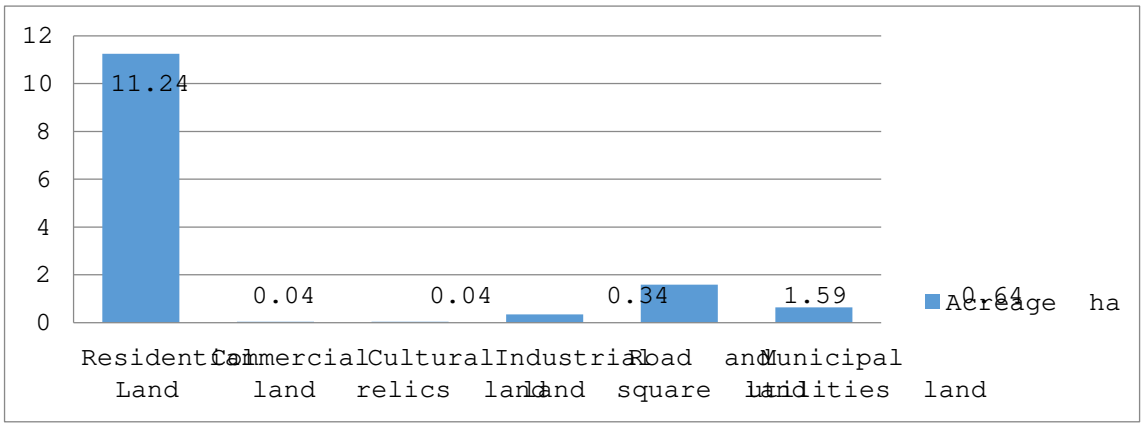

Figure 3 Land Use of Dou Village (2013)

In 2013, the average monthly income per person is 2000RMB. The number of low income people is approximately 62% of all (Figure 4), whose income is below 2000RMB. Some of them rely on agriculture for income, especially the aged. On one hand, agricultural economic helped to protect cultural relics of the village passively. On the other hand, the low income can t fit the need of them all, which result in the disrepair of historic material space. And the number of higher income people is only 13%, whose income is above 3000RMB (Figure 4). All of them work in the city, and live in the village in the evening. The contrast between this village and nearby tourism-based historic villages is so great. Affected by this, local government and some of the residents have a tendency to choose the tourist economy, though tourist economy caused a lot of negative effects in the tourism-based historic villages.

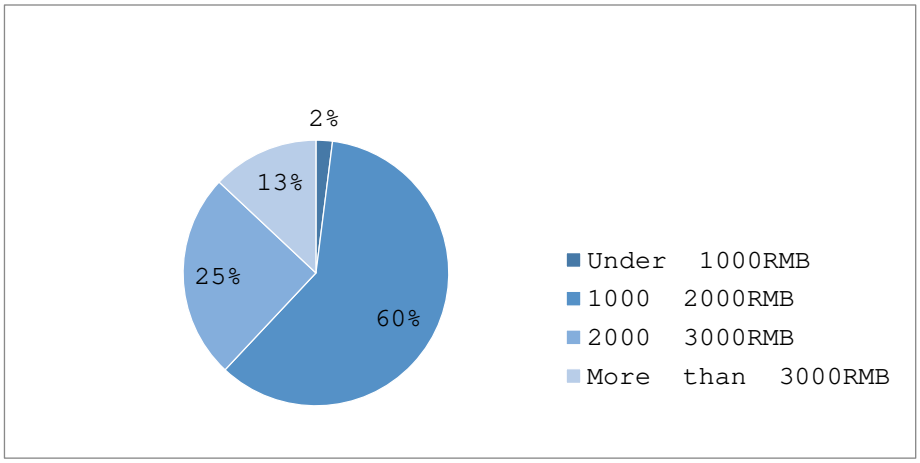

Figure 4 Incomes of Natives in 2013

### *3.4 Population structure and cultural tradition*

According to the official data, there are about 332 households in Dou village, altogether 1040 people. And the number of natives is approximately 98% of all. From the location distribution, 42.4% of the population are located at the west of the village, which is the oldest part of the village. Unlike some tourism-based historic villages, the hollow phenomenon isn t serious in Dou village, though population ageing.

Most of the natives are the descendants of the workers who built the Nanjing city. Some of the traditional festivals are kept here. But the traditional life-style changed a lot. Because of the rise of the industrialized construction way, traditional stone carving skill is on the brink of extinction, which is the most precious cultural heritage of Dou village. Only some old people still keep this skill as a hobby. Losing of cultural heritage and traditional life-style is a widespread problem among historic villages.

## 4 Major participators study

Almost like other conservation planning of historic villages, major participators are local government, superior planning bureau, native, tourist, protection group and planner in this case. And superior planning bureau, tourist, protection group and planner were most concerned with the protection of the historic factors. But the local government and native wanted to develop economic and improve living conditions. And superior planning bureau and local government were the most powerful actors of all, who offered the funds. The others played a limited role in the process (Figure 5).

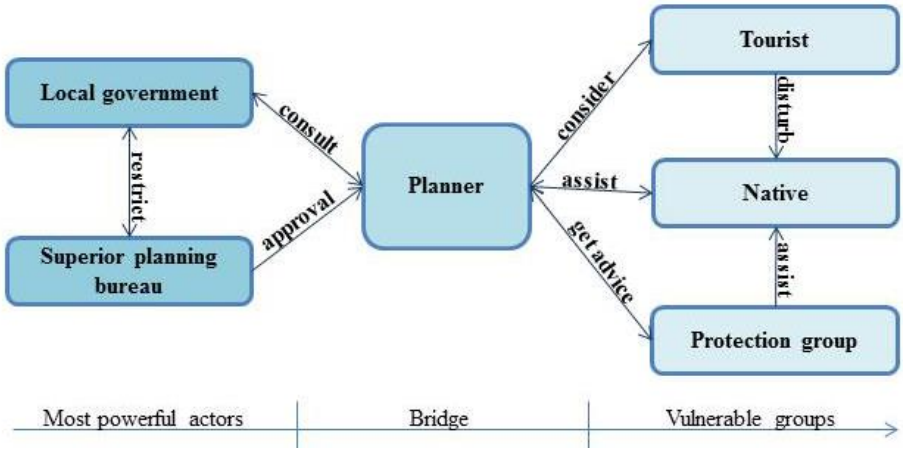

Figure 5 Relationships of Major Participators

### *4.1 Local government*

Local government is one of the most powerful actors in this planning. It not only affords most of the funds for the planning, but also takes charge of the implementation of the programme. So its intention can directly affect the direction of the planning and quality of the conservation work. In this case, the main purpose of local government is economic development. Because tourist economy helped a lot of other villages, it becomes a good choice in the local officers mind.

### *4.2 Superior planning bureau*

Superior planning bureau is the examination and approval department of conservation planning. It is also a powerful actor in this planning. In this case, approximately one third of the planning fee comes from it. Superior planning bureau and local government restrict each other. On one hand, superior planning bureau want to protect this village from being teared down. On the other hand, it has to respect the will of the local government to get the follow-up financing for the conservation work.

### *4.3 Planner*

Planner is the bridge to connect them all. Planners provide efficient conservation and development methods, which the local government and superior planning bureau both seek. In this case, planners have the same aim with superior planning bureau. But they try to find new planning methods to avoid relying on tourist economy, and pay more attention to the will of the natives.

### *4.4 Native*

Generally speaking, Natives are the most vulnerable actors in the process of planning. In this case, most of the natives wanted to develop economic and improve living conditions. Because of the

possibility of demolition, many of them united to struggle for their own rights. So the local government paid attention to them passively. But only a few of them cared about the conservation of the village. Because if the conservation planning is made, they think they can't get compensation of demolition.

### *4.5 Tourist*

To some degree, tourism has contributed to economic recovery. But the tourists are considered as external factors. In this case, the natives didn t get the benefit of tourism. On the contrary, it disturbed the daily life of the natives for the lack of planning.

### *4.6 Protection group*

In this case, the protection group played a limited role in the conservation planning. It is made up of aged natives and retired officials, who used to work in superior planning bureau. They just can give some advice about the conservation.

## 5 Planning methods suggested

### *5.1 Subarea development*

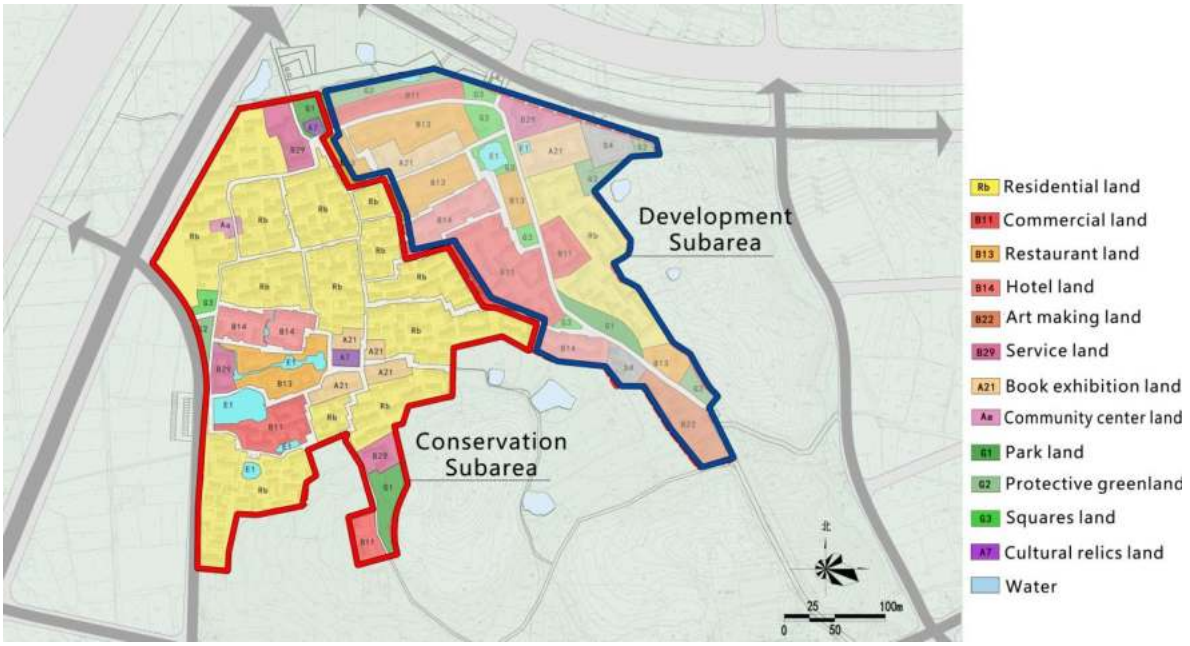

Figure 6 Land Use Planning and Zone Control

First, put economic development land-use outside the core protection area, such as tourism land-use,

commercial services land-use and so on (Figure 6). On one hand, keep the core protection area extend the tradition life-style. On the other hand, through land consolidation, develop suitable economy outside the core protection area to improve the quality of life. Second, strengthen the regulation and monitoring of the develop subarea. The conservation regulations of historic villages have fully developed. But the regulations of the develop part is still under study. And the new developing functions are external factors, which might be inconsistent with the conservation.

### *5.2 Set up the environment protection area*

Set up the environment protection area, to avoid the stress of sprawling of urban area. According to the investigation, Dou village is surrounded by farmland and hills in history, which is still kept the same nowadays. Setting up the environment protection area helps to protect this historic environment element and avoid excessive development of the urban area. And the surrounding farmland is part of the traditional life of the natives. It is also helps to protect the culture heritage.

### *5.3 Unit and small-scale renewal*

Frist, in conservation subarea, use small-scale dynamic renewal (Figure 7). The texture of the space is formed through years. Small-scale dynamic renewal can help to keep the traditional texture in the process. For the high density area, systemize and restore the traditional courtyard space. And give new function to the discarded historic buildings. Second, develop suitable and small-scale commercial activities in the develop subarea. Through house renovation, develop commercial activities step by step. On one hand, this can maintain the naturally formed texture. On the other hand, this helps to reduce development costs.

Figure 7 Units and Small-scale Renewal in Conservation Subarea

## 6 Conclusion

During the research, the most prominent problem is imbalances of the power of the participators. Under the circumstances, the effect of three planning methods is limited. To solve this problem, government should pay more attention on the carrying out of the planning, and give more rights to the local groups. At the same time, government should encourage social organizations to raise funds for the conservation. On one hand, this can ensure the implementation of the conservation program, especially when the local government lack of funds. On the other hand, this might help the local economy develop sustainably. And superior planning bureau should participate all through the program to keep the right direction, and avoid selling the historic village to profit-making institutions.

The conservation program will not end with the accomplishment of the conservation planning. So it is necessary to carry out dynamic planning. Planners should keep on taking part in the conservation program after planning finished. This can assure the successful conservation technically. To some extent, planners connect the vulnerable groups and the power sectors. It is necessary for planners to carry out dynamic planning.

# A STUDY ON THE ACTION MECHANISM OF CONSERVATION LAWS AND POLICIES FOR HISTORIC TOWNS AND VILLAGES IN CHINA*

Tianyang GE [1], and Wenjun HOU [2]

[1]First Author: PhD Candidate, School of Architecture, Southeast University, getianyang@qq.com
[2]Corresponding Author: PhD Candidate, School of Architecture, Southeast University, hwjseu@qq.com

**Abstract:** *In the past 30 years, the conservation of historical and cultural towns and villages in China has greatly developed. On the one hand, this paper reviewed the development, laws and policies system, and action mechanism of the conservation of historical and cultural towns and villages. First, the development of the conservation can be divided into three stages: the beginning stage, the national level conservation stage, and the legal system construction stage. Second, in policy respect, a policy system basing on two laws one ordinance was introduced, including 2 national laws, one national ordinance, several ministerial rules and regulations and over 100 local policies. Third, in conservation mechanism respect, a system of policies was introduced, including historical and cultural towns and v application and approving, conservation planning, administration and financial support. On the other hand, shortages in the conservation were indicated. First, there is lack of ministerial and local policies focus on towns and villages. Second, there are too many administrative government departments and the conservation efficiency is low. Third, there is lack of sustainable development guidance, such as economy, society, population and culture. And these are the fields to be improved.*

**Keywords:** historical towns and villages, conservation laws and policies, action mechanism,

## 1 The development of historical towns and villages conservation in China

### *1.1 The beginning stage (1986-2002)*

The first policy mention the protection of historical towns and villages was made in 1986(Zhao and Wang, 2014). Before that, the protection of historical and cultural cities towns and villages were under the Cultural Relics Protection Law of the People's Republic of China, which was established in 1982(Chinese-People's-Congress, 1982). With the pronouncement of the second batch of historical and cultural cities, the national government suggested establish History and Culture Preservation Districts to protect historical and cultural towns and villages, and set up two selection conditions, which were concentrated historical relics , and reflecting certain historical stage s t ethnic and regional characteristic completely . From then on, the work of provincial grade hist cultural towns and cities selection started. In 1991 Zhejiang Province pronounced the first batch of provincial grade historical and cultural towns, including 15 towns. In 1995, Jiangsu Province

*This work was financially supported by National Natural Science Foundation of China No. 51278113

pronounced the first batch of provincial grade historical and cultural towns, including 4 towns. In 1999, Zhejiang Province Historical and Cultural Cities Protection Ordinance(Zhejiang-Government, 1999) was made, including the details of History and Culture Preservation Districts .

### *1.2 The national level conservation stage (2002-2007)*

The first national grade historical and cultural towns and villages selection started in 2002(Construction-Ministry, 2002). And the <National Historical and Cultural Towns (Villages) Evaluation Standard> was made at the same time, including three major evaluation fields, the degree of original conservation, the scale of current situation, and the certification of value and characteristics.

Table 1 Number of National Historical and Cultural Cities Towns and Villages Approved each Year

| | 1982 | 1986 | 1994 | 2001 | 2003 | 2004 | 2005 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 201 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Historical and Cultural Cities | 24 | 38 | 37 | 2 | | 1 | 1 | 7 | 1 | 1 | 6 | 2 | 4 | 2 | |
| Historical and Cultural Towns | | | | | 10 | | 34 | 44 | 58 | | 38 | | | 71 | |
| Historical and Cultural Villages | | | | | 12 | | 24 | 36 | 36 | | 61 | | | 107 | |

The first batch of national grade historical and cultural towns and villages was pronounced in 2003, 21 years after the pronouncement of historical and cultural cities (Table 1). Although started late, the number of national historical and cultural towns and cities increased quickly in the following years (Figure 1).

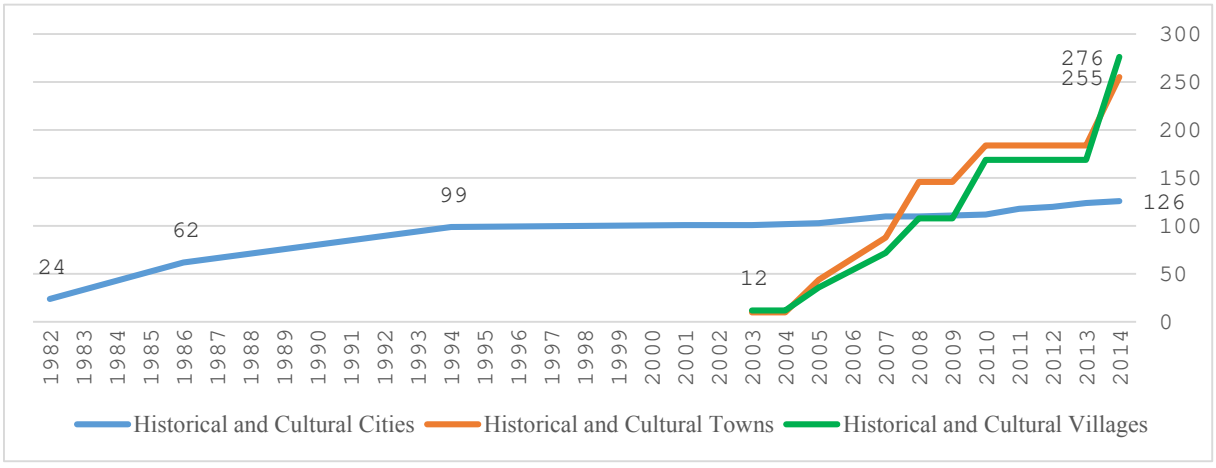

Figure 1 Number of National Historical and Cultural Cities Towns by Year

### *1.3 The legal system construction stage (2008- )*

Urban and Rural Planning Law of the People's Republic of China implemented in 2008 (Chinese-People's-Congress, 2007), replaced Urban Planning Law of the People s Republic of China(Chinese-People's-Congress, 1989). It means the importance of rural area including towns and villages was noticed. In the same year, Historical and Cultural Cities Towns and Villages Protection Ordinance implemented(Chinese-Government, 2008). Together with Cultural Relics Protection Law of the People's Republic of China the legal system of two laws and one ordinance was established.

Also in 2008, the number of National Historical and Cultural Towns overtook it of National Historical and Cultural Cities, and in 2010, the number of National Historical and Cultural Villages overtook it, too (Figure 1). And the numbers are till increasing quickly now.

## 2 Major laws and policies for historical and cultural towns and villages

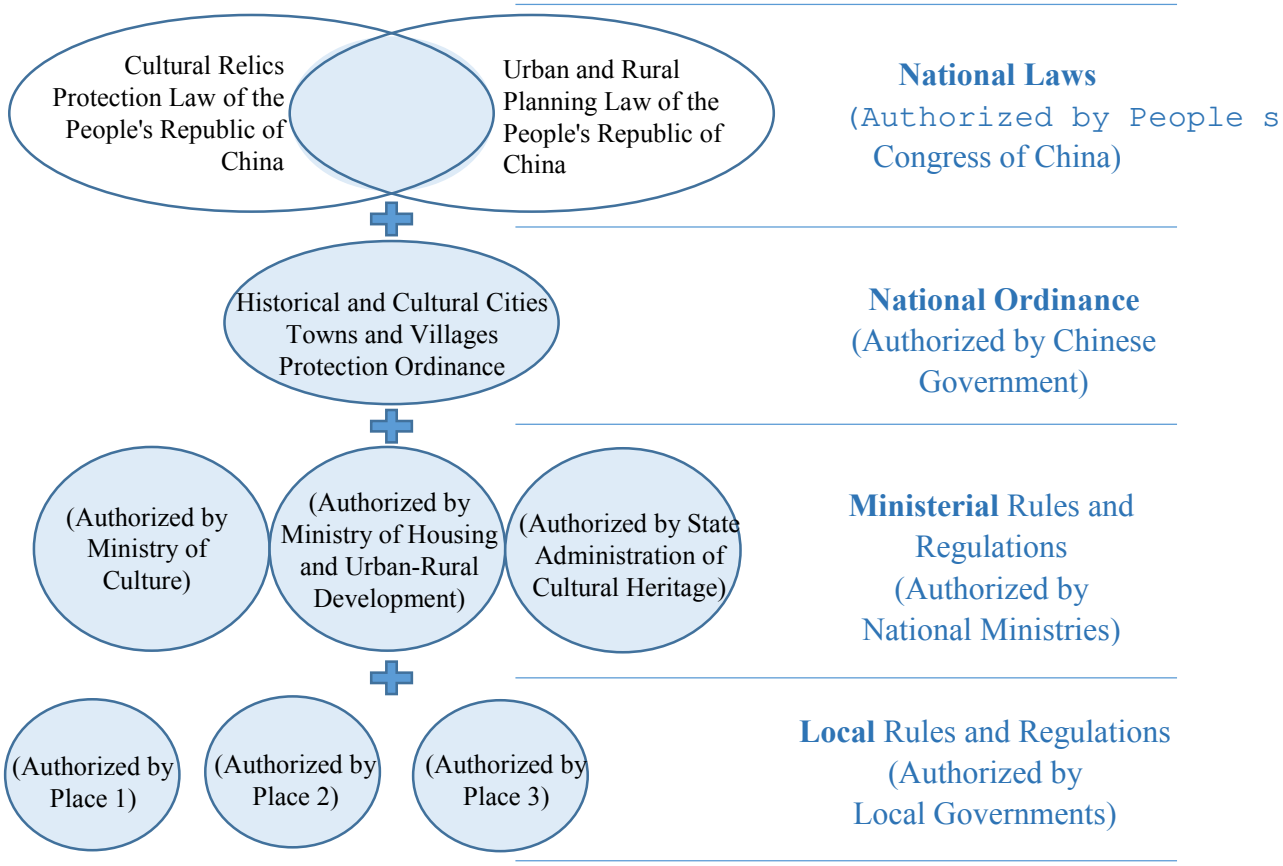

Figure 2 Structure of Major Laws and Policies for Historical Towns and Villages

There are mainly four levels of law and policies for historical and cultural towns and villages, including

two national laws, one national ordinance, several ministerial rules and regulations and many local rules and regulations (Figure 2). Among them, national laws and ordinance are the most import three ones, known as two laws one ordinance , including Cultural Relics Protection Law of the People's Republic of China(Chinese-People's-Congress, 2013) , Urban and Rural Planning Law of the People's Republic of China and Historical and Cultural Cities Towns and Villages Protection Ordi and regulations are always made under the guide of two laws one ordinance .

### *2.1 National laws*

There are two laws concerning historical and cultural towns and villages, The Cultural Relics Protection Law of the People's Republic of China, and the Urban and Rural Planning Law of the People's Republic of China.

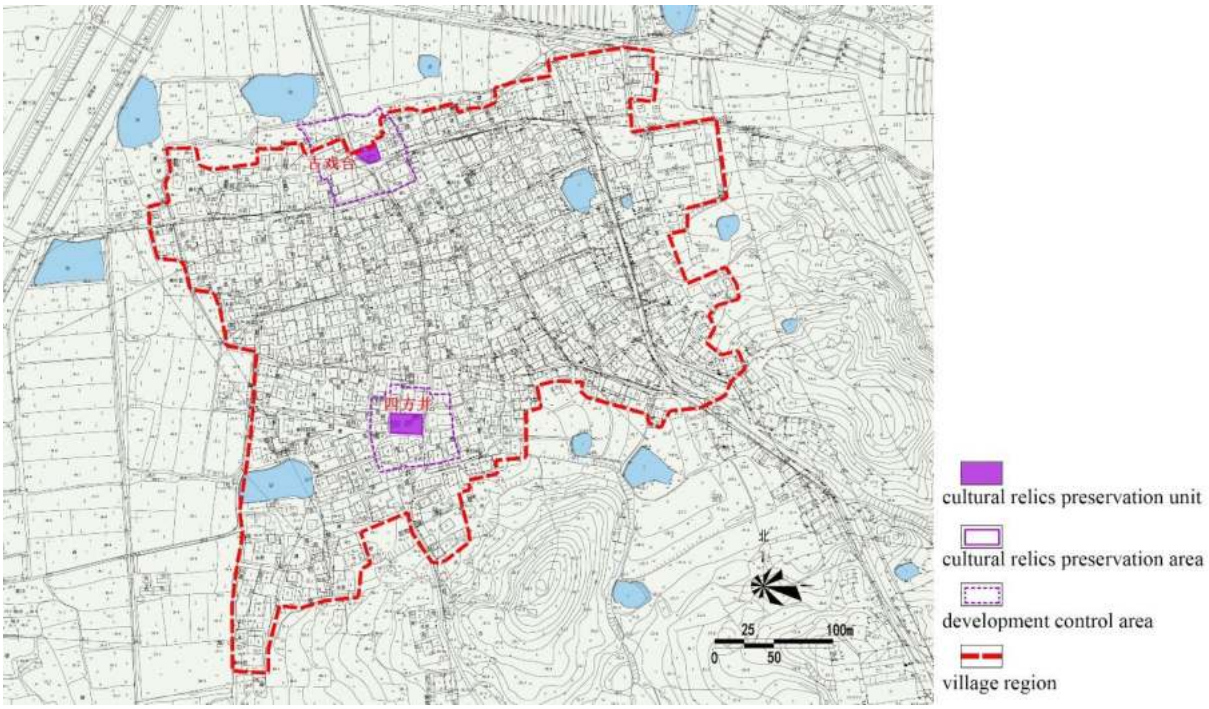

Figure 3 the Cultural Relics and Village Region of Dou Village in China

The two laws have different objects and focusses, like an example shown in Figure 3.The Cultural Relics Protection Law of the People's Republic of China focuses on and protects the most valuable cultural relics, which are always single buildings distributing separately. The Rural Planning Law of the People's Republic of China controls the planning and development of the whole towns and villages, and in all seventy provisions, there are four mentioning the protection of historical and cultural cities, towns and villages.

### *2.2 National ordinance*

Historical and Cultural Cities Towns and Villages Protection Ordinance is the most important policy that focuses on historical and cultural cities towns and villages. It indicates application and approving , conservation planning and conservation measures of historical and cultural cit

### *2.3 Ministerial rules and regulations*

Table 2 Major Rules and Regulations Authorized by State Ministries (Qiu, 2014)

| Authority | Rules and Regulations | Date of Issue | Objects |
|---|---|---|---|
| Ministry of Culture of the People s Republic of China | Measures for Repairing Project Administration of Memorial Buildings Historic Buildings and Cave Temples | 12 Jul. 1986 | Memorial Buildings Historic Buildings and Cave Temples |
| Ministry of Housing and Urban-Rural Development of the People s Republic of China State Administration of Cultural Heritage | Requirements for Protection Plan of Historical and Cultural Cities | 05 Sept. 1994 | Cities |
| Ministry of Culture of the People s Republic of China | Measures for Administration of Cultural Relics Protection Projects | 17 Mar. 2003 | Cultural Relics |
| Ministry of Housing and Urban-Rural Development of the People s Republic of China | Measures for Administration of City Purple Lines | 15 Nov. 2003 | City |
| State Administration of Cultural Heritage | Requirements for Protection Plan Compilation of the Cultural Relics under State Protection | 21 Jul. 2005 | Cultural Relics |
| State Administration of Cultural Heritage | Measures for Compilation Examining and Approving of the Protection Plan of the Cultural Relics under State Protection | 21 Jul. 2005 | Cultural Relics |
| State Administration of Cultural Heritage | Measures for Application Examining Approving and Administration of the Protection Project of the Cultural Relics under State Protection | 17 Jan. 2014 | Cultural Relics |

National ministries also made relevant rules and regulations. There are 7 major ones made by 3 national ministries, (Table 2) including Ministry of Housing and Urban-Rural Development of the

People s Republic of China , State Administration of Cultural Heritage , and Ministry of Culture of the People s Republic of China .

### *2.4 Local rules and regulations*

There are at least 120 local rule and regulations about historical and cultural cities towns and cities. (Qiu, 2014) and there are 6 about historical and cultural villages and 5 about historical and cultural towns (Figure 4).

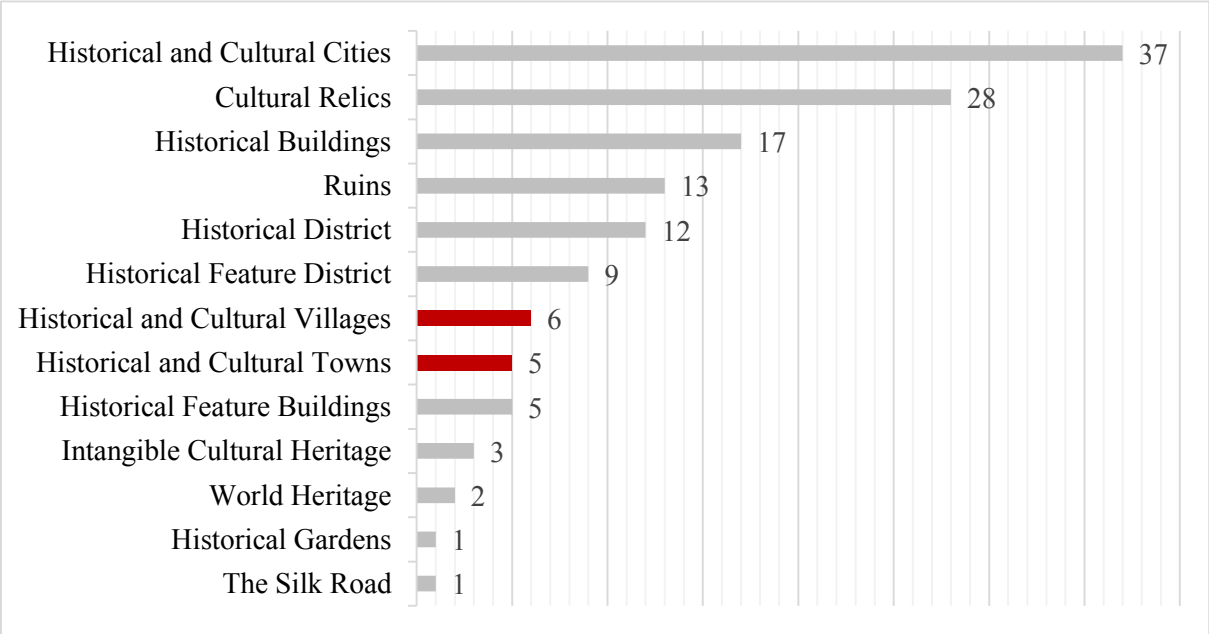

Figure 4 Number of Local Rules and Regulations about Different Objects

## 3 Conservation mechanism of historical towns and villages

### *3.1 Application and approving of historical towns and villages*

There are at least two steps for a town a village to be certificated as a national grade historical and cultural town or village (Figure 5). First, the application for historical and cultural towns and villages should be made by the County Government, and the decision-making power belongs to the Provincial Government. Once approved, the town or village will be pronounced provincial level historical and cultural town or city. Second, the development and cultural relics departments will select from provincial level historical and cultural towns and villages, choose the ones with great historical, artistic and scientific value, and pronounce them national level historical and cultural towns and cities. In addition, some local governments make their own policies, and there might be municipal historical and cultural towns and villages.

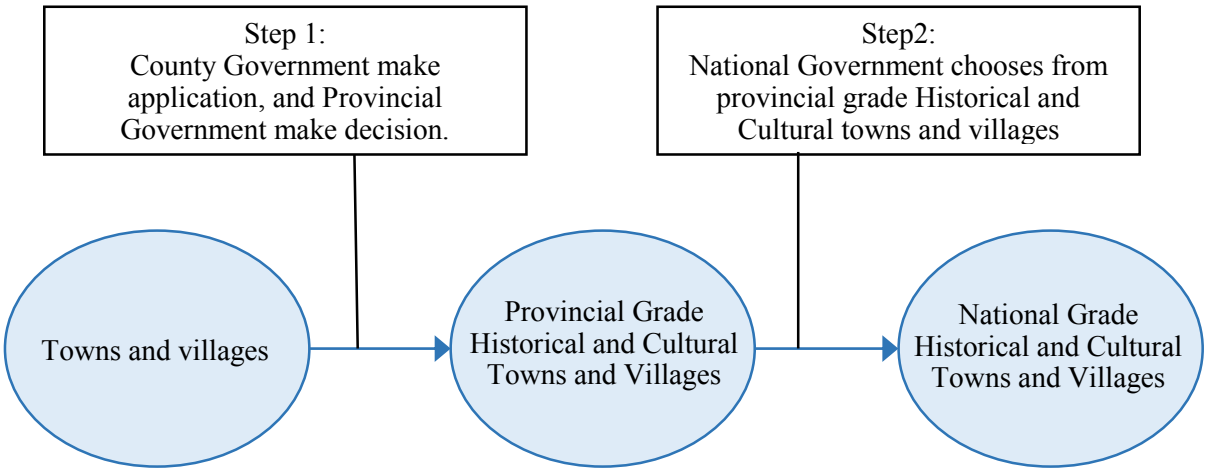

Figure 5 the Minimal Steps to Become a National Grade Historical and Cultural Towns and Villages

Five materials are required in the application (Chinese-Government, 2008). First, evolution history, local characteristics and historical and cultural introduction. Second, traditional construction layout and historical features present situation. Third, protection region. Fourth, list of unmovable cultural relics, historical buildings and historic conservation district. Fifth, the situation, destination and demand of conservation.

### *3.2 Conservation planning of historical towns and villages*

Once pronounced historical and cultural town and village, a conservation planning is required, including five main parts (Chinese-Government, 2008). First, principles objects and region of conservation. Second, conservation measures developing intensity and construction control demand. Third, the conservation demands of traditional construction layout and historical features present. Fourth, the core protection region and development control area of historical and cultural cities towns and village. Fifth, phased implementation program of conservation plan.

Although the conservation plan is demanded to be made after a town or city pronounced historical and cultural town or village, almost all towns and villages make their conservation plans before application. There might be two reasons. First, according to National Historical and Cultural Towns and Villages Evaluation Index System(MOHURD-SAOCH, 2010), an application material with a conservation plan can get 3-8 more points (full score 100 points), depending on the implementation situation of the conservation plan. Second, the materials required during application and the demands of conservation plan are quite similar, as can be seen in Figure 6, and a conservation plan can be easily made meats the requirement of application materials.

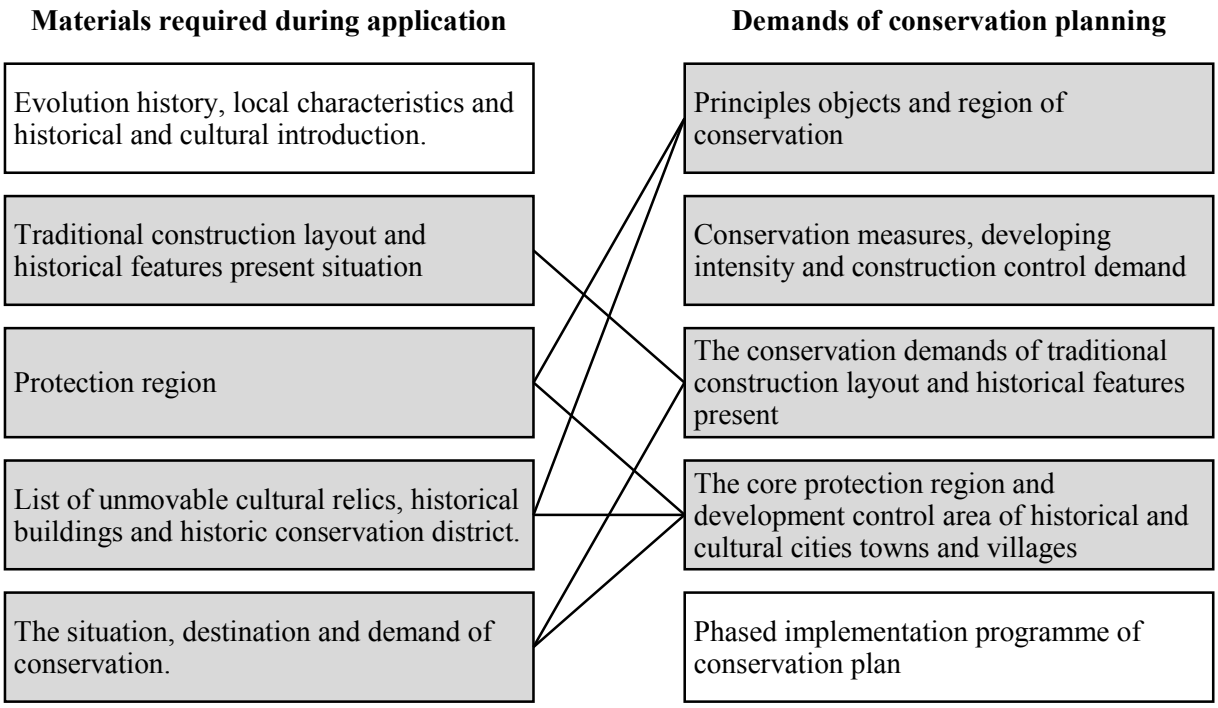

Figure 6 Comparison between Materials Required during Application and Demands of Conservation Planning

### *3.3 Administration of historical towns and villages*

Table 3 Conservation Subjects and Major Responsibility Basing on <Historical and Cultural Cities Towns and Villages Protection Ordinance>

| Conservation Subject Type | Conservation Subjects | Major Responsibility |
|---|---|---|
| National Government | Ministry of Housing and Urban-Rural Development of the People s Republic of China<br>State Administration of Cultural Heritage | Conservation Supervision Administration |
| Local Government at Each Level | Provincial Government | Conservation Supervision Administration |
| | City Government | Conservation Supervision Administration |
| | County Government | Conservation Supervision Administration |
| | Town Government | Conservation Supervision Administration |
| | Village Government | Conservation Supervision Administration |

At the national level, according to <Historical and Cultural Cities Towns and Villages Protection

Ordinance>, the Ministry of Housing and Urban-Rural Development of the People s Republic of China and State Administration of Cultural Heritage are both in charge of historical and cultural cities, towns and villages conservation, supervision and administration. Expert Committee of Hi Conservation(MOHURD, 2007) was founded by both the two government departments in 1996.

At the local level, once a city is pronounced national grade historical and cultural city, the municipal government will usually appoint a leading department in charge of the conservation, such as cultural relics department or planning department. Some cities establish special expert committees, directly subordinate to the municipal government, or subordinate to the cultural relics department or planning department.

For provincial grade historical and cultural cities, towns and villages, there are not specialized organizations, the conservation work is always done by the cultural relics department or planning department.

### *3.4 Funding for the conservation of historical towns and villages*

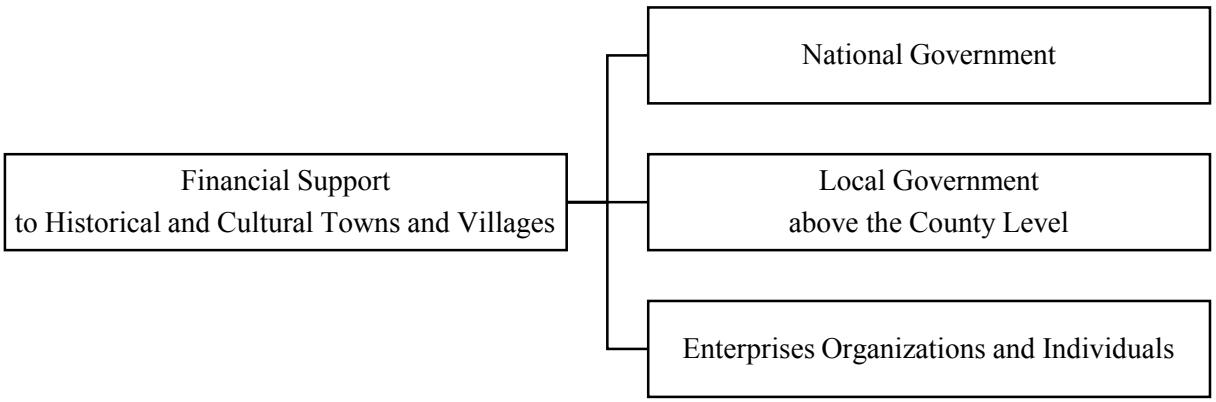

Figure 7 Financial Support Sources to Historical and Cultural Towns and Villages

According to <Historical and Cultural Cities Towns and Villages Protection Ordinance>, the main sources of financial support to historical and cultural towns and villages include three parts: firstly the national government, secondly the local government, and thirdly enterprises, organizations and individuals, as can be seen in Figure 7.

There is a different between the first two sources and the third source. To the national government and local government, financial support is put on them as a responsibility by <Historical and Cultural Cities Towns and Villages Protection Ordinance>. To enterprises, organizations and individuals, financial support is non-obligatory. Enterprises, organizations and individuals are encouraged to make a financial support, while no specific ones are forced to do it.

As can be seen in Table 4, basing on the financial support from the notional government and local government, various experiments have been adopted to develop financial support sources from enterprise, organizations and individuals(Qiu and Feng, 2014).

Table 4 Cases of Financial Support Experiments from Enterprises Organizations and Individuals

| Year | Place | Practice |
|---|---|---|
| 2006 | Wuxi City | The first foundation for the protection of cultural heritage was founded. And 24.8 million Yuan was collected in the first time. |
| 2002 | Suzhou City | Enterprises, organizations and individuals are encouraged to buy or hire historical buildings(Suzhou-Government, 2002), and those who conserve historical buildings well will get reward. |
| 1997-2002 | Xian City | Cooperation were adopted with United Nations, Japan and Norway. International technological and financial supports were used on historical building conservation. |
| Last 10 years | Shaoxing City | Multi Dimension Mechanism of Conservation, collecting money from government, citizen, enterprise and bank, has collected 14 billion Yuan in the last 10 years. |
| 2002 | Lijiang City | Financial support from Global Heritage Fund was received, helping the heritage to go to the world with the financial support from the world. |

## 4 Problems in conservation mechanism of historical towns and villages

### *4.1 Lack of ministerial and local policies focus on towns and villages*

Although the importance of historical and cultural towns and villages has been noticed, there is still lack of ministerial and local policies for towns and villages. The number of national historical and cultural towns and villages is much more than it of cities, and the increasing speed has not slowed down yet. However, the laws and policies of towns and villages are much less than them of cities, especially on ministerial level and local level. Among the seven relevant ministerial rules and regulations (Table 2), there are four focus on cultural relics, two focus on cities, and one focuses on buildings, but no one focus on towns or villages. Among 120 local rules and regulations (from 31 Provinces, autonomous regions and municipalities directly under the central government) (Figure 4), there are only six focus on villages and five focus on towns. It means that most local governments don t have rules or regulations focus on towns and villages. The governance of towns and villages still relays on the policies of cities.

### *4.2 Low efficiency with too many administrative government departments*

There are too many administrative government departments in charge of the conservation work, and it

leads to low efficiency. On the one hand, the administrative government departments are too many. According to Historical and Cultural Cities Towns and Villages Protection Ordinance, Chinese central government, each level local government and their urban planning departments and cultural relics departments take charge of the conservation supervision administration of the historical and cultural towns and villages. And other departments participate together, such as Tourism Sector, Department of Environmental Protection, Agency in Charge of Land, Transport Sector and so on. On the other hand, the work division of these departments is not made clear in the national level policies, and their responsibilities are the same according to Historical and Cultural Cities Towns and Villages Protection Ordinance (Table 3). So, the efficiency becomes low. The conservation planning of historic towns and villages has to be examined and approved to different departments step by step, the communication of them always take too much time. This may hold up the conduct of the conservation.

### *4.3 Lack of sustainable development guidance*

Nowadays, most of the formal policies of conservation planning of historical and cultural towns and villages are focused on the protection of material space, such as historic buildings, roads, or water path, rather than the sustainable development, such as the development of economy, society, population and culture. This leads to unsustainable development of some historic towns and villages. Some local government paid too much attention on material space protection rather than suitable development. In some cases, most of the historic buildings were nicely preserved, but the traditional social economy was damaged. And some traditional lifestyles were lost.

## 5 Conclusions

In the past 30 years, the conservation of historical and cultural towns and villages in China has greatly developed. In 1986, the national government suggested establish History and Culture Preservation Districts to protect historical and cultural towns and villages, which indicated the beginning of villages and towns conservation. In 2002, the first time national grade historical and cultural towns and villages selection started, which indicated the conservation had been raised to national level. In 2008, Urban and Rural Planning Law of the People's Republic of China and Historical and Cultural Cities Towns and Villages Protection Ordinance implemented, which indicated the basic conservation legal system was made.

In policy respect, a policy system basing on two laws one ordinance has been made. Including 2 national laws, one national ordinance, several ministerial rules and regulations and over 100 local policies. In conservation mechanism respect, a system of policies have been established, including historical and cultural towns and villages application and approving, conservation planning, administration and financial support. It is enumerated(Yang and Huo, 2014) that there are 531 national grade historical and cultural towns and villages, 725 provincial and municipal grade ones, and 1561 un-titled ones in conservation.

However, there are still shortages in the conservation. First, there is lack of ministerial and local policies focus on towns and villages. Second, there are too many administrative government departments and the conservation efficiency is low. Third, there is lack of sustainable development guidance, such as economy, society, population and culture. And these are the fields to be improved.

Keywords: rural tourism, Chinese-style peasant economy, farmers interests

Abstract:
*Rural tourism industry brought many undisputable economic benefits to Chinese villages and farmers, which accounted for nearly a third of the economic benefits of the total Chinese tourism market. However, rural tourism has brought intense impact to the "Chinese-style peasant economy" structure, which is the China s rural stable reservoir in the development of Chinese modernization. The rural tourism development pattern, including scale development, diverse planning and market-oriented, have a conflict with the Chinese-style peasant economy , which is charactered by management dispersion, landuse fragmentation and villagers self-administration. The paper researched the plight of "Chinese-style peasant economy" in the development of rural tourism, and further studied the contributions of planning. Firstly, the necessity of the "Chinese-style peasant economy" structure in Chinese villages was proposed. Secondly, the traditional production pattern was broken due to the non-coupling between the rural tourism and the "Chinese-style peasant economy". Therefore, the peasant lost the elastic space and flexible choice in the development of rural tourism. Finally the responsibility of planning in protecting the "Chinese-style peasant economy" structure was discussed. The multiple interests should be harmonized in rural tourism by planning. In particular, farmers interests could be guaranteed and maximized by means of clarifying the land right, protecting rural space and guiding the cooperation.*

## 1. Introduction

Rural tourism originated from Europe and has a history of more than 100 years. It is new attempt for modern tourism extending to traditional agricultural. It is a new form of industry, which combined eco-agriculture and eco-tourism organically by the promotion of tourism. China's rural tourism sprung up in the late 20th 90's.It has played an important role in optimizing rural industrial structure, narrowing the income gap between urban and rural areas, promoting the rural employment, driving the development of related industries, accelerating the cultural exchange between urban and rural areas, and so on. In the 21st century, rural tourism has entered a period of comprehensive development. The increasing attractions, the expanding scale, the extending distribution, all show a good momentum of development. Data show that China's rural tourism income reached 300 billion yuan in 2014, accounting for one-third of its economic benefits of the tourism market. The "first document", signed by the Central in 2015, pointed out the importance of rural tourism development for increasing farmers' income with a large space. And pledged to give full support from land, finance, banking, taxes, etc. Therefore, the development of rural tourism has become a important industrial form for increasing peasant's income.

However, the development of rural tourism is a game process among multi-stakeholder. Developers, government, farmers, tourists and other groups all want to pursue their own maximal interests in the process of rural tourism development. But in the process of the game, farmers are often in the inferior status, and their rights can t be protected properly. So, although the development of brought great material benefits to some extent, the obtained benefits are not sustainable. Considering the reason, it is directly related to the "Chinese small-scale peasant economy" in the Chinese rural society. Therefore, this article hopes to study based on the necessity of the" Chinese small-scale peasant

economy". Then the conflict between rural tourism development and the" Chinese small-scale peasant economy "was analysed concretely, and dissect the root causes of farmers interests being damage Finally, we discussed how to use plan to dilute the conflict in the rural tourism development. Thus to protect the fundamental interests of farmers.

## 2. The necessity of the small-scale peasant economy

Before the industrialization process, small-scale peasant economy exists throughout the countries and regions all over the world. China is a typical small-scale peasant economy country since ancient times. Small-scale peasant economy has existed for thousands of years in the history of China, and is the economic foundation of Chinese civilization's continuation. It has experienced the transition of system, forms and features since the formation. From modern times to the founding period, small-scale peasant economy shows an overall change from closed to open. What s more, due to the im economic development, it presents the transition character from tradition to modern in recent years. Although many western scholars have predicted the inevitable demise of the small-scale peasant economy. It still exist in the Chinese rural society, which has a profound impact on farmers' living and production.

### *2.1 The main characteristic of Chinese small-scale peasant economy*

The concept of "Chinese-style peasant economy" is a long-term study by Professor He Xuefeng， which proposed to describe the agricultural business and rural livelihoods mode, structure on the basis of "semi-cultivated in the intergenerational division of labour based semi workers" in the current stage of China. In particular, with the development and urbanization of China's economy continues to accelerate, a lot of young labour force move into the city for their livelihoods from rural. They leave the countryside temporarily or permanently, making the countryside has become a "three Left groups" (stay for the elderly, women left behind, left-behind children) habitat. These groups are also left to become the main practitioners of the rural economy at this stage. Therefore, the current peasant economy shows different from the one emphasis on family as the main production unit of the peasant economy expressed by the classical theory, but also different from ranch business model by capitalist agriculture. It performs to form a reproduction of labour power mode, based on the peasant economy family and inter-generational division.

#### 2.1.1 Basic characteristics -- "semi-cultivated in the intergenerational division of labour based semi workers

With China's urbanization and industrialization, more and more farmers choose rural migrant to increase the income of workers for family, in order to improve the overall level of income. For a rural households, rural migrant farmers are mostly in young or middle-aged labour force. According to statistics, 80% of farmer families have the phenomenon that young children work away from home, whose parents farm in rural. This structure of semi-cultivated in the intergenerational division of labour based semi w begins form national flow of rural labour since the reform and opening up in the 1980s. The earliest (1970s) appeared in the southern township enterprises. Farmer farm in busy season and work in the other time. This division formed "institutionalized half work half farm" by Professor Huang Zongzhi. Due to the rapid development of township enterprises and the policies allowing farmers to engage in trade and industry. Some labour move into the cities and move into the business. It makes the labours liberating from traditional agriculture. It improves the efficiency of agricultural production, but also improves the lives of farmer level. By the 1980s, migrant farmers began to increase, predominantly male scale. Mostly elderly, women and children are left behind. In the 21st century, the vast majority of young

rural labour force have moved into the city for work or business, who become important part of the urban labour force and important means to improve the living standards of the rural population. On the other hand, after the main labour force flowing out of rural, women's farm, elderly agriculture and peasants planting operations and other forms become the main mode of food cropping. Some carry out featured planting or breeding and some elderly and women who are still strong search opportunity to do "odd jobs" to make money. They farm in busy season and work in leisure day in the towns. Or even do manual processing in the home of the operations. Such as the development of rural tourism is one of the ways to increase revenue for villagers who stay in the village.

### 2.1.2 Essential character -- a stable reproduction form of rural labour

Although with a large number of rural labour outflow, the phenomenon of rural hollowing tends to be serious. Production began to be done basically by old people and women in agricultural. However, the current structure of semi-cultivated in the intergenerational division of labour based semi worke remains a stable workforce reproduction mode. Firstly, from the "semi-farming perspective, the household contract system is the basic agricultural management system in China, and agricultural production is the fundamental mode to maintain income and it is also the guarantee to maintain stable development of China. And with agricultural industrialization and modernization developing, labour for agriculture will be required less and less. The development of industrial diversification, rural tourism and other tertiary industries also led to increasing the added value of agriculture. The basis of agriculture development will further reinforce, and farmers can likely be achieved "income-place" increasingly, therefore staying rural farmers on agricultural production still remains great enthusiasm. Even the old people are not suitable to continue to engage in agricultural production and labour, due to the lands transfer and implementation of contracting policy, the people also can contract and transfer the lands to the other residents of the village to carry on the sustainable agricultural production. Therefore, the structure of "semi-farming" is very stable. On the other hand, from the view of "semi-working", along with the urbanization process promoting, the gap between urban and rural areas is actually still growing. In the current situation, many rural areas cannot satisfy the demand for improved their living standards by simply engaging in agricultural production, due to tensions between people and land. Therefore, the labour force is bound to liberate from the limited arable land resources out into the city to engage in secondary and tertiary industries, which has more productive rate of return. Statistically speaking, the proportion of the structure has been rising steadily when it appears in rural since the 1980s. In the 1980s the proportion is about 20%, and the regional distribution is unbalanced, mainly in the coastal areas; In the 1990s the proportion should be about 40% or more, and the region have been all over the country; After 2000, the proportion rose to 80%, and it has reached a relatively stable maximum value. Such a high percentage may be maintain for 20 years or even more. Because, after 20 years, the parents whose children were the first of the young migrant workers out of business are too old to do farm work. And the young man s children have grown up and start migrants. When they are no longer young, they would return home to take over the farming parents. This realize the reproduction of cultivated in the intergenerational division of labour based semi workers , which is very stable.

### 2.1.3 Spotlighted issues -- the small scale of Chinese-style peasant economy

The small scale of Chinese-style peasant economy mainly shows in two aspects. Firstly, from the macro perspective, the underdeveloped Chinese agricultural modernization and the lack of technological innovation and technology promotion capability have led to a small scale of China's peasant economy and inefficiency of land management. In recent years, to improve the level of agricultural modernization and industrial development has become a great concern of the Chinese government. Since 2004, the first policy document has focused on the "three rural issues" and emphasized the issues of concerning increasing farmer s income, agricultural modernization, rural planning and constru

issues. Rural Tourism Development which will be discussed in this article is one of industrial development path to increase the added value of agricultural production and land management benefits.

From the micro perspective, most of the Chinese current peasant families are running small-scale production and management activities. This is mainly because the farmers produc by land and capital. Compared to peasant population, China's arable land is extremely inadequate. Besides, the accumulation of farm families is limited. It is difficult for the peasants to have sufficient capital and advanced technology to expand production scale.

In addition, studies have shown that: because a variety of agricultural production factors have good divisibility, modern agriculture did not show obvious scales economy advantage within the family compared with other sectors. Therefore, farmers lack sufficient power to expand family business scale internally. Therefore, the traditional idea of self-sufficiency and our household land have made our land management become fragmented. And this is the biggest problem faced by the Chinese Agricultural operators at present. Fragmented land management has eventually lead to excessive inputs of invalid labour, poor land management efficiency, and lower output efficiency.

### *2.2 The necessity of Chinese-style peasant economy*

#### 2.2.1 Chinese small-scale peasant economy always ensure the agricultural income of farmers

Although with the developing of industrialization and urbanization, more and more of the agricultural population will join into the urban population, rural industry is also gradually tend to diversify and farmers' income structure will change. But agriculture has always been the fundamental industry of farmers. China has 800 million farmers living in rural areas, accounting for nearly 60% of China's total population. It's an important safeguard for Chinese stable and healthy development to ensure that 800 million peasants' lives. The main form of peasant economy as a traditional agricultural production to ensure the continuation of the agricultural economy, ensures the ultimate source of income for the 800 million farmers and provide sustainable basic living guarantee for them.

#### 2.2.2 Chinese small-scale peasant economy is the ultimate protection for migrant workers returning home

With the accelerating process of urbanization, China has about one million migrant workers working in cities, become the resident population, but did not enjoy the urban population as a welfare policy should not be the domicile of the urban population in the true sense, no really integrate into the city, so that employment which 200 million people are always at risk. But this is the part of migrant workers to complete reproduction of labour power by the "semi-cultivated in the intergenerational division of labour based semi workers" structure. So that migrant workers at risk of unemployment, you can choose to return the countryside, continue to engage in agricultural production, ensure the overall income of the family. In other words, the vast majority of migrant workers did not sever ties with the countryside. As long as the current agricultural basic management systems stable, staying in the country farmers can still guarantee their life and production stability through diversification of agricultural production and industrial development path similar to rural tourism development, and they may fail to migrant farmers Workers provide a smooth passage to return home.

In addition, for the reproduction of small-scale peasant, the failure migrant workers into the city don't have to stay in the city. Compare to the average of developing countries, Chinese farmers are much more fortunate, because they can return home to work in agriculture. The so-called rights, first and foremost is the right to choose. The choice rights of farmers into the city or return reserved, is to give

farmers the most basic human rights. Because the city failed farmers can choose to return home, so when migrant cannot survive in a decent city, they will choose to return home.

#### 2.2.3 "Chinese-style peasant economy" structure is the China s rural stable reservoir in the development of Chinese modernization

Any developing country in the development are impossible not to meet the economic, financial, social, and political aspects of the crisis that occurred in the city and its most highly developed structure. Once the urban structure of crisis, whether this country has the ability to deal with the crisis or not, has become the key to the country's modernization can be completed. Chinese urban crisis, if the centre of gravity in rural areas remained stable, the Chinese-style crisis manifested in the city, then under the stable centre of gravity of the role of the countryside, and soon stabilize. China Rural fairly stable and provide support for the city of migrant workers huge peasant economy was stable social structure where the centre of gravity of China, is one of the key for Chinese stability in any complex situation.

## 3 The present condition of the Chinese-style peasant economy in the development o tourism

In recent years, the development of rural tourism is increasingly prosperous. First of all, in the circumstance of the experience economy, profound changes have taken place about the idea of the consumer's consumption and the way how they consume than before In terms of the structure of demand , while the tourism consumers focusing on product quality, we find out the increasing proportion of emotional needs among them; In terms of consumption content, Popular tourist products are losing their advantages, consumers begin to pursue the products and services which can reveal their personalities ; In terms of the value and target , consumers have changed from paying attention to the products itself to value the feeling when accepting it; In terms of the way receiving products, consumers are willing to participate in the product design and manufacturing initiatively. Consumers are increasingly emotional, personal, perceptual, changing their core demands from the pursuit of practical to pursuing the experience. Along with the improvement of the traffic conditions and the quality of life of visitors, domestic existing hot spots become crowded, and the environmental quality of urban living people falls down. Cities and traditional sights is no longer able to provide proper and comfortable experience for visitors. While the vast country with diversity natural landscape and rich cultural connotation, acting as a major carrier to the original idyllic scenery and traditional way of life, can provide tourists with multi-level diverse experiences of visual, hearing, and further interaction. Therefore, the rural tourism development has been developing rapidly in recent years, followed with the considerable economic benefits. As too many Subject of interests are involved in the development of the rural tourism, including the government, farmers, corporations and tourists, and farmers are vulnerable groups whose interests will always be subject to a strong sense of market competition. As for the reason, it is because the "Chinese-style peasant economy" structure On behalf of farmers management characteristic is impacted by the rural tourism development.

### *3.1 The characteristics of the rural tourism development*

#### 3.1.1 Multi- subject of interests participation

There are four main relative subject of interests of rural tourism development: farmers, governments, corporations and tourists. The process of the development rural tourism is actually the process of the four subject of interests pursuing their own interests maximally in the game play. Government

determines the development orientation of the whole rural area, guiding rural development, strengthening the infrastructure, attracting foreign investment to build a platform to enhance regional influence by taking charge of the rural tourism planning. The development corporations of rural tourism hope to do some development activities with taking advantages of the rural land, agriculture, ecological resources to obtain maximum profits by cooperating with the government. Meanwhile tourists hope to attain their expected travel experience form the ecological environment and the rural landscape in the countryside with the cooperation projects and activities set by the government and corporations. For rural residents, the priority is to improve the quality of life, by changing the traditional mode of production through the development of rural tourism, increasing the added value of agricultural production and increasing the income of "semi-cultivated" part. Meanwhile farmers hope to improve the environment, improve infrastructure, and improve the living environment through the development of the rural tourism. Therefore, based on the demands of different subject of interests, the process of rural tourism development becomes a multi- subject s participation and game.

### 3.1.2 Large-scale of the development and management

Large-scale of the development and management is mainly reflected in two aspects: land resources and projects. Rural Tourism Development Project is generally based on ecological or agriculture, thus requiring a large area of land, so in order to meet the needs and benefits of large-scale operation of the project, brings out the need for rural development to integrate the existing land resources management. Those common picking garden, organic food cultivation, leisure farms and other development projects, all need the land resources which is centralized, larger scale, and the better ecological basis to meet the needs of project development. On the other hand, even a single project area may not need a large area of land, such as a simple farmhouse, simple handicrafts, and other specialty products for sale, but because the government vision for the positioning and development of the whole area generally requires companies and enterprises to formed an industrial chain forming a sustainable driving force, therefore the scale effect among similar enterprises and the cooperation among heterogeneous enterprises and also need to be gathered on the development and operation of the project is running, to form the whole area of the scale. As used herein, select research Huaijiu road Area Rural Tourism Development Area of Fanchang County, Current situation is there already exists some picking based enterprises, but they business their own way, be independent to each other, there is no agglomeration of scale, and cannot form the entire Area core competitiveness and foreign brand.

### 3.1.3 Government-led, market operation

Development of rural tourism refers to the original landscape has not been carving, the beautiful natural landscape and historic folk culture and tourism with the appropriate resources and tourism products in rural areas, including the Integration and development to rural bucolic, rural architecture community, rural natural environment, traditional farming village farming, rural traditional rural folk culture tourism resources. It is the technical economic activity to meet and attract urban population come here to travel. Therefore, as tourism development, within a certain range land, it is a comprehensive social and technical and economic activities in order to attract and reception of tourists with tourist facilities conducted training and other construction of tourism environment. Thus, the tourism development is a systematic project, mainly premised by the development of tourism, market demand-oriented, tourism resources as the core, focused on improving and enhancing the appeal tourism resources to the tourists, Reaching around a lot to attract tourists and meet their, visit, study, entertainment, or simply relax contains a certain technical content of various needs of economic activity. Therefore, the government leading of unified planning and market demand as the leading factor is one of the important characteristics of rural tourism development.

### *3.2 The impact on the farmers' interests of the rural tourism development*

According to the analysis of "Chinese-style peasant economy and the characteristics of rur development, it is easy to find that there are some conflicts and contradictions on the main feature. The conflicts of the characteristics will impact and even violate the different interests of farmers in different ways which includes the land rights, sustainable economic benefit and environmental benefit.

#### 3.2.1 The landuse right

The characteristic is widespread in the peasant economy that the land management is a small scale, which conflicts with the characteristics of scale management in rural tourism development under the market economy. The conflicts and contradictions are reflected in farmers' land rights. In particular, the land is the most elementary condition for the development of rural tourism, some enterprises and developers ignore the local actual. Therefore the rural collective land is often expropriated. The resources including the land in the development of rural tourism are generally owned by villagers collectively. According to the nature and process of the rural tourism development, expropriation of land is an essential link for most of the rural tourism developments, unless it is spontaneous for farmers to run their own range of small-scale rural tourism model. Land is the most basic factor of production and the basis of survival and development for farmers, and the land right is the farmer's most important property right. So if the farmers lose their land, they not only lose the right of management, usufruct and some disposition, but also a lot of relevant rights and interests attached to land. In the actual development of rural tourism, because the government is engaged in the profitable business activities of tourism market, it has become one of the main beneficiaries in the development of rural tourism. However, countryside and farmers have become spectators, instead of enjoying the economic benefits from rural tourism, they have to endure a series of adverse consequences. The government seized a large amount of revenue because of the wide difference between expropriation compensation and land price. As the developers, the enterprises or individuals will also grab the high profits. As a result, the landless farmers will lose much.

#### 3.2.2 The sustainable economic benefits

Farmers in the small peasant economy have relatively free production autonomy, while the rural tourism development has the obvious market rules that it determines the direction and content by the market demand. Therefore, the independent production and the market operation have a certain conflict in the "Chinese-style peasant economy" which will affects the sustainability of the economic interests of farmers.

The limited space determines the risks when the farmers participate in the development of rural tourism. If the farmers' land is used as a rural tourism development, the agricultural production of farmers is bound to be impacted. Because the limited land cannot simultaneously meet the demands of the scale of rural tourism and agricultural production. Also, the market is always risky, the rural tourism and agricultural production have a strong seasonal and random characteristic. In the rural tourism season, farmers may be obtain substantial revenue because of the successful development of rural tourism. But in the low season of tourism, farmers' incomes cannot be guaranteed, because the land has been occupied by tourism development, they have been out of agricultural production.

On the other hand, project development of rural tourism requires an accurate assessment of enterprises and need to analyse the demands of the market. Once the analysis fails, the fragile ecological space has altered substantial construction and development, its recovery will be very difficult, and it will take a very long period. Therefore, farmers will suffer greater economic losses during this process. Instead of

obtaining benefits through the development of rural tourism, famers lose their land in the construction and development. The reproduction of agricultural land is very inelastic, and the land is poor of reversible. Therefore, after the production independence of peasant economy is destroyed, the economic interests of farmers in the market operation may be only temporary, is not sustainable.

### 3.2.3 The environmental rights and interests

Development of rural tourism is essentially a process during the period of destroy and rebuilt. In particular, in order to obtain economic benefits from the development of rural tourism, the destructive behaviours must have done. This destroy is not a pejorative concept in the narrow sense. In the long term, destroying is the first step and prerequisite to benefit. It can seems to ignore the temporary economic losses caused by the destroying while the damage caused by destroying and the harvest are compared on the economic benefits. But from the point of view of social and ecological benefits particularly the environmental, the countryside is an area with very advantageous ecological. And some countryside also assume the functions of eco-conserving division and ecological conservation areas. Therefore, once the rural ecological environment has been destroyed by the tourism development and construction, not only the primitive rural scenery will disappear, but also the ecological value of the countryside will reduce. It is an obvious manifestation that the farmer s liv greatly diminishes. On the other hand, the rural carried rich and varied cultures and the history is long, industry modernization invasion will inevitably erase the traces of traditional culture, including traditional houses, traditional settlements and so on. And then the traditional architectural culture, neighbourhood atmosphere and long farming culture will disappear. Nowadays, the city's living environment and culture has been buried by the rapid development of urbanization and industrialization. As the last pure land of environment and cultural heritage, countryside assumes a more important and extraordinary ecological, social and historical significance.

## 4 The responsibility of planning-- protecting the "Chinese-style peasant economy" structure and guarantying farmers interests

"Chinese-style peasant economy" is the production and management of Chinese farmers'. Production and life interests of farmer concentratedly reflected in the structure of Chinese-style peasant ec The development process of rural tourism attacks the "Chinese-style peasant economy". In fact, it attacks the structure of existing production and living of farmers. The peasant economy is not without problems, but the main features of the peasant economy still determines the necessity of the existence of it as the above analysis.

Therefore, planning as government action, should effectively slow down the impact of rural tourism development to peasant economy, to ensure the interests of farmers and to achieve maximum benefit of farmers in rural tourism development.

### *4.1 Large-scale of the development and management based on clarifying the landuse right*

The scale operation of rural tourism development is the inevitable requirement under market economy. To protect farmers' land rights and interests as well as to follow the laws of the market competition of rural tourism development, the main way is to operate on a large scale on the basis of making clear of the land rights of farmers, the main means is a diversified land circulation form. Land circulation refers to the transfer of land use rights. Land use right transfer means farmers transfer their land management rights to other farmers or economic organization through subcontracting, transferring, investment, cooperation, lease, exchanging and some other ways. Government encourages farmers to transfer contracted land to professional investors and cooperatives, to develop the scale of operation in agriculture. Diversity land circulation promotes the appropriate scale of operation of rural land,

improves the land utilization ratio and output rate; brings about the agricultural structure adjustment, improves the economic efficiency, promotes the transfer of rural labour force, increases the income of the farmers. It is conducive to agricultural technology extension and the formation and development of the agricultural industrialization management. Diversity land circulation ensure the farmers land ownership and the rights and interests in the rural tourism development.

Resulting from the comparison of various ways of land transference economic performance, and land circulation patterns which has higher degree of marketization brings greater economic performance than the lower one. However, from the comparison of the results of social performance, the result is completely different. Land circulation patterns which has relatively low degree of marketization may have a greater economic performance than the higher one. Different patterns of rural land transfer bring different transfer performance. Brought a kind of rural land transfer modes of economic performance and social performance and better than other rural land circulation patterns. Economic and social performance of one rural land circulation mode may not be better than other modes. Therefore, in the practice of rural tourism development, the land transfer mode should select according to the characteristics of their own country, balance the economic and social benefits, select the most appropriate way of circulation, and meet the needs of the scale of operations, farmers econom and land rights.

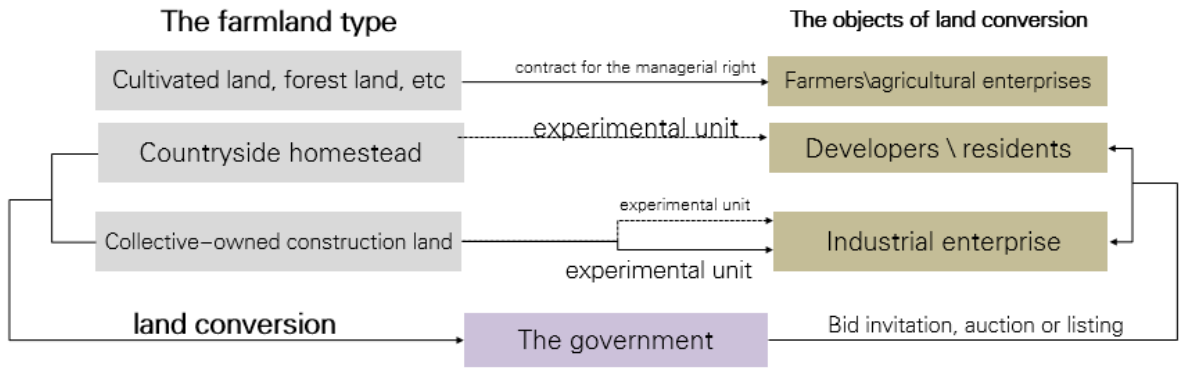

Figure 1. The sketch of land conversion route

### *4.2 Build a control system dominated by respecting the original appearance to ensure environmental interests of farmers*

#### 4.2.1 Low-impact construction of the ecological management and control

The ecological environment in rural areas is the focus of farmers living environmental protection. Including water, mountains, forests, lakes, farmland, biological, atmospheric resources, etc., all of them are the important elements of the rural ecological base. Firstly, urban planning has a duty on building control system about ecological management, clarifying the control limit, formulating the control regulation. Furthermore, urban planning also need to supervise behaviours of tourists and enterprises in the development of rural tourism. Especially for the enterprises, which should be controlled strictly in environmental protection standard. It is important to control the pollutant emission in countryside. The most significant issue is protecting the farmland strictly, because China s grain production is the basis of urbanization and modernization. Removable architecture can be used in construction to reduce the destruction to the farmland. It will be more flexible and sustainable. On the other hand, special planning of environmental protection is essential for rural tourism development areas. The construction of paths

about infrastructure and environmental hygiene facilities should be included. In addition, the overall image in countryside should also be paid attention. For example, the environment of waterfront, lakeside, riverside, hillside, etc. . All in all, low-impact construction of the ecological management and control should be the main principle to achieve the goal which is keeping the rural original appearance and make the construction integrated with nature.

#### 4.2.2 The rural dwellings protection

The significance of the rural dwellings protection lies not only in protecting farmer s human settlement, but also protecting the traditional style of rural image and residential architectural culture. It has great social significance. Including the whole village appearance, for rural residential use and transformation. For the whole village appearance as example, urban planning and design should maintain the mutually relationship between the village and natural environment in harmony. Controlling the skyline from far view of villages to emphasize the outline of mountain. Moreover, controlling the rural buildings and public buildings along the street interface, conducting regular inspections of the village environment, and prohibiting non-standard construction practices to maintain the overall image of village. From the aspect of rural residential using, urban planning can choose the utilization patterns from the whole lease and self-management, etc., which depend on farmers how to participate in Rural Tourism. As for the transformation of rural houses, urban planners must evaluate the rural dwellings to decide to demolish, enhance or protect.

### *4.3 Guide benign cooperation between farmers and enterprises to ensure the sustainable economic interests of farmers*

#### 4.3.1 Cooperation and win-win mechanism

Rural tourism development involves a multi-party including government, enterprises, farmers, etc., so in the development process, development is not the only one goal. It is also significant to protect the interests of farmers in the market behaviour. Therefore, in planning practice, the appropriate business model should be choosed based on the characters of rural tourism development area to achieve the common interests of farmers, businesses and governments. Common cooperative business model including "community + company + farmers" model, "government + company + farmer tourism association + travel agency + farmer" mode, autonomous mode of operation, the overall leasing mode. "Government + corporation + travel agency + tourism association of farmer + farmer" mode, for example, Ping Ba County, An shun City, Gui Zhou Province Tian Longtunbao Cultural Village adopted this business model in sharing of benefits to avoid excessive commercialization. Government is responsible for the planning and construction of infrastructure, and optimizing the development environment. The company responsible for the management and business operation. Rural tourism association is responsible for organizing villagers to participate to opera performances, guided tours, crafts, provide accommodation and catering services, and maintenance and repair of their traditional houses. Travel agencies responsible for market development, organization source, effectively avoid the farmers in the tourism industry may cause excessive commercialization atmosphere to maximize their local cultural authenticity, so that visitors feel real and natural simple folk. The proportion of income allocated as follows: 11% government, 10% of the village committees, 14% of farmers tourism associations, travel agents, 11%, 54% of the company. Because of government intervention and management, and constantly expand the brand effect, so cooperative model has been protection policy, thus greatly ensure the stability and sustainable economic benefits for farmers.

### 4.3.2 Optimize the revenue structure of farmer

With the flourishing development of rural tourism, the revenue structure of the villagers presents different characteristics under the influence of the Chinese small-scale peasant economy". It can be divided into three categories: the first category is migrant income based; the second is farming income based; the third is mainly comes from the tertiary industry developed by rural tourism. The planning should respect the existing revenue structure, as well as the living and production style under the Chinese small-scale peasant economy". And do not break the structure of semi-cu intergenerational division of labour based semi workers . Then further enhance and improve ther according to their own characteristics. For the first category income structure, on the one hand, we should ensure the creation of the living space for the rural staying residents, especially the children's growing space. On the other hand, try to attract them to participate in the project operation by a variety of ways. Thus to increase the overall income level for them. For the second category, on the one hand, the cooperation mechanism between enterprises and farmers in agriculture can be promoted. On the other hand, the tertiary industry which has bigger degree of relation with agricultural production can be increased properly. This can really maximize the value of agricultural products, increase their income other than traditional agricultural production, and make the rural development diversified and sustainable. For the third category, the projects of rural tourism development should be guided to form a good win-win cooperation mechanism. We should focus on the management of the market order, and effectively protect the interests of farmers in the market behaviour.

## 5 Conclusion

This paper researched how the "Chinese-style peasant economy" was impacted by the rapid development of rural tourism, as well as what we can do to mitigate the effects by planning. Since "Chinese-style peasant economy" stands for the Chinese farmers production and liv interests, including the landuse rights, the sustainable economic benefits and the environmental interests, are damaged to a variable extent. Therefore, the paper further studied the contributions of planning in guaranteeing and maximizing farmers interests by protecting "Chinese-style pea structure in the development of rural tourism. The conclusion can be divided into three parts. Firstly, large-scale of the development and management is necessary. The point is to clarify the landuse right by diversified land conversion patterns. Secondly, urban planners should control and protect the rural space morphology effectively, including ecological environment and rural dwellings. Thus to guarantee the farmers environmental rights and inherit the rural traditional culture. F sustainable and maximized interests, benign cooperation between farmers and other stakeholders in the development of rural tourism should be guided by planners.

# CREATIVE-BASED TOURISM DEVELOPMENT IN SMALL SCALE TOWNS: A CASE OF ALA˙ATI

Irem Ince[1], Koray Velibeyoglu[2]

[1]Izmir Institute of Technology, iremince@iyte.edu.tr
[2]Izmir Institute of Technology, korayvelibeyoglu@iyte.edu.tr

**Abstract**

*Today, tourism has rapid expansion with the term of globalization (Hall and Page, 2003). Globalization offers technological innovations in transport, communication and information spreading around the world and it also reduces borders and barriers for culture exchange. Tourism development has been viewed as an opportunity for economic development of many destinations. In spite of the fact that negative impacts embodied in rapid development of tourism based on globalization process. Many tourism areas are in danger of mass tourism that consume sensitive landscapes and characteristics of settlements (Endresen, 1999). In that sense, the new phenomenon of creativity including various concepts such as creative economy, creative class, creative industries, creative clusters and creative tourism comes out as a driving force to contribute development of tourism (Florida, 2002; Landry, 2000; Richards, 2011). For this study, small scale towns, which have a risk of substantial losses of their cultural values, landscapes and way of life due to the rapid development of tourism, is examined in terms of creative-based tourism development. In this context, an urban design approach is defined as a tool that has a hand in guiding creative tourism development. Moreover, urban design toolkit which has various methods and techniques is used for* fostering and understanding creative environment of Ala at , which is small *Turkey. Ultimately, the study investigates creative environment of the small scale town for understanding the dynamics between creativity and tourism in the context of sustainable development*.

**Keywords:** Creative tourism, Small scale town, Urban design toolkit

## 1. Introduction

Development of tourism contributes to change in social, cultural and economic structure of communities. Accordingly, globalization process, which offers lower transaction costs, rise of service economy, knowledge expansion and virtual networks, emerges as a pushing factor that contributes the tourism development (Hall and Page, 2003). In this context, the rapid development of tourism constitutes negative and positive impacts on social, environmental and economic structure of cities, direct and indirectly. While positive impacts of tourism brings opportunities based on economic and social development of communities, negative impacts cause loss of traditions, commercialisation of culture, noise, pollution and waste and rising cost of services (Girard & Nijkamp, 2009). In this scope, especially, small scale towns, which are known with their distinctive characteristics such as accessible places, identity, sociable and tasteful way of life, have risk of over use of cultural resource, loss of cultural identity, undermining of local traditions and ways of life due to the rapid development of tourism (Knox & Mayer, 2009). Ultimately, the rapid and uncontrolled tourism development effects social, economic and physical characteristic of many settlements depended on globalization process.

In line with clarification of negative impacts of the tourism development, the phenomenon of creativity that generates social and economic success in the context of tourism development emerges as a fundamental tool for balancing cost and benefits of tourism development (Florida, 2002; Landry, 2000; Richards, 2001; Pohl, 2010). In this conceptualisation, the phenomenon of creativity with various conceptions including creative economy, creative class, creative industries, creative clusters and creative tourism leads to economic development and growth of communities based on knowledge

exchange (Florida, 2002). Accordingly, creative tourism that promotes knowledge-based activities with the creative individuals, locals and visitors within in the context of creating new ideas, artifacts, and products mainstreams local identity and cultural assets of the settlements (Florida, 2002; Landry, 2008). Ultimately, the phenomenon of creativity emerges as a development tool in the context of sustainable development.

Within this wider array of debates, the term of creativity is generally conceptualized in the context of metropolitan cities in developed countries that have larger networks, strong labor markets and agglomeration economies by many scholars (Seleda et al. 2012; Bell and Jayne; 2009; van Heur, 2010; Lewis and Donald; 2010). However, growing literature has been attempted to identify creative economy of small and medium sized towns in both developed and developing countries that changed their development path towards under increasing globalization (Seleda et al. 2012; INTELI, 2011; Zhang et al. 2011; Waitt et al. 2009; Waitt and Gibson, 2009; Lewis and Donald, 2010; Mc Grahanan et al. 2011, Munoz, 2010). In this context, creative tourism that eliminates the negative impacts of tourism development comes out as a driver force for contributing cultural life of small scale towns.

More central to research, this paper draws attention creative place making process of small scale towns in terms of tourism development. In this context, the paper comprises four sections. The first and second sections introduce literature review on the phenomenon of creativity by an investigation of the relationship between creativity and tourism. The second part examines the case study based on the findings of urban design toolkit, which is evaluated for understanding creative environment. The final section represents briefly summarize of the research and concludes. This section also discusses the importance of creative-based tourism development in small-scale town.

## 2. Theoretical Arguments

The concept of creativity takes its roots from 1980s and it has become the focus of many scholars (Florida, 2002; Landry, 2008; Hessler & Zimmermann, 2008; Verwijnen & Lehtovuori, 1999; Hall, 2000; Durmaz, 2012). In 1980s, the idea of creativity was developed with terms of culture, arts, cultural resources and in the mid-1990s; the cultural industries became creative industries that came forward as a combination of culture, creativity, art and technological products together (Landry, 2008). In the beginning of the twenty-first century, especially with the rise of digital media and networks, the phenomenon of creativity has become have become main debate of sustainable development (Florida, 2002; Landry, 2000; Richards, 2001; Pohl, 2010). In this context, in order to understand drivers of creative- based tourism development, key terms of creativity including creative economy, creative class, creative industries, creative clusters and creative tourism are examined as follows:

### *2.1 Creative Economy*

Creative economy that appeared in the twenty-first century conceptualized with innovation, technology transfer, and intense knowledge exchange of creative workforces (Landry, 2008). Florida (2002) clarified creative economy as a transaction of creative product that put extraordinary value and wealth on science, technological innovation, novelty and intellectual property rights (UNCTAD, 2010) Furthermore, United Nations Conference on Trade and Development (UNCTAD) defined the creative economy as an evolving concept based on creative assets potentially generating eco development (UNCTAD, 2010, pp.15). In this context, Landry and Florida point out that creative economy come into prominence with the concept of knowledge economy . Additionally and Frithsch (2007) emphasize that the creative economy play a fundamental role in cultural and economic development. In this conceptualization, the creative economy has shaped the economic and social structure of cities based on the changes in production systems, technology, labour markets and dynamics in locational agglomeration (Scott, 2006). Ultimately, the creative economy brings opportunities by integrating art and creativity in economic structure of cities.

*2.2 Creative Class:*

The term of creative class developed by Richard Florida (2002) is defined as a sources of creative capital for economic development of cities (Florida, 2002). In this context, Landry (2008) defines the creative class as the group of people including designers, scientists, artists and brain workers, who maintain their jobs with creativity. Accordingly, Florida identifies creative class within two groups as follows: 1) the super creative core, including scientists, social scientists, arch (2) the creative professionals who works in business, finance, the law and advertising in the contex of creative problem solving. He also defines the bohemians including designers performing artists, media and entertainment workers and musicians as a part of creative class. In line with the definition, he claims that creative class needs a certain place to maintain their activities for economic development. In this respect, he identifies the creative class theory with Three T s base on the quality of place . The theory indicates that economic growth of place technology, talent and tolerance (Florida, 2002). Ultimately, social, cultural and environmental amenities of the place come out as an important factor in order to attract creative class for economic growth (Kunzmann 2005; Landry, 2000). For this study, location decision factors of creative class are examined in the context of small scale town.

2.3 *Creative Industries:*

Definition of creative industries varies among countries such as United Kingdom, Hong Kong (China), Japan, Singapore, Taiwan, Australia, New Zealand etc. Accordingly, in 1997, UK department for Culture, Media and Sport launched of Creative Industries Task Force defines creative industries as those activities which have their origin in individual creativity, skill and potential for wealth and job creation through the generation and exploitation o (Council, 2010, pp.16). Additionally, United Nations Conference on Trade and Development (UNCTAD) identifies creative industries as a set of knowledge-based economic activities that constitute link with traditional knowledge and cultural heritage (UNCTAD, 2010). In this concept, creative industries, which consist sector of advertising, architecture, arts and antique markets, crafts, design, fashion, film and video, software, computer games and electronic publishing, music and the visual and performing arts, publishing, television and radio, have been classified with various models and system that shift among countries. For this study, the classification system of the UNCTAD, which focuses on cultural heritage and tradition knowledge, is used for mapping creative industries. The UNCTAD classification system has four broad groups including heritage, arts, media and functional creations and nine subgroups. The following table (Table 1) demonstrates the classification system of the UNCTAD, which is used in this study in the context of creative-based tourism development.

Table 1. Classification Systems of Study
(Source: UNCTAD, 2010)

| **Creative Industries** | | | |
|---|---|---|---|
| **Heritage** | **Arts** | **Media** | **Functional creations** |
| **Traditional cultural expressions**: arts and crafts, festivals and celebrations;<br><br>**Cultural sites:** archaeological sites, museums, libraries, exhibitions, etc. | **Visual arts:** painting, sculpture, photography and antiques;<br><br>**Performing arts:** live music, theatre, dance, opera, circus, puppetry, etc. | **Publishing and printed media:** books, press and other publications;<br><br>**Audiovisuals:** film, television, radio and other broadcasting. | **Design:** interior, graphic, fashion, jewellery, toys;<br><br>**New media:** software, video games, and digitalized creative content;<br><br>**Creative services:** architectural, advertising, cultural and recreational, creative research and development (R&D), digital and other related creative services. |

*2.4 Creative Tourism*

Creative tourism, which appeared in 2000s by Richards and Raymonds, comes into the approach as an extension of the cultural tourism (Richards 2005; 2011). UNESCO (2006) defines creative tourism as travel directed toward an engaged and authentic experience, with participativ heritage, or special character of a place, and it provides a connection with those who reside in this place and create this living culture (UNESCO, 2006:3). In this context, Richards and Wilso emphasize the importance of the link between cultural landscape and creativity in terms of tourism development. They claimed that cultural landscape of cities such as festivals, cultural routes, museums, cultural heritage constitutes a strong link between the tourists, the local and creative individuals in terms of creative tourism. Accordingly, the following figure (Figure 1) demonstrates the model of creative tourism. In this context, creative tourism engages with active participation in order to access to culture via creative initiatives (Smith, 2009). For instance, Creative Tourism Barcelona program offers the project that supports local artist in order to foster creative industries. In addition to Barcelona, Obidos, which is a small town in Portugal, organize the project of for the development of creative tourism. In that sense, they provide flexible spaces to work and live by regenerating historical disabled buildings. In this project, the town generates the creative places for constituting links between local community and artists. As well as, Nelsonville, which is a town of the US, Ohio State, also promote cultural and artistic events in order to connect with the locals and creative individuals. Based on these creative activities, many creative individuals chose to locate in Nelsonville (Selada et al, 2011). Consequently, creative tourism, which is fundamental tool for protecting cultural assets through creative activities, promotes interactive participation of the creative individuals, visitors and locals.

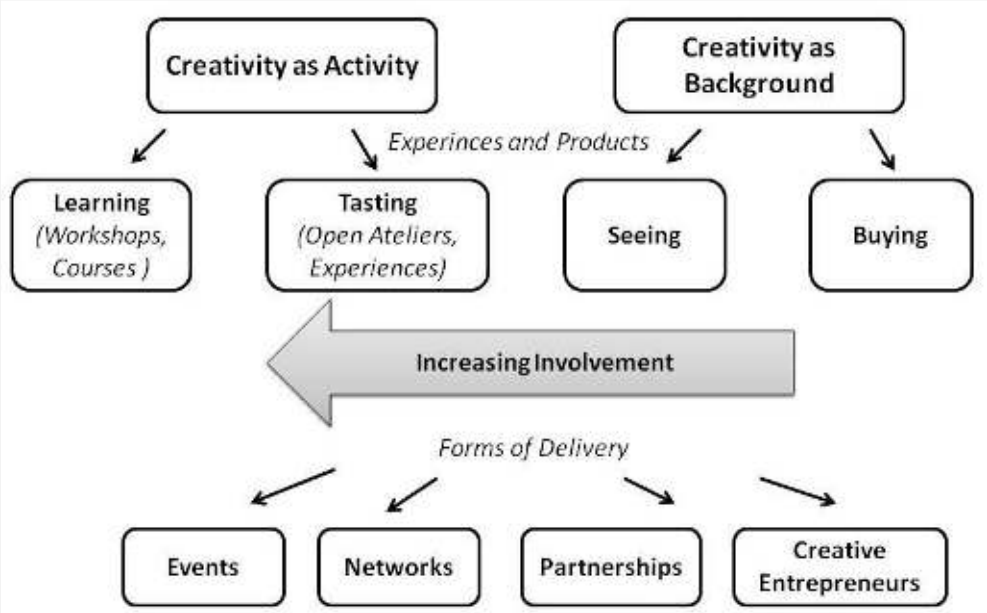

Figure 1. The Model of Creative Tourism
(Source: Richards, 2011)

**3. Case study: The Small** Scale Town, Ala at

Ala at , where is located 79 km from center of zmir (see Figure 2), is one of the small sc
Izmir with the population of 11.004. (ABPRS-Address based Population Results, 2012-
http://www.turkstat.gov.tr). Ala at has evolved under various eras including Hellen
Byzantine and Ottoman. In this scope, the town has gained tourism popularity depended on its
multicultural ethnic background, authentic architecture, seashores, vineyards, climate, natural beauties
and coastal facilities such as surfing activity. In about twenty year s per
significant transformation in the context of tourism development. In that term, planning decisions and
governmental organizations that generated positive and negative impacts on physical, economical and
social structure of the town affected this transformation process. Today, the town becomes a unique
tourism destination based on its tangible and intangible heritage. In this respect, the study focuses on
Hac Memi District that is located on the center of Ala at as a yet untou
of creative tourism.

Figure 2. Location of Ala at
(Source: Google Maps, 2013)

### *3.1 Methodology*

The study applies the mixed method research techniques of urban design approach. In this scope, urban design toolkit for creative place making that includes various analyses for understanding the context of creative clusters is evaluated in four phase. Firstly, components of tourism and creativity that come from literature review are defined for understanding creative place-making process. Secondly, diagnostic analyses including accessibility, behavior observation, mental mapping, social diversity map, cultural assets map and interview are generated according to components of tourism and creativity. Thirdly, predictive analyses including design policies, creative-based strategies are specified for scenario development. Finally, urban design toolkit for creative place-making that has two main parts including diagnostic analyses and predictive analyses was used at the case study of Ala at for understanding operational structure of the toolkit (see Figure 3) (Ince, 201

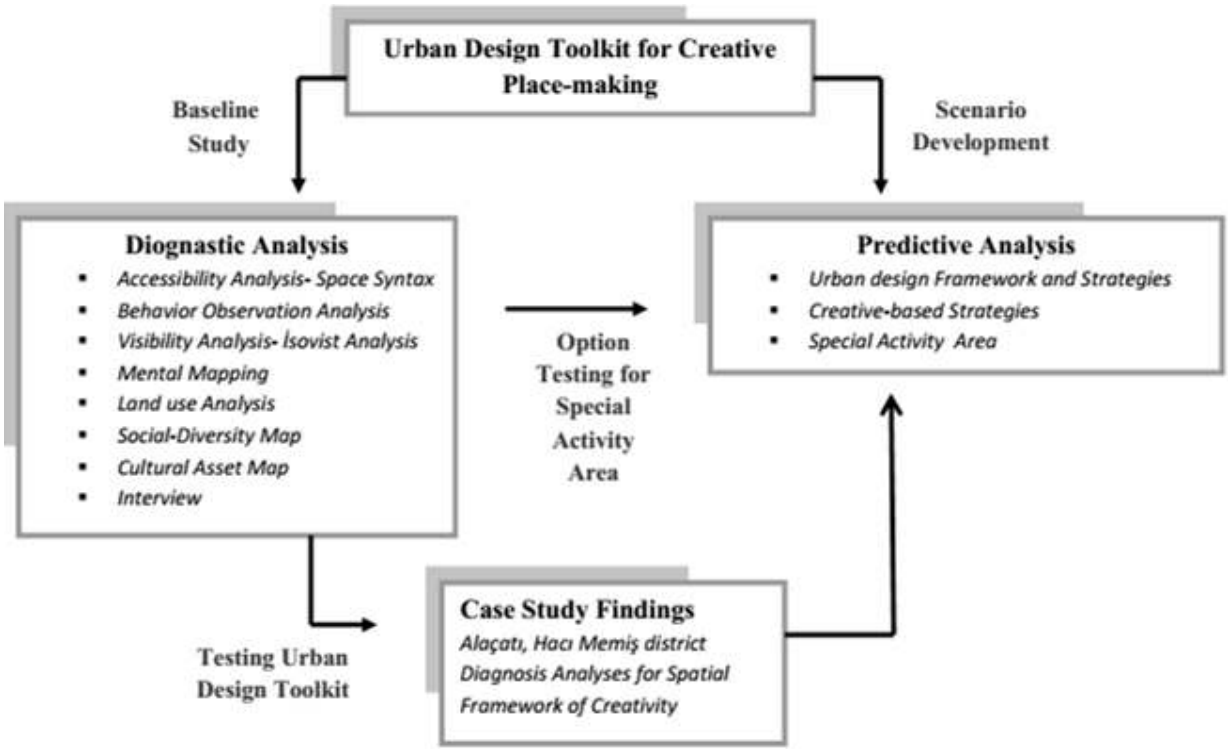

Figure 3. Urban Design Toolkit for Creative Place-making

For this study, the diagnostic analyses of space syntax analysis, cultural assets map, creative cluster mapping and interview are selected from the toolkit based on the limitations of study including date access and study time. Additionally, creative based strategy defined in predictive analyses of the toolkit is also generated for fostering creative environment of the town. Consequently, creative place-making toolkit that provides options with many tools for understanding and enhancing creative environment is used in the case of Ala at .

### *3.2* Emergence of Creative tourism in Ala at - Hac Memis District

According to interview results and site observations, the creative activities firstly have emerged in the Hac Memi District. The creative individuals including photographers, designers, and ceramist have chosen to locate in Hac Memi district since 2000s based on different motivations. In this scope based on results of the interviews, emergence of the creative tourism in Hac Memi dist described in three phases as follows: (1) The banning of the Antique bazaar in 2009; (2) Characteristics of the district including natural, physical and cultural; (3) Clustering of the creative individuals that bring positive impact on social networking. Firstly, in 2009, many antiquarians located and opened antique shops in Hac Memi District due to the banning of the Antique Ala at . In that term, art and antiques market, crafts, fashion and design s industries based on UNCTAD classification system emerged in four years at the town (UNCTAD, 2010). In this scope, the Antique bazaar came out as one of the pull factor of the creative clustering process of the town. Secondly, in 2010 and 2011, ceramist, designers, the owner of art galleries moved to the town depended on the cultural, psychical and natural characteristic of the town. Thirdly, in 2012 and 2013, many young creative individuals including fashion designers moved to the district for reaching out the community and generating their ideas with other creative individuals. Ultimately, Hac Memis District becomes one of the known creative clusters for both to individuals and the district is still in the center of creative clustering process (see Figure 4).

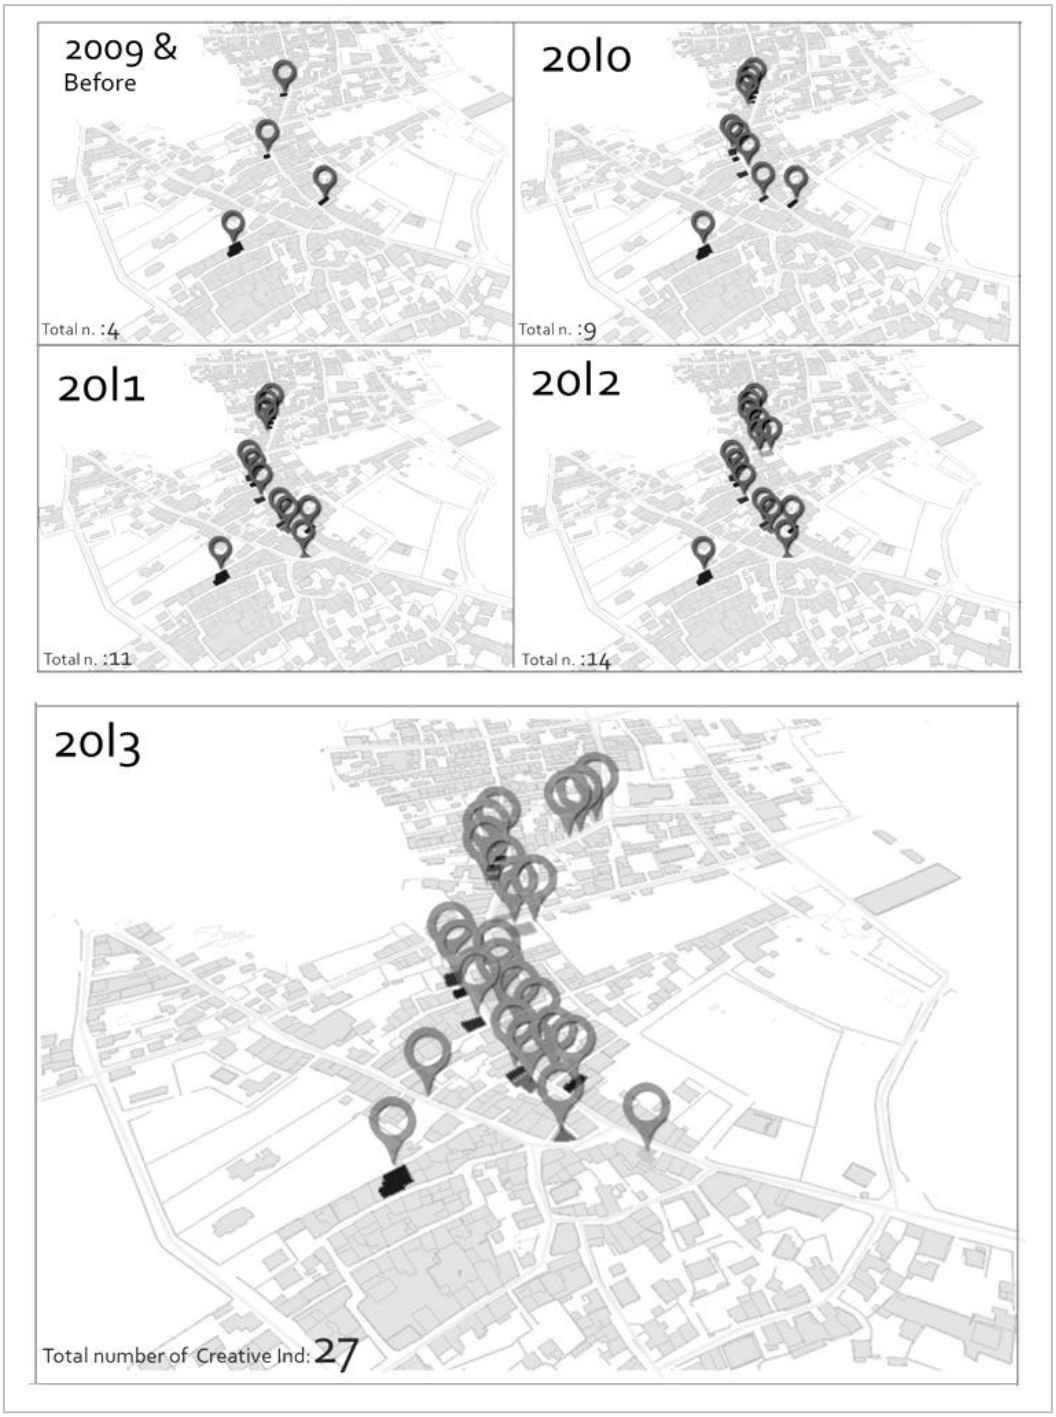

Figure 4. The evolution and location pattern of the creative individuals

***3.3.*** Generating Creative Place Making Toolkit for Ala at , Hac Memi District

The following analyses including interview, cultural assets map, space syntax analysis, creative cluster mapping defined in diagnostic analyses of the toolkit were used for understanding creative environment and creative place-making process of the Hac Memi District. Moreover, creative based strategy which leads to understand potential creative environment was constituted based the outputs of diagnostic analyses.

*3.3.1 Interview:*

Interviews provided to understand creative individual s location choices, lik terms of characteristic of the creative environment. In this study, interviews were conducted with eighteen creative individuals including the pioneers based on snowball technique in August 2013. The interviews gave detailed information about location patterns of creative individuals and the positive and negative impacts of creative clustering process in terms of creative tourism. Additionally, the interviews also revealed the relationship between the locals and creative individuals based on creative-based tourism development. In this context, the findings of the interviews demonstrated that creative individuals are working to preserve the tangible and intangible assets of the town. Furthermore, in social sense, creative individuals generate knowledge-based activities including workshops, festivals, exhibitions and micro-scale projects for promoting local lifestyle, maintaining the cultural assets and socializing with the locals. For instance, one of the respondent (43, male, has an art g Memi District) explained the project of Art Farm . In that project, they organized the pla the creative individuals, locals, visitors and academics meet via symposiums, art galleries, workshops and concerts. He claimed that they (the creative individuals) aimed to develop the creative tourism during the whole year via knowledge-based activities. Additionally, creative individuals enhance the physical quality of the town and they regulate street management as for promot district in the context of creative-based tourism development. For instance, one of the respondents (male, musician, collector and designer, has an antique shop in Hac Memi District called Es stated that:

> We (the creative individuals) gather among ourselves for avoiding the det *pattern, keeping the sound, noise in certain level. We gather for our street. Generally, we gath*er at the Dutlu Kahve .

The findings also demonstrated that creative individuals bring economic vitality to the district by working with locals and supporting the small creative businesses. Ultimately, the major positive impacts of creative-based tourism come into the prominence as follows: economic vitally, connecting locals, improving quality of public space, supporting community, and constituting vibrant spaces. Respectively, positive impacts of creative- based tourism can be summarized in the following table (Table 2).

Table 2. Positive Impacts of Creative- based Tourism

| **Physical Sense** | **Social Sense Knowledge- based actives** | | | **Economical sense** |
|---|---|---|---|---|
| | **Workshops** | **Festivals** | **Organizations** | |
| - Constituting vibrant spaces<br><br>- Improving quality of public space<br><br>- Preserving historical site. | - Connecting with the locals.<br><br>- Supporting community. | - Carrying artistic identity of the town in both national and international level.<br><br>- Maintaining the cultural assets | - Socializing with the locals. Discovering the cultural values of Ala at which sunk into oblivion.<br><br>- Protecting local cultural values. | - Supporting the small creative businesses especially the business of the young talents<br><br>- Working with locals based on art and craft production<br><br>- The length of the tourism season |

On the other hand, based on the interview s results, negative impacts of creativ comes out as prices of goods, rents and habitat loss due to rapid development of tourism. According to interview s results, many responded complained about high rental rates due the dev service tourism. In the last two years, the workplaces of locals and creative individuals threatened by the restaurants and cafes that caused the increase in the rents. On another point, negative impacts of creative-based tourism were eliminated with creative clustering process such as over use of cultural resource, undermining of local life, noise and pollution. Ultimately, many negative externalities of the mass tourism were reduced with creative-based development process.

*3.3.2 Space Syntax Analysis:*

Space Syntax analysis, which demonstrates the most accessible places based on p skills, is defined as a tool for identifying well-connected place and primary pedestrian routes in terms of vitality and permeability (Hillier et al., 2007, Carmona et al., 2003). The following figure (Figure 5) shows the potential movement choice map of the town, which measured integration R800m and calculated the angular closeness up to 800m (10 minute walk). The analysis has been done for according to formal and informal pedestrian routes in order to understand potential and high movement routes. In this analysis, red lines reveals the most chosen routes, which also indicates the current routes of creative individuals working places. Similarly, yellow lines demon potential high movement routes of the district, where the creative individuals have started to locate. Moreover, the space syntax analysis indicates the well-connected places where the creative individuals gather and stimulate their knowledge-based activities. Ultimately, space syntax analysis offers insights on the creative spaces for improving creative environment of the district.

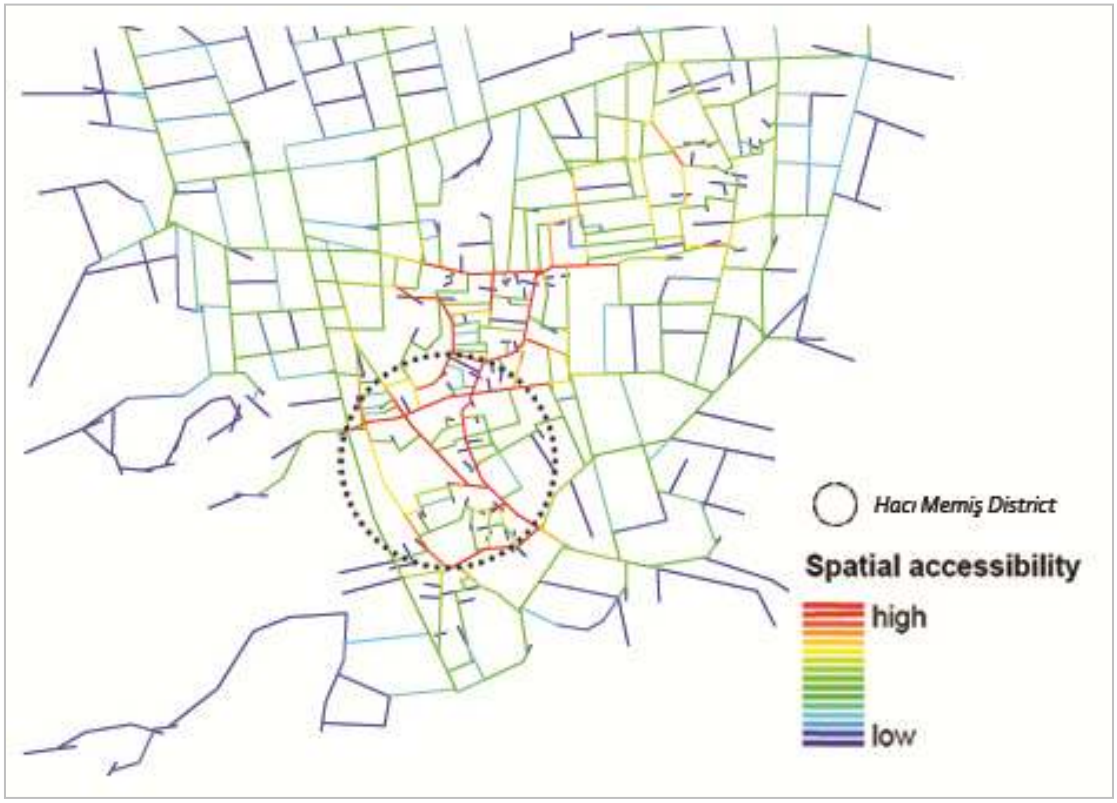

Figure 5. Potential Movement Choice Model of Hac Memi District

*3.3.3 Cultural Asset Map:*

Cultural asset map, which illustrates cultural resources including cultural heritage, industries, occupations, organizations, events and festivals, comes into the prominence as a fundamental tool for transforming the intangible and invisible assets in terms of creative tourism (Crawhal, 2008; MCPI, 2010). Furthermore, in this study, cultural asset map illustrates the physical cultural assets in order to generate key resources such as art, culture and heritage in terms of creativity. For this study, cultural asset map analysis has been applied for identifying places, events and organizations of the town as for fostering the creative environment.

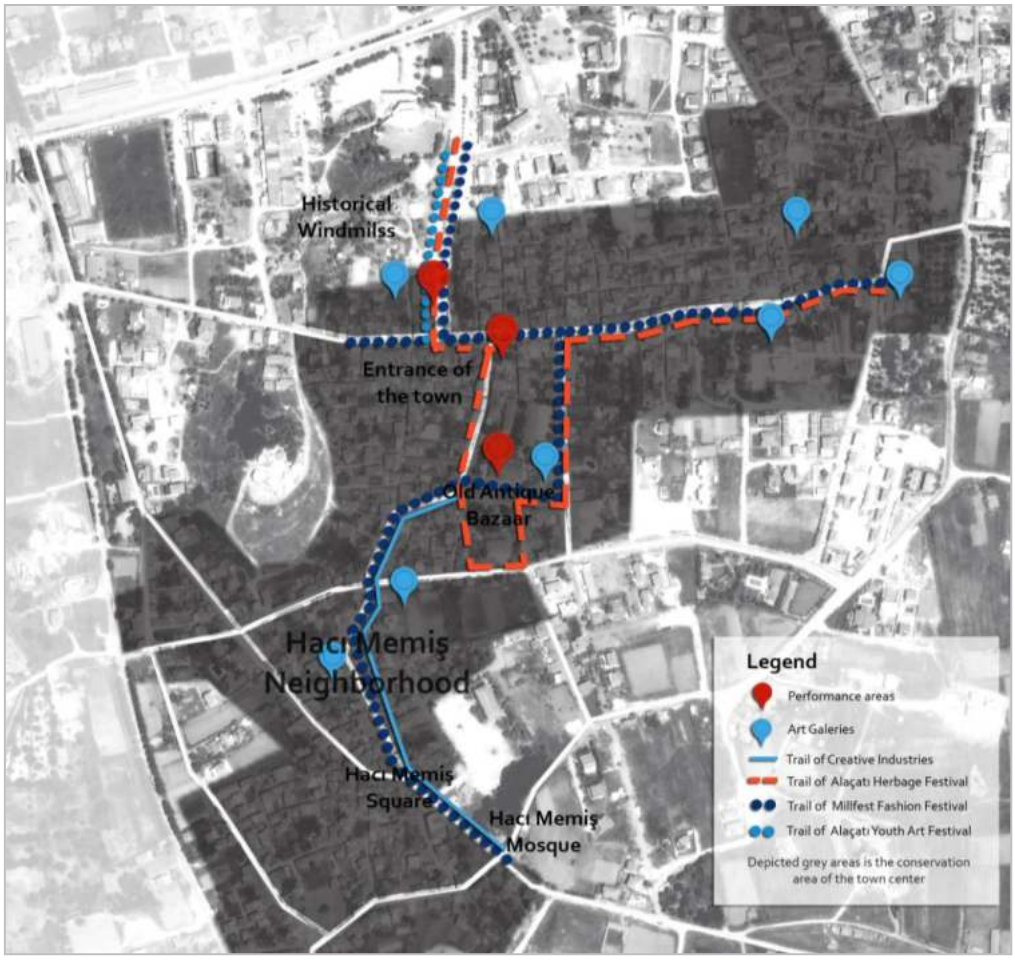

Figure 6. Cultural Assets of the Ala at

In Ala at , four associations including Tourism Association of Ala at , the C of Ala at , Ala at Art Friends and Ala at 2020 organize festivals for maint reflecting invisible assets of community. For instance, Ala at Art friends, which is a group of art enthusiasts formed by the creative individuals, organize workshops and festivals such as Youth Art Days in Ala at for promoting art life of the town. Today, there are six festivals organize associations including Ala at Herbage Festival, Ala at Youth Art Festival, Cup, Millfest Fashion Festival, International Ala at Festival, Ala at Fishing Fes hand, the creative individuals also organize street exhibitions to illustrate tangible and intangible assets of the town. Ultimately, invisible assets of the town come into the prominence through these festival and organizations. Accordingly, the cultural asset map of the town demonstrates the link between cultural assets and physical structure in order to generate creative place (see Figure 6).

*3.3.4 Mapping Creative Clusters*

Mapping creative clusters provides spatial and statistical data about creative industries in order to clarify the size and contribution of creative cluster in terms of employment, value and exports (Higgs and Cunningham, 2008). In that sense, the creative cluster mapping analysis demonstrates the location pattern of creative industries, where creative individuals stimulate their activities.

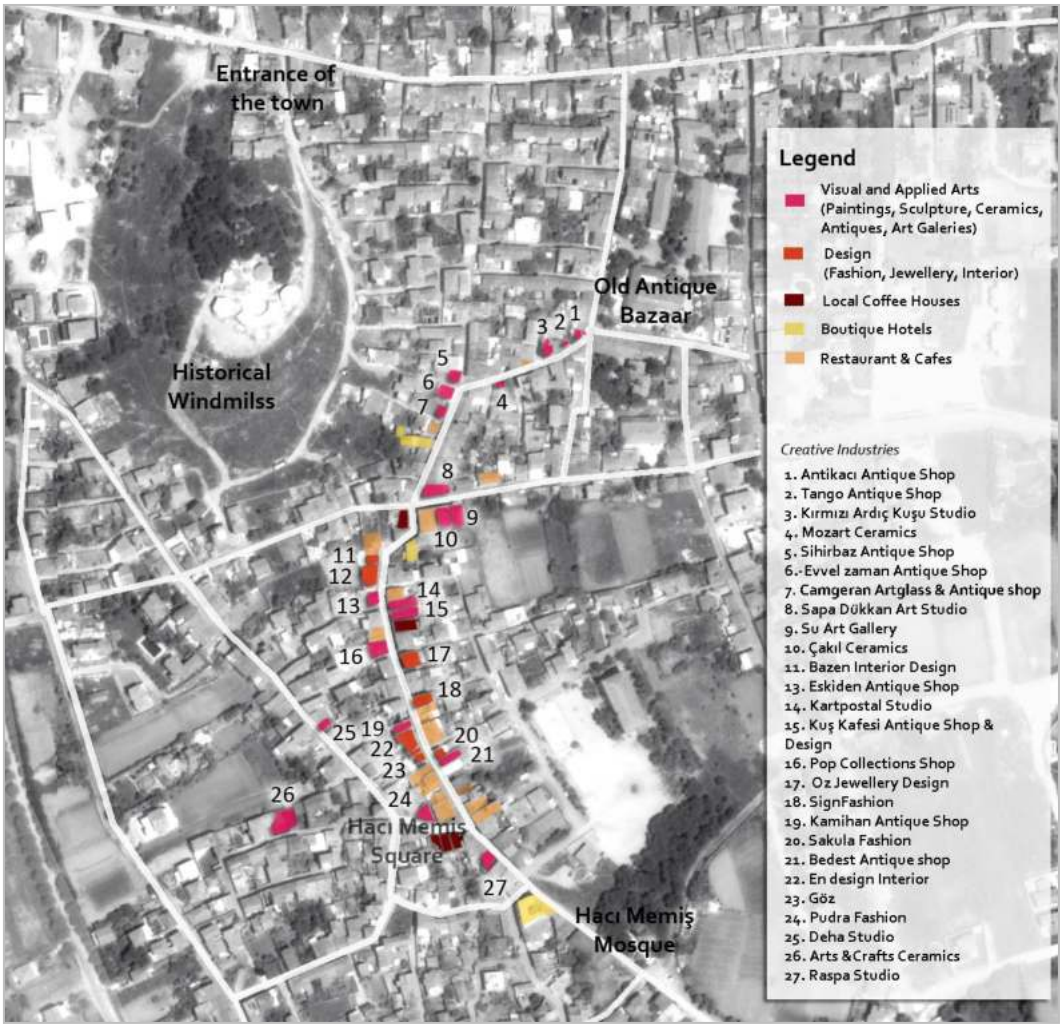

Figure 7. Creative Cluster Map of Hac Memi

For this study, the creative cluster mapping have been done for the Hac Mem UNCTAD classification system that includes design and visual and performing arts (UNCTAD, 2010). The analysis illustrates the detailed land use map of creative industries o including art galleries, antique shops, fashion, design and ceramic studios. Furthermore, the creative cluster mapping analysis also demonstrated the local shops (e.g. coffee houses, grocery) of Hac Memi District in terms of creative-based tourism development. Ultimately, the analysis indicat twenty seven creative spots of the Hac Memi district that provide oppor between the locals, creative individuals and visitors (see Figure 7-8).

Figure 18. A View from the Workplace of the Glass Artist

*3.3.3.5 Creative-based Strategies*

Creative-based strategy defined in predictive analyses of the toolkit is identified as a tool for fostering creative environment. Creative based strategy aims to promote endogenous assets, specific amenities, natural landscape, cultural heritage and creative atmosphere in order to encourage creative works in urban fabric. According to Seleda et al. (2012), creative based strategy is mainly based on three main dimensions as follows: (1) Governance that promotes the creative economy, (2) Endogenous resources based on natural and built environment, social and symbolic capital, economic and cultural activities, (3) Territorial embeddedness related with territorial position; urban densities; and accessibility. Thus, creative-based strategies, which constitute policy and design strategy for creative place-making, enhance creative activities in urban fabric through interactive participation.

In this study, creative-based strategies have been done according to the outcome of diagnosis analyses including space syntax, cultural asset maps, interview and creative cluster mapping. Outputs of diagnostic analyses, which provides detailed data about the size and contribution of creative cluster business model, the projects and organizations of the creative individuals, events and festivals of the town, constitutes a baseline study for understanding the creative environment of the town. The following figure (Figure 9) illustrates the findings of diagnostic analyses including cultural assets map, creative cluster mapping and interview. For the study, creative-based strategy has been developed based on two dimensions including governance and endogenous resources for achieving creative-based tourism development. Firstly, in governance part, the role of agents including non-governmental organizations, creative individuals, local citizens, municipality, which was defined in the findings of the cultural asset map and interviews, enhance the creative place making process. Accordingly, the findings of diagnosis analyses revealed that the role of agents promotes the creative- based tourism development. Furthermore, they mitigate the negative impacts of tourism development through projects, organizations, and festivals. For instance, street management , whic

by the creative individuals, protects local life of the town. Addition to street management, the creative individuals organized the projects including art farm project and protecting the local coffee houses, which foster cultural assets and local life of the town. In that sense, these specific strategies generated by the agents including non-governmental organizations, creative individuals and local citizens must be enhanced by participatory process in terms of creative tourism. Secondly, endogenous resources such as cultural, natural, aesthetic and built assets of the town come into prominence as an important tool for fostering creative environment. In this scope, infrastructure and support programmers become crucial (Seleda et al., 2011; 2012). Additionally, creation of creative spaces emerges such as live-work houses, studios, performing art spaces, meeting points comes out as an important factor in the context of creative-based development (Gertler et al, 2006). Respectively, according to findings of diagnosis analysis, the current creative activities of the town are concentrated on high movement routes that are shown in the findings of space syntax analysis. In this scope, in order to promote creative activities of the town, potential high movement routes can be defined as development routes of the creative activities in terms of creative tourism. Accordingly, new creative activities must be developed on the potential high movement routes by offering performance areas, open studios, arts workspaces, and exhibitions. The creative spaces, where the locals, creative individuals and visitors exchange their ideas, also must be enhanced visually and aesthetically for attracting the creative tourist (Markusen et al, 2010). Ultimately, the creative based strategies, which offers potential development routes of creative activities, enhance the creative based tourism development based on the findings of diagnosis analysis.

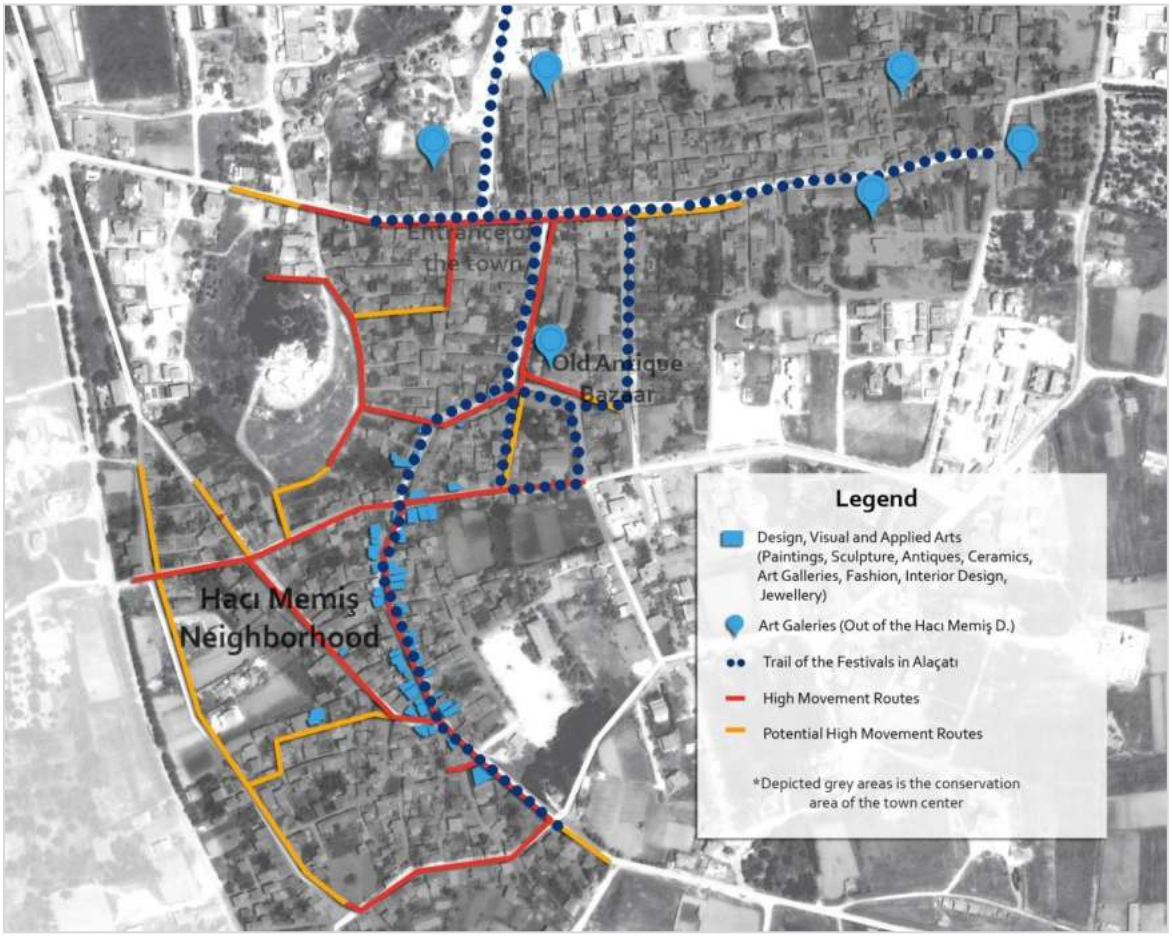

Figure 29. Diagnostic Analyses of Hac Memi District

## 4. Conclusions

In this study, creative clustering process is examined in small town settings. In this scope, urban design toolkit that was evaluated for understanding characteristics of creative environment was used for understanding creative clustering process in Ala at , Hac Memi District which e creative-based tourism development. The findings of the toolkit represent creative clustering process of the town in the context of tourism development. Furthermore, creative-based strategies defined in predictive analyses of the toolkit reveals the potential development routes for creative activities for enhancing creative clustering process. In this scope, this process can be enhanced with creative- based strategies for contributing creative tourism in small town settings. Ultimately, benefits of the concepts of creativity in terms of tourism can be summarized in following part.

Creative clustering process controls the development of tourism in small scale town. In this scope, the agents including non-governmental organizations, creative individuals, local citizens, and municipality emerges as a control mechanism for eliminating negative impacts of tourism development. Especially creative individuals who engaged in creative clustering process aim to promote local lifestyles and cultural assets of the town. In this scope, they organize micro-scale projects, organizations and festivals for the locals and visitors. The creative individuals, who strengths the identity of town, also add value on the physical quality of the town in order to enhance vibrancy of the street life. Moreover, creative tourism constitutes interactive participation between the locals, creative individuals and visitors for contributing the local economy (Richards, 2011). Creative tourism also keeps tourism alive both in summer and winter seasons and brings economic vitality in the town (Walker, 2010, Richards, 2011). On the whole, this study claimed that creativity is not solely based on metropolitan phenomenon and place-making does matter as a consistent location factor for art-based communities. In that sense, creative tourism in small scale town, which provides an opportunity for taking a place in global economy, contributes to the healthy development of small scale town (Seleda et al, 2011; 2012).

# Coastal tourism in New Zealand: a challenge for local culture in a changing era?

Kareem Ismail
PhD Researcher, (School of Architecture and Planning, NICAI, University of Auckland),
kism817@aucklanduni.ac.nz

Keywords: Sustainable coastal tourism, Maori indigenous culture, Chaos theory.

## Abstract

*Tourism sustainability is based on its ability to represent local culture and being beneficial for the community. This paper deals with this topic through investigating the relationship between coastal tourism activities and local communities in five case study areas in New Zealand and comparing them according to sustainable tourism indicators. Data were collected and analysed using mixed method research approach through A) Case study visits and literature review to identify the tourism system* characteristics and connecting them with theoretical tourism models such as Mckercher s chaos models. B) Semi-*structured interviews were conducted with local community representatives to get their perception on the effect of coastal tourism activities on their culture and tourism strategies implementation. The results showed that the lack of regional tourism strategies leads to weakening of the institutional structure managing coastal tourism activities in New Zealand causing fragmentation in the responsibilities of different agencies. Local and iwi community representatives express their dissatisfaction of the planning for tourism, its negative effects on their culture and lack of job opportunities in tourism. However, they appreciate the efforts made by some governmental authorities such as MfE, DOC and some local councils in protecting coastal tourism environmental assets and their cultural heritage. The study recommends formulation of updated tourism strategies on the regional level connected with New Zealand tourism vision 2025, enhancement of community participation through using adaptive management approach, incorporating local iwi culture in tourism activities and increasing tourism job opportunities for local community members to achieve sustainable tourism outcomes.*

## 1. Introduction

Tourism activity is considered the largest business sector of the world economy according to a World Travel and Tourism Council (WTTC) 2015 report, tourism makes up around 9.5% of the global Gross Domestic Product (GDP), at approximately 7 trillion US dollars, and it is forecast for this number to increase to almost 11% of the global GDP by 2024. International tourist arrivals have doubled in 13 years from 528 million in 1995 to 1087 million in 2013, and forecasted to reach 1.8 billion by 2030 (UNWTO, 2014). Tourism also creates millions of jobs annually, in 2013 approximately 266 million jobs where generated by the tourism sector (WTTC, 2014). Moreover, the Asia- Pacific region was the fastest growing region in the last four years in terms of the international tourist growth, with 15 million more people visited the region in 2013 than in 2012 (UNWTO, 2014).

Therefore, studying coastal tourism, its effect on the local culture and ways to increase its sustainability is the focus of this paper. This is important because coastal tourism is considered one of the fastest growing forms of tourism in recent decades, where coastal destinations act like magnets that attract tourists to visit and enjoy various activities. Reports from international organisations such as United Nations World Tourism Organization (UNWTO) showed that eight of the top ten worldwide tourism destinations in 2014 were coastal countries (UNWTO, 2014).

The paper starts with indicating research importance to New Zealand, followed by reviewing of literature showing special relationship between indigenous communities in New Zealand named as iwi

and the coast. Then discussing the conceptual model through reviewing tourism models (linear and chaos models). The mixed method research was used in this research, were mix between qualitative techniques (interviews and document analysis) with quantitative techniques (sustainable tourism indictors) are discussed, followed by brief about the selected case studies. The analysis is based on investigating the effect of coastal tourism in local iwi culture and its coastal sites and that analysis is represented through positioning case study areas on different stage of the tourism life cycle.

The discussion continues through proposing a sustainable development framework and how local community and iwi could participate effectively in its stages to ensure their local culture is protected against any threats from mass coastal tourism activity. This is followed by conclusion specifying the main issues extracted from analysis and suggestions to solve the issues and limit its negative impacts.

## 2. Research importance to the New Zealand context

This area of paper response to the importance of coastal tourism and its relationship with local communities and effect on local cultural, this is important for many countries especially in the Asia-Pacific region. The study is important for New Zealand for a number of reasons. Firstly, there is a growing importance of tourism activity to the New Zealand economy, considering it is the second largest export category in the country s economy and contributing to almost 4. with one in every 10 New Zealanders working in the tourism industry based on Ministry of Business, Innovation, and Employment statistics (MBIE, 2014). New Zealand government try to develop tourism to be a major contributor to the country s economy in the future. The g Zealand Tourism Strategy (NZTS) stated that by 2015 tourism is valued as the leading contributo *a sustainable New Zealand economy* (Ministry of Tourism, 2007, p.6).

Despite that, the goal was not achieved, but the governmental desire still exist through the New NZ Tourism Strategy 2015 aims to double the revenue coming from tourism sector from $ NZ 24 billion in 2013 to be $NZ 41 billion by 2025 in New Zealand Tourism Vision 2025, through improving the competitiveness level of New Zealand tourism in the international market (Tourism Industry Association New Zealand, 2014).

Secondly, an important part of this competiveness is the tourists experiencing local culture along with their enjoyment of the natural coastal environment (beaches). More than 1/3 of the total international tourists visiting New Zealand in 2013 stated that their main reasons to visit the country was the spectacular landscapes and natural beauty (Tourism Industry Association New Zealand, 2014). This future vision is not only focusing on the economic aspect, but depends on the brand 100% Pure New Zealand that promotes the country, as a place where environment is best reserved in the international tourism market, combining landscape with the indigenous culture to create a competitive tourism product that attract international tourists (Tourism Industry Association New Zealand, 2014)

Therefore, in order to achieve the tourism vision 2025 and increase the count tourism sector, it needs lots of investment in the tourism industry. However, this investment growth means increase in tourism activities and its pressure on the coastal areas and local culture sites. Although MBIE produced Maori Tourism Action Plan in 2011 (MBIE, 2011) to maximize revenue from Maori tourism sector, but its main focus was in increasing profit without major emphasis on protection of the heritage sites or local culture. Although their recognition that Maori culture is important part of the visitor experience. **Therefore, this paper tries to answer the question about the status of sustainable tourism practice in the selected study areas in New Zealand and their effect on the local culture.**

## 3. Maori, tourism and the coast: complicated relationship

The coast represents a special value for iwi Tangata whenua (Traditional name for iwi) consider themselves as the guardians for the coast (Kaitiaki).The role of kaitiaki involves a responsibility to ensure that the mauri (life supporting capacity and essence) of the coastal environment is protected, and that coastal resources are sustained for future generations to enjoy. This role and special connection with the coastal environment appear in the following activities:

a) Sites and areas that reflect the long relationship of tangata whenua with the coastal environment, including nohoanga (temporary campsites), taurangawaka (canoe landing sites), pa (fortified settlements), ana (caves), wahipakanga (historical battle sites) and pouwhenua (traditional markers, landforms/trees), fishing grounds.
b) Cultural and spiritual sites including islands, peninsulas, headlands, and inlets.
c) Wahitapu, including urupa (burial sites) and wahitaonga (treasured places or things).
d) Mahingakai values, including kaimoana (food sourced from the sea), taongararanga (plants for weaving/manufacturing), and rongoa (medicinal species) customary use/management practices, including rahui, mataitai and taiapure (Quality Planning, 2015).

This special relationship was translated through the principles from treaty of Waitangi and in the last decades through number of documents such as Awaroaki Manuka for Ng ti Te Ata in 1991 and The Cry of the People Natural Resource and Environmental Iwi Management Plan in 2008. Through these documents, Tangata whenua try to reflect their holistic and integrated management approach towards the coastal environment and aim to protect their coasts and local culture. (Quality Planning, 2015).

The relationship of iwi with the coast is also recognised in Resource Management Act (1991) and Coastal Policy Statement NZCPS 2010, both recognises that tangata whenua are kaitiaki of the coastal. Different policies in NZCPS also focuses on protecting the coastal areas that are of special value to iwi and recognising the Maori culture values in the coast.

Furthermore, tourism is accused of being destructive to the environment and local culture. Studies and theories were made to test this claim; concepts introducing tourism as a sustainable activity began to rise, and others tried to convert tourism towards more environmentally responsible trends like the eco-tourism concept (Crenat & Gourdon, 2007).

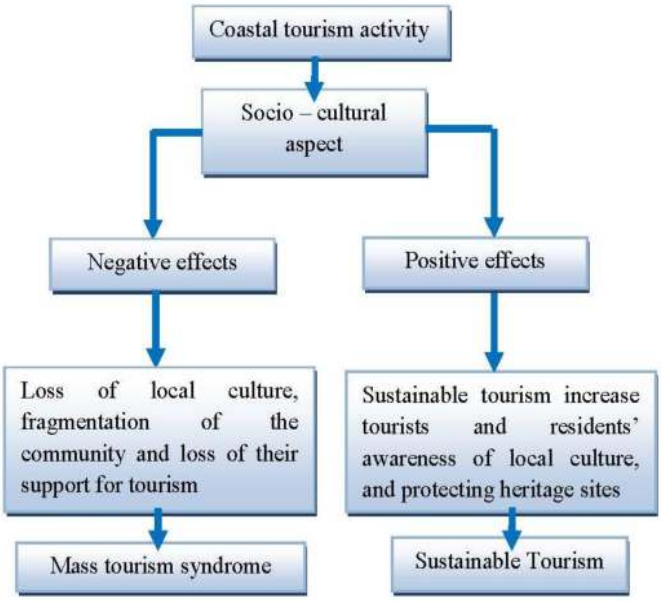

Figure 1: Coastal tourism effect on socio-cultural aspects

Reviewing such concepts is important to this study because they enlighten us to considering new perspectives for the tourism activity. A definition provided by the World Tourism Organization (1999) states that: *sustainable tourism development meets the needs of present tourists and host, while protecting and enhancing opportunities for the future. It is envisaged as leading to management of all resources in such a way that economic, social and aesthetic needs can be fulfilled, while maintaining cultural integrity, essential* ecological processes, biological diversity and life suppo (Weaver, 2006, p. 20).

## 4. Conceptual framework

Tourism is a complex activity; one of the earliest definitions of the tourism system, was introduced by Leiper (1990), responding to the emergence of the sustainable development concept. Leiper defined the tourism system as a linear controlled system depending on traveller/ tourist journey from the traveller generating region, then departing to the transit route region where the travel industry exists and flight takes place to reach the tourist destination region.

Other researchers, such as Miller *et al.* (1999) explained that the tourism system could be described as an interaction between three main components (Figure 2). The Locals (L) representing the traditional communities, and Tourists (T), either domestic or international, and Brokers (B), who are representing the private sector. Miller added that the tourism system is constrained by human and natural settings, and that tourism has a direct impact on both the social and natural environment. This model tries to explain the dynamics of the tourism system and its interaction with the surrounding environment and local community, and focuses on the analysis of the power dynamics and internal relationship between system components.

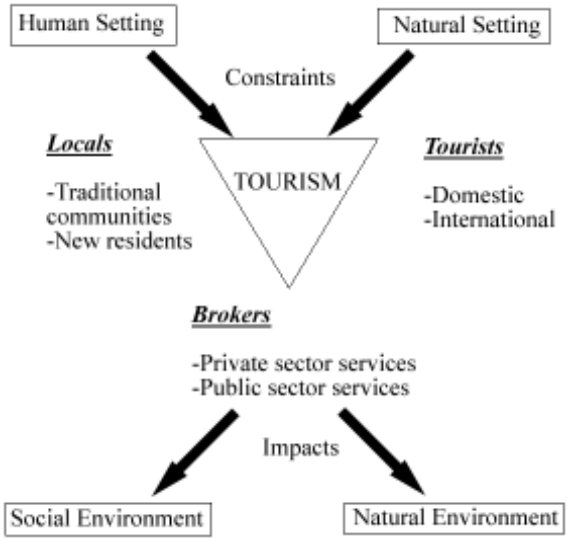

Figure 2: The B-L-T model from Miller *et al.* (1999)

However, it does not emphasise the effect of the external factors like political and socio- economic factors on the system. Other researchers like McKercher (1999) argued that the linear, controlled, predictable Lepier s model (1990) is not entirely correct, as the tourism plans produced accord this perception were failing to achieve their goals, and that these linear models fail to reflect the dynamic nature of tourism or describe the complex interrelationships that exist between organisations managing tourism challenge including local community and their culture.

He then introduced the chaos model of tourism (Figure 3), where the tourism system is described as an open model where there are continuous movements happening between the different elements of the system and that each of these elements is interconnected. McKercher added to the Leiper s system components communication sector which connects travellers to destinations, consider non-tourism externalities like changing political, economic, or social conditions and outputs of the system.

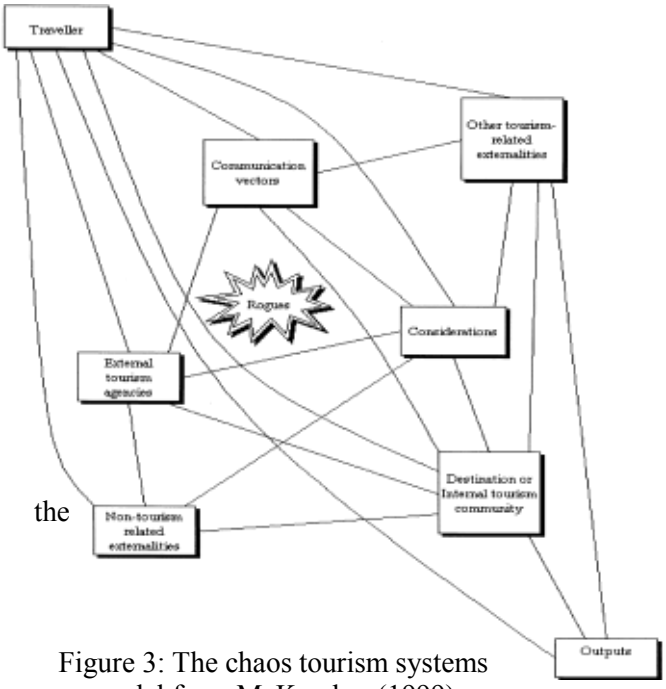

Figure 3: The chaos tourism systems model from McKercher (1999)

The tourism system components were defined further by Leiper (2004, p.) As it comprises of five elements: tourists, generating regions, transit routes, destinations regions, and tourism industries which combine to enable tourism to occur in practice (Figure 4). Responding to the rapid changes that happened in the tourism industry, its booming growth in the 1990s and as a step to emphasising external factors ignored by Miller. Leiper modified the model and suggested that the tourism system works in an operational context that includes economic, socio-cultural, political, technological, legal, and environmental variables.

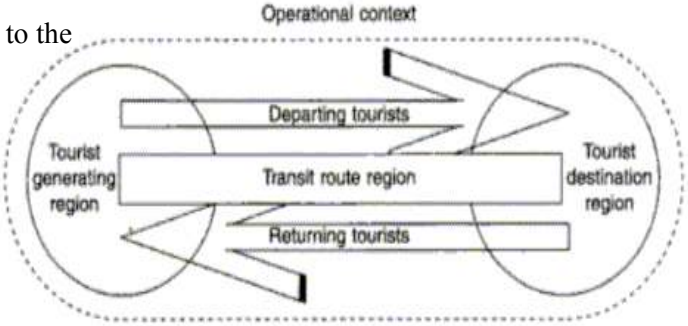

Figure 4: The tourism systems model from Leiper (2004)

However, the external factors were more generalised in the chaos model, and combining the characteristics of McKercher s model with the attributes, detailed description T model will create a better integrated definition of the tourism system that does not ignore the destination environmental, socio-cultural, economic and institutional features. In addition, the Leiper model could serve as a base to describe coastal tourism patterns in the selected case study areas.

These previously mentioned models tried to deal with the challenges facing the tourism activity, but to face the challenges the status of tourism in the selected destination must be identified precisely. Although it is older research that of Bulter (1980) produced what is known as the tourism life cycle model that clearly explains the changes happening in the tourist destination. Despite the age of this model, it is still widely used to show the evolution of tourism in any destination.

This model (Figure 5) explains the five main stages of tourism development focusing on tourism resorts. Firstly, the ***Discovery*** stage where the destination is gaining popularity and more economic opportunities are opened to provide services to meet the needs of tourists. Secondly, ***Growth and development*** stage where more tourists visit the area with more promotion of tourism activity and more demand for tourism development and infrastructure.

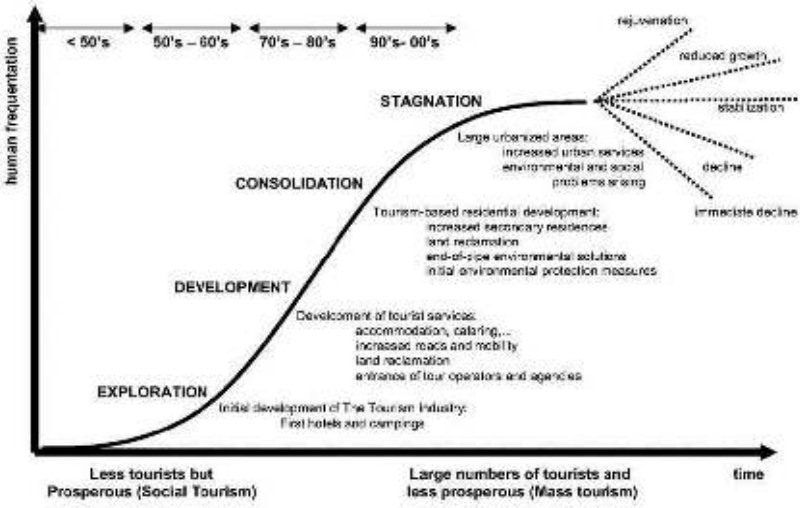

Figure 5: the life cycle tourism model from Butler (1980)

Thirdly, the ***Success*** stage where the area s facilities are fully utilised with mass tou old forms of tourism. In this stage, the destination begins to lose its identity and culture, for the benefit of international and non-unique aspects of service and culture. Fourthly, the ***problem stage*** where the destination became neglected and little of the original features of the natural environment remains. That affects the economic revenue coming for the community from tourism. Lastly, the ***decline and rejuvenate*** stage where the system either decline or develops to a sustainable pattern.

## 5. Methodology

The analytical methods are based on the triangulation between qualitative and quantitative methods (Figure 6). The qualitative methods depend on and content analysis of statutory and non-statutory documents. The Nvivo software package as a qualitative analysis tool was used to analyse interviews, and based on the responses investigate the relationship between tourism activity, and integrated coastal management practice in the case studies. In addition, identifying the main issues from the view of key personalities managing the coastal areas, and the relationship between policies stated in statutory documents and practice. In terms of practice, the quantitative methods of research come into perspective, depending on Indicators that were developed based on a collection of related national and international indices (Table 1).

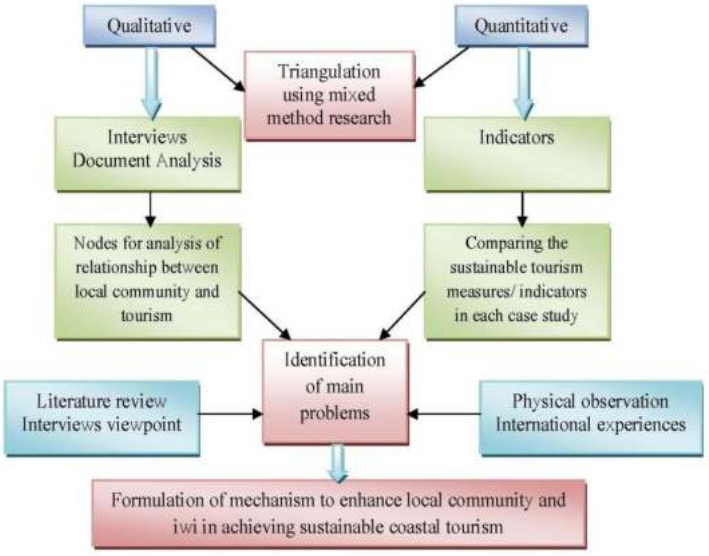

Figure 6: Chart explaining methods of data analysis

Table 1: Selected sustainable tourism indicators from literature used in the study from (UNEP, 2009)

| Section | Indicator |
|---|---|
| Sustainable tourism public policy | % of the destination with a sustainable tourism strategy plan |
| Customer Satisfaction | % of visitors that are satisfied with their overall experience in the destination |
| Recreational activities and their effects on the environment | Variety of coastal based activities and % of the coastline affected negatively by those activities |
| Sustainable Tourism Management in tourism enterprises | % of tourism enterprises in the destination involved in environmental protection |
| Protecting and Enhancing Cultural Heritage | % of the destination covered by a policy or plan to protect cultural heritage |
| Maori involvement in tourism activity | % of Maori based tourism activities operating in the destination |
| Community/social impact | Number of tourists per 100 residents / % of residents who are satisfied with tourism in the destination |
| Protecting and Enhancing Cultural Heritage | % of the destination covered by a policy or plan to protect cultural heritage |
| Quantity and Quality of Employment | Direct tourism employment as % of total employment/ % of seasonal tourism jobs |
| Tourism performance | Average length of stay of tourists (night)/ occupancy rate in commercial accommodation per month |
| Tourism Flow | Number of tourists per month/ relative contribution of tourism to the destinationys econom |

The results from indicators enforce the community / iwi perception (qualitative methods).

## 6. Case study areas

Five case studies (Figure 7) were used to investigate the relationship and effect of coastal tourism activity in local culture, and they were selected based on the following criteria: its importance to New Zealand tourism industry, the development pressure on coastal areas, variety and characteristics of tourism activities (including cultural, heritage sites) and different management approaches. A brief of them as follows:

Figure 7: Map showing location of the case study areas

***Paihia and Waitangi area (Bay of Islands)***
The area is considered the gateway to the Bay of Islands, a main tourist destinations in the north of the North Island. The area includes the significant Waitangi historical grounds; (where the Treaty of Waitangi that formed New Zealand was signed), along with some of the sacred islands for local iwi on the Paihia coastline, and Russell the first European settlement established in New Zealand (New Zealand Tourism, 2012).

***Whitianga (Coromandel Peninsula)***
Considered by many researchers as the holiday capital of New Zealand (Peart, 2009), ***Whitianga town*** on the eastern coast of the peninsula is a major tourism destination, close to Auckland metropolitan. Whitianga coasts are facing pressures such as erosion threats and increasing coastal tourism that negatively affecting scared coastal sites for iwi.

***Akaroa (Canterbury)***
The coastal town of ***Akaroa,*** is a major tourism destination in the South Island with rich cultural heritage (the remains of the only French settlement in New Zealand). It is also a main stop for cruise ships in Banks peninsula, in close proximity to Christchurch city.

***Abel Tasman National Park***
This ***National Park*** is a great example of protected areas and marine reserve regulated under the Department of Conservation (DOC). It shows the efforts to integrate coastal management between unitary authority, DOC, local community and iwi to control tourism and protect coastal assets.

***Marlborough Sounds***
These unique sensitive sounds represent a good example of coastal tourism in the South Island where there is a mixture of activities such as recreation, aquaculture, marine farming activity, and historical

significance locations for local culture. Due to its location, the area is considered the main gateway to the South Island with frequent ferries connecting it with North Island (Wellington, NZ capital).

These case studies have different management systems for coastal areas and tourism activity, between the dual system (regional and district councils), and the unitary authorities that amalgamates the two councils in one authority in Abel Tasman and Marlborough Sounds.

## 5. Analysis

The analysis is represented through the tourism life cycle, where the placement of case studies within the stages of the cycle, helps in identifying the characteristics of tourism activity including relationship between the activity and local culture. In addition, due to its flexibility, the tourism life cycle helps in predicting the future of tourism activity. Starting with **Akaroa** that could be placed in the ***Growth and Development*** stage (Figure 8), as the area is having an increase in tourism accommodation facilities, demand for better tourism development and infrastructure (CCTB, 2013).

This increase is responding to the growth in tourism industry and in number of cruise ships visiting the township. That increase create threat on local culture and put more pressure on the local infrastructure and tourism accommodation facilities overall. However, there are concerns about the iwi s role in the tourism activity and accessing the coastal area (Dyanna Jolly Consulting and Ng Papatipu R nanga Working Group, 2013). They are still ignored and their activity is minimal in the perspective of mass tourism visiting the area. Moreover, the characteristics of one day visits of cruise ship tourists with day trips from Christchurch does not allow the opportunity to fully explore the culture and heritage of Akaroa, with need for support in regional level (Canterbury tourism) and local level (Christchurch City Council).

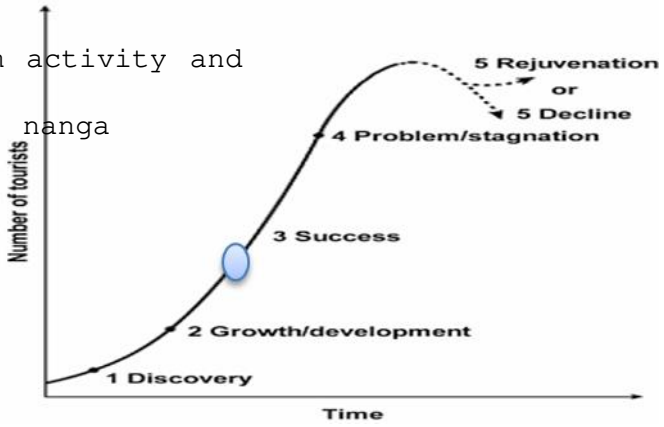

Figure 8: Placement of Akaroa in tourism life cycle

In terms of future trends, the area seems to be heading towards the stage of Consolidation (success), meaning the area is ready to increase its facilities to cater for more mass tourism. However, there is the threat of the area suffering from mass tourism symptoms by losing its identity and culture for benefit of attracting international tourism and that is concern of the residents.

**Paihia and Waitangi** could be placed in the ***Problem/ Stagnation*** stage (Figure 9), where the area is facing a number of problems. Economically, the tourism operators complain of the short tourism season (only in summer season). Also the need for upgrading tourism facilities and lack of promotion strategies limits the number of tourists.

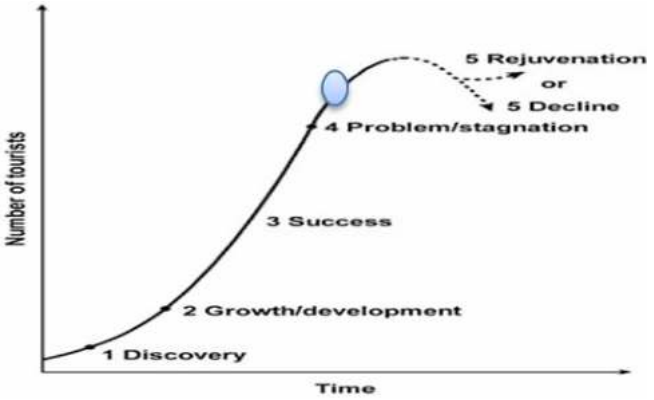

Figure 9: Placement of Paihia & Waitangi in tourism life cycle

Environmentally, catchment pollution in the Waitangi area and lack of maintenance for tourism facilities create pressure on the coastal tourism assets, especially in the Waitangi, and mean limited coastal tourism opportunities in the Waitangi beach and also it negatively affect the cultural heritage sites nearby Waitangi grounds. Another point adding to these problems is the vulnerability of ecological systems and short-term coastal defence strategies in the area make some beaches inappropriate for swimming and recreational activities and effect negatively the tourism experience.

The cultural tourism is based on coastal areas in Paihia specifically Waitangi grounds and other cultural sites in Northland region. However, iwi trustees supported by analysis of indicators show concerns about protection of these sites and efforts to increase tourists aware

The future trend of tourism in the Paihia and the Waitangi area is hard to predict. Although of community desire to develop and diversify the tourism activity through initiatives such as upgrading Paihia waterfront, along with regional and local councils support, all these factors facilitate the growth of tourism activity and head it toward a rejuvenation stage.

However, there are some points that could challenge this rejuvenation future for tourism activity in the area. The lack of funding from regional and local councils towards upgrading tourism facilities and the area s infrastructure. The lack of extensive promotion of the area for international tourists makes it lose competition with attractive destinations in the South Island or Auckland. This could push the area towards a stable status or even a decline in tourism activity. However, this depends on the cooperation degree between community, iwi, the public sector (regional and local councils) and the private sector.

In the case of **Whitianga**, the area could be placed in the ***Success / Consolidation Stage***, (Figure 10). This conclusion is based on a number of factors. The first is the full utilization of the area s tourism facilities, through the construction of new tourism accommodation, as well as the upgrading of the existing accommodation. This comes as a respond to cater for the mass numbers of tourists visiting the area.

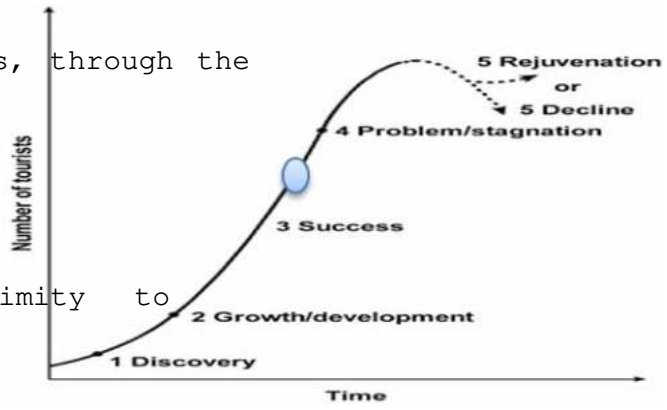

Figure 10: Placement of Whitianga in tourism life cycle

The area s relative proximity to Auckland, and its famous reputation, makes it one of the main destinations in New Zealand forecasted for the next 4 years (MBIE, 2013).

This means that the mass tourism styles coming from Auckland or international tourism are replacing old forms of tourism. The focus is on providing greater commercial tourism activities, such as recreational fishing, cruises, and kayaking, rather than cultural activities with very little input of iwi heritage in the tourism products offered in Whitianga.

The absence of a strategy to increase iwi participation and their input into the tourism activities, and an absence of a regional tourism strategy to promote the area s heritage are all factors c destination losing its identity for international mass tourism market needs. Another aspect is the absence of sustainable tourism guidelines for the area, and desire from investors to increase their revenue from tourism activity. This desire is reflected through the expansion of the yacht marina and construction of major residential projects on the coastal area such as Whitianga waterways project.

The area is predicted to head toward stagnation / a problem stage where the environmental and social problems are increasing, negatively affecting the tourism activity and local culture sites. However, there are factors that could slow the transition of the area to this problem stage. Firstly, the settlement between the Crown and the iwi tribes in the Waikato region, which includes Whitianga, is in the final stages (TCDC, 2014). This means that the iwi community will have more involvement in the coastal area and tourism activities by being the biggest owner of land in the region. The second factor is DOC s conservation efforts and its control over the marine reserve in the Ca means protection of the area s natural and cultural value. Finally, there a Waikato Regional Council to protect Whitianga s coastal areas against coastal problems.

The **Marlborough Sounds** area could be placed in the ***Stagnation / Problem stage***, (Figure 11). This conclusion is based on the increase in urban sprawled tourism development along the Sounds settlements such as expansion of yacht marinas, increase of camping sites, holiday homes, and tourism accommodation facilities. The Sounds ecological characteristics allow more marine activities to exist, such as aquaculture, marine farming, and recreational fishing. These activities try to benefit the local communities and integrate them with the tourism activity, but the ability to integrate is a matter of debate.

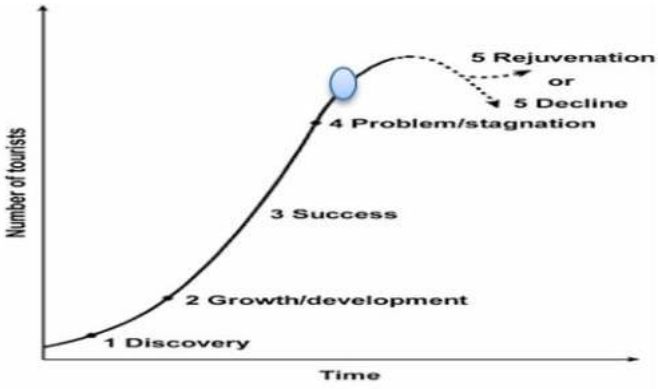

Figure 11: Placement of Marlborough Sounds in tourism life cycle

The conservation of the Sounds unique systems is a priority for the community, DOC NGOs and the government through the Unitary Council are trying to balance between the economic benefit, the environmental protection of the resources, protection of cultural coastal sites and maximize contribution of iwi and the local community in tourism activity.

The future trend is hard to predict, due to the large scale of the case study area, its unique features, and the variety of coastal / marine activities happening in the area. Therefore, it could be concluded that the area is heading towards a reduced growth stage where growth in tourism activity will be controlled due to combined efforts from Marlborough District Council, DOC, and the local community. Success in achieving this goal could lead to a shift to a more sustainable status for the area. This conclusion could be challenged with the power of investment in the Sounds and lack of strong regulations that protect the unique features of the area, an absence of a clear tourism strategy and reduction in the funding from DOC will limit their ability to fully protect the Sounds. All these factors could easily lead the area towards a status of stabilization or even a decline in the tourism activity and making the local cultural more vulnerable to thresholds.

In the case of **Abel Tasman**, the area could be placed in the ***Growth / Development Stage***, (Figure 12). However, in practice, due to the special status of the area as a national park with some parts covered under the foreshore marine reserve. As a national park, there are restrictions on the number of tourists, a limitation on the tourism facilities and development allowed (certain camping sites) which ensure sustainable practice of coastal tourism activity. This gives discussion of the tourism in this protected area a different perspective that focuses on the environmental sustainability of the coastal tourism assets and protection of local culture rather than economic aspects.

Therefore, placement of the area within the tourism life cycle would be slightly deceiving, as it is an area of controlled tourism activity that is unlikely to go through the phase of more growth (Success) or problems, unless one of the management factors is compromised. Therefore, it is fair to place the area in a sustainable status in regards to tourism activity, although the park s integrated management team is trying to upgrade the camping facilities to cater for more efficiently to more tourists with fewer effects on the coastal area and local heritage sites.

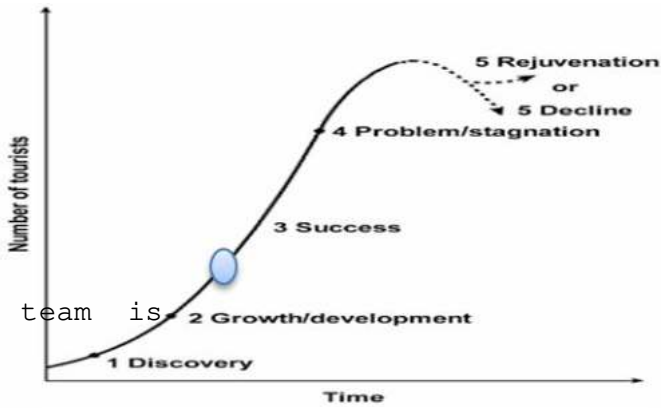

Figure 12: Placement of Abel Tasman in tourism life cycle

This sustainable status is supported by the tourism operators working in the national park and marine reserve areas adhering to DOC regulations and their desire to protect the are they are the main attractions for tourists and thus the tourism operators ma addition, the cooperation between iwi organizations, DOC and tourism operators lead to better recognition of the natural and cultural heritage in the area.

## 6. Discussion of results: Enhancement of public participation and iwi involvement

Public participation is a major factor in the sustainability of coastal development and tourism activity. In New Zealand, the role of iwi is an essential part of the process because of their special relationship with the coast, discussed earlier in this paper. The case studies analysis and discussion have showed issues regarding the degree of public participation and effectiveness of the role of iwi in decision-making process, coastal management, and tourism activity. Therefore, this section includes discussion about the role of public participation in the different stage of the suggested management framework (Figure 13) and ways to enhance it for the aim of protecting local culture.

Starting with the ***coherence building stage***, the participation of the local community and iwi in the plan preparation process is vital, and needs to be continuous in every stage of the plan preparation process. This participation is needed because of their knowledge about the existing issues to solve, identify the main goals, heritage sites to conserve and opportunities to enrich.

However, document analysis and personal communication with local community board representatives and iwi trustees showed that this role is practised at the end of the process before issuing the plan, and /or is covered quickly through public hearings without any in depth discussion to get public perception about the coast. This practice deprives the decision makers from getting the valuable contribution of the public and iwi, also making the local community feel excluded from the management process.

Following that, in the ***spatial planning stage***, the local community could help in identifying the main coastal issues and their exact locations based on their daily practice. This will add a spatial dimension to the coastal plans and help in implementation of its policies. Another important aspect is the iwi management plans; their knowledge (Kaitiakitanga) and role as guardians of the land (resources) plays important roles in identifying the heritage sites which carry importance to the local culture. However, many iwi prefer to avoid identifying their heritage sites on a spatial scale to limit accessibility and avoid any vandalism to these sites.

There are some successful examples of effective public and iwi participation in managing and conserving the coast. In Abel Tasman National Park Foreshore Plan, iwi and the local community are supporting the conservation activities and sustainable tourism practice in the park. The same practice happen through the steering group in Whitianga with public and iwi participation helped in the formation of a Whitianga coast action plan to protect the coast and its heritage sites from erosion.

The role of local community and iwi trustees as taxpayers is essential in the ***implementation stage***, because they are the source of funding for the district councils from their taxes. Their participation in conservation projects through logistical support facilitates implementation of these projects and ensure their success. This support is clear in the public participation through funding of Janszoon Conservation Project in the Abel Tasman National Park, also through funding from Focus Paihia community group to build a new waterfront for Paihia Township to encourage tourism activity.

For the ***incorporation stage***, the local community and iwi have little contribution, because they do not have any legislative power to enforce. Local community board members / councillors, as representatives of their communities, play consultative roles rather than having real power to enforce.

In the ***monitoring stage***, the community could be the best to monitor any changes happening to their beaches and coastal heritage sites. In the case in Akaroa, community helps in getting samples of recreational water quality in periodical basis. The same idea happens on a bigger scale in Abel Tasman National Park, where residents in Torrent Bay monitor any changes that happen in their area and cooperate with DOC to eliminate any degradation to the coastal environment that are significant.

In the ***information technology stage,*** the community and iwi help in increasing the transparency of data through public hearings. They could be a valuable source of information that increases regional and district council knowledge of the issues and opportunities in the coastal area. Paihia Urban Design Guidelines Report and iwi Mahaanui management plan in Canterbury are good examples of this idea.

In the ***research stage,*** the community could help in creating some research documents in cooperation with district and regional council. This case is clear in the preparation of Marlborough Sounds Coast Mapping Report for the Marlborough District Council (MDC, 2013), where local consultancy and iwi trustees helped in mapping the coast and identifying the culturally significant sites.

In the ***promotion of creative ideas stage***, the community plays an important role in identifying issues that face their local community and its coastal environment and creating some solutions for these issues. Their role also extends to protecting the coast through sustainable use of its resources based on the Kaitiakianga principles, which is almost similar to sustainable development concepts, aiming towards keeping the coastal systems and heritage sites in a resilient status for future tourism.

The main way to protect local culture from threats including mass tourism negative effects, come from enhancing the public role in the decision-making process through focused consultation with local communities. However, based on analysis of existing iwi management plans in the case studies, indicators and interviews with iwi trustees many of them showed their concern about being excluded, as they are only being consulted in the late stages of the plans preparation, knowledge in coastal protection measures which add to the threats on local culture.

The consultation should not be limited only to the community representatives but also through public hearings and focus groups with local experts to ensure different viewpoints are heard. In addition, adaptive management can make the residents act as partners in the daily management of the resources through their participation in monitoring, research process, and increasing awareness of local culture.

Another important aspect is spreading awareness in the local community of coastal issues and the significance of local culture and heritage sites. This is happening in different scales through local NGOs in Whitianga, Paihia and Waitangi, and in the Marlborough Sounds. Adding to the organisations, some of the local tourism operators are spreading awareness through their tours in the coastal area and by educating tourists about the importance of marine reserves. The role of iwi is extremely important as discussed earlier, because in some areas they have customary rights settled according to the Treaty of Waitangi such as the case in Whitianga and Paihia.

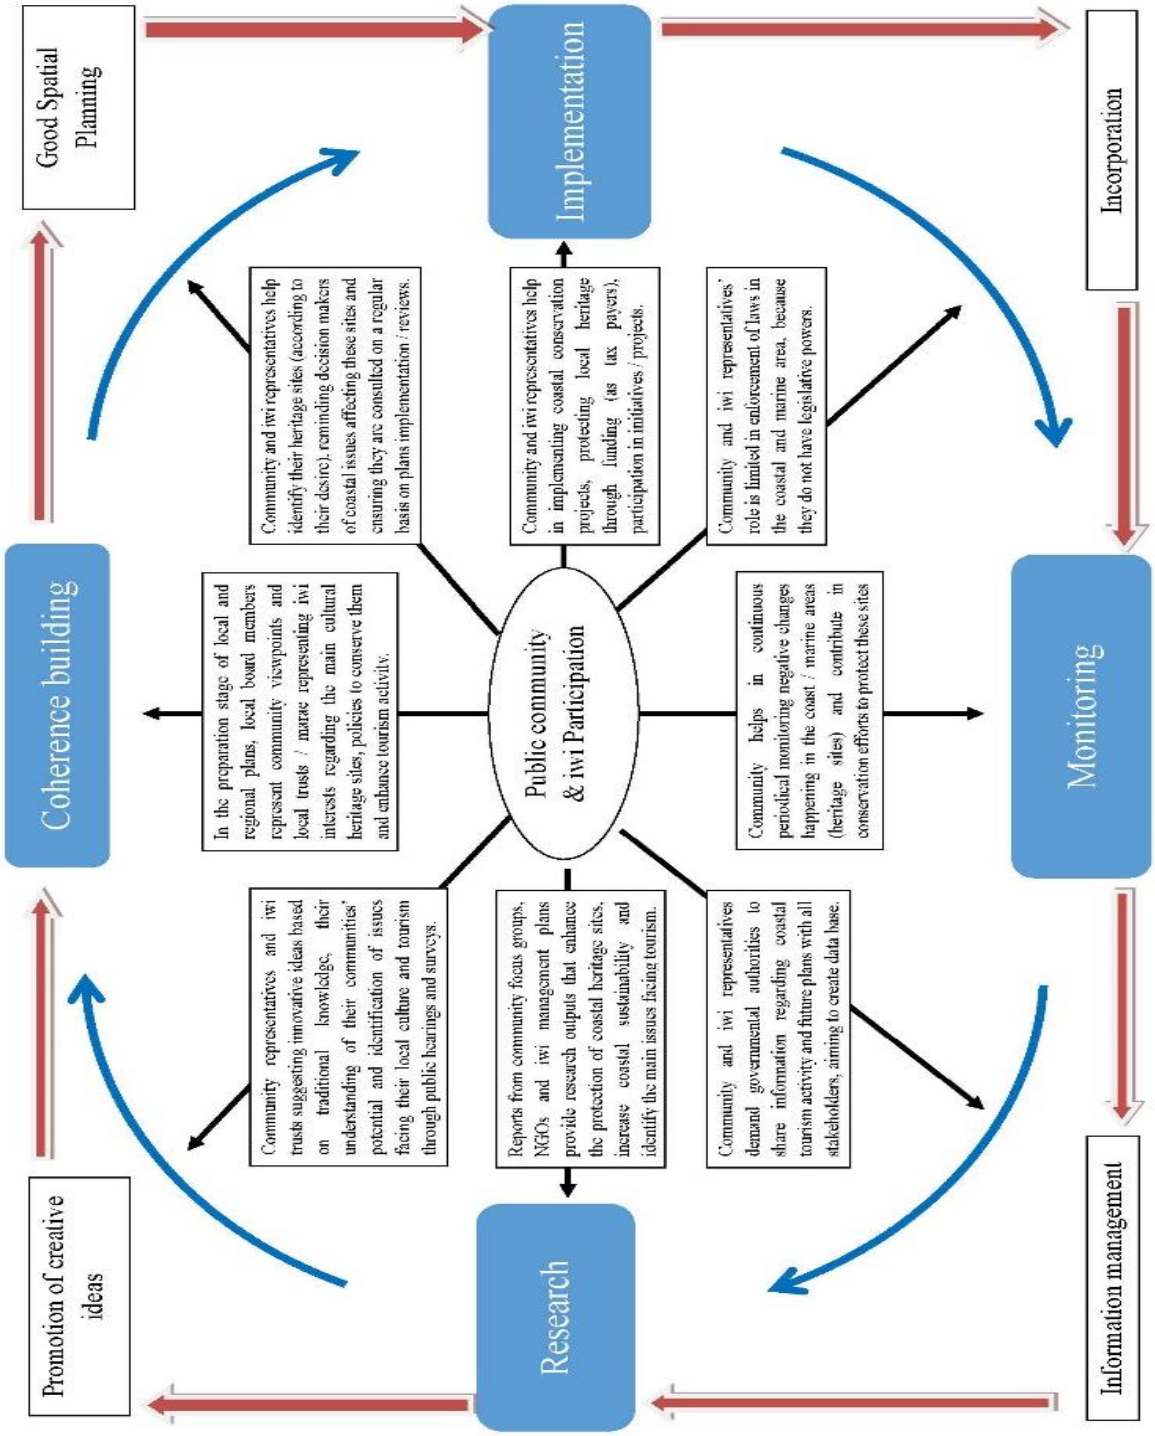

Figure 13: The role of community and iwi participation in the different stage of the suggested management framework to achieve sustainable tourism

However, the rights iwi have to access the coast is still a controversial issue and is tackled in statutes such as Marine and Coastal Area (Takutai Moana) Act 2011. In the absence of a nationwide survey about iwi satisfaction with the current situation, it is rather difficult to conclude about this relationship between iwi, tourism and the coastal management process. In order to change this situation, more empowerment of iwi representatives to represent the different voices of their tribes is required, through increasing their responsibilities in coastal areas as guardians of these resources rather than users, to achieve sustainability in these coastal areas and have maximum protection of local culture.

## 7. Conclusion

The content analysis and interpretations from the interviews and indicators analysis have shown number of issues that are facing sustainable tourism achievement across all the case studies:
A) **Mass tourism syndrome:** The increase of tourism activity means the coastal areas lose its biodiversity, fragmentation of landscapes and pressure on local culture sites.
B) **The short tourism season** issues as the tourism operators have complained about the short period of the tourism season, as most of the tourist visits are concentrated in the summer season, and the lack of diversification of tourism activities, depending on coastal tourism assets effecting heritage sites.

C) **The degradation of tourism facilities issue** arise from the case study areas which suffer from degradation in the services of coastal activities such as wharfs, yachts pier points and public services..
D) **The lack of tourism promotion:** The absence of regional tourism strategies negatively affects the activity in the case study areas, as the efforts to promote tourism activities are mainly made by local district councils through I-sites.

In addition, there are number of results obtained from the analysis of sustainable tourism scheme in the selected case study areas, 1) The absence of code of practice or a national strategy for sustainable tourism practice that incorporates the sustainable tourism concept more in tourism operations or which has legislative power over the tourism operators across the country. 2) The existing national tourism strategies, such as New Zealand Tourism Policy 2015 (Tourism New Zealand, 2007) or the new modified version New Zealand Tourism Strategy 2025 (Tourism industry association New Zealand, 2014), both focus on economic revenue, and it do not emphasis on neither the conservation of the coastal tourism assets nor the protection of heritage sites as sustainable tourism practices.

3) There are no middle level policies or plans at the regional level to translate the national tourism policy to the operative level at the local level. The role of the regional tourism organisations needs more reinforcement through legislation. 4) The community board members role is to deliver community perception to the governmental agencies. However, their role needs more enforcement in terms of formulating community consensus about tourism activity and increasing their awareness of the coastal issues and sustainable tourism practice. This could happen through holding community workshops, focus groups, getting funding for community initiatives in cooperation with local councils, and encouraging NGOs role, and iwi involvement in coastal protection measures.

5) The role of iwi is restricted due to the fragmentation of their own administrative structures because of conflicts between some tribes, as well as not having any power regarding coastal management or tourism practice. Therefore, this role needs to be enforced by making iwi management plans obligatory and prepare them in accordance to regional coastal plans and statements. These plans need also to discuss tourism and deliver methods to protect their heritage and significant cultural sites.

Such practices discussed in this paper could help in converting coastal tourism to be more sustainable and being a method to increase awareness of local culture rather than being a threat to it.

# MEGA-EVENTS DECOUPLED FROM LONG-TERM PLANNING: SHORTCOMINGS AND LEARNING FROM THE ISTANBUL 2010 EUROPEAN CAPITAL OF CULTURE

Zachary Jones[1]

[1]Politecnico di Milano, zachary.jones@polimi.it

## Abstract

Cities are increasingly turning to mega-events to secure much desired global rec
future economic investment. While events such as the Olympics or Expos are gener
of city centers, sometimes entirely divorced from the existing urban fabric, one
embedded within the city itself: the European Capital of Culture. The ECoC is a
consisting of cultural events typically situated within the city itself as well
surrounding region. One of the longest running continuous EU policy programs, th
operated for 30 years with over 50 cities holding the much coveted title. How ca
utilize this mega-event for the greatest benefit to the city?

This paper specifically focuses on Istanbul and its tenure as the 2010 Capital o
the event s use and conservation of the urban built heritage in connection with
to the ECoC, the Istanbul Metropolitan Municipality organized the Strategic Plan
as the Historic Peninsula Site Management Plan. Both documents largely ignore th
possible integration into a long-term strategy for the city. This oversight reve
found between large-scale events and host cities. The paper investigates the roo
divisions, the negative outcomes of such a disconnected and short-sighted approa
the opportunities for planning to integrate culture and complimentary economic a
commercialization and tourism.

Keywords: Istanbul, European Capital of Culture, Strategic Spatial Planning

## 1. Introduction

Over the last several decades, culture has firmly embedded itself within the pla

Healey (2009) recognizes the increasing trend of the production of strategic pla
merely to meet certain technical requirements or expected standards, but are oft
processes. Due to varying and sometimes vague descriptions, strategic plans risk
rhetoric, incapable of producing action (Palermo and Ponzini, 2010). Many of the
can be found in the case of Istanbul.

## 3. Context of Istanbul

Istanbul is the largest metropolitan area in Europe with over 14 million residen
range from 15–17 million) with many recent immigrants arriving from other parts o
2010). Due to this continuous expansion, Istanbul is a city in the midst of a pe
urban transformation while seeking to solidify its place as a global city (Soysa
years of history and functioning as the seat for 3 separate empires, Istanbul did not tru
recognized tourist destination until the 1990 s (Gokturk et al, 2010). According
Istanbul is also a city without a history of hosting festivals, yet in the last
to host many different events with Istanbul 2010 being the crowning achievement.
trend of cultural activities in the city is recognized within the municipality me
as part of an intentional policy to use the culture and tourism sectors as one o
future development of the city (IBB, 2011).

For Istanbul, the primary component of the cultural strategy is the promotion of
built heritage. Since 1985, Istanbul has had 4 sites inscribed in UNESCO s World Heritag
located within the historic peninsula. They include: Sultanahmet Archeological P
Mosque; Zeyrek Mosque (Pantocrator Church); and the Istanbul Land Walls along wi
areas of each site (ISMD, 2011). The majority of the ECoC program was located wi
areas of the city center (Bilsel, 2010) and these four sites, along with the ent
peninsula, were included in the Site Management Plan prepared by the IMM for UNE
site management plan has been a requirement for all UNESCO World Heritage sites
(UNESCO, 2005) and was also made a legal requirement for all historic sites in T
2683 (ISMD, 2011). Due to the lack of a site management plan for several years,
number of infrastructural and redevelopment projects located in and around prese
considered adding the heritage sites of Istanbul to the World Heritage in Danger
2011 (Marquart, 2014). Overcoming these prior negative associations may have the
factor in the decision to focus so heavily on the built heritage during the ECoC
conservation and preservation projects serving as part of the year s events (Bil
focus on built heritage, as well as actively preserving sites, the Istanbul 2010
Culture Agency, the organization responsible for the event, was appointed the ma
responsible for funding and preparing the Site Management Plan (ISMD, 2011).

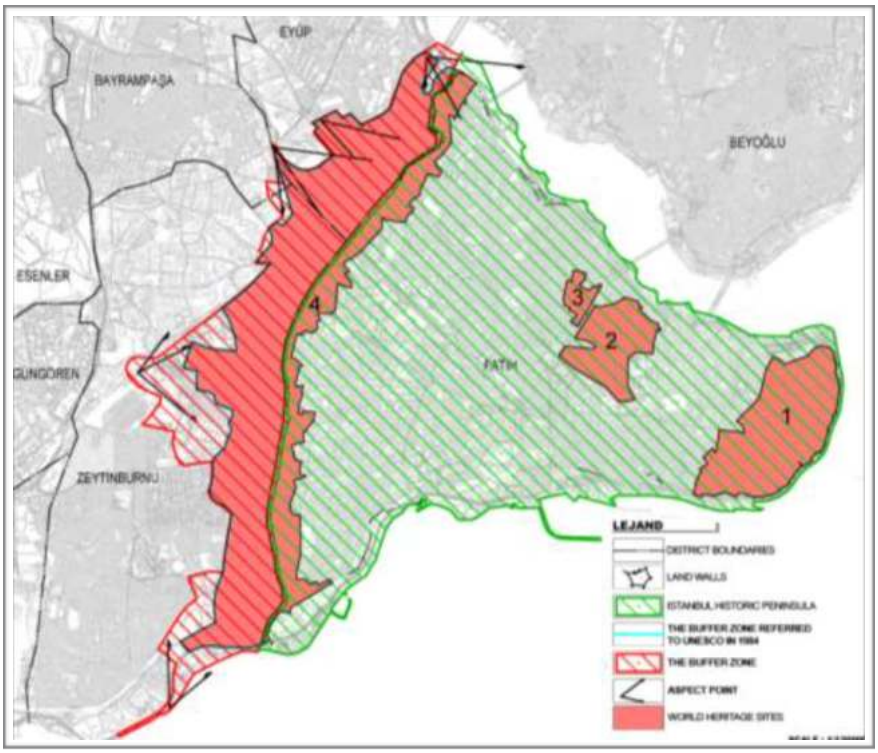

Figure 1. The Site Management Plan Area in green with the four UNESCO World He highlighted in red (ISMD, 2011).

While preparing the site management plan, the municipality also prepared the Str 2014, covering the entire municipality and focusing on 8 core areas. The sixth a Services Management and is devoted to: Contributing to the Protection and Promo Heritage of the City and Enrichment of Cultural Life (IMM, 201, p.12). This pap portion of the strategic plan. These documents accompany an existing local distr along with a metropolitan scale Environmental plan.

To better understand the particular situation of Istanbul, two heavily discussed literature and the plans themselves, must be mentioned: law 5366, the Law on Pr Renovation and Utilisation by Revitalisation of Deteriorated Historical and Cult referred to as the urban renewal law, and law 2634, the Tourism Encouragement L essentially allow the individual municipality districts to redefine a conserved or tourism areas and approve projects to be implemented on these sites. Throug designation from a conserved area to an urban renewal or tourism area, new devel sites no longer need to meet the stringent preservation codes required for prote additional law passed in 2012, numbered 6306, the Law on the Transformation of Areas un Disaster Risk has also been used to renew areas found within the historic penin determined to be prone to damage or destruction from earthquakes. These laws hav continued demolition and redevelopment to occur within the historic peninsula, a factor in UNESCO s consideration of adding Istanbul s world heritage sites to th these particular laws are relatively recent, Aygen (2013) notes that already in

certain historic and culturally significant sites were declared as unsafe or haza
them legally removed. Similar tactics were used again in the 1980 s to increase
the historic center. Therefore, these modern laws are merely the most recent ren
planning technique in Istanbul. The impact of these laws is not limited to the p
these historic areas, but also to their social and economic diversity as minorit
Roma and Kurds have been removed and relocated (Candan and Kolluo lu, 2008).

## 4. Contents of the Site Management Plan and Strategic Plan 2010–2014

Strategic Planning is first implemented in Istanbul in the mid 2000s, becoming a
with updated plans to be produced every 5 years, the first being issued for 2007-
The subsequent Istanbul Strategic Plan 2010–2014 defines it s purpose as increa
life of the citizens of Istanbul (IMM, 2011, p.7). No specific references are m
what outcomes it produced. This plan envisions cultural services, and the touris
growing into an important component in the city s continued development and the
new cultural identity for the city. The structure of the plan begins with a curr
followed by a stakeholder and SWOT analysis, leading to future outlooks and conc
of monitoring and evaluation processes. The stakeholders addressed include both
institutional actors, though these parties are considered separately. Citizens
ensuring the preservation of sites with continued availability and accessibility
Corporate/institutional interests focus mostly on meeting European standards of
cultural activity. The SWOT analysis considers the participatory feedback, but t
directly involved in creating the final analysis.

The stated end goal for cultural areas is the protection of assets through sustainable p
with the intent to continue to develop and disseminate future cultural events. T
emphasizes both conservation and the continued festivilization of the city. Th
briefly recognized as an opportunity through the SWOT analysis, it is not again
any discussion regarding future events. Though other cities, such as Lille 2004,
ECoC to launch a long-term cultural program (Paris 2011), no strategy is suggeste
major event might be used to accomplish one of the stated goals for the city. Mu
regarding conservation is geared towards raising awareness of culture for touris
many specific numbers are given of the total square meters of protected areas or
buildings to be conserved by 2014, details of exact locations or which organizations are
for these works are lacking entirely. Despite the apparent specificity, the plan
how or even why the listed goals will be accomplished. The plan also lacks any r
Management plan, the document being developed specially to guide future conserva

The Istanbul Historic Peninsula Site Management Plan, produced by the metropolit
comply with both Turkish law and UNESCO requirements defines itself as a stakeh
strategic plan. Though not published until 2011, the work is a project of Istan
one of its longest lasting legacies. Like the municipality s strategic plan, thi
thorough analysis of the existing situation, followed by a SWOT analysis, inform
input, and results in a detailed list of problems with numerous prescribed actio
issue. The plan identifies, in total, 10,413 cultural properties located within
additional existing intangible culture such as traditional crafts, guilds, and c

municipality, with the actual creation of the plan. As in the IMM Strategic Plan
failure to mention use of the ECoC to promote long term efforts despite the even
conservation and preservation projects (ISMD, 2011). While there are a total of

Shoup and Zan (2013) point out that only 20 deal explicitly with conservation in specified sites.

## 5. Actors, Stakeholders, and Multi-level Governance

A complicating issue when dealing with conservation and preservation is the invo leveled governance. In Istanbul, these layers range from the involvement of loca international government organizations. At each level are actors with varying re are often unclear, both to outside observers and the actors themselves. The hist mostly within the Fatih district, which has jurisdiction for conserving cultural Related departments within the metropolitan municipality includes the Directorat Directorate of Conservation, Application and Supervision (KUDEB); Directorate of Historic Sites; and the Directorate of Construction Affairs. Within the central Ministries of Culture and Tourism and the Ministry of Environment and Urban Plan whom oversee preservation in Turkey (Marquart 2014). UNESCO, an agency of the Un also provides guidelines and standards for protected areas like those in Istanbu structure and hierarchy of responsibilities is a commonly noted problem. Both pl existing governance system as one of the main obstacles to effective preservatio opportunity to establish a more straightforward structure. This negligence may b direct involvement of the metropolitan municipality in the production of the pla freedom to propose needed change. As suggested by Bayraktar (2012), this complic be an intentional design to divert power back to the central government by obscu allowing for the eventual approval of contested projects.

In the midst of this vast web are the stakeholders who are directly invested in the site d of living or working as well as the many institutions that are indirectly connec involvement with issues of planning, preservation, culture and/or tourism. Withi stakeholders are involved, meeting the participatory planning requirement of s inclusion typically involved workshops organized for participants to lend their providing input for the SWOT analysis, resulting in objectives that informed the specified in the IMM strategic plan, the site management plan cites over 100 par workshops, representing the perspectives of architects, planners, preservationis However, It should be noted that these stakeholders were involved in only very s the work and not active participants throughout its development.

## 6. Defining Problems

Strategic planning encourages the involvement of a diverse field of actors and s to define a broad range of future goals, but also to understand and define the e SWOT analysis used is a rather traditional approach to defining and addressing p analysis becomes the basis for the rest of the plans and focuses on very specifi problems. The analysis recognizes the need for specific sites to be better prese actions to be taken, but there is no further in-depth study to consider the caus need of restoration or how to prevent future degradation. The causes may be due pollution, general disinterest in preservation, etc., but without seeking to und remains likely that these same sites will continue to face similar obstacles in fall into the category of problems Rittel and Webber (1973) famously termed wic These problems may not be immediately visible and often do not have easy or obvi any at all, making them all the more difficult to address. The identification of 5366 as both an opportunity and a threat within the SWOT analysis hints at some

issues by revealing the existing divide between various stakeholders. For some, build new, modern developments is considered an important economic opportunity f whereas others view this action as a direct threat to preserved areas. By not th root causes of the problems facing the city s built heritage, the proposed solut their ability to respond to and address issues. As previously mentioned, and rep strategic plans, the complex governance structure with its unclear boundaries is identified problems, yet none of the proposed actions attempts to deal with this problem.

Despite the failure of these plans to directly address the existing governance s plan to connect Istanbul 2010 to a series of future events, a separate document Strategic Vision, a project sponsored by Istanbul 2010 to address the organizati surrounding the Topkapi Palace, considers these pressing issues. Produced by an from the UK before either the Strategic Plan 2010–2014 or the Historic Peninsula Plan, this document suggests a series of short-term interventions for Istanbul 2 15–20 year vision for the site. This document specifically references the need t catalyst for future programs and the importance of starting immediately. Additio recommends alternate governance models that could be established to better ensur continuity of the site (Metaphor, 2009). Despite the development and promotion o external consultants working with local experts, these aspects were not transfer developed plans.

The process used by the two strategic plans to define problems comes from a very of strategic planning as a set standardized international convention. The IMM St it has been developed in accordance with the strategic management approach, thou ultimately determines that no single step-by-step approach exists (Albrechts and the same way, the site management plan follows a standard established by UNESCO World Heritage Sites. The production of these two plans is therefore not solely problems and proposing solutions, but also contain certain political motivations or westernized standards (Soysal 2010). In this sense, strategic planning can means to a particular end, but also, or perhaps instead, an end in and of itself preservation, plans existing just to be plans are rather useless if they lead to

## 7. Planning Results

Regardless of the primary intent behind these plans, it is worth noting the impa order to better understand what strategic plans are capable of producing. Both p every year with new plans to be developed every five years. The longest projecte a maximum of five years. This time span is a limited period in which to establis With this constraint, the plans become buried in hundreds of overly specified re specific actions and projects to be conducted without considering the overarchin the specific actions detailed, Shoup and Zan (2013) note that very few have any actual preservation. They describe the plan as a document filled with buzzwords, significant and specific preservation steps to be taken. Many of the plans promot create more plans. The authors also point out that while general sources of fund actual operational budget for any of the projects is stated nor funding promised

At the end of 2014, the strategic plan for 2015–2019 was released. This updated 2010–2014 document and highlights some of the differences between the methods of plans, but is silent on the outcomes of the earlier work. The stakeholder and SW

that many of the cultural goals for the city are similar if not identical to tho
plan (IBB, 2014). One of the main products of the site management plan was the c
additional governance body, the Istanbul Site Management Directorate. Despite th
organization, the group s primary role is not in managing the entire site, but i
other responsible groups (Shoup and Zan, 2013). Though essentially a planning bo
future role for this organization or how it will continue to function as it lack

## 8. Review of Strategic-ness

In considering these two plans, which present themselves as strategic documents,
asked: Are they actually strategic plans? Despite the warning provided in the
institutionalization of strategic planning is precisely what has occurred in Ista
approach has become legally required for both plans with the metropolitan munici
approval. A general lack of innovation and creativity can be observed with both
traditional analysis methods to reach standard solutions. The heavily relied upo
as the basis for the work, yet from this analysis no clearly defined vision emer
the many proposed actions. Nor does it attempt to utilize the 2010 ECoC event as a means o
establishing a long-term cultural focus within the city, despite explicit intent
cultural events.

The example of Istanbul reveals clearly that following a step by step process ca
innovation and creativity. In this instance, many contributing factors share res
of strategic-ness within the plans. Through her research, Marquart (2014) iden
academics and professionals involved in the development of the site management p
were ignored in the final document as well as others who were removed from the c
disagreeing with the official vision. A host of cultural, political, historic, s
some of which have been discussed in this paper, contribute to this particular c
production of these un-strategic plans.

While further research can lead to better understanding how actual strategic plan
implemented, Healey (2013) raises another valuable question in seeking to unders
through which planning ideas transfer between nations. Though not specifically a
planning, this tool serves as a relevant example of how ideas spread from one co

Originally a radical idea developed from corporate strategies in the US, strat
over the course of decades become a standardized document for cities and organiz

Keywords: Disneyland Shanghai, Cultural difference, planning perspective

Abstract: *After more than ten years negotiation, Disneyland ultimately decided to locate in Shanghai. This article firstly makes an introduction of the background of Disneyland in Shanghai, and analyzes the balance of its investment and return, explores cultural difference, which will help culture exchange Disney culture was brought to Asia, and local culture in Asia, especially in China, affected western culture other than Disney culture. On* the other hand, it ll help Walt Disney World and government to plan a better Disneyland which is well catered to the visitor s ta

*Furthermore, it explores the strengths and weaknesses of five existing Disney worlds. It analyzes the influence on economic, cultural, planning and governance/management field, and costs and benefits. From the study of Disneyland worldwide, especially Disneyland Hong Kong, according to the background of Shanghai and China, several suggestions are proposed to Disneyland Shanghai, to present an initial exploration of the range of issues that can be raised about the influence of the Disney theme park on Shanghai.*

*Finally, this article draws a conclusion---an agenda for further research and policy analysis from a planning perspective, including their operation mode, competition with other theme parks and its survival issue, and ticket price and ticket selling system. Last but not the least, it analyzes the potential influence on the price of land and house, as well as the stock market.*

## 1. Introduction

The Walt Disney Company announced in November 4, 2009 that the Project Application Report (PAR) for a Disney theme park in the Pudong district of Shanghai had received approval from the relevant authorities of the central government of China. After more than ten years negotiation, Disneyland ultimately decided to locate in Shanghai. Besides several accidents and transfer of personnel in Walt Disney and Shanghai municipal government, there are still other important factors for such a long period negotiation. First it is a huge public project, which could greatly affect the public s benefit. Therefore, the government must take careful consider project making profit.

Secondly, the openness of national policies and strategies, including opening up the retail sector to foreign investment, are also restrictions which slow the advent of Disneyland. In fact, the reason why the negotiation in 2003 passed peacefully away is also the result of delayed approval issued by the State. According to the "Industrial Catalogue for Foreign Investment" made by State Economic and Trade Commission, the construction and operation of this large-scale theme park was included to the scope of limited industry of foreign investment. This is what Disney had never encountered before in Japan and France. Not alone with such a large area in Shanghai, a city with a serious shortage of land issues.

Additionally, Shanghai and Disney need each other, which is why they are both so patient. Facing the global economic depression, Disney becomes more important for Shanghai to stimulate its economy, to promote its GDP and employment rate. Theme parks in Shanghai are very scarce. So far in 2015, there were only two theme parks in Shanghai---Jinjiang Park and Happy Valley. While theme parks in China now are increasing, they are still not well-developed systematically. Most of theme parks in China are concentrated in Shenzhen, south of China. And there are few theme parks in middle China, nevertheless, there is absolutely no theme park in northeast and west of China.

Therefore, Shanghai Disneyland will definitely make up the gap of the tourism in Shanghai and China(Figure 1).

1 Hong Kong Disneyland (area for visitors is no more than 20 hectares. Total area:126 hectares)

2 Hong Kong Ocean Park (17 hectares)

3 Shenzhen Happy Valley (35 hectares)

On the other hand, Walt Disney also needs Shanghai, a perfect city with tremendous market potential, to expand its business and broaden its brand influence. China i dynamic, exciting and important countries in the world, and this approval marks a very significant

milestone for The Walt Disney Company in mainland China, said Robert A. Iger, CEO of The Walt Disney Company.

Furthermore, this article also analyses the balance of investment and return, and explores cultural difference, which will help culture exchange Disney culture was brought to Asia, and local culture in Asia, especially in China, affected western culture other than Disney culture, such as Chinese food, Gong Fu and Monkey King. On the other hand, it ll help Walt Disney Wo local government to plan a better Disneyland which is well catered to the visito

**2. Strengths and weaknesses of five existing Disney worlds**

Walt Disney Parks and Resorts now includes a collection of five of the world vacation destinations Disneyland Resort, Anaheim, Calif.; Walt Disney World Resort, Lake Buena Vista, Fla.; Tokyo Disney Resort, Urayasu, Chiba, Japan; Disneyland Paris, Marne-la-Vallée, France; and Hong Kong Disneyland Resort, located on Lantau Island.

In this part, this paper will explore the strengths and weaknesses of the five existing Disney worlds, as well as why some of them fail and some of them succeed. I ll make a comparison of these five Disney lands and mainly focus on Disney Hong Kong and Disney Tokyo, especially Hong Kong, which will have the most important influence over the development of Disney Shanghai.

*2.1Disneyland Resort, Anaheim, Calif.*

It was opened to the general public July 18, 1955. Currently the park has been visited by more than 515 million guests since it opened. It is the second most visited park in the world, behind the Magic Kingdom at Walt Disney World(Figure 2).

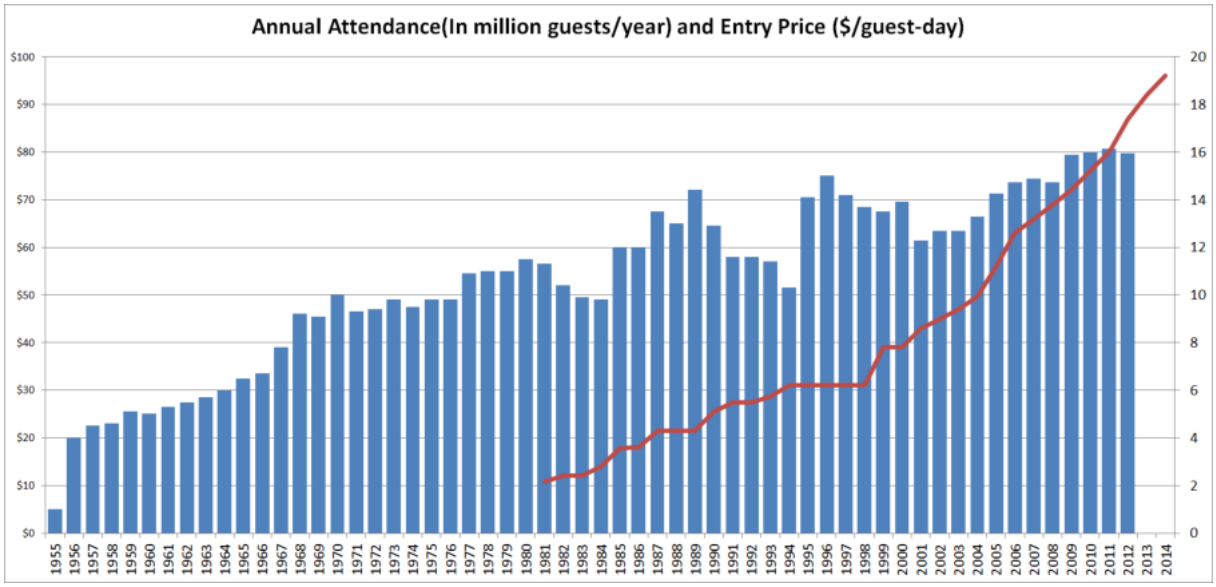

Figure 2. Attendance of Disneyland Park in California(Aerotheque,2014)

*2.2Walt Disney World Resort, Lake Buena Vista, Fla. (Magic Kingdom)*

It opened on October 1, 1971. It is the most visited theme park in the world. The Magic Kingdom was built in a larger area. It was the only theme park on the resort at the time and opened concurrently with two hotels on the property. The park opened with twenty-three attractions, three unique to the park and twenty copies of attractions at Disneyland.

*2.3Tokyo Disney Resort, Urayasu, Chiba, Japan*

Tokyo Disneyland is a 115 acre (465,000 m²) theme park at the Tokyo Disney Resort located in Urayasu, Japan, near Tokyo. It was the first Disney Park to be built outside of the United States and was opened on April 15, 1983. The park was constructed in the same style as Disneyland in California and the Magic Kingdom in Florida. It is owned by The Oriental Land Company. Tokyo Disneyland ranking it as the third-most visited theme park in the world, behind its American sister parks, the Magic Kingdom and Disneyland.

It is the most successful Disney world overseas, a genuine copy of American Disney world, because the different culture rightly meets the taste of Japanese who seeks unconventional and new experience. Japanese like cartoon very much. And visitors could willingly accept American elements. TDL is now ranked the country s number one date course A majority of Japanese women TDL the single greatest pleasure-giving experience of their lives. There are stories of couples who got married because of Avi D. Raz, (1999)

*2.4Disneyland Paris*

Occupying 566,560 m² (140 acres), it is the largest Disney park based on the original in California. The park opened as Euro Disneyland on 12 April 1992.

Modifications to the park were made to protect against changes in weather in the Parisian climate. "People walk around Disney World (sic) with humidity and temperatures in the 90s, and they walk into an air-conditioned ride and say, 'This is the greatest,'" said Eisner.

The park, as well as its surrounding complex, initially failed to meet financial expectations. It fails because of several reasons. Firstly, the company is over confident which result in the inadequate research of European visitors. Europeans are very economic, while products and hotels in Disney world are overpricing. Wine forbidden for employees had intrigued huge dissatisfaction and resent. Wine is also instead by coca cola which sell to visitors in Disneyland, ignoring the fact that French people like wine so much. And fast food is provided at lunch time, which totally conflict with the customs that Europeans like enjoying their lunch, sometimes for several hours. the fact that French are dominate by their local culture and very proud of it, especially offended by arrogant attitude of American manage leaders, they turned to have more exclusion and repulsion of American culture.

*2.5Hong Kong Disneyland*

Hong Kong Disneyland is located on a reclaimed land in Penny's Bay, Lantau Island. After years of negotiations and construction, the park opened to visitors on September 12, 2005, considered an auspicious date according to Chinese almanacs for the opening of a new business. Disney attempted to avoid problems of cultural backlash by attempting to incorporate Chinese culture, customs, and traditions when designing and building the resort, including adherence to the rules of Feng Shui. For instance, a bend was put in a walkway near the Hong Kong Disneyland Resort entrance so good "chi" energy wouldn't flow into the South China Sea. Seasonal entertainment, such as Disney's Haunted Halloween, A Sparkling Christmas and Disney's Chinese New Year, are held in the park to celebrate main festivals. (Wikipedia, 2005)

Hong Kong Disneyland is different from Tokyo Disneyland. In Tokyo, domestic tourists accounted for 95% of the total population, so the park s language is mainly Japanese. Hong K use three languages: English, Mandarin and Cantonese. The capacity of the park is 34,000 visitors per day, and is the smallest Disneyland Park. It has so far fallen short of meeting its targeted visitorship figures. The park's small size is often cited to explain its under-performance. Currently 22.4 hectares (55 acres) in size, it will be expanded to 27.4 hectares (68 acres) when three new themed areas are completed. Eventually, the park capacity will increase to handle up to 10 million visitors annually over a 15 year expansion period.

Hong Kong Disney was criticized for the overcrowding problems[1], food safety[2] and fingerprinting[3] issues. However, the park did little to solve these problems.

## 3 Influence on economic, cultural, planning and governance/ management field, costs and benefits

From the study of Disneyland worldwide, especially Disneyland Hong Kong, according to the background of Shanghai and China, several suggestions are proposed to Disneyland Shanghai, to present an initial exploration of the range of issues that can be raised about the influence of the Disney theme park on Shanghai.

### *3.1 Economic issues*

Disney Shanghai has a tremendous influence on various fields, such as tourism, hotel, commercial, catering, building industry, real estate, and cultural industry, as well as the price of land, house and stock market. It was said that Disneyland Shanghai would promote more than one trillion values of GDP output (hundreds of billions of dollars), and provide millions of jobs. From the macro level, Disneyland Shanghai enriched the park system of the whole city. As a famous international brand, DLS will play an excellent benchmark in the consumer market as well as related industries and other deputy industries and products such as cartoon, movie, and media. Firstly, it s commercial development, especially the real estate, among which, the hotel and catering is the most prominent industry, because after the opening of DLS, the previous short-term visitors will stay three to four days instead of two to three days, which will definitely bring large amounts of benefit to hotel, catering and other service consumerism.
What s more, DLS will drive the development of the city, in addition to related facilities, as well as the surrounding commercial industry.

### *3.2 Cultural issues*

Culture and activities

Disneyworld must keep the spirit of creation all the time if it wants to conquer Chinese markets again, besides Chinese are not so familiar with Disney cartoon characters. They have their own characters which are their hero symbols such as Monkey King and Hua Mulan. It is hard for Disneyland to be charming to visitors and for visitors to have real fun being in a park with a totally unfamiliar theme and unknown characters. Therefore, there are two ways for Walt Disney to deal with this issue. One is to add some familiar Chinese characters into the theme park, to intrigue people s to expand the influence of Disney cartoons on the youth in China, such as better promoting its movies and products. It was said that Shanghai Disneyland will integrate Gong Fu into their performance. However, they should be careful to prevent the performance from becoming a hodgepodge, with diverse characters and completely different performances that nobody knows what it is going on.

It is a good paradigm that Disneyland Hong Kong held special activities during the special spring festival. In Shanghai Disneyland, more custom traditional anniversary activities should be associated right according to the holidays in China. On one hand, Chinese people could celebrate their festivals in Disneyland instead of other places. On the other hand, people on holidays are a big fortune to Disneyland, because they ll have time to travel.

---

[1] During Chinese New Year 2006, many visitors arrived at the park in the morning bearing valid tickets, but were refused entry, because the park was already at capacity.

[2] The officers investigated a food-poisoning case in the park's restaurants.

[3] Visitors to Hong Kong Disneyland have their finger biometrics scanned at the entry gate.

**Food**
There is only one Japanese restaurant in Disneyland Tokyo, which is the most popular restaurant in TDL. And there is only one Chinese restaurant in Hong Kong too. While in Shanghai, I think it is better to provide various Shanghai special snacks and restaurants for visitors to have more choices. Because most of the parents cannot get used to the American food, especially the fast food, it is Disney s responsibility to not just let the consumers have a good time, but also

**Landscape**
Feng Shui is well brought into Disneyland Hong Kong, which is a good reference for Shanghai. What s more, Shanghai Disneyland should consider more of its local landscape cha the whole Disneyworld well-coordinated with the surrounding landscape, instead of building a full closed castle, totally separated from the surroundings. Further, it could study the ancient Chinese art of Landscape gardening. Shanghai lies in the region of Jiangnan which is pretty famous for their ancient gardens. If Disney could learn the essence of garden on the Yangtze Delta, it will be a great creation and a new era for Disneyland Design.

**Overseas replication problems**
The difficulty of Disney's overseas expansion, first of all, is culture. All of the industrial chains of Disney are based on its strong cultural identity. Disney culture is deeply rooted among the United States. But out of the United States, can other countries and regions accept this?

For example, in India, could the Bollywood song and dance culture, with a high degree of recognition of the market, make room for receiving foreign culture? Can China accept both the traditional Eastern way of thinking as well as the culture of English-speaking countries? A 32-year-old Ms. Wang in Shanghai told reporters, "For those Mickey Mouse stories in Disneyland, I am not familiar with it and not very interested."

This may be the complexity of a typical mentality of Chinese consumers. Of course, in China, another key factor of Disney overseas expansion is the policy. Many overseas films may not be able to be introduced at the same time into the Chinese market, and through the relevant examination, many films will be shut out, which means the strong distribution system in the U.S. market cannot be copied without changing.

> *"We are also aware of the problem, but it is very difficult to go beyond. We can know the schedule of the film in advance in the United States so that we could simultaneously start the design and production process of consumer goods, but in China, you do not know whether this film will be introduced, or screening. Then all-consuming retail derivatives are difficult. "Disney insiders* said. Policy *constraints are temporarily unable to go beyond, but once the policy has been relaxed in the future or now through Disney's English language training of potential customers growing up, Disney maybe receives rewarding in various industrial fields in China." China and the United States chief knowledge experts Zhao Huan Yan admitted. (Jun Li, 2009)*

*3.3 Planning and governance/management issues*
*3.3.1 Market strategies*
In the process of entering the international market, whether to use global marketing strategies (or standardization strategies), or localized marketing strategies (or adaptive strategies), is an important decision that multinational markets are facing. Walt Disney Company brought the U.S. model to Tokyo, Japan, and received success. However, when the same management system, experience and value were copied to Europe, there emerged a lot of problems. Then what strategies should Disneyland adopt to get the ultimate benefit from China? To ensure Shanghai Disneyland in China gets ultimate success, so that the Disney Company and the Shanghai Government can achieve a win-win situation, we should make a combination of globalization and localization according to operating status of theme parks in China, as well as Disney's experience and lessons in Hong Kong, Japan and France.

**The globalization of product brands**
For Disney, its main essence is reflected in its culture and management. Disney's culture --- relaxation, leisure, and happiness is its biggest attraction and its heart and soul of long-term success. Taking into account the issue of Chinese and Western cultural differences at home and abroad, some scholars believe that Disney would be a purely American style which will have conflict with the nation's indigenous culture, because China has its own culture --- Monkey King, Nezha and so on. However, I believe that service expectations are very susceptible to be influenced by mother culture. This expectation is formed by their cultural background and past experience. If its core culture is polished and localized, it probably is not the world-renowned theme parks which customers would like to see, and thus it will lose its distinctive characteristics and the soul with unique personality.

If Disney culture wants to get acceptance from customers, it must be able to be compatible with the customer's own cultural ideas. There is a considerable difference between Japan and France in this respect. Japanese continue to maintain their own cultural content as uptake and processing independence, so the profitability of the Tokyo Disney may exceed the parent company; while France is a highly sensitive nation, they resist American culture, and therefore the entire United States-style Disney with a high profile moved to Europe, will inevitably lead to a struggling situation. For the Shanghai Disneyland, in this market, one of the reasons that people choose foreign products is that there is no similar product on the domestic market, and then only the original pure American-style will have more attraction to visitors. Otherwise, without such special features, people might choose "Happy Valley" with a relatively cheap price in Shanghai in the future. Only if the global standardization of culture and corporate come true could Disney be awarded with an advantage of corporate image and brand loyalty.

**The localization of marketing strategies**
(1) Localization strategy needs to study customer requirements and desire to design the products they want.
(2) Localization strategy needs to consider the cost customers are willing to pay.
(3) Localization of marketing should let guests get the information or services of Shanghai Disneyland conveniently.
(4)We must communicate with customers effectively by adopting a localized marketing strategy.

**Localization of human resources**
Local talent can not only reduce operating costs, but is also an inevitable choice to occupy the Chinese market. According to the cultural background, customer requirements and the changing business of the outside world, Disneyland's management and staff should have to make corresponding adjustments to adapt to the current environment ( Lu Yiou, 2007).

In Tokyo Disneyland, almost all high-level management and most of the staff are Japanese, leaving only a small management United States team to act as advisors and consultants; while in Hong Kong and France, the park is almost full of United States people. Clearly, the team is facing flexibility in the management in satisfying the local market needs and communicating with local staff with communication barriers. Therefore, only if Shanghai Disneyland will recruit local staffs, can Disneyland truly meet the needs of customers.

*3.3.2 Risk and Crisis Management*
Disney basically does not share the market risk, and investment risk. If all of the risks of a huge international tourism project are on the local government, it will be eventually undertaken by every taxpayer. Therefore, from the country s interests, the supervision authorities should prevent enterprise from "abusing" competition among cities to make profit. The land sector could conduct market supervision through regulating land or other resources.

*3.3.3 Operation mode*
The advent of Disneyland greatly stimulates the price of housing and land in surrounding areas. But the customers and developers should be careful about it because whether it will be worth the crazy

rising value or not is still a puzzle. As it is known to all, Disneyland always hold harsh negotiation conditions and strict requirements for the surrounding land use and business facilities. It wants to have full control of the surrounding area and is unwilling to drop one penny out of its pocket. There are several operation modes of Disneyland, one probably is full-closed mode, meaning all of the entertainment, consumption, and accommodation are in the park, in which way there will be relatively small impact on the surroundings like Disneyland Hong Kong. Disneyland Hong Kong located in Zhuhaowan, Dayu Mountain, which is far from the downtown area, and transportation around is very inconvenient, so the visitors have to stay in the park and do all of the consummation within the park.

It is horrible to see the lights in Disneyland are on, but the surroundings are still in the dark. Another mode is keep hotels a distance to the Disneyworld, which could bring up the development of the areas between and around them like Disneyland in Florida and California. That is absolutely a better way for Shanghai s development. Long before Walt Disneyland decided to come to Shanghai, real estate experts from Hong Kong asserted that Shanghai Disneyland would not drive the development of the surrounding property market. Because of the harsh negotiation conditions Walt Disneyland holds, the surrounding residential and commercial land will be far away from Disneyland. Therefore we should fight with the Walt Disneyland company for the second development mode, only in which way could we stimulate the regional economic benefits.

Furthermore, urban area development of Shanghai is currently too dense. The population could be shifted outwards with the extension of many industries. In fact Disney is a good foothold.

Moreover, quite different from Disneyland Hong Kong, from the previously published land use planning we can see, Shanghai Disneyland is not far away from the city's commercial center. If Disneyland Shanghai allows visitors with tickets in and out in business hours in one day without limiting the number of times, then visitors can choose to have meal in Chuansha town which is about 3 kilometers away.

Chuansha town is always the commercial center of the suburban area in Shanghai. The commercial facilities have been well developed before Disneyland moved here. Therefore, the commercial activity and accommodation of visitors could easily be satisfied here. Obviously, Shanghai Disneyland could introduce the development of local commercial shops and hotels, and then stimulate the market demand for hotel, shops, etc. After a large amount of tourists visit Disneyland and surrounding areas, demand for employment will definitely be increasing, which then stimulates the demand for residence.

*3.3.4 Facilities and transportation*

Recently, Shanghai Development Strategies Institute is investigating the transportation, facilities and etc. at Pudong area. Mass Transit Line 11 will link Disneyland and the downtown city. After Disneyland is built up, there will be a Disneyland station. Pudong Railway will soon commence building, and Disneyland is only 3 kilometers from Chuansha town. Chuansha town's main advantage is convenient transportation and complete facilities. It is close to Pudong airport, and north of Haigang new city, south of Waihigh bridge, west of the highway, and connected with mass the perfect place for development.

*3.3.5 Modifications to the park*

Like Disneyland Paris, modifications to the park were made to protect against changes in weather in the Shanghai climate. Windows in Disneyworld are small and weirdly set up, sometimes in order to pursue the beautiful effect of façade. But in Shanghai, the climate is completely different from Florida or California. It is wet and hot. Windows are too small to satisfy the requirement of ventilation and natural light. If we use artificial lights and air-conditioning to maintain the whole building system, it will be a big waste of energy. Therefore, architectures should be designed acco rather than form.

*3.3.6 Public participation*

What s the result of ten-year negotiation? How will they plan and design Shanghai Disneyland? All of these questions should open to the public instead of being a secret, because Shanghai Disney is not only a tourism project, but at the same time, also a big public project with huge government investment.

Though the project is so urgent, there are still three problems needed to be discussed publicly. First of all, it s the government investment. If it wants to get the support from the public, the financial investment cannot be decided only by the government officials, it should also open the related information, and allow the public to express its opinion completely to protect t know and supervise.

Secondly, whether Disneyland Shanghai can make a profit is a problem. Opponents take Disneyland Hong Kong and Paris as the failure examples, pointing out that American culture is already out of date, and 80-year-old Mickey Mouse s money-making ability is far less than previous years. Therefore, the profit plan should be opened to the, and at the same time ideas could be collected.

Thirdly, how to guarantee the public interest requires an open discussion. Since Disneyland Shanghai is a government investment project, the taxpayers profit should be protected. Theref situation of Disneyland Shanghai should be transparent.

Actually, about the Disney project, whether it is those Disney items in America, or the Disney project in Shanghai, there is always some voice of opposition, maybe because Disneyland costs too much money, or is perhaps hiding critical information. Though the project has been approved, Shanghai municipal government still needs to answer why the Disneyland is built to the public.

*3.3.7 The relocation of residents in resettlement*

According to the original planning, the first phase of Disney project occupies two natural villages, and part of another village, including 1800 households, 6000 individuals. Therefore, the relocation will not be a big problem to deal with. The land of these villages has been frozen for nearly ten years, forbidden to develop and build factories, which let the villages lose the develop opportunities. Therefore, the municipal government should compensate villagers by relocating them.

*3.4 Costs and benefits*

Walt Disney is famous for its smart business head. Take Hong Kong Disneyland for example, Hong Kong SAR Government has spent 22.45 billion Hong Kong dollars for land formation, construction of transportation networks and other infrastructure facilities and another 3.25 billion Hong Kong dollars for Disneyland construction, only got 57% stocks, while Disney Corporation only invested 2.45 billion Hong Kong dollars but got 43% share. In order to introduce Disneyland to Hong Kong, Hong Kong Disneyland was accepted the harsh conditions: location of cities as a major capital investment side, is responsible for construction at the same time, and no matter how many visitors, how bad the business situation, the government must pay tribute to the Walt Disney Company with a fixed rate of return. Compared with Tokyo Disney, Disney Corporation only got 10% for ticket fee and 5% from other products income.

As for Disneyland Shanghai, the government should carefully deal with the cooperation with Walt Disney. Walt Disney has a much more mature business system and market strategies, therefore, it is hard to prevent Walt Disney from taking advantages of Shanghai government. But Shanghai government had negotiated with Disney for 10 years, it is said that Shanghai Disney government invests 24.48 billion renminbi (which more or less equal to the expense of an aircraft carrier) and will have a pretty similar way of pooling funds with Disney Hong Kong, therefore, though we have no choice on the macro direction of investment, we could hope that Shanghai will have a better result than Hong Kong in details. On the other hand, with a decline in its commercial performance, Walt Disneyland is going to expand its business including stepping up propaganda efforts on commercial products and activities such as providing free TV programs. All of these show the attitude of Walt

Disneyland and its purpose---to gain access to Chinese market. So not only Shanghai needs Disney, Disney also needs Shanghai. There is no necessity for Shanghai government to sign an unequal agreement with Disney.

## 4 Conclusion---An agenda for further research and policy analysis from a planning perspective

*4.1Operation mode*

The future cooperation mode of Disney Shanghai will be the operation mode like Disney Hong Kong. Since the municipal government is the largest stockholder, we should try to avoid setting everything within the park. We should struggle with Walt Disney to create great values, because the real value is outside the park.

*4.2 Competition with other theme parks and itself (survival issue)*

**Disneyland Shanghai v.s. Jinjiang Park**

Jinjiang Park now has more than 30 large and medium sized rides. In order to meet the growing domestic and foreign tourists and cultural entertainment and fitness needs, Jinjiang Amusement Park in recent years is constantly adding new items. In May 2003, it also built large luxury double-decker merry-go-round projects, which won the favor of Chinese and foreign tourists. The strengths of Jinjiang Park are the good location, convenient transportation and much lower ticket price than Disney.

**Disneyland Shanghai v.s. Happy Valley**

Happy Valley is famous for the landscape and large-scale of stimulating mechanisms. It is so successful because it focuses on incorporating cultural factors into the theme park's construction and development process. The theme parks not only fully reflect the Chinese elements, such as Prachuab Sensation area in Chengdu Happy Valley, Shanghai beach in Shanghai Happy Valley, but also make an excellent combination of Chinese and foreign culture, such as through various forms of festive activities, turning Chinese customs and the world's cultural heritage into performance form. However, Disneyland has its own stories, long history and deep culture. These two theme parks will have different attractions.

**Disneyland Shanghai v.s. Disneyland Hong Kong**(Table 1)

Table 1. Disneyland Shanghai v.s. Disneyland Hong Kong

| | **Hong Kong** | **Shanghai** |
|---|---|---|
| Land use | The first phase of the park area is 126 ha. | First phase of the park area is 116 ha, while after completely completing, the total area will be 4km2, which will be several times of DHK. |
| Short time profit | Before opening of the park land development and facilities construction already brought 12 billion yua while building the park and facilities brought 9 billion yuan, providing 16,000 jobs. | Stimulate economy and promote employment rate. |
| investment | The total investment of phase 1 is 14.1 billion yuan and related facilities invested by HK government is 15.2 billion yuan. | Total investment is 24.48 billion yuan |
| Market management | Annual visitors now are 4.5 million. According to questionnaire, 90% of visitors | DLS is 6-8 times larger than DHK. Population of S is 2.5 times of HK. Visitors |

| | | |
|---|---|---|
| | satisfied with the park, 92% visitors willing to revisit. | are 3 times of HK. So visitors of DLS are expected to reach 2 times of HK, 10 million. |
| Long term profit | Estimated to obtain 148 billion net benefit in 40 years provide 35,800 jobs. | Provide 50,000jobs. 80 mainland visitors will be attracted to Shanghai. |
| Influence on stock market | From the launching to the building, DHK set off market investment boom in the stock market. Related stocks gained tremendous gains. | Disney has a huge and far-reaching impact on a city s economy and variou and related stocks associated with construction related to real estate, industrial chain-related stocks are abnormally hot. |

The estimated ticket price of Shanghai is close to Hong Kong, while the area of Shanghai is much larger than Hong Kong, maybe 8 times larger. Disneyland Shanghai is only 20 minutes by bus from Pudong airport. The broader crossing visitors could stay for 48 hours with visa waiver. And mainland visitors have no need to go through exit formalities. Besides, the expense on accommodation and transportation is much cheaper than Shanghai. All of the advantages indicate that the competition is inevitable.

Hong Kong Disney Park s attendance was 5.6 million in the first year, one-third o expected to be from mainland China. Others are from Guangdong province, South China and Southeast Asia. Therefore, Hong Kong Disneyland's market objection is mainly in South China and Southeast Asia, while Shanghai Disneyland will mainly attract visitors from the mainland. The Chinese market could entirely accommodate the existence of two Disneylands. Whether a win-win situation or a lose-lose situation will be achieved, will be due to whether these two theme parks could create their own characteristics and attract different people.

**Competition with itself**

Theme Parks in Shanghai are hard to survive. In the last century, the late 90s, " Universal Paradise", "American fantasy Paradise" and the Jinjiang Amusement Park were very popular. Now, except for Jinjiang Amusement Park, which is still on business normally, the other two parks had to go out of business.

According to the survey, the Chinese theme parks spent 150 billion yuan, of which 70% are at a loss of status, only 10% make profits. It is not because Shanghai has not enough market demand for theme parks, but result from investors blind investment without serious market res entertainment Shanghai people need. The supporting facilities, management, services, transportation, etc. cannot keep up, thus resulting in the batch of the theme parks that mostly ended in failure.

*4.3 Ticket price and ticket selling system*

Tickets price

Consider the competition with Disney Hong Kong and whether people could affo whether visitors are willing to revisit it. It was said that the ticket price wi (more than 40 dollars), which is a little high for citizens. I believe most of go to the Disneyland Shanghai twice with that price.

Ticket selling system

Because of the lessons we learned from Disney Hong Kong, a sophisticated reservation ticketing system should be introduced, particularly for tour groups. Improve communication with major mainland travel agents and close monitoring of tourist flow.

*4.4 Influence on the land and house price, and stock market*

Customers and developers should be careful of the risk of the big business. We c
how long the land, house, or the stock will be increased and whether it will fall after the rise.

*4.5 Theme park Area*

It was said by some media that Disneyland Shanghai will be the smallest Disneyland in the world, with only 116 hectares. That is definitely not the ultimate area. The municipal government has already levied 4 $km^2$ of lands, therefore, there is no doubt that the 116 hectares are only the first phase of construction of the core area of the park. And the smallest park rumor soon co

*4.6 Investment and return*

With the similar investment with an aircraft carrier, how to obtain benefit becomes the hottest topic. For DLS, keeping the ability of creation and innovation, expanding deputy commercial and product, and promoting media propaganda are the paramount issues.

*4.7 Generating other theme parks*

Perhaps driven by DLS, Guangdong Original Power Culture Communication Co., Ltd., who Pleasant Sheep and Big Bad Wolf --- the most popular cartoon in China now, even surpassing Mickey Mouse, started to pick a location for its theme park.

The last but not the least, a theme park about Pilgrimage to the West sho definitely achieve great success because of its diverse characters and interesting stories.

# SOCIAL COHESION BETWEEN HERITAGE AND TOURISM

Moreira, Maria da Graça

CIAUD, Faculdade de Arquitetura, ULisboa, gmoreira@fa.ulisboa.pt

Keywords: cultural heritage, tourism, cultural associations

*Planners have the responsibility to promote social cohesion of a territory. In some regions the cultural heritage is a very strong resource that must be valorized to achieve this goal.*
*One of the main opportunities to develop tourism is by the implementation of cultural local heritage.*
*The development of cultural planning can give to the planners a new tool.*
*Analyzing under another perspective, we can verify that the social cohesion at the local level, has been supported during the last decades on organizations spontaneously emerging from the population.*
*When urban planning does not have conditions anymore to value the territory with investments in new constructions, in part due to the current economical difficulties, a new look at the potential of the populations and their culture can be a very interesting alternative namely to develop tourism activities.*
*The study that has been undertaken is meant to identify some organizations that are keepers of some interesting cultural heritage in peripheral territories of the Metropolitan Area of Lisbon, its characterization and classification, its mapping at the local level and in the context with the cities where they belong.*
*With this information local planning can create spaces of visibility within these communities. These spaces can be associated with inside spaces or with the appropriation of public spaces that may gain new dynamics with the activities that are developed there.*

## 1. Introduction

This paper analyzes the relationship between the need to promote social cohesion and the tools that urban management can use to achieve this; planners have the responsibility to promote social cohesion of a territory as part of their qualification and in the benefice of urban economy.

The concept of a cohesive society works towards the well-being of all its members, against exclusion and marginalisation, creates a sense of belonging, promotes trust, and offers its members the opportunity of upward mobility (OECD, 2011)

In inner urban areas the sense of belonging has its roots in who always lived there, but often the people's impoverishment process, creates a form of territorial marginality that is difficult to be eradicated, so in these parts of the cities the sense of belonging tends to decrease when the population living there disappears or at least is significantly reduced and the area became socially emptied. This process is known and now local authorities have tried to fight it using various types of urban tools.

For a while, national or local governments used the financial programs for housing rehabilitation hoping that with this change, the population could return and grow, and together with those who had stayed there, increase social cohesion. This hypothesis was not verified and later on requalification interventions were made within public space with no social component.

This process that has been observed in many urban areas led the search of new instruments to regenerate the old areas by appealing to the memory and its materialization in heritage.

This new approach that connects to the development of urban economy, calls other populations particularly through tourism in urban areas that will use the assets as the purpose of the visit.

The heritage that we can find in the cities has two faces: the material or built heritage that considers building, monuments and architectural ensembles, and the intangible heritage more directly related to the population and therefore also linked to social cohesion (Choay, 1999).

The intangible heritage has been preserved among others by associations that have this goal (Veschambre, 2008) but also by others who were there and were keeping important aspects of intangible heritage, being in a way they themselves an heritage place.

## 2. Characterization of local associations in Portugal

The Associations are formed by the organization of groups of persons around some common interest that can be either cultural or of leisure (according to portuguese legislation) and are quite often in Portugal a place where the intangible cultural heritage of the group of associated and their families is kept alive.

When we analyse the associations of local scope, in the Metropolitan Area of Lisbon we note that they can be classified according to their objectives in:

- Cultural associations with vocation of cultural production and promotion
- Cultural and leisure associations promoting compatibility between culture and leisure or recreation
- Sport associations developed towards the practice of sport

In some cases we can verify by the name that was attributed to them, that they have as goal the organization of individuals with the same territorial origin, organize the association in function of common activities or of support to the families of the associated.

Among this vast set, this paper as chosen to study the cultural and leisure associations, in one parish, because they have been an important element of social cohesion and are those that explicitly or implicitly preserve intangible heritage of the population where they are inserted.

In some towns developed around big cities and in the respective metropolitan areas, the importance of intangible heritage that most often corresponds to its geographic origin, prior to the migration towards urban areas is the most important intangible heritage the population have.

With this group of characteristics we find some centres of municipalities in the Metropolitan Area of Lisbon, and among them the city of Almada gathers a varied group of associations and was therefore chosen as case study.

## 3. Almada, The case study

The city of Almada has a remote origin. The first traces of human occupation date from the neolitic and it has been since inhabited.

Until the XIX century it was an independent town, that developed slowly in the bank opposite to Lisbon, connected to the rural territory around it and to the Tejo river. It played always an important role in the defence of the Tejo estuary and of the city of Lisbon, but due to other aspects, among which the earthquake of 1755, it hasn t many significant built heritage.

Since the middle of the XIX century the process of industrialization changes quite significantly its population profile, with the migration of the population to work in the industries that were created in the banks of the river Tejo, namely in the area of Cova da Piedade.

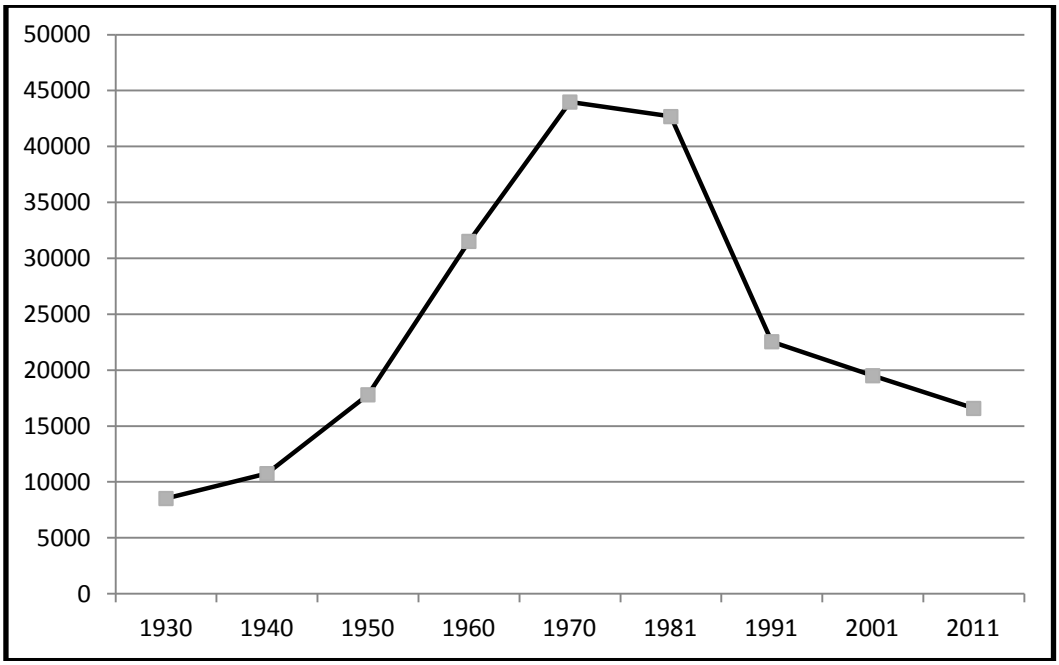

*Figure 1. Evolution of the population in the municipality of Almada and in the parish of Almada (1864- 1930) Source: INE*

Population growth in the municipality and in the parish of Almada becomes meaningful since the middle of the XIX century till the middle of xx century (Fig. 1).

It is the population of the rural world that comes to work in the secondary sector that will create the first cultural and leisure associations located along *Rua Capitão Leitão*, central axe of the city centre of that time (Fig. 2).

Since 1970 the population of the parish of Almada decreased moving to new parts of the municipality, and the old inner city suffers in his social image.

The first finance programme in this area began in 1989 in the area of "*AlmadaVelha*" and since then several programmes were implemented there (Moreira, 2002).

In the last years the municipality is focused in supporting the local associations with the objective of to promote cultural and social regeneration to local people but also to the population of all Metropolitan Area creating a cultural cluster in this old inner area

These associations have the mission, expressed in their names, of organizing activities that help to surpass needs and to fulfil the times of leisure in a time when mobility was reduced and the technology of sound and image non existing, so creating philharmonics was a priority and at the same time were built the places where to perform.

The first association, "*Sociedade Filarmónica Incrível Almadense*" was started in 1848 and created the first philharmonic, the fist theatre and the first cinema in town; it also built a party hall of big dimensions where are still performed different shows, namely of Portuguese rock bands.

The "*Academia de Instrução e Recreio Familiar Almadense*" founded in 1895, also as a philharmonic ~~also~~, a theatre, dance teaching and a library. They built a big hall for shows, and cinema, being the biggest in the municipality with conditions to present a diversified number of shows.

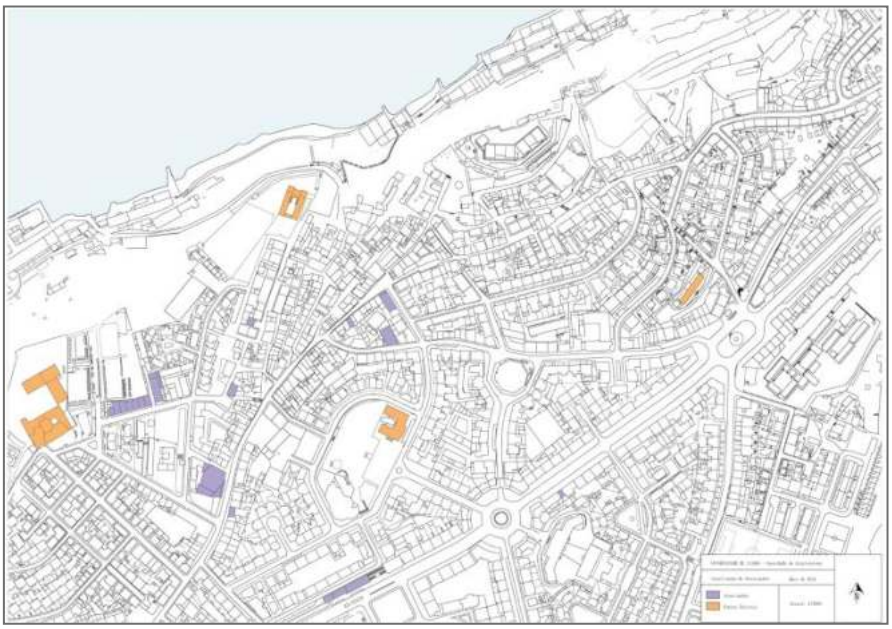

*Fig.2- Localisation of some Associations in Almada*
*Source:FAUlisboa*

In the 90 s of the ~~XX century~~ new ~~surgeon~~ associations were created, also located in the consolidated tissue of Almada, but with quite a different profile. These have no build heritage, using temporary facilities belonging to private owners or to the municipality or using public spaces.

The music component loses relevance and formation in performing arts dominate, namely theatre.

The Cultural association *O Mundo do Espectáculo* is a project created in 1990-91 wit giving education and promoting animation in the arts area targeting a differentiated audience.

The "*Teatro Extremo*" started its activity in 1994, becoming a cultural association in 1996. It organizes since the festival *Sementes – Mostra Internacional de Artes para o Pequeno Público* ("Seeds - International Arts Performance to Younger Audience") and has its facilities in a garage in an habitation building.

The "*Associação Cultural e Artística de uma Sociedade Original*" (ACASO) was founded in 1997 with the aim of promoting plastic and visual arts.

"*ASSIM SER: Associação Intercultural Brasílica de Portugal*" founded in 2009 to promote the intercultural dialogue, promoting social and leisure activities, towards fairer world, better and more equitable, aiming the valorisation of human beings and their integration in society.

"*Associação Al-Mada – Associação Cultural e Recreativa de Almada*" created in 2009 with the objective of promoting cultural and leisure activities.

This group of associations has the ability to intervene in urban space whether being land marks through the activities that they periodically develop and that duly advertised can be important to the dynamics of the city, or by the ability of connecting social groups and its support to the urban

economy of city. The Municipality has been helping to promote their activities and is presently trying to integrate in the municipal planning these group of urban actors.

## 4. Conclusions

The Cultural Associations have played an important role in the cohesion of the population that had migrated from the rural areas, mainly from the South of the country, and can be in the present an important tool in the area.

Local municipality has supported in an expressive way these associations as it recognizes their role in the qualification on the population, therefore in the qualification or revitalisation of the city .

The associations are a material and intangible heritage that can attract new population to their activities in special theatre from the Metropolitan Area but also foreign tourists.

It is important that their characteristics are kept as an element of urban cultural development.

Local planning must use these actors of urban life as partners in regeneration policies of the cities

A framework of analysis for the governance of heritage protection

Traditionally heritage policy in the Netherlands was organized in top-down hiera objectives of policy were served by creating a regime existing of rules for the and landscapes, providing subsidies for narrowly defined goals – leaving little discretion to beneficiaries of these subsidies – and by bringing the maintenance valuable heritage sites in the hands of government agencies. Within the paramete in the cases where heritage was not given status of official protection, it was (commercial and non-commercial) to decide whether or to what extend protection and worthwhile. With respect to the New Dutch Waterline this meant for example that sold to an entrepreneur, which transformed the site into a residential area. Bes private stakeholders and top down regulation, governance has emerged as a third collective action problems. Governance has profoundly different characteristics

problem at hand, their relationship with others and opinions about right and wro
explain the success or failure of interaction.

Actors and Arenas

The metaphor of an arena is often used to describe the material and social setti
interact. "The term action arena refers to the social space where individuals in
and services, solve problems, dominate one another" (Ostrom, 2007, p.). Most lit
arenas and actors can only well be understood when their embedding in institutio
included in the analysis. The institutional perspective underlying the elaborati
institutions as 'rules and norms' (Ostrom, 2007) formal and informal procedures
conventions that shape patterns of behaviour (Hall & Taylor, 1996). They pro
cognitive templates for interpretation and action (Hall & Taylor, 1996, 939).

Shaped by institutional conditions these arenas have a variety of characteristic
frustrate collaborative action. The network of actors forms an important dimensi
arena. The characteristics of the network include the range and density of the n
of the ties between actors. Which actors are members of the network and to what
mutually dependent? Governance is often deemed an appropriate approach for situa
been described as shared power worlds (Crosby & Bryson 2005). On the one hand th
makers that hold relevant powers and resources should be part of the network. On
larger the number of actors involved in solving the problem at hand, the more di
based approach gets (Ostrom, 1999). Which channels of communication exist? How f
actors encounter each other? These are important features, as it is known that g
communication and durable relationships increase the changes of cooperative beha
(Ostrom, 2007). Moreover, the level of trust between actors is often mentioned a
success factor in governance, assuming trust facilitates conflict reduction (Heale
strategic uncertainty, and thus investments in uncertain collaboration processes
interdependent actors with diverging and sometimes conflicting interests. (Klijn en K
594)

Arenas bring together actors from different backgrounds. In this situation effic
given. Differences in (organizational) cultures may form barriers for interactio
compared to trading zones in which traders from different cultures that speak
(jargon) have to find ways to conduct transactions. Anthropologists are familia
cultures encountering one another through trade, even when the significance of t
of the trade itself- may be utterly different for the two sides. (Galison 1997,
2006). The more actors that will be able to develop a local infrastructures of
instruments (Galison 2010) that enables such an exchange, the more likely that
be possible. Trading zones are therefore defined as local infrastructures in w
exchange planning ideas, proposals, and opinions by using exchange languages (Ma
18). This exchange language is created by the actors and concerns the physical p
way, the planning object sets the boundaries for the arena in which actors inter
language addresses the locality of the planning object, and includes planning co
practical solutions. It is a highly specific inter-linguistic structure to faci
between two or more pre-existing linguistic cultures (Mantysalo et al 2013: 11).

A further determinant of the successful governance concerns management of proces
Since parties in governance arenas are mutually independent there is no actor th
means to steer other actors. As a result the actor managing interactions has negotiating
skills, skills to bind actors and skills to forge new solutions that appeal to various actors whos
resources are required to implement solutions (Klijn and Koppenjan, 2012, 593). Also ind

Draft, do not quote or disseminate

of the process manager is often mentioned as an import factor, so that he/she wi
parties involved (De Bruijn & Ten Heuvelhof 2008, De Vries, 2008). Moreover, a s
the part of the actors in the arena to the problems that are on the agenda is a very important
(Klijn and Koppenjan, 2012)

Furthermore, an important characteristic of actor arenas concerns the configurat
constellation (Scharpf, 1997) or action situation (Ostrom, 2007), concerning the
involved in interaction aimed at solving particular problems. The degree to whic
backed up by means to achieve them, are compatible or incompatible, largely dete
space for solving problems. In addition the nature of the problem that is addres
of solutions that are possible. A dimension that is commonly used is the extent
excluded from using a good or service and free-riding can be avoided. If exclusion is ir
to realize or deemed undesirable, individual actors are very unlikely to provide
some sort hierarchical intervention or cooperation will be needed. In considerin
problems that will influence the range possible solutions and modes of interactio
think about the temporal and physical characteristics (including the geography
(Ostrom, 1990).

In general, when institutional capacity shared meaning, concentration of power
procedures for decision-making (Healey, 1998) is larger and other circumstance
allows for more comprehensive and elaborated forms of collective action (Scharpf

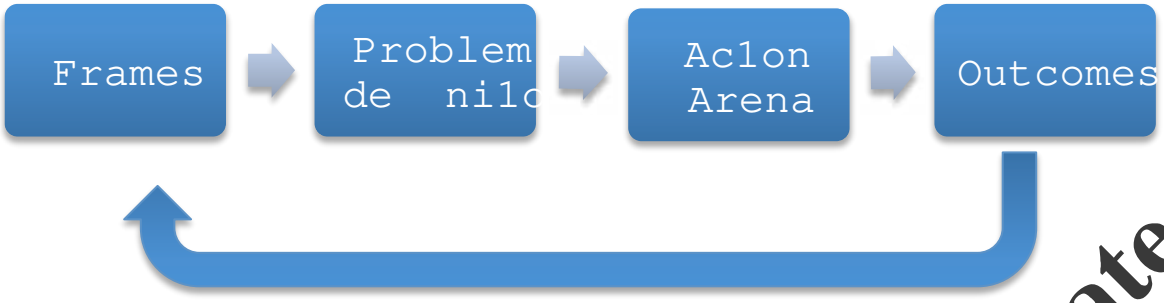
Framing
The framing literature (Tversky and Kahnman, 1981; Rein and Sch n, 1994; Hajer 2
that the way actors perceive the arena, the institutional conditions that shape
problems at the center of the arena, rest on frames. The term frame refers to t
conception of the acts, outcomes, and contingencies associated with a particular
a decision-maker adopts is controlled partly by the formulation of the problem and part
norms, habits, and personal characteristics of the decision-maker. (Tversky and
453). These structures of belief, perception and appreciation (Rein and Sch n,
actors down certain paths rather than others (Murdoch, 2004, 50). A frame deter
perceived and interpreted (Rein and Sch n 1994). Framing theory suggests that fr
what actors see as being in their interest and, therefore their problem formulat
solutions are grounded in different problem-setting stories (Rein and Sch n 199

These frames can be subject of change through exchange and learning, although so
basic beliefs about causal effects of policy interventions- are more susceptible
fundamental believes about right and wrong (Sabatier 1988). Furthermore, Rein an
assume that intractable policy controversies can only be resolved when re-framin
actors will change their perceptions on the problems, their own and other s role
necessary to understand the frames that actors apply in interaction and not accep
definitions and rules as given and per definition unchangeable.

It is important to note that frames are not floating free around but are grounde
sponsor them (Rein & Schon 1994: 29). This means that the institutional backgrou
related deeper-rooted beliefs make it more likely to sponsor certain frames. Fur
(1988) hypothesizes that policy actors form collaborative ties on the basis of s
form advocacy coalitions. This means that coalition partners are selected by how
beliefs of others. As a result, within an arena actors can often be grouped toge
sometimes four coalitions.

Draft: do not quote or disseminate

Building on the previous, the following conceptual framework is built:



The conceptual framework is built on two premises. Firstly, actors are mutually
collective action problems and second, that actors hold different frames, and th
problems and the actor arena differently. Hence, actors define the problems and
individually, but in order to reach collective action, actors need to reframe the nat
collectively. The action arena however, consists of different institutional fact
regulation, knowledge and other resources that constrains the ability of actors
outcomes of this process affect the frames of actors.

In reconstructing the episode of the invitation planning for the Island of Schal
on the different building blocks of the conceptual frame. The analysis is based
the process as it happened, using documents and interviews focusing on who was i
proposals were made, and which meetings took place. This was complemented by usi
to reconstruct the perceptions of the stakeholders on these events.

Case description
Some key characteristics of the Schalkwijk have been brought forward in the intr
paper. Summarizing briefly: with an invitation planning development strategy,
started a bottom up process in which local entrepreneurs, investors and farmers
up with initiatives that would support the revitalization of the New Dutch Water
former military defense line is a UNESCO world heritage site and has the official statu
Landscape. Typical in this case is that farmers sold lands anticipating national
development in the area. Thanks to the land deals, many (former) farmers have re
the area and real estate developers are willing to support any development to co
Most farmers have their roots in the region and feel strongly connected to it. L

In the arena in which the invitation planning process is taking place at first s
are active. First, there are governmental actors. The municipality takes the rol
and initiator in developing the Island of Schalkwijk. The project bureau New Dut
Line s main aim is protecting the cultural heritage values of fortresses and lan
variety of government actors is involved as transformations in the area touch on
responsibilities: the water board, the province, the State Forestry Commission a
Department of Waterways and Public Works. Second, there are 17 (former) farmers
indicated to be prepared to invest in leisure services in the area. Their intere
aligned and in some cases actors are direct competitors. Third, there are multiple pr
(AM Vastgoed, Bouwfonds and ASR are the developers with the biggest share; 800 o
hectares of land are in the hands of real estate developers). The governmental a
interests and are guided by different frames as the Q-sort analysis reveals and t
in unity, as the government sector is not without problems. The other actors in
fragmented action by the public sector as one of the major problems to establish
between public and private actors. Roughly sketched, on the one hand the governme
formulated ambitions for the area and the private sector has the resources to re
other hand private parties are in many ways dependent on public agencies. Many a
the private sector need permits and require changes of planning regulations. Fur
many investments at least partly are aimed at creating public goods, which makes
for exploitation by free riders, they look to the government to co-invest. In sh
interdependency between actors from the public sector and the private sector, bu
relationship between these two groups of actors is rather asymmetrical, with gov
dominating the process.

Research findings: Frames
Five different frames are found in the Island of Schalkwijk case with a cumula
variance of 63 percent. This means that the five frames cover 63 percent of all
the 24 respondents. In other words, 63 percent of the colored cloud (figure 1.1)
frames. With the pre-flagging mechanism of the Q sort software, respondents are

Discussion

The Q sort methodology reveals that actors hold diverging frames that are based perceptions on the nature of the problem at stake. The public actors involved de different scale levels. The municipality as the main organizer of the process de of a coherent set of leisure services as the key challenge; they see the current the area as the main problem, because many farmers stopped farming as they sold the municipality defines the main policy problem at a local level, the managemen Dutch Water Defense Line perceives the protection of the landscape and heritage object policy problem. The New Dutch Waterline Defense Line is seen as a coherent colle objects: this makes the openness of landscape, the historic-cultural value of th authenticity of the defense line as their main policy concerns. The private acto two groups: the ones that are competitive and are not very willing to cooperate actors and the entrepreneurs that seek for alliances with other local actors. Th most private actors follow is of a much more practical nature: they want their p profitability of their plans is protected.

The frames of the actors diverge also on how actors perceive their role, the rol the rules of the game in play. The municipality chose for the so-called invit approach , meaning that they want to facilitate the planning process. The munic meetings and develops criteria for local planning initiatives. In practice, the perceive this facilitating role differently. They perceive the action arena as a the municipality forces the entrepreneurs to translate their individual plans in plan for the Schalkwijk area. The entrepreneurs have to adopt their plans to bur well as to plans the other entrepreneurs proposed. The entrepreneurs feel that t completely different branch of the economy. They are frustrated by the variety o dropped on them from different public agencies. Sometimes these rules and regula particular solutions.

The institutional analysis revealed that institutional factors hamper integratio the arena. An important factor is the bureaucratic structure behind the resource project. To get access to the budgets available for the project, plans have to m regulations, set by various actors, to justify public support for private plans. provide a stimulus to spend public money at high speed since there are fixed exp Another important institutional factor is the issue of accountability that limit servants to act. Although there is the clearly articulated ambition to support l still have to report on the most things they do since governmental action have t transparent, this means that civil servants cannot always act as quick as they w measures that were taken during the process made civil servants risk averse and justification, also a factor that contributed to a sometimes slowly operating an When analyzing the process from the angle of communication the dominance of the comes to the fore in several ways. In overcoming differences in organizational c construction of an exchange language the process seem to have failed. The gramma Water Defense Line heritage project and used by the municipality Houten have not development of a shared vocabulary or exchange language. At some point, for exam municipality asked the entrepreneurs to invent a collective market strategy for many entrepreneurs openly questioned. Conceptual language and the meeting cultur source of annoyance on the part of non-governmental actors. Some entrepreneurs f absorbed their plans.

The lack of trust among the other actors appeared to be another defining factor in the ac history the Island of Schalkwijk contributed to the lack of trust. Most resident

Draft, do not quote or disseminate

were against housing development in the area, while the municipality supported i
blame the municipally for not representing their residents with regards to this
to developers created also distrust between the (former) farmers. Whereas many f
that they were not willing to sell land, many of them did sell eventually. The d
actors is an important institutional factor that hampered reframing. Important t
most entrepreneurs believed the level of trust increased during the process.

Conclusion

The case of the Island of Schalkwijk shows that the transition from government t
fraught with inconsistencies. Paradoxically, the desire to give room to non-gove
contribute to heritage protection goes along with many actions to maintain contr
Because governance by definition implies the involvement of a variety of actors, most go
actors translate their desires into instrumental rules. As a consequence actors
project are confronted with a stack of regulation. Furthermore, because the tran
driven to a great extent by austerity measures, governmental policies are very m
quantified targets. These targets are at odds with the innovative ambitions of t
extent imply a step in the dark. As a result, stakeholders are overwhelmed by bur
requirements and feel stripped of their own responsibilities.

The followed analytical framework revealed the frames actors hold as well as the
conditions that affected the reframing attempts that appeared in the planning pr
of framing theory and institutional analysis can provide a comprehensive outlook
success and failure of negotiations in actor arenas. This paper shows that struc
of frames can reveal how actors perceive their role in governance processes, wher
analysis made clear that institutional factors hampered actors to actually take
Consequentially, mismatches appeared at 3 levels. First, the inconsistency betwe
and action frame that the municipality of Houten holds: the invitation planning
regulated, putting the entrepreneurs entirely on the wrong track. Second, the le
problem was defined: municipality, regional authorities and entrepreneurs all fo
problem definition and the rather fixed regulations hindered interactive reframi
conditions that were set for public expenditure seemed to be not applicable on th
entrepreneurs developed. This bureaucratic reality did not match with how the mu
own role. The three revealed mismatches show that institutional theory and frami
mutually exclusive and can be applied together in a case study. Although both th
very different assumptions, when combined they provide us a better understanding
processes in governance arenas.

# PERMANENT PUBLIC ART FROM THE PERSPECTIVE OF CLAIMS AND CONTEXT

Petra Vlachynska

Institute of Urban Planning (Faculty of Architecture, CTU in Prague), vlachpet@fa.cvut.cz

Keywords: permanent public art, claims, context

**Abstract**

*Permanent public art is one of the layers of the city. In the Czech Republic the practice of public art dramatically changed after1989. All the legislative and institutional support that regulated and ideologically controlled this domain was abolished. New strategies and policy have not yet been established. However, new permanent public art is still installed into the cities.*
*This contribution analyses three phases of the process leading to the new art in the city. Claims, context and art itself are three elements of the whole. They have equal importance. Theoretical understanding of claims, context and art can lead to the precise articulation of future claims, appropriate expectation and better evaluation of benefits. Claims are specific in time and space. Claims, often expressed by the subjects initiating the process of creation, represent mental soil. They are formulated in official strategies (general level) or discussed for the purpose of a specific work. The importance of context developed significantly in the last decades. Context is considered a crucial element in the meaning of public art. Location of important public art, monuments and memorials requires a complex approach and the involvement of artistic professionals, architects and preservationists. Art in public spaces lays on the intersection of different forces: artistic individuality and public interest, sensitivity for actual issues as well as long-term values.*

## 1. Introduction

In this contribution I would like to present the results of the continuing research on the permanent public art installed in Prague after the Velvet Revolution in 1989. Two aspects of permanent pubic art, claims on public art and context of it placing, are addressed and provide theoretical perspective. Official permanent public art in the city is shaped by various actors who participate in vision making, artist selection, decisions on placement and other tasks. The claims are emphasized by the different actors and the understanding of the potential of a specific place are crucial for the success of the artwork, acceptance from the public, and integration in the public space. In the 1980·s the role of public art in urban regeneration was strongly advocated and supported by municipalities, urban planners and developers. In Europe and the USA numbers of new public artworks emerged. Critical writing from different perspectives including artists, cultural theorists and urban and cultural geographers appeared in the late 80·s (Hall, 2003). In the last three decades the important body of the literature has opened up the multi-professional discourses. In the Czech Republic the production of public art is less prolific compared with the situation before 1989 and with other European Cities (1). Professional criticism is rare. Strategies and support for permanent public art have not been developed by any municipality. The exceptions, to some extent are Liberec and Brno. NGO Spacium (active from 2001 to 2010) in collaboration with Liberec municipality succeeded in placing several new sculptures in the city and the region. In the city of Brno the long term municipality project Statues for Brno organizes competitions for monuments and sculptures.

As a part of the introduction I will mention the different concepts and definitions of public art. Afterward I address the complexity of the phenomenon of art in urban spaces. Although art situated a city works as a solitary detail and its effect is more acupunctural, the scope of the question overlaps with dimensions of urban design as summarised in the Mathew Carmona and col. book Public Spaces Urban Places (2010). Therefore the phenomenon of permanent public art requires the perspective and knowledge of various professionals.

### *1.1* What makes Public Art Public ?

What are the specifics of art in the city? How is Public art different from mere Art ? Is it category? Or is it an independent area of cultural production? All these questions are relevant, there is no such thing a single definition of public art. Cameron Cartier defines four conditions for public art and at least one must be fulfilled: 1. Public art is in a place accessible for or visible to the public: *in public*. 2. Public art is concerned with or affecting the community or individuals: *public interest*. 3. Public art is maintained for or used by the community or individuals: *public place*. 4. Public art is paid for by the public: *public funded*. (Cameron and Willis, 2008, pp. 15). Cher Kraus Knight argues that "art is most fully public when it extends sincerely emotional and intellectual access to its viewers" (Knight, 2012, pp. 23). In contrast, Patricia Phillips defines public art rather than on the basis of its presence in the public space or the importance of accessibility to a wide audience, but on the basis of challenged issues related to public sphere (Senie and Webster, 1992, pp. 298).

### *1.2 Complexity of Permanent Public Art*

Official permanent public art similar with architecture creates the built environment of the city and together they share three fundamental characteristics. Firstly, public art and architecture enter the space of the city for a period of time which is not clearly defined. It is presumed their presence will last for decades, centuries, or even for ever . The permanency of public art is often pro with temporal and community based tactics which are less object oriented and more public concerned. There is also the argument of the inability of permanent public art to address the actual issues in a changing society (Miles, 1997; Pavlickova, 2003; Whybrow, 2011). Secondly, art in public space needs the official agreement of authorities and institutions. It is part of the policy of the state, city or private sector. This is one of the reasons why the reputation of permanent public art is so low in the creative communities (Cartier and Willis, 2008). Autonomy of the artist and art declared by modernists is threatened. The artist becomes the instrument and co-author of political and economic power instead of critically examining it. Thirdly, permanent public art, as with architecture, transforms the city scape, thus the citizens are inevitably exposed to visual and spatial effect.

Art in the city is only structure without any specific practical function. It is created by an unrepeatable meeting of art and space in an unrepeatable historical moment. Behind every artwork lies astory that refers to the process shaped by the main questions: What is the idea of the project? Why do we want to create it? How will we do it? Where will the art be placed? Some authors emphasize the need of situated knowledge of various actors or group of actors (Pavlickova, 2003; Zebracki, 2012). Typical participants in the process include artists, architects, city and state institutions, NGOs, cultural theorists, private investors, contractors and citizens. Actors share responsibility for dealing with the various aspects associated with the planning and implementation of art in the city. Their competence varies, although they may overlap.

## 2. Methodology

The first part of the research examining the claims and context is based on the theoretical literature of art theorists and cultural geographers. The historical perspective on official state programs in USA creates the background for actual strategies and discourse. The conceptualisation of context and overview of claims summarized in the book Public Artopia (2012) written by cultural geographer Martin Zebracki are highlighted as a contemporary theoretical framework.

In the case study of permanent public art in Prague after 1989 I present the set of results from the current research. The research concentrates on the influence of political changes on public art and quantitative analysis of Prague·s art-scape and visual typology.

## 3. Claims on public art in strategic programs and critical reflection

> The history of art has sometimes been presented as a history of styles. The history of public art will more likely be seen as a history of intentions (Miles, 1989, pp. 39)

Official permanent public art is driven by a specific intention or set of motivations more or less declared. In some cases, a genuine intention to place a statue in the city is hidden from the public, in others it is clearly expressed and fulfilled. Intentions articulating a process and leading to the placement of a sculpture are possible to examine and refine by demands that the actors place and have the competence to ask. Evolution claims on public art can be viewed in two domains. First is an official strategy and policy of countries, cities, institutions and organizations that support and implement public art. I will mention the most fundamental of them in the history of public art programs in the USA and the actual claims defined in the documents of various organisations and institutions. The second domain is the critical writings on various aspects of public art.

*3.1 History of claims on public art*

In 1982 The Fairmount Park Association was founded in Philadelphia. This private non-profit organization, later renamed as The Association for Public Art, was the first company focused on the promotion of public art and urban planning. Its founders believed in the value of art in public spaces as an extension of the museum. Art should not be an exclusive matter. Art has the potential to play an important role in the life of the population of Philadelphia. Until 1906 art originated only in the Fairmount city park, later the organization's activities have spread into the area of the city "as the counter of expanding industrialism and to promote and foster the beauty of Philadelphia, in its architecture, improvements, and the city plan" (Bach, 2001, pp. 13). In 1959 Philadelphia was the first city in the nation to accept the percent-for art program, three years before federal percent-for-art policy was established. The nation-wide support for public art opened the Federal Cultural program, which was a part of President Roosevelt·s policy known as the New Deal that was supposed to allevia impact of the economic recession of the 1930s. The support program was incorporated into several separate projects. For the period up to 1935 the most effective was the Public Works Art Project (PWAP), which lasted from 1933 to 1934 (Cartier & Willis 2008). His goal was to create jobs and decorate federal buildings (post offices, schools, libraries, museums). In 1935 the largest and most important government program to support the arts-the Work in Progress Administration (WPA) was launched. It included the Federal Art Project (FAP), designed by visual artists. This program lasted until 1943, when the US entered the Second World War. The WPA tried to learn from past experimental programs. One of the goals of the new WPA was to strengthen the relationship of artists and their communities to prevent the lack of jobs and outflow of artists in large cities. The FAP was a centrally managed program, however, it was able to influence cultural production at the regional level throughout the United States (Adams and Goldbard, 1996). Crucial support and proliferation of public art came in the 60s through two federal projects. The General Service Administration (GSA) launched the Art-in-Architecture program in 1963, which was the first state program in USA to use 1 % of the budget for the construction of federal buildings for the creation of art integrated into the architecture. The program was put into life during the onset of President Kennedy's inauguration. Kennedy was aware of the ugliness of fast growing cities and the unsatisfactory state of federal buildings (Radisic, 2007). The program established three principles: 1. Distinguished building design should be acquired from the finest American architects. 2. No official governmental style should be allowed to develop. 3. Attention should be paid to each building·s site for its location and beauty. However, perceived the presence of art in architecture as decoration (Radiscic, 2007). The revision of the program initiated by President Nixon brought closer collaboration with another federal organization, the National Endowment for the Arts (NEA). The first new requirement placed on the Chief Architect emphasized the selection of the locality for art and integration into the overall design of the building (Radisic, 2007). One of the first realizations was Flamingo by Alexander Calder, designed and engineered for the Federal Centre in Chicago. The NEA initiated its own program named Arts-in-Architecture, which aimed to strengthen the democratic distribution of power in the field of commissioning and realization of art in public spaces. The growing influence of the private sector accounted for the program to strengthen local government and NGOs, which initiated the project and used NEA support for the partial funding and organizational patronizing (Radisic, 2007). NEA and GSA have undergone radical transformation since the negative reactions on the installation of Tilted Arc in 1981 by internationally renowned sculptor Richard Serra. Both programs tried to democratize and support the idea of public art but the results suggest promoting certain cities and locations using

the work of internationally acclaimed artists as an attractive product and brand the cause lies in a definition of public art only in terms of presence in public space. Art is alienated within its context and often in a sharp aesthetic or spatial contrast with a built environment. A radical revision of the objectives of both programs occurred in the second half of the 80s, after eight years of litigation between supporters and opponents of Tilted Arc installed in Federal Plaza in New York and 1989 removed (Knight, 2008).

In the 60 s and 70 s many American cities adopted the percent-for-art ordinance and drew up plans to strategically support art in the city. In the 70s the public art policy expands in Europe. Since 80·s art is advocated in urban regeneration planning thus the importance of site-specificity is advocated and implemented in the strategic documents. The website managed in past by Arts Council in England [(4)] www.publicartonline.org.uk, surveys, informs and publishes sets of data and documentation valuable for different purposes such as research, commissioning and strategy making. The public art policy programs of many England cities are listed. In Vienna the organisation KOR enhances and funds new public art. Documentation is accessible through a virtual archive. KOR published eight guiding principles in its website. Four of them mentioned the urban related aspects of identity of place, revitalisation and social issues. Between 2004 and 2014 KOR supported 72 permanent projects. In Denmark KOS, museum of public art, collects the artwork relevant to the process of creation (models, sketches, drawings, video documentation). KOS manages an interactive map of Denmark permanent public art. The city of Chicago in its official website describes public art as site specific artwork commissioned through *community-based process* . The definition itself incorporates democratic values of public art. To support public art there is not only percent-for-art ordinance, although it is a powerful instrument. The aim of this short survey is underpin the variety of the states and cities engagement in awareness of public art and improvement the quality of new artworks.

*3.2 Theoretical reflection of claims on public art*

Comprehensive overview of claims on public art are formulated by Martin Zebracki in the book *Public Artopia* (pp. 26-27). He mentions various authors as an inspiration and source of thoughts for the summary (Hall, 2003a, b; Selwood, 1995, Miles 1997). Zebracki appoints first physical-aesthetic demands where art contributes to the attractiveness of the place and thus encourages greater use of urban space. Art also increases the visual and aesthetic quality of the site and stands as a landmark. Other qualities can be mentioned too. The second area includes economic demands. For example, increased investment in the arts, support for economic regeneration by creating a visually more attractive environment, support for marketing and promotion of a certain town or city, providing employment opportunities for artisans, transport, or the promotion of cooperation between public and private sectors. The third area concerns social issues, which range from promoting interaction within the community, helping to integrate, support for social change, reducing vandalism and making a secure environment, supporting links between artists and professionals who have an influence on the built environment, such as planners, architects, engineers, landscape architects. The last group of issues is related to the cultural and symbolic level. Art is able to raise awareness of the history of the site, promote national identity and inspire further actions and ideas, promote the identity and character of a place.

The aforementioned issues are interrelated and it is possible to distinguish hierarchy within them. Respectively, some claims - for example, the creation and promotion of national identity through a monument to anti-Nazi resistance is paramount and require the utmost care and multidisciplinary discussion. Claims such as creating job opportunities for transport companies and contractors is rather a positive side effect. Hall and Robertson (2001) pointed out that officially formulated demands are often essentialist, critical reflection on the implementation is rare. There is also lack of evaluative tools for both, the art and the claims.

**4. Contextual approach in public art**

The importance of site-specificity has grown distinctively in the last decades. As Kwon (2002) proves this evolution was influenced by new tendencies in the art world and the proliferation of modern sculptures in the public domain in the 60·s and 70·s. Artists such as Richard Serra, Robert Smithson, Donald Judd and many others re-contextualize their installations in the space of the gallery. They also discard the aura of authenticity of a sculpture, composing the objects from prefabricated materials. They escape the system of artistic production in realisation of the landscape installation in the great distance of civilisation. Landscape art is sometimes seen as forerunner of public art (Rendell, 2006). At the same time the advocacy of public art and creation of policy in many states and cities increased the number of new realisations. But sculptures are placed without any significant relation to architecture or place. They serve as an aesthetic object or decoration. The alienation of the artistic object and public space is characteristic for already established modernist principles of the autonomy of artist and art. Theses art objects are later on described as plonk art , plop art o the square (Whybrow, 2011). The reaction is strong criticism of the mentioned practice and a growing interest in the context of public art. From the 80s several new modes of use and strategies were explored. The aim of this contribution is not to reproduce the phases of evolution of site-specific tendencies in public art ending in process oriented community practices. I would rather emphasize the crucial position of context through five paradigms conceptualizing the interrelations of art and public space as presented in afore mentioned book by Martin Zebracki Public Artopia (2012, pp. 15 16). The first paradigm, Art *in* public space , is based on mere presence of art in public space, without a fundamental connection with a place as is typical for socialist sculpture. The second paradigm Art *of* public space , re/valuates public space and thus includes all art connected with the public and issues related within the public sphere regardless of whether it is placed in a public space or in a museum. Following the essay of Patricia Phillips Temporality in Public Art (Senie ed., 1993), art is truly public when artists critically challenge all political and social issues. For example Kris installation, Memento Mori: Of One·s own Volition , street light turned up towards the Nuselsky Bridge has the power to redefine a sad history. A tacit and neglected place of personal human tragedies is overriden by a powerful embodied of a moment of hope. Arts constitutive role of public space defines the third paradigm Art *as* public space . Democratic values integrated in the notio space is driven through art. Such as Maya Lin·s Vietnam Veteran Memorial in Washington, whi works with landscaping, and movement and strength of a complete list of the names of fallen soldiers. The forth paradigm Public space *as* Art , is very much presented in the tendencies of the 70·s and 80·s where art with function was advocated as valuable and not generating conflicts. The realisation of art as urban design and furniture sculpture (Whybrow, 2011) amenities were supported. In Prague, the Bollards of Karel Nepras installed in 1993 in front of the Lichtenstein Palace have not yet been accompanied with other creation of a comparable artistic quality. The last paradigm Art *for* public space , art representing public space, is typical for the most of the monuments and memo Sculptures as a statement or attractive image representing the subject may also be included. The sculpture I love Money , designed by Jan Slovencik and Iva Junkova placed in front of the College of Banking is an example. The architecture of the building is more monotone than original and the locality itself suffers from poor urban planning. In a space primarily used by car drivers the sculpture provides outstanding visual quality supported with humour. These five paradigms are schematic and provide orientation in the continuous conceptual interrelation of context and public art. The boundaries are open for overlapping and interconnection. Zebracki defines the sixth paradigm as implementation of all five concepts. Through Zebracki·s innovative summary I intended to show the complexity of problematic of permanent public art as an integral part of a particular place which is, in the words of Lucy Lippard, the intersections of nature, culture, history, and ideology. (Lippar

**5. Permanent public art in Czech Republic: Case Study Prague after 1989**

*5.1 Situation before 1989*

By the1950·s, the socialistic state of Czechoslovakia totally governed the permanent public art practice. The first decade of socialism is connected with the construction of expensive monuments. The most famous and demanding was the realisation of the Stalin monument dominating Prague from Letna hill. Avery close collaboration and connection of architecture, statuary and mural painting was supported. The idea of total work was less and less influential at the end of 5(

costs by Khrushchev, the new Russian leader (Karous, 2012). The cult of the former head of the Russian state J. V. Stalin collapsed and in 1962 the monument was blasted, seven years after the completion. Since the 60s the Czechoslovak state has supported the creation of a smaller scale sculptures, often without direct ideological connotation (Karous, 2013). Massive support and distribution of sculptural and mural works suggest the use of art as a tool for strengthening cultural influence and a clear definition of its borders. Due to percent-for-art ordinance, adopted in 1961, sculpture production entered the period of greatest proliferation through its participation in the centrally planned construction. In 1965, the efforts to strengthen cooperation between architects and artists were culminated in the document Resolution of the *Government of the Czechoslovak Socialist Republic on the use of fine art in construction projects* which contained 14 principles. Preparations for the architectural design and engaging art work was carried out in with the cooperation of three institutions, the State Commission for capital construction, the Union of Czechoslovak architects and Union of Czechoslovak artists. Decision-making powers related to the selection of the artist and the ultimate decision on implementation was entrusted to the Czech Fund of Fine Arts (Karous, 2013). Architects had the task of selecting artists and jointly submitted a proposal to the Commission. Artists and had secured supply contracts, if they were willing to keep the circuits themes and formal language of exhausted modernism.

*5.2 1989-2014*

After 1989, the Czech Republic had a radical transformation of cultural policies associated with the production of art in the city. Institutions that were designed to promote and control public art in the cities were cancelled. Percent-for-art law was revoked. The overall character of new works in the territory of Prague and the number of new annual installations changed significantly after 1989. What seems to be unchanged is tentative interest in permanent public art by politic authorities and cultural professionals and the questionable quality of some of the new realisations. There is no official strategy by State or municipal governments. Consultancy (on a commercial basis or provided by NGOs and cultural institutions), which facilitates communication between different participants and helps formulate visions for art does not occur in the Czech Republic.

The capital city of Prague on www.praha.eu has not yet published any report, concept or strategy to support art in public space. In 2014 IPR (The Institute for planning and development of the city of Prague) published a *Handbook for design of public spaces*, which defines seven principles for placement of art in public spaces (pp. 273-276), (semantic and spatial relationship to a place, choice of location should not be coincidental, the importance of collaboration between architect and artist, evaluation of site-specific conditions before assignment for art, scale selection and material responsibility for maintenance, a plaque as an aesthetic element). In the text, the emphasis is on the relationship with the context: "A work of art should never be taken out of the context of time and place, but rather to resonate in a particular locality" and "Artwork contributes to the quality of public spaces, if aptly reflected its ideological and spatial relationship to the place "(pp. 273). The text accurately describes the problem of existing public art ex post set up in urban space, t support and quality selection. The manual is binding according to the subject to which it relates. For districts and private entities it serves as a basis and a tool in the creation of further development for Prague city and contributory organizations drawing on the city's budget is binding (pp. 14-15). This text is unique in the Czech environment.

In Prague various subjects create a new impetus for the implementation of art. For example, Lamp under Nuselsky Bridge artist, Kristof Kintera, initiated in cooperation with the civic association Dvojka Sobe (Souskova, 2012). The NGO Automat commemorates the accidental death of its founder Jan Bouchal, installing a silver bicycle on the street light pole close to the place where the accident happened. In 2014, the Gate of Infinity sculpture was revealed as a result of the cooperation of the Prague 3 municipality and the sculpture studio at the Academy of Arts, Architecture and Design. Two years before, in collaboration with the same studio, Praha 9 realized the statue The Dancer in front of Polyclinic in Prosek. The Private College of Banking commissioned the design and implementation of a significant attractive sculpture I Love Money . A rare example of the use of art to promote a

housing development project is Kejruv Park, even though the quality of integration in site is more than arguable. It is obvious that although the number of new works after 1989 has decreased significantly, Prague (at least its centre) has become a space where a wide range of initiatives have entered the field of official public art, for now without clearly defined rules. Some of the art-works were donated to the city and they remain despite the loud criticism of the professional sector and institutions. If there isn t any regulation at the level of government, it is an opportunity for municipalities and the local authorities to develop their own public art strategy, guidelines for dealing with donations and failed realisations.

*5.3 Mapping of permanent public art in Prague*

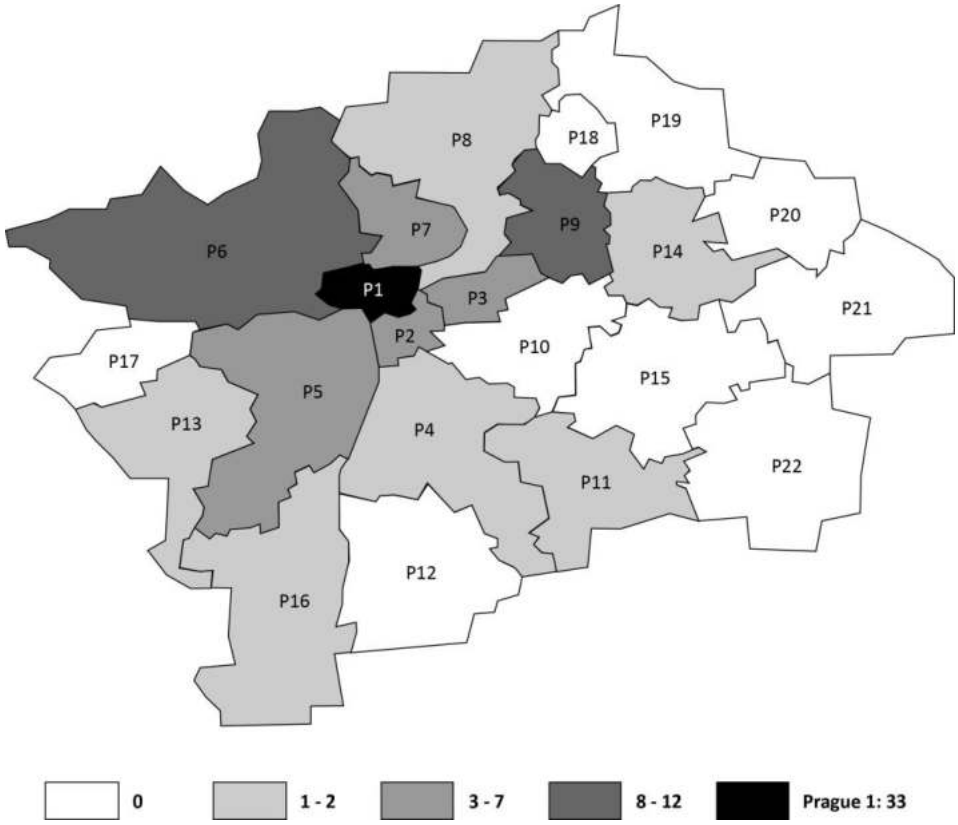
Permanent public art installed in Prague after 1989 has still not been thoroughly investigated. The partial documentation and mapping is provided online the Prague City Gallery archive and internet database www.socharstvi.org. The Aliens and Herons Project focuses on socialist sculptures from 1948 to 1989.

To create a database the main source was the internet, terrain survey, checking tips and literature. The database covers public art from 1989 until April 2015, however, it is still open and its final appearance will coincide with the current situation at the time of completion of the research (i.e. 2017). As far as the public space is concerned, the works are placed in freely accessible public spaces, public space with the regime (parks) or in the private space, which is freely accessible (exteriors of business centres, arcades), but under certain visual control (guards, cameras). Also included were three-dimensional works that are physically tied to architecture (except commemorative plaques and busts) and then the works, which, although located on private property of an institution or a housing complex, but the way they are installed clearly directs to the audience "behind the fence". What is important is visual and semantic overlap in the public space. Data referring to each part include: installation year, title, author, material, location (administrative district, location based on identification, other specifications), visual category. There is also data whose collection is still unfinished (photo-documentation, type of process that initiated the establishment and location of work - open or invited competition, gift to the city, individual activity, initiative, civic associations). The starting point for creating a visual typology is drawn from Zebracki (2012). There are four categories of art: 1. Monuments and memorials 2. Statues (figurative and abstract sculptures) 3. Installation/ environmental art/ landscape 4. Art with function. The first category includes only monuments and memorials that have been explicitly intended. Works that from the viewpoint of the artist's motivations are commemorative are assigned to the second or third category. Installation and other forms of permanent art, which avoid the classical concept of a sculpture on a pedestal as the centre of attention are assigned to the third category.

*5.4 Artscape and visual typology - quantitative results*

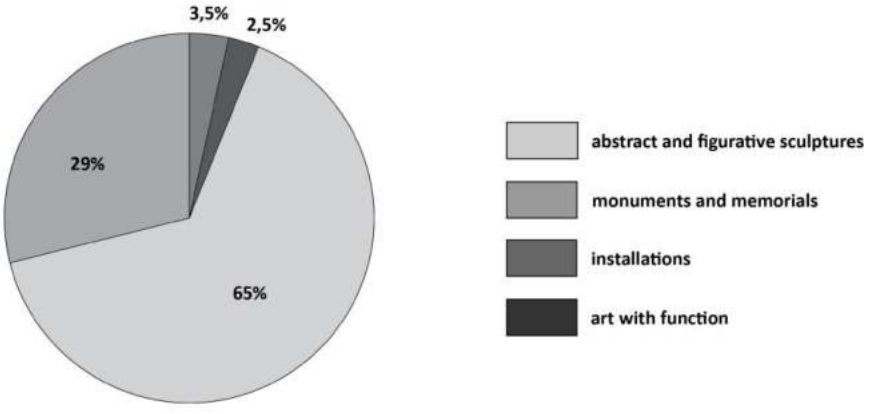
From 1989 to 2015, 82 works originated in Prague. That represents approximately 3 new works per year. 12 works are part of the two groups of sculptures (Hadovka Sculpture Park, sculptures in the development project Kejruv Park). 33 pieces, 40 %, are located in the administrative district Prague 1, where 2.35 % (29,586 out of a total 1,256 million; data released by CSO in 2014) inhabitants have permanent residency. It is in contrast with other administrative districts where none of the remaining 21 districts have more than 11 works. In nine administrative districts there has not been created any artwork in the post-revolution period. See Table 1.

Table 1. Quantity in administrative districts



In terms of visual typology, mapping generated the following results: The group of monuments or memorials includes 24 works. Then there is the 53 abstract or figurative sculptures. There are only three installations which can be identified as working: Time Machine on Letna known as the Metronome, the twisted lamp Of his own volition under the Nuselsky Bridge and Aeronaut , which is in the Hadovka Sculpture Park. Only two works operate with function: Bollards in front of the Lichtenstein Palace at Little Side and Bench again part of the Hadovka Sculpture Park. See Table 2. 40 sculptures engage realistic rendering of the human figure or object, based on the tradition of classical sculpture.

Table 2. Quantification of visual typology



## 6. Conclusion

From the ongoing research of the artscape in Prague, the following outputs emerged: 1. Number of new public art-woks and proliferation within districts 2. The quantitative survey in visual typology. 3. Prague has a great lack of policy making, evaluative methodology of various aspects in public art issues. 4. Some results need further research and interpretation, for example, the concentration of works in Prague 1 district which is 30x 3x higher than in other districts of Prague. There is also the question of the absence of public art in the nine districts.

For a better understanding of the situation in the permanent public art-scape in Prague after 1989, the notion of claims and context in the theory and practice were addressed and researched in the body of documentation and literature. The claims on public art were developed in time through various state programs. Since the 80s, theoretical reflection and the academic sphere have shaped the thinking and created new input in policies and strategies of municipalities and states. Contextual approach, site-specificity, public art as place making this terms are inherent for both academic discourse and strategic documents.

**Notes:**

(1) In Prague in 1989 2014, 82 new public art works was installed. KOS, virtual museum of public art in Denmark, provides 209 record in the same period in Copenhagen. Martin Zebracki mentions 375 public art in Amsterdam public in 1985-1999 and 156 in 2000-2009 (2012, pp. 63). KOR in Wien, in 2004 2014 supported 72 new permanent art-projects.

*Supported by the International Exchange Program for Graduate Students, Tongji University (No.201501028)

## Abstract

*With the development of social economy, the renewal of traditional lane residential areas in Chinese cities is significantly affected by consumer culture. In the case of Shanghai, Lilong (the local name of lane residential area) renewal has always been combined with tourism and commercial strategies, and has created a new format of urban development since 2000. In this paper, 5 typical Shanghai Lilong areas are selected. To study the characteristics of consumer groups, motivation, behavior, the attraction of street space and cultural elements of these areas, a questionnaire survey is conducted, and the commercial structures of the 5 samples are also analyzed. The paper has discovered that the characteristics of the main consumer groups in Shanghai Lilong are represented by 3 Hs (high education, high income, and high social class) also by lower age, higher percentage of international population and distinct regional features (far higher percentage of native Shanghai people), etc. Through a statistical analysis, 4 representative consumer groups are identified: white-collar workers, college students, foreign tourists and business people, and natives of Shanghai, whose core motivation of consumption is considered to be the construction of social identity and self-identity, reflecting complex values and behavior characteristics. To better cater to its consumer group s motivations, the Lilong keeps on strengthening the significant characteristics of consumer culture like unique, historic and aesthetic features, as well as the middle to higher consumption tendency and the density of significance. The author argues that the renewal of traditional Lilong has really improved the image of the city and stimulated consumption, but also led to some potential problems, such as the social contradictions, the loss of the authentic culture represented by Lilong, and the superficial trend of cultural connotations in consumption. This research is intended to provide a case study for the renewal of traditional Lilong or lane residential areas in Chinese cities and some reflections on corresponding problems.*

**Key words:** *consumer culture, Shanghai Lilong, consumer motivation*

## 1 Introduction

As the development of social economy in Chinese metropolises produces abundant material products, the first-tier cities, represented by Beijing, Shanghai and Guangzhou have entered consumer society. In a consumer society, consumer culture is featured by mass consunmption which is more for symbolic significance rather than the real value of the purchased commodit

significance could be understood as a certain social position or some cultural residential areas, which carry the historic culture of a city with unique cultural connotations and architectural symbols, can bring special historical and cultural experience that ordinary residence areas can not offer to consumers, but creates in reality some scarcity in the historic culture of traditonal lane residential areas(Steven Tiesdell, Taner Oc, Tim Heath,1996). Once excavated, the scarcity will in return create great economic potentials. The universality of consumer cultur pursuit of people and broader, deeper market needs, producing a new round of the traditional lanes renewal. As a matter of fact, the consumer culture has begun to affect the renewal of traditonal lane residential areas in Chinese cities profoundly. Since 2000, the lane residential area renewal in Shanghai has been combined with tourism and bussiness, shaping a new format of urban development, which, on one hand perceives great popularity and on the other, presents some potential problems.

In this paper, five representative lane residential areas: Xintiandi, Sinan Mansions, Tianzifang, Duolun Road, and Dongping Road are chosen as research targets. A questionaire survey was conducted about consumer groups, consumer motivations, consumer evaluation of the cultural characteristics in the sample lane residential areas, so as to go deeper into the social contradiction and cultural matters of the renewal pattern combined with tourism and business. The causes of these problems are discussed in this paper, and hopefully it can provide some suggestions for the renewal of other similar traditional lane residential areas in Chinese cities.

## 2 Relevant researches and research questions

### 2.1 Relevant researches

#### 2.1.1 Research on consumer motivation

Many scholars have introduced consumption theories related to social studies into the study of consumer culture in urban space. For example, there is the study of symbolic e by Shron Zukin. Based on Chinese consumers behavior at McDonald s, American Anthony M. Orum and Chen Xiangming put forward some consumer motivations as follows: 1.special experience; 2.social interactions; 3. social status (Anthony M.Orum Xiangming Chen, 2002). The majority of Chinese scholars criticize the negative effects on urban space caused by consumer culture. For example, Bao Yaming, who specializes in social science, has studied the negative consumer psychology in bars, such as the emotional expression and self-identity verification (Yaming Bao, 2001). Ma Jiewei also carried out researches on bars, he pointed out that it is the simulation of the past time and present development, the connection of local features and multinational imagination that attract consumers (Jiewei, 2006).

According to Maslow s theory of hierarchy of needs, consumer motivations are div needs and high-level needs. Consumption needs influenced by consumer culture include consumption conceptions and behaviors based on identity which are seen as the high-level needs for a sense of belonging, respect and self-actualization, while the basic needs are out of physiological needs and security concerns. Identity includes self-identity and social identity , the role some takes for us. It is an attribute given by others and the identity of the social group that one belongs to (Qing Wu, 2009). Self-identity is defined by oneself for his character, quality, temperament and appearance. It is the identity of self-attribute (Ning Wang, 2001). Through research and interview, the authors found that consumer motivations are somewhat closely related to social identity in Lilong space: status motivation, social motivation, and conformity motivation; consumer motivations are also closely related to self-identity: hedonic motivation, taste motivation and personalized motivation.

### 2.1.2 Research on evaluation of characteristics of Lilong

This part is to summarize the characteristics of consumer culture in Lilong based on theoretical studies and the pre-survey. The theoretical study tries to summarize some vocabulary to describe Linong s characteristics from mass media and journal articles. To evaluate lan Xintiandi and Tianzifang, the main concerns are focused on several aspects: 1. Historic significance, or the basic feature of lane residential areas, some representative words used old Shanghai culture , and classic culture ; 2. Uniqueness. Lane residential areas boast features that stand out to compare with other areas around. 3. Fashion. Fashionable culture, industries and environment are integrated in Lilong and will lead the cultural trend in future. 4. High-end consumption. Characteristic and the high-end service facilities and the assembled consumer groups demonstrate the high-end characteristic of these areas. 5. Unfairness. Traditional lane residential areas tend to become exclusive spaces for the strong social groups, where only the needs of social elites are satisfied. 6. Quality and nostalgic feelings. Nostalgic culture and romantic environment always attract people and make them eager to stay. 7. Artistic atmosphere. The Lilong area is full of artistic tastes, such as architectural space, studios of fine arts, photography and sculpture, street art, and artists. 8. Cultural integration. Lilong is the integration of the new and the old, the modernity and fashion, the Chinese tradition and western styles.

To avoid inconsistency of opinions between consumers and the authors, this paper uses the induction vocabulary mentioned above in the questionnaire survey for consumers to choose the most suitable ones. Then, the vocabularies with highest frequency will be selected for a classification analysis, to initially define the cultural characteristics of lane residential areas. Further research will be conducted in later formal investigation.

### 2.2 Research questions

Previous researches start with both social issues and consumer psychology, while in this section, the following questions will be studied from consumers perspective:

(1) Who are the consumers in the traditional lane residential areas?

What are the characteristics of the consumers, including their age, education, and social class? Who are the mainstream consumer groups?

(2) What are the consumer motivations?

Why people like to consume here? What are their psychological needs? What are the different motivations among different consumer groups?

(3) How do consumers evaluate the cultural characteristics in traditional residential areas? What are the cultural characteristics of Shanghai Lilong?

(4) With the renewal pattern, what are the hidden problems of Lilong?

## 3 Research design

### 3.1 Sample selection and introduction

To answer these questions, five traditional lane residential areas are chosen as samples in this paper, they are Sinan Mansions, Xintiandi, Tianzifang, Duolun Road, and Dongping Road (see Figure 1). Of the five samples, Xintiandi, Tianzifang, and Sinan Mansions belong to Huangpu District. Duolun Road belongs to Hongkou District. Dongping Road belongs to Xuhui District. These samples are chosen in consideration of the following reasons: (1) great social influence; (2) representative renewal patterns; (3) different business models and consumer groups. The consumption mode of Xintiandi, where the consumer group mainly consists of foreign people, therefore is a foreign consumption-oriented place; Tianzifang, where consumers are mainly foreigners and younger people, it is tourism consumption-oriented; Sinan Mansions consumption mode is an upscale-club c high-level consumers make up the majority of its consumer group; Duolun Road, featured by cultural collection, has less consumers; Hengshan Road s consumption mode, built for consumer groups Shanghai-style night-life culture, includes white-collar people and the native residents.

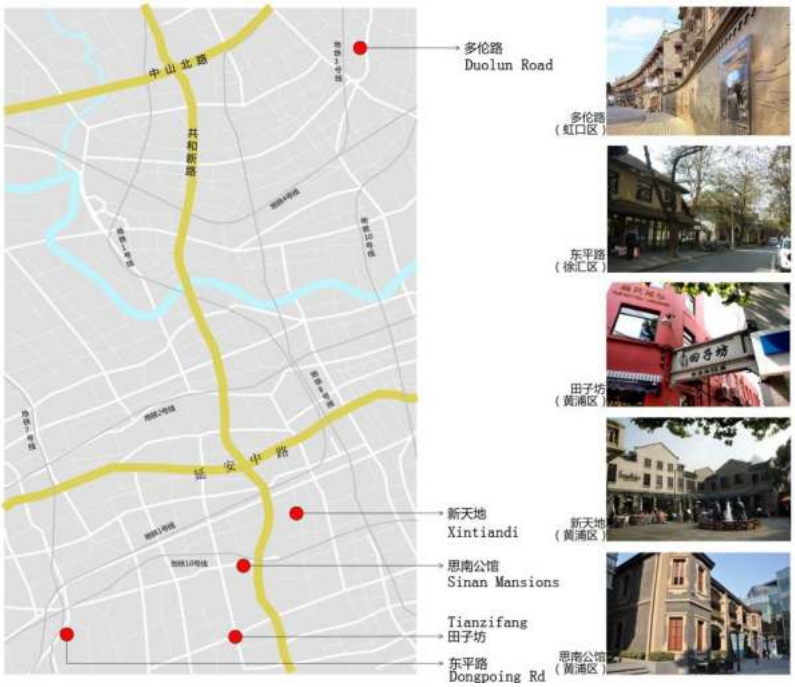

**Figure 1.** Map of the five samples

Through observation of the five samples, the business characteristics of traditional Shanghai lane residential areas are analyzed from the perspective of consumer culture. The reasons of success and failure of these areas in terms of business are also summarized to provide references to the renewal of traditional lane residential areas.

### 3.2 Questionnaire survey and problem evasion

#### 3.2.1 Questionnaire design and survey

The questionnaire survey is an important means for this research and the questionnaire is

designed mainly for consumers/tourists. The questions include the identity information of respondents, consumption conditions, psychological needs, motivations, perception and evaluation of the sample areas. Before the questionnaires were formally handed out, more than 50 questionnaires had been pre-surveyed and problems were checked out, then the formal questionnaire was re-designed for the research survey.

To collect authentic and effective questionnaires as much as possible, the questionnaires were handed out at random in the sample areas. The respondents were mainly the consumers of all kinds in the areas. In order to make sure that the sample areas are comparable, the survey time was kept consistent, most of which were conducted at weekends, and there was a certain ratio of questionnaires handed out on week days. The survey was conducted in 2014 from August to October and 948 questionnaire papers were collected. With 82 invalid questionnaire papers, there were 866 valid ones and the efficient rate was 91.4%. The number of papers differed according to different scales and the numbers of people in the sample areas.

### 3.2.2 Problem evasion

Beyond any doubt, defects of this questionnaire survey are unavoidable. For example, it is more convenient to conduct a survey on tourists hanging outside the restaurants and shops in the sample areas; it is more convenient to collect questionnaires from Chinese than from foreigners; the elderly are more likely to refuse the participation in the survey. The following routes are designed to evade these problems:

(1) Proportional relation of respondents is determined through a general observation to ensure the comprehensiveness of respondents;

(2) According to the measuring method of sequencing, the basic attributes of crowd (gender, age, education, profession, place of residence) are separately surveyed. Then the crowd proportion is counted as a weighting basis to arrive at actual crowd relations;

(3) Besides, questionnaires are handed out at different street passageways and squares to ensure the randomness of handing out questionnaires and the authenticity of crowd proportion;

(4) Through interviews with working staff in the areas such as servants, shopkeepers and public securities, crowd proportion can be deeply understood in terms of sensibility and compared with research results. If the difference is small, the accuracy of the results is verified, but if there is a big difference, the causes need to be found and better research methods shall be discovered and applied.

Hopefully, the ultimate research results can faithfully reflect the structure of respondents.

## 4 Research findings

### 4.1 Characteristics of consumers

According to statistics, the mainstream consumers showed the following characteristics (see Figure 2-5):

(1) social chatacteristics: 3 Hs chatacteristic, that is to say, people higher income, and higher social class account for a very large proportion;

(2) age characteristics: low in age , that is to say, young and middle-mainstream consumers and among them, college students account for a larger proportion;

(3)nationality characteristics: foreign consumers occupy a fairly large proportion; the proportion of foreigners in five sample areas range from 30% to 60%, about 45% on the whole;

(4) regional characteristics: the number of local consumers is far beyond tourists from other parts of China.

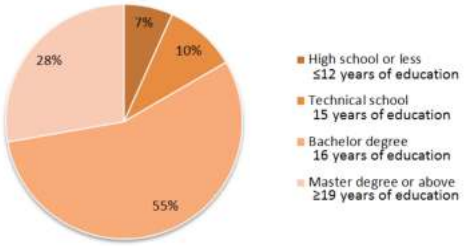

Figure 2. The structure of consumers education

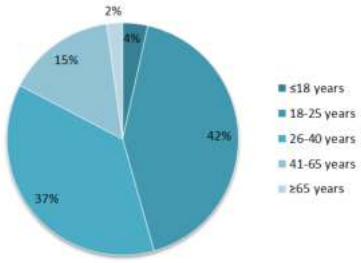

Figure 3. The

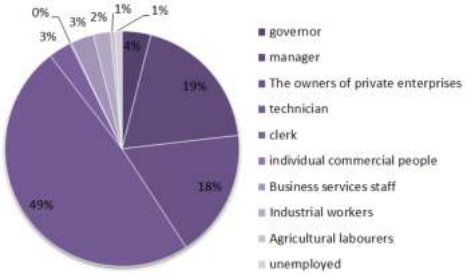

**Figure 4.** The proportion of ten occupations

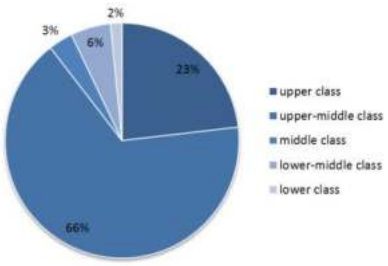

**Figure 5.** The proportion of social classes

### 4.2 Psychological needs and activity characteristics of representative crowd

Based on data analysis, this paper studies consumers psychological mot characteristics of the four representative mainstream crowds: white-collar workers ( 3H s groups), college students (low age groups), international consumers and local tourists, and evaluates the cultural characteristics of traditional lane residential areas.

#### 4.2.1 A comparison of consumers psychology

Through a statistic analysis, it is found that there are both communality and difference in the consumer motivation structure of the four mainstream crowds, showing complex values and behavior characteristics. Based on standardized survey data of psychological needs, different scores are used to reflect consumer psychological needs. There are four categories of scores with x as the psychological needs. For example, x 2 2 x 2.5 2.5 x 3 and 3 x, mean that the corres psychological needs do not exist , with a certain tendency , with an obv stand out (see Figure 6).

[1] *Questionnaire of Psychological Needs* is designed on 5point scale method. In data statistics every reply is given a score point. For convenient calculation, in this paper, never totally agree; don t agree; no opinion; agree; totally agree are assigned to 0 1 2 3 4 respectively. It can be seen that 2 stands for unclear attitude; smaller than 2 means disagreement. The smaller the score, the stronger disagreement. On the contrary, the bigger the score, the stronger the positive attitude. When the numerical value is 3 , it means the attitude toward the item is rather clear.(Refer to 24-45 questions in the Attachment A Questionnaire for specific problems)

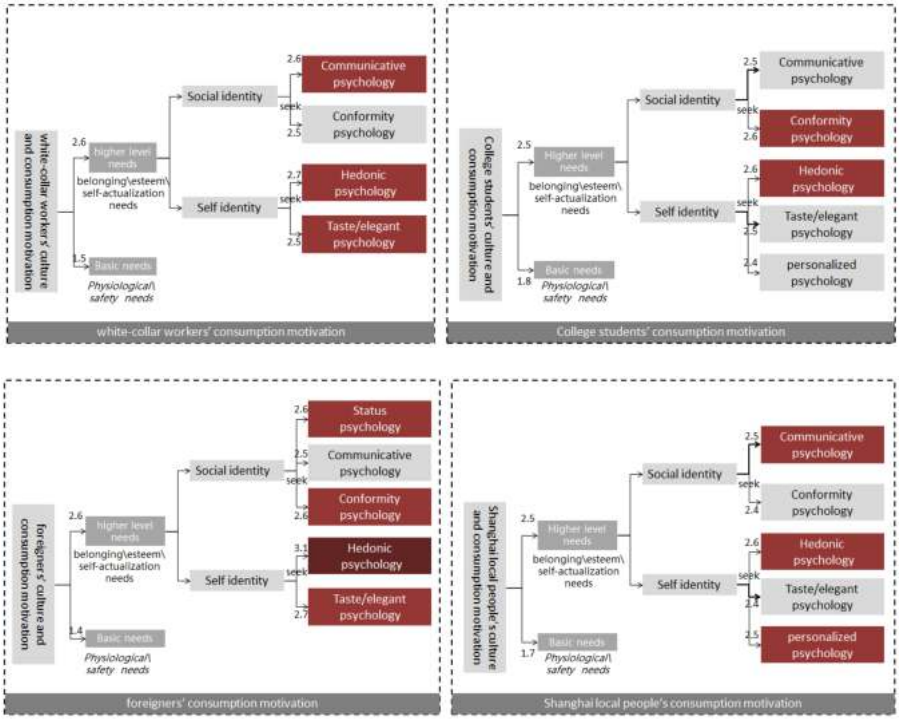

**Figure 6.** A comparison of psychological demand motives of 4 groups

(1)Communality: hedonic and communicative psychology stands out, while status psychology is not so strong.

The demand motive of consumers is clearly partial to higher-level needs, which is far above basic needs, while the needs for self-identity is far above social identity; hedonic consumer motivation (which belongs to self-identity), the communicative and conformity consumer motivation (which belong to social identity) are obvious.

Thus, it can be concluded that on one hand, consumers care about their own happy and comfortable feelings, so they demand a better environment of the areas, including the elegant style of shops and the delicacy of goods; on the other, they care about the interpersonal communication so they seek suitable places in order to make friends and cultivate social relations as well.

(2) Difference: each group has a different psychological demand structure

The difference of psychological motivation of each group is mainly demonstrated by different structures of six molecular groups. Hedonic consumer psychology can be clearly seen in each group, but that of the international group is relatively the strongest; personalized psychology of the white-collar group and the international group is relatively weak, while their conformity is relatively strong; conformity and personalized psychology of college students and local people in Shanghai are clearly seen, which demonstrates that all groups are influenced by both the reputation of the sample areas and their own complicated psychological needs for personal preference, uniqueness and distinctive things. The psychological needs of consumers are complex and contradictory.

### 4.2.2 A comparison of typical activity characteristics of each group

The main activities of the white-collar group include dinner party, business-related interview, working lunch and so on. Although these activities belong to catering and leisure services, what white-collar workers consume are actually the cultural atmosphere and petty bourgeois tone of Shanghai Lilong. Meanwhile, their requirements for space include a graceful environment, well-equipped facilities, private spaces and so on;

Young students are curious about society and history, and their major purpose of coming to Lilong is to experience more and know better about themselves. What they pu culture and artistic atmosphere of the areas. In addition, the creative culture and the fashionable elements can satisfy their curiousness to pursue something new.

Activities of foreigners are mainly for social interaction, business and fun. On the one hand, they are attracted by bars of different kinds and styles; on the other, they are also attracted by the architectural space with local cultural characteristics. Their affection for history and culture is embodied in their experiences of enjoying the architectural space, rather than historical stories and soft culture.

The main activities of Shanghai local people are experiencing the culture of old Shanghai and enjoying trips on weekends. They are attracted by the cultural symbols of old Shanghai and the spatial features of traditional lane residential areas. They are also attracted by the original and creative cultural atmosphere, surreal romantic sentiment, literary and artistic scenes as well.

### 4.3 Evaluation of cultural characteristics of Lilong areas

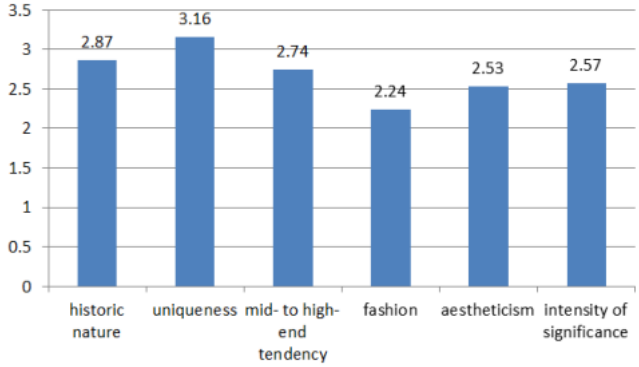

**Figure 7.** Evaluation on the characteristics of Lilong areas by consumers[2]

The questionnaire is designed based on scale design of every single characteristic. The score of 2 means a vague attitude of the respondents to the characteristic, that is, they do not agree and they do not deny either; 3 means they agree about this characteristic; 4 means degree of recognition, based on the scores, is divided into 3 limits: 2.0 , 2 are divided into 4 levels, represented by y . In case of y<2, it means consume characteristic; 2 y 2.5 means that the characteristic gains certain recogniti the characteristic is quite obvious; 3 y, the characteristic really stands consumers highly evaluate the characteristic of uniqueness ; then that of historic n

[2] *Questionnaire of Characteristic Evaluation* is the same as *Questionnaire of Psychological Needs,* designed on 5 point scale method. In data statistics every reply is given a score point. From never totally agree to totally agree , every reply is assigned to a number from 0 to 4 . In the final statistics, 2 stands for unclear attitude, the smaller the score, the stronger disagreement. On the contrary, the bigger the score, the positive attitude is stronger. (Refer to 22-27 questions in the Attachment A Questionnaire for specific problems)

historic nature and uniqueness actually supplement each other because hist
uniqueness and material space is the carrier for both uniqueness and histo
tendency is also an obvious characteristic, showing an apparent social disti
aestheticism and intensity of significance also gain a score greater than 2
residential areas not only conform to aesthetic requirements but also serve as something like a
meaningful and cultural space. mid- to high-end tendency and fashion have recog
degree, showing the whole consumption level and consumers in Lane residential areas are not so
high-end and fashionable . (See Figure 7)

1 Prominent feature: uniqueness

Uniqueness is the most prominent feature of the traditional lane residential areas and it even
exceeds the basic cultural characteristic of historic nature . That means
characteristic is far more appealing to consumers and culture consumption for uniqueness is of greater
significance in the consumer society. Uniqueness is the quality that all pr
Therefore, Lilong areas also need to show their unique features while being made into a tourist product, they are unique in both material space and cultural connotation. After renovation, the traditional Lilong areas are emancipated from declining and backward environment facilities, shines with their uniqueness to attract a great number of consumers.

2 Obvious characteristic **I**: historic nature and mid- to high-end tendency

Historic nature is an important cultural resource both in consumer cul
residential areas to rival market which is centered on economic interest. Hist
by the architectural space of the traditional residential areas such as brick walls, hipped roofs, and stone gates. They are different from modern architecture and carry the memories of old times, making it easier for people to experience the culture and the historic nature of the areas in old times. Besides, the art stores and creative industries related to the culture of old Shanghai help to increase the historic taste of the areas.

The characteristic of mid- to high-end tendency is also widely recognized, which is
with consumers evaluation on consumer price of the areas. The price is conside
and belongs to a mid to high level. On the other hand, it is because the consumption level is affordable to consumers they choose to come here. Compared with other industries, the consumer price here also belongs to a mid to high level. According to the questionnaire data, 45% respondents think of the consumer price here as ordinary, 16% as slightly cheap, and 34% as slightly expensive. The data show
that consumption level of the areas is a mid to high one, so the mid- to high-e
obvious characteristic.

3 Obvious characteristic **II**: aestheticism and intensity of significance

The characteristics of aestheticism and intensity of significance are p
cater to the needs of consumers for beauty and cultural significance in c
more possible for consumers to use their imagination, receive a spiritual joy and realize self-value in a graceful environment of specific significance. On the one hand, the renovation of traditional lane residential areas restore the original pleasant scale, balanced proportion, exquisite building components and graceful greenery landscape; on the other hand, the new architectural elements, the reformation design of showcases and greening, all the increase of sculptures and decorative articles
beautify the environment and manifest the characteristic of aestheticism .

The characteristic of intensity of significance is partly rooted in the history, traditional lane residential areas and partly influenced by consumer culture. The areas are created into places of significance, for example, some of the areas have been defined as creative area, and Shanghai culture brand . Many shops are labeled as Old Shanghai Culture , Fresh and Young Culture , etc. In such places of significance, consumers are a relax, improve emotional communication and cultural identity among friends, thus to gain spiritual solace and joyful emotion.

4 Tendentious characteristic: fashion

The characteristic of fashion is recognized by some people but it is not a also not consistent with the comments of media. Fashion is usually connected with the opposite of history and tradition . The elements of fashion can more historic and traditional nature of Lilong areas. The traditional symbols of transformed by modern design philosophy and technology into tall and straight gates, transparent glass windows and well-organized streets, along with fashionable stores and creative articles of daily use, adding fashionable elements to the areas. Tradition and fashion could cause confli intensities, so how to make a good integration of them is a real problem.

## 5 Problems of renewal

### 5.1 Social problems

#### 5.1.1 High-end consumption brings about issues of social equity

Nothing is wrong about high-end consumption itself, but if the renewal of residential areas is centered on high-end consumption, serious social equity issues and vicious competition problems will stand out. In the courtyard with green hedges and under the extravagant lights in the traditional lane residential areas, the general public still have to face economic, cultural and social pressures that are new to them.

This problem cannot be solved within Lane residential areas. It is often followed by problems of social stratum differentiation. If the traditional residential areas are transformed to be distinctly high-end, it indirectly reflects the serious problems of social stratum differentiation within Chinese urban society. But if we take social equity into consideration, we still hope for the emergence of a civilianized renewal to serve and appeal to the general public.

#### 5.1.2 Disharmony with the surrounding communities

We can see clearly from five sample areas that they are not in harmony with their surrounding communities, especially in the case of Tianzifang and Duolun Road. Xintiandi is thoroughly renewed and the project has transformed the old Linong architectures and the indigenous people completely, who had dwelled in the area of Taiping Bridge around Xintiandi. The southern and northern parts retain an imprint of Lilong or the traditional residential area, while the other parts have been transformed into modern skyscrapers. After renewal, Xintiandi is, to some degree, in harmony with those high-end residential areas nearby, while the areas around Taiping Bridge are still mingled with the crowded, cluttered and old-fashioned Linong areas waiting for transformation. In Duolun Road area, only one block has been renewed, thus the indigenous communities on both sides are preserved. However, the renewed business functions on the road are totally far from the daily life of the

community residents and Duolun Road is only used as a roadway. As a result, Duolun Road area and the bilateral communities form a striking contrast. Tianzifang also has this problem. Tianzifang, on the one hand, has been used to develop economic interests by some indigenous people; on the other hand, it induces conflicts with other indigenous people. Noise, crowds and behavioral interference have resulted in much protest.

5.1.3 Over-Westernization tendency

Over-Westernization tendency refers in particular to the Westernization of consumers. Shanghai is an international city so it is understandable for some areas or blocks to be highly Westernized or internationalized. However, there is a matter of degree. If every area in the city is Westernized, then it is a real problem, particularly seen in Xintiandi, Sinan Mansions and Tianzifang. In these traditional lane residential areas, a great number of Western-styled coffee bars, restaurants and bars gather there[3] instead of Chinese traditional halls. More and more consumers gathering here are mostly Western tourists and white faces.

**5.2 The loss of the authenticity of cultural matrix**

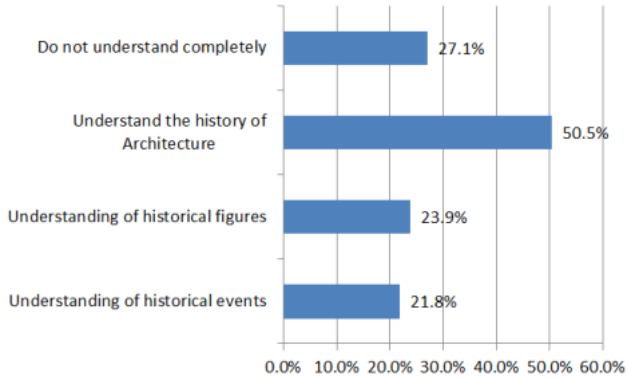

**Figure 8.** Research on consumers knowledge about the history of the traditional Lilong ar

It can be seen from the results of questionnaire survey that the authenticity of the culture of the traditional lane residential areas is not closely related to satisfactory evaluation.[4] First, consumers do not know about the culture of traditional lane residential areas well. Data shows that nearly 30% of the consumers even do not know about the culture at all, among them, nearly a half do not know about the architectural history of the areas, and about 80% do not know about any historical figures or events (see Figure 8); second, consumers cannot tell if the authentic history of the areas has been reserved; even though they know the need to preserve their history, they do not know how to do it; third, in the five sample areas, consumers satisfaction has no positive correlation to the authenticity. Xintiandi is a typical example, where much authentic information of history has been lost. However, consumers are most satisfied with Xintiandi. Duolun Road and Tianzifang do well in preserving the authenticity of history but consumer s evaluation is rather jus Figure 9)

[3] Surely, there are problems like environment pollution and fire hazard caused by the lampblack of Chinese restaurant, but is there any solution?

[4] In the questionnaire, whether consumers understand the culture of the sample Lilong areas, and whether they deny these Lilong areas have preserved well the original history are investigated (Refer to 20-21 questions in the Attachment A Questionnaire for specific problems); at the same time, the satisfaction of consumers for Lilong areas are evaluated from two aspects: satisfaction on the environment and facilities of Lilong areas; the emotional satisfaction. (Refer to 49-54 questions in the Attachment A Questionnaire for specific problems)

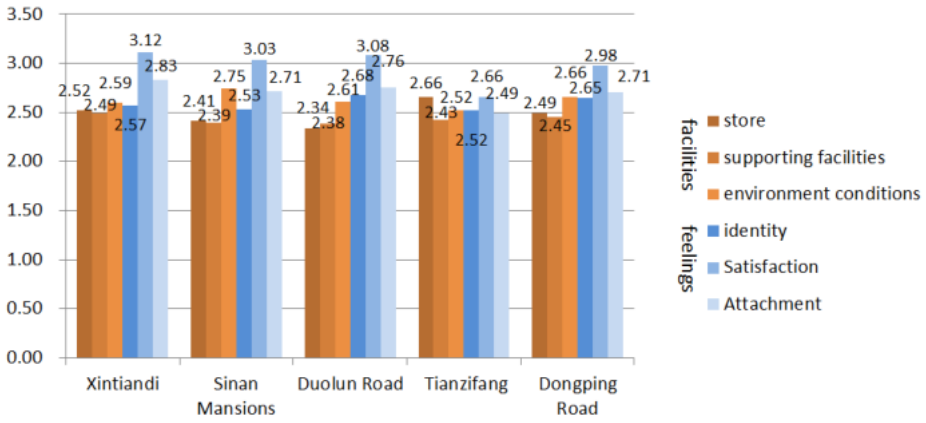

**Figure 9.** A comparison of consumer satisfaction in the sample areas

It suggests that consumers are blindly interested in the traditional lane residential areas, it is also the main reason why so many false historical symbols are used and historical symbols misused. For instance, the pattern of the gate of Shikumen (the stone gate house) is ubiquitous, while the real logic in the application of those historical symbols is neglected. It is because consumers do not look into the truth of history and instead, they often show their affection for this kind of misusage. In this way, the culture of the traditional lane residential areas is gradually divorced from the real connotation of the culture of traditional Shanghai lane residential areas.

5.3 The problem of excessive symbolization

The most important characteristic of consumer society is being full of various cultural symbols (Celia Lury. 2003).The intensity of significance, which is mentioned as a cultural characteristic of Shanghai s traditional lane residential areas before, is the intensity of symbols. A culture, information symbols and meaningful space, high intensity of symbols should be controlled within a reasonable range. Once the degree is exceeded and there is excessive cultural information, negative effects will be caused. Excessive-symbolization in Shanghai traditional Lilong areas can be explained from the perspective of quantity and quality .

(1)Excessive quantity

Excessive quantity is mainly reflected in the symbol information provid forms. Linong space and architectural size are both small but their commercial value is increasing gradually as the cultural value of Linong space is demonstrated. Besides, commercial interests are everywhere. With shop rent increasing and more detailed division of stores, the traditional lane residential areas are invaded by more and more commercial stores, countless commercial advertisements and store logos crowd the street with a non-stopping trend, which all lead to excessive commercial information per unit area of the areas. Wandering in the narrow and small street, you can find that various logos, conceptual meanings and symbol information are coming from straight ahead, and even historical culture is covered by them, thus leading to a sharp conflict between commercial culture and historical culture. Of the 5 sample areas, Tianzifang is the most typical example, where tourists are easy get the impression of being vulgar and chaotic. ( see Figure10)

**Figure 10.** Commercial symbols are flooding Tianzifang

(2)Excessive quality

Excessive quality of symbols mainly refers to impractical exaggeration a places even make vulgar, distorted and forced-associated cultural statements to cater to tourists. Such cases can be commonly seen in commercial advertisements and happen not only in cultural descriptions of tourist spots, but also in traditional lane residential areas. For example, lots of goods are connected with Shanghai traditional culture for irrelevant reasons, works of art are becoming vulgar, while some simple products are labeled gadgets of creative culture and so on.

## 6 Conclusion

After an investigation into 5 sample areas of Shanghai s traditional Lilong that the characteristics of main consumer groups in the areas are 3 Hs (high education, high income, high social class) low age, higher percentage of international population and distinct regional features (far higher percentage of native Shanghai people), etc.

Through a statistical analysis, 4 representative consumer groups are identified: white-collar workers, college students, foreign tourists and business people, and natives of Shanghai, whose core motivation of consumption is considered to be the construction of social identity and self-identity, reflecting complex values and behavior characteristics. To better cater to motivations, the Lilong areas keep on strengthening the significant characteristics of their consumer culture like uniqueness, historical value, aesthetic views and mid- to high-end consumption tendency. The authors argue that the renewal of traditional Lilong areas in Shanghai has really improved the image of the city and stimulated consumption, but it has also led to some potential problems, such as social contradiction, the loss of the authentic culture represented by traditional lane residential areas, and the superficial trend of cultural connotations in consumption. This research intends to provide some reflections and serve as a reference for the renewal of traditional lane residential area in Chinese cities.

Keywords: Waterfront, cultural corridor, Shanghai Xuhui District

The waterfront area as an important strategic region of the international metro cultural turn in urban planning and management through international experienc area in Shanghai Xuhui District is the last remaining urban waterside area developed completely in Shanghai on a large scale and a complex of municipal fu waterfront landscape, urban waterside public space and industrial sites renovati

Through field research and investigation, studying its planning history and interviewing, referencing case studies, this article analyses the rebuilding city image and place, the roles and responsibilities of government and public agencies in operational capacity, local culture production of value and wisdom, education o cultural rights and responsibilities in the development of cultural corridor Shanghai Xuhui District. In conclusion, it indicates a culture-centered concept key to sustainable development in Waterfront Area in Shanghai Xuhui District; a n waterfront planning in contemporary metropolis that takes the middle path will e

## 1. Introduction: Cultural Turn

Nation reconstruction and economic recovery after World War II make cities enter development and expansion phase globally. Beginning in the 1970s, arts led str into culture led strategy with a broader meaning, began to be regarded as one urban renewal. Originated in the United States, this cultural turn spread to E other regions in the mid-1980s and began to impact on the development of cities 90's. This strategy by counting cultural resources into the urban planning and c contributing to the creation of public value, in the development stage of nowada produced three models. Although these three models all demonstrate the use of cu the process of urban planning, the goals are different, thus should be different

The first model is the simple use of cultural resources to promote the practice model takes the economic recovery and attractiveness promotion of the city as a obvious economic directivity characteristic. However, this model has brought a s development dilemmas. Among them, the most prominent dilemmas are dilemma of spa result in the tension of center periphery areas in the city and increasing g space; dilemma of economic development, which indicates the development of cultu cultural tourism projects are just tendencies to stimulate cultural consumption, local production chain of culture; dilemma of cultural investment, which points decide that public funds should be invested in short-term cultural festivals or facilities. (Bianchini & Parkinson, 1993)

The second model is the community movement, which is based on community, with si
characteristics of social directivity, focuses on the combination of traditional
culture and economy, the growing of the autonomy of the public. Western European
on fulfilling the public responsibility in cultural participation, and the built
and identity. Its practice is the use of non-governmental efforts to establish a
local vibrant cultural life and the activation of community traditions, to highl
features, to promote community integration. In the context of globalization, mod

## 2. Cultural Planning of Waterfront Area in Shanghai Xuhui District

Waterfront area in Shanghai Xuhui District is located in the southern extension
Huangpu River development, starts from Rihui Port in the North, ends in Xupu Bri
with a vast depth, extends to South Zhongshan Road and Longwu Road, and 2010 Sha
Park site across the river. It is one of the few downtown Shanghai land resource
planning and development.

### 2.1 History and Characteristics

According to the Huangpu River Controlled Detailed Planning of Southern Extensi
Waterfront area in Shanghai Xuhui District is divided into B, C, and D three uni
of 7.4 square kilometers, length of 8.4 kilometers along the riverbank. Within t
area of 8.546 million square meters, 287.2 hectares can be developed, and buildi
million square meters. Before 2003, the land use function in waterfront area in
District included 46% industrial and transportation land, 26% residential land,
road and square and 7% other usages. Building typology included factory building
buildings, residential buildings, public buildings and other types, in which val
and warehouse building take the largest quantity. (Sun, 2011)

Table 1. Development Information of Waterfront Area in Xuhui District

| Unit | Land area | River line | The total construction area | Land area to be developed | Gross leasable area |
|---|---|---|---|---|---|
| B | 180.2 hectares | 1.9 kilometers | 262 ten thousand square meters | 118.9 kilometers | 190.6 ten thousand square meters |
| C | 439.1 hectares | 4.3 kilometers | 529.7 ten thousand square meters | 142.3 kilometers | 294 ten thousand square meters |
| D | 119.3 hectares | 2.2 kilometers | 62.9 ten thousand square meters | 26 kilometers | 26 ten thousand square meters |
| Total | 738.6 hectares | 8.4 kilometers | 854.6 ten thousand square meters | 287.2 kilometers | 510.6 ten thousand square meters |

French National Library are located here. London's South Bank in London, after
development of half century, has transformed into Europe's largest arts center,
and old warehouses. Tate Modern, the British National Theatre, Shakespeare's Glo
Theatre all located there.

From the urban development point of view, Left Bank belongs to bottom-up spont
pattern, while the waterfront area in Xuhui District is closer to South bank of
planning model. Compared with both, the waterfront area in Xuhui District also h
location advantage, but more importantly, culture environment - art in Paris, th
UK cannot increase by short-term material built environment, which takes quite
accumulation, also needs the role of cultural, political, economic, and arts to

Another unignorable case of cultural planning is Baltimore Inner Harbor developm
1954. As a result of the regional development victory, the concept of Cultural
to the US and the world. Since the beginning of the development of Baltimore Inn
industry has played a significant role in the core strategy of the decadent area
manufacture was replaced by leisure tourism and cultural consumption. From the b
GBC (the Greater Baltimore Committee) to the Wallace company in charge of by Jam
development had the same basic idea: large-scale mixed-use flagship projects in
like the Charles Center (1959), Maryland Science Center (1976), World Trade Cent
Conference Center (1979), Festival Market(1980), the National Aquarium (1981), c
museums and other cultural facilities (1980s).

Baltimore, not only contributed to the success of waterfront development in the
including New York, Miami, Atlanta, New Orleans, Portland, and also the emergenc
number of intentional or unintentional followers all around the world, and even
invited to personally guide urban development in other cities. Aquariums, convent
museums, IMAX theaters, open public space, festivals and other large markets of
typical basic elements are moved to Sydney, Birmingham, Glasgow, Manchester, Bar
Melbourne, Izmir, Cairo, Shanghai, Columbus, Kobe, Rotterdam, Malaga, Rio de Jan
Kuwait City, Cancun, Guanica. Only in 1983, about 4000 representatives visited B
cities around the world, were eager to learn about how this outstanding urban re
2003)

Baltimore model can be simply summarized as following: the new public-private pa
policy and private capital based on cultural as development principles

Cultural corridor outdoor museum complex began with the construction two art g
Museum and Yuz Museum. Coincidentally, these two art galleries are the brands' s
The first ones are located in Shanghai Pudong (2012) and Jakarta (2009). Accordi
and Yuz Museum can be described as the West Bund versions with certain art galle

experience and brands. Cultural corridor of the overall plan includes a series creating a cultural environment, also includes a series of cultural policies.

Yuz Museum as the first museum project settled in cultural corridor , transform architect Sou Fujimoto, has a total construction area of over 9500 square meters old building (Former Shanghai Aircraft Manufacturing Factory Hangar) as much as created a transparent glass facades extending house on the eastern side. Its whi minimalist style are different from the old building, but make the new and old t convergence. (Yuz Museum, 2013)

West Bund Art Museum, which is to be put into the construction, as a public art from private museum. Led by the Government, designed by British architect David Bund Art Museum try to create an artistic and cultural exchanges between home an communicate through various top art exhibitions, cultural activities, a platform experience, to provide opportunities for the public and young people to contact

From a series of strategies of cultural corridor , we can clearly see the trace and Baltimore model , for example, the transformation of the industrial heritag complex functions, public space optimization, post-industrial landscape, and the strategy of architecture as media. However, the unique characteristics of waterf District also make it a different model of urban renewal in old industrial areas partnerships with private capital, and public participation in cultural events a experience for future.

4. Event: West Bund 2013. A Biennial of Architecture and Contemporary Art

It is against such background that the West Bund 2013. A Biennial of Architectu Art came into being. West Bund 2013, host by People s Government of Shanghai Xu undertaken and supported by Tongji University, China Academy of Art and Shanghai Development Group Co., Ltd. West Bund 2013 is an emerging biennale that combines architecture with contemporary art, and Asia s first international, interdiscipl exhibition. The biennale invited over one hundred architects and artists of inte create an avant-garde architectural and artistic spectacle characteristic of the 2013).

In the biennial, there is a unique component that is the outdoor Fabrica . This pa focuses on the core concepts of pre-fab and in-situ . The exhibition invited architects and artists from China and worldwide to work in-situ along the waterf incorporating their work into the surroundings (total area must not exceed 200 s can be a part of the main Biennial events and can also remain on as permanent wo exhibition is over (for example functional buildings such as newspaper kiosks, c stores.) One of the best examples is the project of Johnston & Mark Lee (the Uni outdoor exhibition, which became Shanghai Photography Art Centre after the exhib May 2015. The unique space features a number of semi-oval halls, a interior with ceilings and skylights, which make crescent soft natural light shines into hall, at the without affecting the experience of visitors. External shape of the building is smooth circular body blocks, and concrete area with rich texture, which play a c bold, contemporary design once as an important work of West Bund Biennial, combi with experimental gallery space. Part of the funds to carry out this non-profit sales of gallery s collection. The center also received funding from other publi

# Fall of Traditional Settlements and Countermeasures of Contemporary Planning

Seeking for balance between historic value and contemporary demands in the preservation of traditional settlement in Ancient Huizhou Area

Ziying ZHANG[1], Jingzhu OU[2], Ming TONG[2]

Key words: traditional settlements in Ancient Huizhou Area, classification methodology, preservation framework

***Abstract:*** Over the past three decades modernization in China, the traditional sett
*precious resources of both culture heritage and tourism have increasingly gained favor of tourism and entertainment. Consequently, the settlements gained profit for its resident while faced with a conflict* from three aspects. First, contradiction between the residents demand for moder and authentic feature continuation; second, contradiction between tourism s dema *and authentic feature continuation; thirdly, the authentic feature have to remain as exactly the core value and sustainable dynamics of this area. Therefore, planning have to consider an approach balancing resource conservation, economic development and living conditions improvement. The paper takes a comprehensive view of the development trend taking the traditional settlements in the Ancient Huizhou Area as an example, trying to build the framework for the traditional settlements preservation that well balances the three aspects mentioned and guide further projects. Framework building is based on careful investigation in which summarizes the central features and typology along with the all the settlements' layout database. Then the settlements are classified by their historical value to differentiate the preservation strategies guaranteeing the optimization. According to that we come up with differentiated planning countermeasures for preservation and optimization of their historical value and practical performance. It is concluded that the traditional settlements are classified to six types which are integrity-remained settlement, partially remained settlement, structural remained settlement, environment-remained settlement, limited authentic buildings remained settlement, decaying settlement. And for each typology specific planning disciplines and strategies are proposed.*

## Study background:

Over the past three decades modernization in China, the traditional settlements
resources of both culture heritage and tourism have increasingly gained the favor of tourism and

entertainment. In a consequence, the settlements gain profit for its resident, and in the same time, they are faced with a challenge balancing resource conservation, economic development and living conditions improvement. This study is subject to the National Key Technology R&D Program No. 2012BAJ08B01 and a Project supported by the National Natural Science Foundation of China (Grant No. 51378362) which taking a comprehensive view of the traditional settlements in the Ancient Huizhou Area as an example, summarizing the central features, typology and spatial structure. Then come up with differentiated planning countermeasures for preservation and optimization of their historical value and practical performance. For each typology specific planning disciplines and strategies are proposed to achieve sustainable development.

## 1 The historic process and value of traditional settlement in Ancient Huizhou Area

### 1.1 The historic process of traditional settlement in Ancient Huizhou Area

The traditional settlement originated from the Pre Qin period (before 221BC) then prospered in the Middle of Qing dynasty. (About 1750 AD) during which the main features of traditional settlement is developing with a strong planning consciousness rather than growing freely. The concerns or the function, integrity and symbolic meaning had been emphasized which is a reflection of the social needs, nationality and cosmos of the day when economy and culture were thriving.

### 1.2 The multi- layer historic value of traditional settlement in Ancient Huizhou Area

The historic value of traditional settlement in Ancient Huizhou Area can be measured in the following aspects: the environment around the traditional settlement, the spatial structure of traditional settlement, and the building communities of traditional settlement. The environment value lies in the "Fengshui" wisdom that ancestors in Huizhou Area used to guide their choice to the site of traditional settlement. The country landscape in Huizhou Area appears to be fabulous as the traditional settlement scattered beautifully in the countryside bring a rare sense of wealth and conscious gardening. The artificial space is well organized which represents the structure value of traditional settlement. The artistic space sequence starts form the nature then smoothly transit to the artificial public space, afterwards arrives in the space of private garden. Correspondingly the space are related to nature, streams of water, street and courtyard. The building communities of traditional settlement is of great architectural value that it even has a name called Huizhou Architecture. The typical architectures are village house, ancient temple and garden. Among above the traditional houses are of the biggest quantity and remarkable features as the location and planning structure reflect the influence from the mountainous landscape and Fengshui culture. Additionally the decoration style is a natural product of local aesthetic trait.

### 1.3 The differentiated situation of the historic value remains of Huizhou traditional settlement

Concerning the whole Huizhou territory, the historic value remains of the traditional settlements differentiates in several situations. The first situation is that, the authentic feature continuation of traditional settlements is perfectly preserved. Also are their integrity and harmonious unity. The village, the most common form of the traditional settlement, mainly consists of historical buildings. In the second grade situation, the authentic feature is basically maintained while new buildings merge within old ones. The historical buildings in the settlement is of certain preservation value. In the third grade situation, No original historical buildings remains while the traditional village structure is. The spatial structure and texture of old street and lane somehow survived. Following by the fourth grade situation in which the authentic architecture and original village structure are both lost but the harmonious surrounding environment is well protected. Although in such village the traditional architectural feature is not in significant level and the size of the village is usually medium or small, the relationship between the village and its environment is typical treasure given by the agricultural civilization. Finally, in the fifth village only several authentic buildings are still standing surrounded by other newly built ones. There is no a community of traditional buildings but single one of certain historical value.

## 2. Factors and Criterion for Classification and Evaluation

### 2.1 Factors

Through the study of historical value in Huizhou traditional settlement, it can come to the conclusion that the historical value of Huizhou traditional settlement mainly in four aspects: (Table 1)

Table 1:The factors of historical value evaluation

| **Building Community** | **Settlement structure** | **Surrounding environment** | **Historical buildings** |
|---|---|---|---|
| Historical authenticity | Spatial structure | Mountain | Historical span |
| Core scale | Spatial feature | River system | Cultural value |
| Historical street | Location theory | farmland | Craft value |
| Historical block | Traditional function | vegetation | Historical value |
| Historical building scale | Specific function | Nature relationship | Relic value |

**Value of building colony** is the integrated form presented by the built environment of a settlement. Space factor of Huizhou traditional settlement mainly includes: the landscape pattern of natural environment surrounding the village; the integral pattern of the settlements internal built space; the core space settlements consists of public buildings and its gathering space in front of it, such as ancestral hall, theatre and academy; and common local-style dwelling houses as the settlement texture.

**Value of settlement structure** is the layout system of surrounding environment, site selection and construction, which reflect the Ancient Huizhou Philosophy of "oneness of man and nature ".

Including the location theory, spatial pattern, spatial characteristics, traditional function and special function, etc.

**Value of the surrounding environment** is the natural environment around villages which can fully reflect the traditional village farming culture and seclusion culture, including mountain, water, farmland, vegetation and the interaction relationship between settlement and nature.

**Value of construction monomer** is specimens represents the ancient Huizhou architecture, decoration art and construction technology. Evaluation factors include history length, cultural values, craft value, historical value and `relic s` value, etc.

Extract elements respectively from these four levels in both dimensions of its typicality value and preservation of the status quo.

## 2.2 Criterion

Classification evaluation is based on the above four value aspects, and followed the principle of integrity, so that it starts from the integrity evaluation of the authenticated building colony, and then evaluates the structure, environment, construction monomer in turn. Thus evaluate the integrity of each settlement, and its traditional characteristic.

Evaluation indicators extracted from the four values are synthesize and sifted, forming the index of the classification evaluation criterion. The evaluation index are selection by means of value metrizability and effectivity for thoroughly reflecting the value state. Therefore, the building colony value will judged by authenticated retained degrees as measured by percentage. Other values of structure, environment, and monomer will be evaluated into: Intact or Destructed and Death.

Value of building colony lies in the traditional mode of inhabitation settlement, namely to fully maintain the authenticity. With the purpose of evaluating the authenticity, the indicator being chosen is the proportion with area of historical building and the surroundings in the total settlement built up area. According to the data of the ancient villages in the UNESCO's world heritage list, proportions of historical buildings and surroundings with a total area in the whole village area are concentrated in more than 60% . Therefore, 60% will be a threshold value. Finally, evaluation standard of building colony is identified as area proportion of historical building and its surroundings in the village, which evaluated into three levels: more than 60%, 30% to 60%, 0 to 30%.

Value of settlement structure reflects in the pattern of organization order in settlements artificial environment which is mainly constituted by the streets and public spaces. The evaluation considers the integrity of the history street structure; the usability of lanes and streams traditionally serving as transportation in residents daily life; the usability of spatial structure of the settlement serving as special functions such as firefighting, water supply and drainage, security and defense; or incarnation

of classic traditional theory in site selection and spatial planning. So space features and intact is chosen as index evaluated into two categories: Well Preserved or Destructed.

Value of the surrounding environment lies in the wisdom of fusion between settlement and natural environment, and emphasize completeness of various natural elements surrounding settlements, as well as the harmonious relation between settlement and its surrounding environment. Therefore, harmonious degree of settlement and natural is chosen as evaluation index, evaluated into two categories: Well Preserved or Destructed. Destruction of harmonious between settlement and natural environment means that integrity of the natural environment has been destroyed, or environmental degradation, or new construction violating the original harmonious landscape.

Value of construction monomer reflects its historical value and academic value. The evaluation will take heritage registration system as an indicative consultation to confirm featured buildings as historical culture specimens which have important value in its history, culture, or construct craft. This value will be evaluated into two categories: Yes or No.

## 3. The classification and optimization principle of traditional settlement in Ancient Huizhou area

### 3.1 Value-based classification of traditional settlement in Ancient Huizhou area

Put the index mentioned in the second chapter According to each one's importance in a descending order, then we get a matrix showing the value in several index .Then from the Matrix we concluded in the following types of traditional settlement in Ancient Huizhou Area. (Table 2)

Table 2:The classification of traditional settlement

( Integrity value to Monomer value )

| Settlement / Factors | Integrity-remained | Partially remained | Structural remained | Environment-remained | Limited authentic buildings remained | Decaying |
|---|---|---|---|---|---|---|
| Building Community | >60% | 30 to 60% | <30% | | | |
| Settlement Structure | Well Preserved | Well Preserved | Perfectly Preserved | Damaged | Damaged | Damaged |
| Surrounding Environment | Well Preserved | Well Preserved | —— | Perfectly Preserved | Preserved /Damaged | Damaged |
| Construction Monomer | —— | —— | —— | —— | Yes | No |

Integrity-remained settlement, namely the historical buildings form a complete community and occupy more than 60% of the total built area in the settlement. Besides that the authentic feature and spatial structure are well kept. The houses, waterfront, squares, central buildings stay in the old harmonious relationship. With a natural beautiful environment, farmland matches perfectly with the settlement while the artificial works with the nature. In such type of settlement, it not a single historic building of high value but the community of traditional buildings so historically high-valued buildings is not a necessity.

The second type is partially remained settlement in which the historical buildings occupy 30% to 60% of the total built area in the settlement. Besides, in the community of historical buildings, the main original spatial structure remains and is easily distinguished. The surrounding environment hasn't been damaged yet. The artificial space and nature space form a coherent whole.

Compared to the integrity- remained settlement, the partially remained settlement share some basic feature such as its environment are well-kept but the degree to which the settlement integrity is protected is not in such perfect condition as the former.

As for the structural remained settlement, the historical buildings inside which cannot form a community as they could possibly scattered around isolated from each other. The built area occupied by the historical buildings is no more than 30% of the total. The settlement has gone through a renovation process during which most of the authentic buildings are replaced except the whole structure and street skeleton. Consequently, the fabric, building density as long with the average height of the village resemble that in the past days. The surrounding environment has been inherited .Wisdom can be learned from its smart location decision-making.

Environment-remained settlement are those in which the historical buildings inside which cannot form a community and even whole spatial structure is unfortunately lost. Space being out of order lacking systematisms. The surrounding environment has been inherited in harmony with the settlement or "village".

In the limited authentic buildings remained settlement, the historical buildings inside which cannot form a community and even whole spatial structure is unfortunately lost. The surrounding environment has been damaged consequently harmony with the settlement or "village" is lost too. The only value comes from several single historical buildings.

Decaying settlement, all the elements composing the central value of the traditional settlement is lost.

### 3.2 Optimization principle classified by historical landscape value of Huizhou traditional settlement

Settlement of different value of traditional features, adopting different optimization principles and measures.

Integrity-remained settlement complies with optimization principle of Conservation, namely taking "integrity conservation strategy, from the perspective of dynamic, fully protecting of the space of lanes and alleys, texture arrangement, spatial structure, holistic pattern, construction group, the surrounding environment and all the historical element factors in the settlement. Historical buildings must be repaired, by principle of repairing the old as old", in accordance with the same way as original. Simultaneously, external new constructions shall be conventional, and be harmonious with history atmosphere.

Partially remained settlement complies with optimization principle of Improvement, namely partitioning the complete traditional area as intensive reserve area, and preserving integrally all historical elements in the reserve area, the same as the Conservation " principle, and zones outside the reserve area can be new. New constructions shall follow traditional texture, spatial logic, and be harmonious with traditional architectural style inside the reserve area. Above all, the new construction shall take responsibility of fixing the deficient texture outside the reserve area. Residents have the permission to make a certain function change, on the basis of the life needs, in their own ordinary local-style dwelling houses. The change shall follow the no- damage principle of the traditional architectural style and its surrounding environment.

Structural remained settlement complies with optimization principle of Update, namely updating the suitability of modern life on the premise of conserving the traditional settlement pattern. At the same time of necessary facilities to improve residents' life, new constructions will be permitted on the basis of the life needs. New construction shall be strictly in line with the existing landscape, traditional texture, spatial structure, scale, density, height, and the relationship between architecture and core public space.

Environment-remained settlement complies with optimization principle of Renovation. First of all, preserve the surrounding natural environment and keep the traditional way of farming and crop varieties, in order to ensure that the surrounding natural landscape traditions can be conserved. Adjust architectural composition of the existing settlement, in the meantime, so as to create atmosphere of traditional life, and convenient residents' daily life. Priority among priorities is the control of settlement s scale and its relationship with the surrounding natural environment, to ensure the harmonious townscape.

For the limited authentic buildings remained settlement, the optimization principle is Guide. That is to primarily conserve important historical buildings and cultural relics with its vicinity, entirety repair following the principle of repairing the old as old", so as to keep traditional style of buildings and the surroundings. Then generally guide the constructions in the settlement, to restore historical atmosphere

of the settlement in aspects such as texture, scale, and architectures, and ultimately preserve the important historical buildings with the effect of atmosphere foils.

For decaying settlement, the optimization principle is new-built. That is to migrate and relocate, according to the needs of economic and social development, to save land, and implement other measures beneficial to the construction of residents' production and living, and economic development. The establishment of the new settlement shall take traditional planning theory as construction guidance.

## 4. Conclusion

It is concluded that the traditional settlements are classified to six types which are integrity-remained settlement, partially remained settlement, structural remained settlement, environment-remained settlement, limited authentic buildings remained settlement, decaying settlement. And for each typology specific planning disciplines and strategies are proposed that place differentiated priority on preservation, optimization, innovation, reparation, guided construction and construction. Such planning disciplines and strategies are to guide further preservation project or development project to guarantying the quality of whole structure and spatial system.

# How the Dark Tourism Development Effect on Post-Disaster Reconstruction – the Case Study

Yue Zhong[1], Jia Feng[2]

[1] Xi an University of Architecture and Technology, 283630831@qq.com
[2]Xi an University of Architecture and Technology, 592282193@qq.com

Key words: Dark Tourism, , Role of Planner, Wenchuan.

Abstract: After catastrophe, sites and relics in disaster-hit areas usually deve provides many opportunities for the local government to improve economic develo employment and to solve other problems there. However, as national large-scale r and private donations decrease gradually, social concerns for disasters reduce the sustainability of reconstruction will be faced with challenges. This article Country, which is the epicenter of the "5.12 Earthquake" happened in Sichuan 2008 as a case study. The author discuss the dark tourism development one of the ma planned after the catastrophe and its effect on local urban and rural de structure and government policies based on the literature review, statistics dat as field research. The article focuses on the changes of mainstream culture relations, the correlation of development of tourism and other local industries in the development process of tourism which due to the cultural background a psychological characteristics, etc. This article tries to clarify the role of p development, provide the basis for planners to deal with the problem faced w Wenchuan correctly, and provide reference for other disaster-hit areas developm

## 1. Research Background

### 1.1 The concept of dark tourism

The conception of Dark Tourism is first put forward by John Lennon and Malco book Dark Tourism: The Attraction of Death and Disaster. It is defined as touri sites historically associated with death and tragedy, such as trips in the sit tourism generates strong emotional shocks in a deep way, which is totally diffe projects just for fun. Inspiring the courage of tourists to face the disaster sincere advice and warning to avoid repeat of tragedy.

### 1.2 Research status

The history of dark tourism research in academia is not long, but the number of
is large. Among them, according to the international record by Philip R. Stone
nearly 2000 related articles which use dark tourism as the keywords in googl
and the number came to 63900 in 2011. In China, by the end of May in 2015, the
91 articles which are mainly about dark tourism on CNKI and analyzed their st
know the real research of dark tourism in China started from the turn of the cen
climax in research process was caused by the earthquake in Wenchuan.

When running through the related articles, the author finds that most of the
concept defining, resource classification of dark tourism, the behavior motivation
of dark tourists, the stakeholders of dark tourism, the development mode of
dispute and effects, and they merely paid attention to the role definition and
planners in dark tourism planning.

## 2.Rethinking the development of dark tourism in Wenchuan

### 2.1 Overview of the development of black tourism in Wenchuan

#### 2.1.1 The reason why Wenchuan develops dark tourism

From the aspect of internal factors, Wenchuan earthquake has been considered
devastating natural disasters in recent years. There are various types of disa
tourism resource including inhabitation community sites of human beings, eart
hazards sites, destruction sites of previous tourism attractions and so on. B
touching stories emerging from the earthquake rescue are valuable and preciou
development of the dark tourism in Wenchuan.

Referring to the external environment, Wenchuan is a comprehensive travel
combines natural landscapes, folk customs or histories and adventure tourism
there are abundant and high-quality tourism attractions surrounding Wenchuan s
Huanglong and Wolong giant panda nature reserve. Overall, the earthquake touris
matched and integrated with these surrounding scenic spots, which can become
tourism resource.

Most importantly, the earthquake has raised Wenchuan s awareness and popularity
level. Additionally, people have paid much attention to the disaster and the rec
area, which is another aspect to gain the focus with high degree. Hence, the
people is essential to the development of black tourism in Wenchuan.

2.1.2 The Planning work for the development of dark tourism in Wenchuan

Reconstruction is a long process, so making a positive and scientific developme
meaning for the affected areas. Wenchuan enjoys its abundant tourism resource, a
of tourism has been paid highly attention.

Aba, where Wenchuan located, has become a separate area compiled in the "Aba
Reconstruction Implementation Plan" as the tourism industry-leading in the Sic
plan. The plan identifies three tourism brands: World Wildlife Heritage and
Tibetan and Qiang Cultural Tourism Brand and Earthquake Relic Tourism Brand.

This shows that although relevant plans propose to carry on earthquake relics
landscape sightseeing, earthquake science education and earthquake simulation e
monuments, memorials, relief spiritual wealth, and earthquake disaster science.
also arranges two earthquake tour lines: Chengdu Yingxiu Wolong Sigunia
Xiaojin Baoxing Chengdu, and Chengdu Yingxiu Maoxian Beichuan,
However, it also lacks targeted research and planning for dark tourism.

2.1.3 The action of the development of dark tourism in Wenchuan

In Wenchuan county, the development of dark tourism is placed as a very impor
second year after the disaster, the product of One day exploring the epicenter
promoted very quickly in Wenchuan, The highlights of this product included
resettlement village for the victims, White Flower Bridge, location of the hypo
the sky, Xuankou middle school site, the apron prime minister used, "5.12" l
Yuzixi viewing platform, and earthquake fault zone, etc.

After seven years of development, "5.12" memorial has become a national AAAA l
and the preparatory work for "Big Love World" cultural park, which takes grea
content, has been carried out, however, there is no more and deeper tourism p
tourism appears. And the tourism products are still mostly ruins sightseeing
humanistic spirit shown in the earthquake relief, lacking science education p
hazard research or on simulation of earthquake that can be participated in. (Tab

Table 1. Overview the black tourism products system in Wenchuan

| Class | Subclass | Content |
|---|---|---|
| Sightseeing category | The site of the earthquake ruins | Xuankou middle school site White Flower Bridge location of the hypocenter earthquake fault zone Yuzi |

| | The natural wonders of the earthquake | Rocks fell from the sky. |
| Education category | The exhibition about events of the earthquake | The memorial hall for the hypocenter, the memorial hal for Qiuguanghua, etc. |
| | The popular science about the earthquake | Lacking |
| Experience category | | Lacking |

## 2.2 The impact of development of dark tourism to Wenchuan

### 2.2.1 The development of dark tourism brings positive impacts to Wenchuan

1) Improvement of the construction of infrastructure

Before the earthquake, domestic and foreign visitors could only entered Wenchua 317 National Highway, there is no routine traffic tools between Tourist Attract the reconstruction and the development of dark tourism , which is quickly fo earthquake, the tourism infrastructure and supporting facilities of Wenchuan is the highway between Chengdu and Wenchuan has been fully available. Also, num between Wenchuan, Yingxiu, Xuankou, Shuimo and the Wolong giant panda nature re ecological scenic spot have good traffic capacity. Similarly, tourism facilities farmhouse, have also been greatly improved, all kinds of infrastructure like wat communication facilities, are far higher than the level before the earthquake.

2) Promotion of the economic growth

Based on Wenchuan county tourism related statistical data (Figure 1), before 200

less than 100 million domestic visitors, total tourism income was only about 2.3
the county has received more than 666 million domestic visitors, total tourism
billion yuan, comparing with 2007, it increased of 713.35% and 1139.89% resp
during the seven years of the development of dark tourism, Wenchuan s touris
income showed stable upward trend, the economic benefits brought by tourism has
before. (Yanzhen Wang, 2013.)

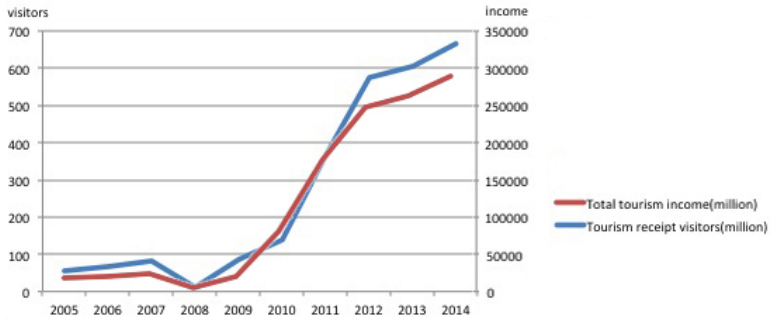

Figure 1. The development trend of tourism of Wenchuan county, 2005-2014
Source: Statistical bulletin for national economic and social development of Wen

3) Increase in employment

Tourism industry has strong linkage effect, the development of the tourism indus
promote the development of its associated service industry like catering accom
and retail and transportation, and it will reversely promote tourism developme
same time, also indirectly promote the development of other industries. (Jing L
effect not only promotes the growth of tourism and related industries, also br
jobs.

After the Wenchuan earthquake, dark tourism has a great demand for labor, al
employment level, low employment threshold, which is an important choice to ea
employment of earthquake. Xie Yuanlu, who is a professor of Sichuan Normal Uni
that in Sichuan province, the employment arrangement of every one person in to
drive the employment of 4.7 persons in entire society. (Yuanlu Xie, 2008.) Acco
2014, the county led 10000 people in employment.

2.2.2 The development of dark tourism brings negative impacts to Wenchuan

1) Hurt the emotion of residents

In the study of whether Wenchuan is suitable for developing dark tourism, some s

perception and attitude of local residents towards to develop dark tourism bas
ruins. (Zhi Li, 2011.) The results show that most residents have a positive
developing status, and focus the progress of the development. So the scholars t
of dark tourism conform to their expectation about post-disaster reconstructior
emotional taboo of local residents.

However, as per the field survey results (Figure 2) of the author, even if
occurrence of the disaster, there are still partial local residents believir
behaviors of tourists in dark tourism had caused harm to their emotions, and dar
expanded the psychological shadow brought by disaster to them.

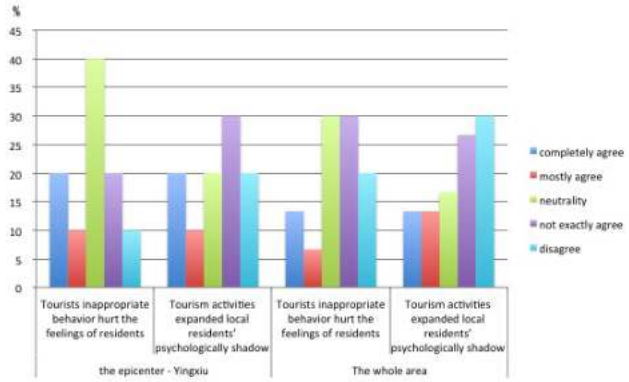

Figure 2. Residents attitude towards Dark tourism bring certain emotional damag

It can be seen that local residents maintained positive attitude to the develop
conforms to social exchange theory just because of the advantages and benef
However, the consent of local residents on the development of dark tourism wit
does not represent that they are not harmed in emotion.

2) Impacted on the mainstream culture

There are many natural landscapes within Wenchuan County, such as Wolong gian
reserve, Sanjiang ecological scenic spot, and there are also many cultural res
Qiang culture and the three Kingdoms cultural relics, etc. Wenchuan County has
hometown of Chinese folk art Qiang embroidery village", it is also the hometo
that are called the living fossil. (Committee of Chinese Cummunist Party and the
of Wenchuan County, 2011.) However, according to the main tourist attractions ir
searches on the Web after a period of development of dark tourism (Figure 3), I
dark tourism resource like Wenchuan earthquake memorial and Xuankou Middle Sch
more than people's attention comparing to other resorts.

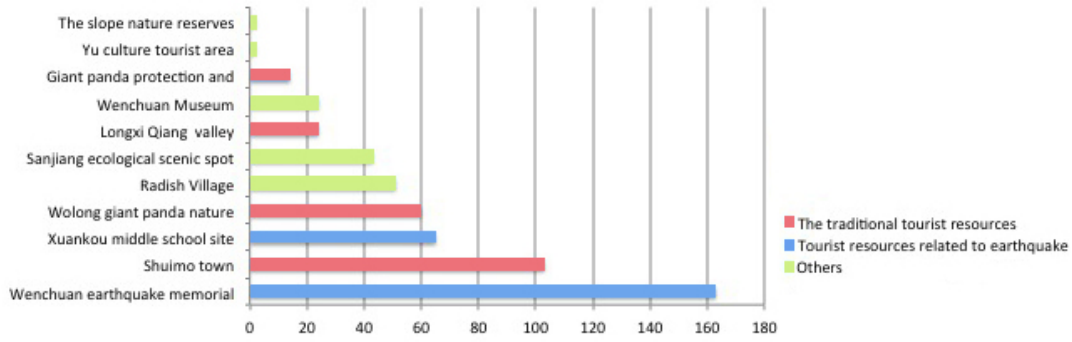

Figure 3 Search volume for major tourist attractions in Wenchuan County,

Source: http://www.mafengwo.cn/travel-scenic-spot/mafengwo/10691.html

And through the feedback of the questionnaire survey to local residents (Figure residents made it clear that the local cultural identity gave by the dark tour local traditional culture, and the number of residents who think the dark impacted on the local traditional culture, is only less than one third.

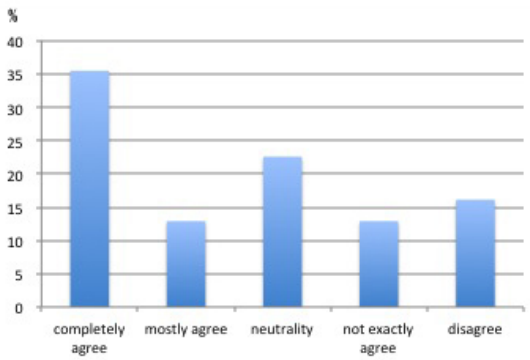

Figure 4. Residents attitude towards dark tourism on local traditional culture

Therefore, whether it is from the perspective of the outside of Wenchuan under point of view of local residents, the original culture, landscape resources an the traditional culture to them in Wenchuan, are suffering from the shock by tourism resources and the characterization of new cultural elements for them aft

3) Widened the gap between the rich and the poor

Figure 5 shows that it is generally believed that economic interests generate only benefit certain people. In particular, on one hand, in the initial stage o tourism, partly original rich residents recovering rapidly after disaster and benefit the most because they occupy most of the catering and lodging marke

advantages of capital and connections. On the other hand, residents living ne
tourist transport centers of dark tourism can get more economic benefits from th
tourism through low-budget personal business as they have easier access to most
dark tourism.

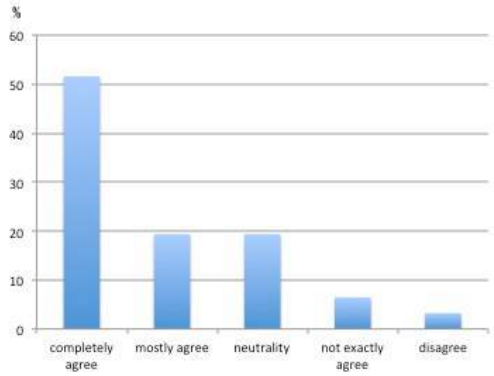

Figure 5. Residents attitude towards Dark tourism benefit only certain

The unfair distribution of tourism benefit widens the income gap between reside
to notice that some residents who benefit from dark tourism emigrate from Wench
cities like Chengdu after income improving result from the longing for city
earthquake, which causes not only the tense relationship between neighborhoods t
also increased uneasy of local residents.

3. Discussion on the role of planners during the process of post-disaster recons

Based on the analysis of the problem above,and combined with the development c
tourism with scientific planning. The author believes that, for dark tour
post-disaster reconstruction, planners should pay attention to the following fou

## 3.1 Composite type of product - make a transformation of product type multiplex

As mentioned before, after seven years of the development of dark tourism, the t
is still related to relics, memorial stadium in disaster and use them as sellin
the form of production is mainly in low-end and extensive ones. However, this s
so simple, is not enough to support long-term development of dark tourism .

Therefore, when designing dark tourism commercial activity, planners should fir
activate relic-type resources via stage play exhibiting earthwork relief humani
hand, it can facilitate disaster-hit area residents to acquire benefit via dir

tourism activity; on the other hand, it can show the cheerful and positive life in the face-to-face contact between tourists and survivors.

Secondly, planners can design tourism products with strong participation and s and education connotation such as geological disaster scientific research and experience combining with anti-seismic lab, so as to further enrich the vari products and strengthen local tourism attractiveness.

Finally, similar to tourism product of any theme, only all-weather commercial a attract and retain tourists. Thus as to Wenchuan, increasing night products with pos such as candle blessing concert to change the tourism commercial activity of morning to have a look and coming back to city at night for lunch can not only income, but also promote the mutual understanding between tourists and local re be of positive significance to the development of dark tourism.

### 3.2 Humanities concern - from tourists first to the local residents first

Dark tourism plays a positive role to educate tourists cherish life. However, d needs to be based on a period of painful memories that will bring some emoti residents inevitably. Especially for Chinese, who have traditions and cultural peace and luck and avoid disaster, death etc., although there are a number of cases in international arena, deep-rooted traditional attitudes and patterns of taboo to present dark tourism by the form of disaster and death.

Hence, during the development of dark tourism planning, planners should pay atte Firstly, we must respect and understand Wenchuan local residents traditions and If it involves some sensitive issues, such as death and disaster, planner shal project that is acceptable for the earthquake survivors, and the project shall b that planner understand local people s wishes and fully respects their trad emotions. In addition, to avoid dark tourism bringing back local residents pa tourism shall reduce the description of pain of the disaster, and tend to guide memory for the earthquake victims.

Secondly, the development of dark tourism in Wenchuan is certainly conducive t economy and promote reconstruction. However, there are some over-commercializat dark tourism exploitation - such as chrysanthemums can be presented in Xuankou through buying flowers in the form of donate , which is also a kind of dama self-improvement Wenchuan survivors. Therefore, planner should adhere to the gov organizations as dominant role when they designed the dark tourism operators

business conducts which will undermine the image of the local residents and hurt residents.

Finally, planner should not only make arrangements for dark tourism products, d work, etc., but also should take guidance measures to the behavior of dark to guidance for Xuankou middle school site, cemeteries of killed people or othe restrict tourists disrespectful act, such as frolicking, inappropriate photogra act would incurring discontent of survivors.

### 3.3 Combining with present and future – from a single cultural element to elements.

With regard to the dark tourism that was caused by earthquakes and other nat development of its tourism activities often went out attention as time gradually in the development of dark tourism in Wenchuan, the impact of new tourism Wenchuan surpassed its original tourism label, such as Panda Hometown , Qi Village if we just stressed the earthquake relics and failed to combine its local to Then, as the memory of calamity gradually faint, the existing competitivenes resources will reduce.

Therefore, designers must be clear when plan the tourism that Epicenter Wench cultural element caused by natural calamity and people s attention. It could be cultural element in local in a short time, but it must has the overall relation the other cultural elements based on powerful nature and long cultural tradition

In the real action, designers can do from two aspects. From the perspective o Xuankou middle school site, location of the hypocenter and other local touris Wolong giant panda nature reserve, Mt. Siguniang etc., to form a continuous com belt. From the perspective of the content of the products, combine the villag relics and damaged with the concentrated areas of Zang and Qiang ethnic minor show the new look of affected areas in the form of reconstruction and the t contains Zang and Qiang culture, natural scenes, and other tourism advantages tourism can benefit other affected resorts and tourism resources in the early t same time, it can also maintain sustained vitality in the local tourism resource

### 3.4 Contacting with different space – from point-like development to the development

The unfair distribution of income from dark tourism, as discussed above, could

management measures like giving jobs and welfare to moderately benefit the di
More importantly, fundamentally integrate dark tourism resources and rural area
engage local people from different areas to be a part of the dark tourism throug

With regard to tourism resources, the planner of dark tourism should alloca
spatially according to their distinctions. For example, the horrifying disaste
named after Wenchuan, at which the core of the tour should have been. But res
famous Xuankou Middle School site were located in Yingxiu, a town 60km away fr
Given such circumstance, the planner should regard Yingxiu as resource-rich tour
main target is to the relics original and real, while Wenchuan should be regarded a
tourism region where artificial efforts should be done through publicity and exh
disastrous earthquake. By doing so, we can build up connection and spatial cor
asymmetrical tourism resources.

For the development of urbanized tourism, villages and small towns in Wenchuan
foundation for leisure agriculture rural tourism by planting cheery and kiwi f
actives don t operate as a holistic business even though they re all named after We
planner could try to boost the bundled development for dark tourism and rural
providing better traffic connection and planning themed activities. With these
attraction of dark tourism to the whole region instead of several key nodes, we
tourism business that benefits all of our people.

4. Conclusion and outlook

In recent years, the development of dark tourism in Wenchuan has been increasi
also brought some influence to Wenchuan. From the related planning, practice an
tourism in Wenchuan, it can be seen that the development of dark tourism is a
also needs multiple participations. As the strategists whom the local governmen
and local residents rely on together, the planners should fully pay attention to
culture and psychological characteristics in the planning of dark tourism, pro
from being hurt in the dark tourism activities. At the same time, the planners s
interests for most people by the means of spatial layout, product design to sai
order in the developing process of dark tourism and make overall judgment ab
development of the local entire tourism including black tourism to make sure th
of dark tourism that are suitable for different phases after disasters in the lo

In addition, to discuss the influence of dark tourism in post-disaster reconstr
combine the dark tourism planning with economic and social development planning,
overall urban planning, land use planning, ecological control planning, urb

planning and so on. How dark tourism planners promote the post-disaster recon
background of combining rules should be an important subject that needs to be e
future.

# TRACK 16

# Planning Responsibilities in the Face of Information Technology

## Track description

Co-chairs: **Paulo Silva**, **Michele Campagna**

In the rising era of big data and ubiquitous computing and sensing, new information resources open unprecedented opportunities for knowledge building, design, evaluation and decision-making support in spatial planning. Public institutions are not anymore the only actor controlling information flows as authoritative sources of information are paralleled by volunteered ones opening new possibilities for pluralism in knowledge building.

Since the welfare state crisis spatial planning became an activity not anymore exclusively under public control. The need to share responsibilities implies also the share of information. Collaboration and communication became critical factors for more responsive forms of planning as societal claims for access to information in planning may became a way to build citizenship and democracy. Hence, Information flows became central in planning debates.

However many ethical issues arise related to personal privacy, selective access, data representativeness or transparency of data processing. How to provide equal access and equal opportunity to use the information? How to get those without effective access to ICT participating in planning? How the responsibilities should be spread among all the actors?

Considering the information technology development, the shifts in planning processes and the claim for new ways of government, authors are kindly invited to submit their contributions aiming at clarifying such issues as:

- What is the role of information in decision making?
- Does more information mean better planning?
- How can information technologies adapt to a context of planning within fuzzy responsibility?
- How can information sharing deal with contexts of poverty, marginality and unequal access to ICT, contributing to citizenship and democracy?
- How do planning professionals integrate new technologies into the planning process?

These issues contain a less explored debate around ICT and spatial planning, which, considering the topic of the present congress makes much sense to be addressed. Such themes as Geodesign, Spatial Data Infrastructures, Volunteered Geographic Information and Social Media, Big Data, Virtual Geographic Environments, spatial analysis and models, Planning Support Systems, and Smart Cities are particularly welcome, but the track is open to the combination with other relevant themes raised by this topic such as governance, public participation or planning processes.

# The Role of User-Generated Emotion Data and their Optimized Visualization for Planning Decision-Making

Benjamin Sebastian Bergner[1], Daniel Steffen[2]

[1]Urban Sociology, University of Kaiserslautern, Germany, benjamin.bergner@ru.uni-kl.de
[2]AG wearHEALTH, University of Kaiserslautern, Germany, steffen@cs.uni-kl.de

Keywords: Emotions, GIS-based Visualization, Event Monitoring

## Abstract

*With the rise of wearable technologies in the field of ambulatory assessment and commercial body monitoring products, the human being itself becomes a sensor of its immediate environment. In particular, user-generated vital data allows to draw* conclusions from peoples emotions *at every time and everywhere. This fact poses the question to what extent this data can be used for planning decision making.*
*For decades, ambulatory assessment methods have been* used to identify humans emotions *linked to distinctive stimuli. The research is mostly done in laboratories under controlled conditions. Knowledge transfer to real world applications is still rare due to many uncontrollable environmental issues. Psychophysiological monitoring, however, shows high potential of transferability to real-world studies.*
*If this user-generated emotion data is to be used for planning decision processes, many challenges have to be met: a) providing valid physiological, geo-referenced data in a real world environment, b) preparing and processing data for following analyses, c) joining individual and environmental meta data, d) optimizing emerging visualizations and identifying emotional stimuli as basis for planning decision-making.*
*The research at hand confronts these challenges, exemplified by a case study in the field of urban safety and security. It aims at identifying stress eliciting stimuli during an open air event. The methodical approach comprises physiological data collection and analyses, standardized questionnaires of stress experience and event perception, subjective self-assessments and spatial analyses of the surroundings as well as the combination of the results in different GIS-based visualization techniques.*

## 1. Introduction

Planning decision-making in urban and environmental planning is a highly complex process involving strong responsibilities. These responsibilities are manifold - including ecological, economical and sociological aspects. Planners, as main coordinators of spatial planning processes and therein different groups of players, have the duty to ensure citizens quality of life by preparing decision-making basis for politics. Citizens quality of life is reflected on different levels. Besides standard of living and social security, everyday quality of life is shaped by built environments and acceptable surroundings. To determine areas that are perceived as uncomfortable or unsafe, classical methods like interviews, observations or standardized questionnaires are used to collect the needed information. All these methods have the short-comings, that information is based on cognitive self-perception, experiences and social desirability. For a few years now, thanks to the fast technological progress, it is possible to measure and track physiological vital data as indicators for emotions in spatial environments. That in turn gives social scientists and urban planners the benefit to receive information about ci being (or stress) free from the mentioned short-comings at every time and everywhere. As precondition, people have to be equipped with body sensors for measuring physiological changes and

GPS trackers to determine their positions and routes. This method of psychophysiological monitoring implicates that it is still experimental, but shows high potential to get a more concrete and self-uninfluenced picture of spatial environments from a citizens perspective.
In this paper, the authors want to introduce and discuss this methodical approach as a real-world application, based on the experience of environmental planning studies on the one hand and the methodical approach exemplified at an open air event on the other hand.

## 2. Research Background

Improving human well-being is an essential part of many planning actions. The aspect of feeling safe and secure in the immediate environment influences the behaviour and provides a positive image of the space citizens live and move in daily. Environmental planners can strengthen that feeling by shaping the space around us adequately, e.g. accessibility for disabled people or avoiding places which cause anxiety with the help of lighting concepts. In practice, many disciplines (sociologists, psychologists or event planners to name a few) deal with this topic.
The research at hand is part of the research project Support Systems for Urban Events Multi-criteria Integration for Openness and Safety (MultikOSi) , research programme Research 2012 - 2017 , topic Urban Safety and Security , funded by the German Federal Ministry Education and Research. In the sub-project Social Aspects for Comfort and Safety at Urban Ev the authors occupy themselves with the measurement of well-being of event attendees, the planning and organization of safety as well as spatial components. In case of measuring the well-being, classical methods like questionnaires, observations and interviews are conducted, but extended by the here presented psychophysiological monitoring in a real world application.

### 2.1 Contextual Background

Communities are more and more in competition in order to obtain the status of an attractive place of residence and an attractive travel destination. Part of liveable communities and environments are increasingly open air events like city festivals, sport events or concerts. A favourite instrument in public sector marketing is the organisation of big events, which are magnet for numerous visitors of different milieus (Häußermann/Siebel, 1987). They allow the experience of entireness, community, mutuality and corporate identity for people with different backgrounds. In terms of socio-scientific collective experience, festivals and events are understood as largely emotional, by affect dictated events. They produce current, spontaneous, emotional and enthusiastic behaviour, which is not only socially allowed, but actually desired (Gebhardt, 2008, p.207). The common order is often dissolved. Violation of the order are in part explicitly allowed or tolerated (e.g. at street festivals). This behaviour includes a certain risk concerning the safety at events. Current state of research says, that feeling safe is an individual condition or emotion. This condition is composed of the general framework of (public) space and the personal perception (Floeting/Seidel-Schulze, 2012, p.1058). Spatial framework conditions are variables like path width, soil conditions, barrier-free design, view-shafts, lighting and knowingly placed obstacles (Reuter et al., 2012). Subjective attributes are factors like individual sense of self-worth, the capability of the body or the openness when dealing with other groups of people. Especially with increasing age, the dwindling of body s own capability leads to heightened percep of safety in (public) spaces and thus to heightened expectations towards safety measures (Ziegleder et al., 2011).
Visiting an event also comprises the arrival and departure, respectively the routes attendees take to come to an event and leave on their way back home. Planning an event consequently involves transport infrastructural aspects. Many events are characterized by security controls at the entry of a closed off area in order to avoid certain sources of risk. Masses of people can also be a danger for the attendees. That happens when the entries are too narrow, contraflows are allowed or the outflow of

people doesn t work (e.g. at the catastrophe at the Loveparade in Duisburg 2010). Another reason long queuing times, with the consequence of building up a throng where people get bothered by others. Every now and then triggered stress and feelings of being unsafe can lead to risky behaviour towards other visitors or private security personnel, as well as to avoidance behaviour, and strongly affect the safe course of the event. Safety, security and comfort are significantly dependent on social action, attitudes and value systems of the visitors of the event. According to the sort of visitors, the chosen safety measures differ (e.g. quantity of private security personnel, barriers (fences, hoarding), etc.). A further relevant factor is the trust of visitors in available information in case of risk as well as trust in present private security personnel. In addition, the trust of private security personnel in event managers/planners and hosts plays a major role. Last-mentioned protagonists have the duty to execute a risk management based on a risk assessment in case of danger or emergency (Renn, 2010, p.165). These facts emphasize that planning of events is a highly complex process, involving many different players and information channels. The consequences of a bad planning are obvious the endangerment of the health and well-being of event visitors and all involved parties on-site. The guaranty of a safe stay is an essential requirement for large quantities of people visiting communities and events. An attractive and successful event thereby contributes to an improvement in identity and image and to an increase in competitiveness of a community (Getz, 2012, p.40).

Event planning and the ensurance of safety of such events is in a way comparable to tasks environmental planners are confronted with, regarding the complexity and involvement of different groups of players. Though, the constructional actions are generally temporary with the exception of really big events, like a Football World Championship or Olympia.

The example of the sense of safety in space and especially at events emphasizes the importance of emotional data of visitors and security personnel. If this data can be made available properly, it can influence planning decision-making for upcoming events as well as environmental planning actions in terms of design of space.

## 2.2 Methodical Background

As part of subjective well-being, emotions are a current, affective state of the individual, triggered by immediate experienced stimuli or events (Diener et. al, 1997; Kahnemann/Krueger, 2006; Fischer, 2009). In literature many differently named basic emotions exist. One of the leading researchers and pioneers in the study of emotions in context of facial expression is Paul Ekman. In his early work he distinguishes between six basic emotions: happiness (enjoyment), sadness, anger, surprise, disgust and fear (Ekman/Friesen, 1971), which are still valid in his later work. Anger and fear are highly negative emotions, which are follow-ups of stressful situations (Lazarus, 1993, p.12). According to Lazarus/Launier (1978, p.296) stress is any event in which environmental or eternal d exceed the resources of an individual, social system, or tissue system . F nonspecific response of the body to any demand (Selye, 1976, p.53). For both stress scientists, not only internal factors, but also external and environmental factors are responsible for experienced stress. Selye (1976, p.54) names specific environmental factors like air pollution and social influences as antecedent condition for stress, Lazarus (1993, p.5) names harm, threat and challenge, experienced in the environment or within the person. *Harm* refers to psychological damage that had already been done [ ]. *Threat* is the anticipation of harm that has not yet taken place but may be imminent. *Challenge* results from difficult demands that we feel confident about overcoming by effectively mobilizing and deploying our coping resources (Ibid). He further gives the exa unpleasant state of mind that may seriously block mental operations and impair functioning Just the terms threat, or in case of events the term danger, and harm are crucial conditions, which especially event planners want to avoid. Possible threats to events have to be identified in the planning process beforehand, in order to formulate danger avoidance and minimization strategies. Threat, or

danger, at events implies a situation or behaviour, which causes harm and damage to property or people with a high chance, if the course of events is unhindered (Drews et al., 1986, p.220).
Event planners as well as all involved groups of players (e.g. communities, fire brigade, police, private security companies, emergency rescue services, etc.) can fall back on manifold experiences concerning possible dangers at events. Resulting in an extensive catalogue, these are for example crowds, fire, collapse of constructional parts, danger by violent or drunken people or breakdown of relevant infrastructure (Hessian Ministry of the Interior and Sports, 2013).
Consequently, the event visitors themselves can act as immediate and direct detectors for threats or risky situations. If and how danger is individually perceived by visitors depends on their subjective, intuitive risk perception. This risk perception is affected by different factors. These are given information about the source of danger, psychological processing mechanisms of feeling unsafe and previous experiences (Renn, 2010, p.163).
In summary, there is a consistent story here; that feelings of safety have an interdependence with risk perception, emotions, feeling stressed and physiological changes, triggered by certain situations which are environmental, inner psychological processual or determined by social interaction with other people.
In research, emotional experiences in linkage to distinctive stimuli are typically acquired in laboratory experiments under controlled conditions and self-reported data, in form of questionnaires and interviews. The principal aim of the research at hand is the investigation of real-life emotions beyond the laboratory. The experience of emotions in laboratory settings can likely differ from natural unfolding emotions in the real world. Influencing factors for example are the lab environment itself, the feeling of being controlled, the alien technical apparatuses and sitting immobile for at least many minutes (Wilhelm/Grossman, 2010, p.555). The acquisition of emotion data via questionnaires and interviews also has its short-comings. They rely on retrospective memory recall with the problem that information can be forgotten, especially over a long period of time. Most recent events can also influence the overall ratings of emotion. Furthermore, retrospective recall is subject to idealized self-concepts and -perception, social expectations and desirability (Wilhelm/Grossman, 2010, p.556; Redelmeier/Kahnemann, 1996, p.6.; Pohl, 2004). When the specific aim is accurately as immediate experience, these factors [of retrospective recall] induce error variance at the best and systematic bias at worst (Wilhelm/Grossman, 2010, p.556). The here presented study engages in providing naturalistic emotion data in a real-world application, derived from physiological data (e.g. skin conductivity, heart rate) of test people during an open air event. The test people act as a sensor of their immediate environment. The authors want to find out where (spatial), when and in which situations stress as precondition of feeling unsafe is experienced. Almost all current scientific knowledge about emotions is based on laboratory research or inferred from retrospective reports, although understanding real-life emotions is clearly the principal aim (Wilhelm/Grossman, 2010, p.552). Ambulatory assessment means the objective real-time data acquisition of physiological marker with the help of wearable devices, which are more and more operational outside the laboratory (Papastefanou, 2009, p.443). Within ambulatory assessment, psychophysiological monitoring offers the most pragmatic and reasoned method to continuously and objectively measure vital data of test people. Other methods are experience sampling and behaviour recording. In case of psychophysiological monitoring, measurement devices are wearables with primarily non-invasive sensors. The measurement specifically focuses on changes in vital data, triggered by the prime biological emotion- and stress-reacting systems (Wilhelm/Grossman, 2010, p.559). Two main criteria for identifying affect-based physiological changes have turned out: a) Changes in vital data have to be recorded in real-time and for every instant during the study; b) the measurement must not hinder or disturb the individual in order to avoid the collection of influenced vital data by the method or measurement device itself (Bergner et al., 2012, p.740). For real-world studies it is also important to know where exactly the changes in physiological data have taken place. So it is necessary to equip the test people with a GPS (Global Positioning System) tracker, while moving through the study area.

After gathering and analyzing the resulting data for indications of certain emotion patterns, the next challenge is to make the data available for further analyzing in the context of space.

## 2.3 Visualization Background

The idea of mapping peoples perceptions and emotions in space is not new. Kevin Lynch with his concept of mental maps worked out, that people are able to memorize paths and key locations in urban environments and draw a mental image of the city they live in. He found out that five basic elements exist, which people perceive and construct their mental image of a city from. These are paths, certain areas or districts, significant edges (e.g. walls), nodes (e.g. junctions like crossroads) as well as landmarks. How these elements are perceived is a two-way process between observer and the observed object (Lynch, 1960). Almost half a century later, Christian Nold introduced his projec Mapping as one of the first psychophysiological monitoring projects in the cont His intention was to use this method as a participatory bottom-up approach to improve a sense of community and citizens own identity with their residential area. Nold deals with the question how citizens perceptions of community and environment will change when they become aware of their own and others intimate body states (Hope, 2009, p.75). In his studies (e.g. Greenwich Emotion Map) he sent people through their residential area, equipped with a galvanic skin response sensor at the finger as well as a GPS tracker for locating the wearer s position on earth. In ret shows the participants their walk as a personal emotion map. The track shows the wearer s geographical location while the height indicates the intensity of physiological response at any particular point. The response can be positive or negative and requires active interpretation to make sense of it (Nold, 2009, p.67). Despite the weaknesses in data accuracy and subjective interpretations as well as visualization, Nold coined the term Emotion Map or Emotional Mapping and is seen as pioneer in combining psychophysiological indications of emotions and geo-referenced data in a spatial context.

The visualization of geospatial data is an important task in environmental modelling, data analysis, and geographic applications. Specifically, two-dimensional maps offer a well-known way to present a static visualization of geographic data. Additional variables can be displayed with the help of contours, colours, and heat-map overlays.

However, when considering complex data sets that contain geographic locations, time series, and multiple variables, the visualization and data mining of spatio-temporal data is a challenging problem. When thinking of multivariate time series it is also important that the visualization is tailored to the needs of the end-user, i.e., both domain experts and non-specialist public, in a way that the visualization instantly shows whether something is good or bad.

The main challenge in visualization of spatio-temporal physiological data is the integration and optimization of emerging visualization techniques as basis for the planning and decision process. Having information displayed in a way that it is easy to understand is crucial. Without this kind of visualization the participation of the public in a decision and / or planning process is limited. The visual effectiveness (Guo et al., 2006) concerns the usefulness of data views in revealing patterns. With a large data set, data items can overlap in the visual display and make patterns very hard to perceive.

With the aim of effectively visualizing multivariate, spatio-temporal data mostly two solutions have been proposed in literature: (1) animating data in a 2D representation or (2) extruding 2D representations into a third dimension. Digital Globe Systems, e.g. 3D virtual globes, meet these requirements and offer the possibility to use the third visualization dimension.

The idea of a digital earth was described for the first time in 1991 by Ne Snow Crash : A globe about the size of a grapefruit, a perfectly detailed re hanging in space at arm's length [ ] It is a piece of [ ] software called, simply, Ea interface that [ ] uses to keep track of every bit of spatial information that

weather data, architectural plans, and satellite surveillance (Stephenson, 1992, p
Berlin company ART+COM developed TerraVision , inspired by Stephensons novel
system on SGI-units. TerraVision is a 1:1 virtual copy of planet earth. One significant feature of TerraVision is the human machine interface. With the help of an interface, designed like a globe, the so called Earthtracker, the user gets the possibility to navigate to every desired spot on earth interactively and in realtime over the virtual globe (ART+COM, 1994). The first and free consumer based virtual globe system was developed by NASA and was called World Wind (NASA, 2013). For the first time, it was possible to import and export spatial data through a user interface. In addition, the integration of Web Map Services and the visualization of textured meshes were realized. Keyhole Earth Browser, in the beginning operated by Keyhole, was the initiation point for the development of Google Earth, which is today the best-known and widespread software for digital globes. As associated programming language, the Keyhole Markup Language (KML), also developed by Keyhole, is established as an Open Geospatial Consortium (OGC) standard by now.

All the above-mentioned systems offer different import and export functions, but there are only a few options to develop some additional new types of visualizations. There are some software tools available, which can transform collected data into 3D visualizations, which need to be combined manually for an appealing look. An integrated and interactive 3D-GIS application, which allows the easy integration, visualization and animation of heterogeneous data are not available today.

Within this paper the authors target the visualization of spatio-temporal physiological data, i.e., stress at a specific location at a specific time, from multiple users during large events. Stress is a major concern in our daily life and impacts both individuals and society. Furthermore, stress is a big concern when looking at the safety during events with a large audience, e.g., soccer games or music festivals.

Due to the nature of the data that has been collected during the execution of the experiment, as described above, visualizations have to be applicable for multivariate spatio-temporal data. Guo et al. (2006) present a geovisual analytic approach and the implementation of a visualization system for space-time and multivariate patterns (VIS-STAMP) that integrates a suit of visual, computational and cartographic methods. The implemented system is capable of effectively detecting and visualizing geographic, temporal, and multivariate patterns in multiple ways using a self-organizing map (SOM) and a parallel coordinate plot (PCP). The authors state that the system is limited when it comes to small-sized spatial objects, since they are barely visible on the used two-dimensional maps. The technique Lexis Pencils provides a way of viewing event history data. The approach uses a pencil metaphor and maps different time-dependent variables onto different faces of a pencil, starting with the top of the pencil (Francis, 1997). This visualization allows controlling the color mapping, the width of the pencil faces, and the assignment of the variables to the faces. Here, the pencil point could mark a static location in the spatial context of a 2 ½ D or 3D representation. The advantage of this approach is that both continuous and discrete variables can be shown in one plot. However, depending on the complexity of the time series this technique might not be tailored for large time-dependent data sets. Forlines et al. (2010) present the Wakamevisualization system. The Wakame system extends a multi-dimensional radar chart (2D technique) for static data by extruding into a third dimension to represent time. Thus, sequential measurements become radar-graph profiles at different heights of the ground plane. The shape that is formed by the radar profiles at different heights, i.e., at different time steps, illustrates the changes in the time-dependent dataset over time. As with the previous visualization techniques this method allows assigning different colours to the variables of the dataset, i.e., the vertices of the radar profile. However, in order to create an easily understandable visualization the user has to pay attention to the ordering of the variables around the centre axis. Tominski et al. (2005) present the Helix icons for visualizing spatio-temporal data on maps. This technique is especially useful for time-dependent data that has cyclic characteristics. A spiral helix provides the geometric shape. The helix icon is made of a spiral ribbon where every time step extends the ribbon in angle and height. Again colour coding can be used to encode data values along the ribbon. In order to be able to represent multiple variables the ribbon can be subdivided into smaller ribbons. Finally, the

interested reader is referred to the work of Aigner et al. (2010) providing a detailed overview of different visualization techniques for time-oriented data.

## 3. Relevance and Objectives

The education of environmental planners is already in certain terms a cross-sectional field of study and in praxis very interdisciplinary. There are many information and data channels a planner has to filter and coordinate. In case of sociological aspects, like the identification of well-being in spatial environments, classical methods like questionnaires and interviews with citizens are primarily used. With the rise of new wearable body sensors it is possible to identify indications on human emotions towards their imminent surroundings everywhere, at every time and in particular unaffected by personal views, experiences and social desirability.
The main objective is the development of a decision support tool for planners across disciplines. The tool should better the understanding of emotions and consequently of the behaviour of people in and towards space with the help of body monitoring technologies. Out of it the questions have to be answered how the emerging emotional data is visualized and what conclusions can be drawn.
Exemplified by a case study at an open air event, the authors want to illustrate how body monitoring technologies can be applied, what data can be elevated, how this data is processed and visualized as support tool for planning decision-making. The usage of ambulatory assessment in real-world studies is still experimental. As a consequence the following challenges are inherently methodical:

(a) providing valid physiological, geo-referenced data in a real world environment
(b) preparing and processing data for following analyses
(c) joining individual and environmental meta data
(d) optimizing emerging visualizations and identifying emotional stimuli as basis for planning decision-making

The potential gain for environmental planners in general and in context of safety of open air events is obvious. In a last step, the authors critically deal with the usage of this data and their significance for decision-making at this juncture of research.

## 4. Conceptual Framework and Study Design

In order to exemplify the introduced methodical approach and in context of safety at events, an experimental case study at the event Back to the Woods Open Air 2014 in Gar
July 2014 was conducted. It is a one-day outdoor music festival with about 5000 attendees. The event was stopped and cleared because a massive thunderstorm with intense rain, lightning strike and sudden drop of temperature has occurred.
The resulting data was derived from six student test people, whereas three were female and three male and aged between 20 and 24. An average state of health, no physical limitations as well as a typical age for the character of the event were preconditions. The test people didn t have to perform a s
task during the study. They should behave naturally and in their usual way. Only if they get too drunk, they should end the study and come to the meeting point. After a short briefing, the test people signed a letter of agreement and data protection. Next, the measurement device for physiological data, in form of a comfortable wristband, was strapped around their left wrist, in order to provide an adjustment period. Before the beginning of the study, the test people had to complete a self-evaluation questionnaire concerning their actual mental state. Afterwards, they received a GPS tracker and a tape recorder for subjective self-assessments when they felt extremely stressed and unsafe. All the devices were switched-on at the same time for later data synchronization. Then they were sent out to experience the open air festival at the event area for as long as they desired. At the end of the study,

the devices were turned off and the test people had to complete a general questionnaire with questions to event affinity, perceived sense of safety, social basic data, personality traits and the same self-evaluation questionnaire concerning their actual mental state as at the beginning of study.
The research area is situated on a meadow, enclosed by woods and two streams from north-west to south. The complete area is surrounded by a hoarding. The main entrance and the pay desk are located in the south/south-west. In the eastern part there is the main stage, in the western part and the central area opportunities to get food or drinks. There exist four emergency exits: one to the south and west, two to the north. For later spatial analysis, it makes sense to classify the research area in different specified zones (dancing and stopover, bar, food, toilets and entrance) (see chapter 6).

## 5. Methodology

A mixed method approach, including psychophysiological monitoring, self evaluation questionnaires, subjective self-assessments as well as visualization techniques and spatial analyses, should meet the challenges specified before. The first challenge consists in providing valid physiological, geo-referenced data in a real-world environment (a). For physiological data acquisition the sensor wristband BMS Smartband was used, developed and manufactured by Bodymonitor Systems Gilching, Germany. It measures skin conductivity, skin temperature, outdoor temperature, triaxial acceleration and electrode contact pressure. The BMS Smartband enables to collect peripher-physiological data in real-time and location-independent (www.bodymonitor.de, 2015). The authors aim to identify stress reactions by the test people as precondition for feeling unsafe. Basic emotions reflecting stress are anger and fear (see chapter 2.2). These emotional reactions come along immediately with changes in the autonomic nervous system activity, which is reflected in specific physiological parameters (Kreibig, 2010). In consensus with researchers in emotion, a negative experience (anger or fear) is existent, when skin conductivity increases (Kreibig, 2010, pp.401/403) and shortly after that skin temperature decreases (Kreibig, 2010, pp.401/404). A well-known example is the cold sweat, resulting from fear. These findings were confirmed in a statistical validation study with the BMS Smartband. Here, it was ascertained that collected changes in skin conductivity (increase) and skin temperature (decrease), measured by sensors on the inner side of the wrist, during stress episodes are reproducible (Papastefanou, 2013). The theory behind this and the measurement device itself proves, that valid physiological data can be provided. In regard to the aspect of geo-referenced data, the GPS tracker G-Log 760 by TranSystem Inc. (www.transystem.com.tw) was used, which collects satellite signals every second. A later synchronization with the physiological data was hereby unproblematic.
Preparing and processing the resulting data for following analyses (challenge (b)) was carried out retrospectively. Especially the processing of the physiological data is a time-consuming work, which is absolutely indispensable if done properly. A necessary first step is data reduction to a one second signal, because of the sample rates (e.g. skin conductivity:ten samples/s (10Hz)). Added up in about five hours, 180.000 samples are received. The serial nature of ambulatory dat identification of the specific time points when abrupt and statistically significant level shifts occur that may be associated with psychological or other events (Wilhelm/Grossman, 2010, p.565). To avoid measurement artifacts, which can influence the overall structure of data, especially if changes in physiological data are considered, an early visual examination of the elevated raw data is essential. With the help of proper algorithms in appropriate software, the resulting data consists of gradient values for every second. The algorithms have been improved, compared to former studies, and a testing of different intensity levels of stress has taken place. As result, high intensity indications of emotional stress reactions with at least a duration of three seconds are focused in the present study. After analyzing certain physiological patterns defining a stress reaction (Bergner et al., 2011: pp.250/251) and identifying the time in which a stress reaction had occurred, this data is merged with the proper GPS coordinates (challenge (c)).

Figure 1: BMS Smartband (www.bodymonitor.de) & physiological patterns defining a stress reaction

Besides the psychophysiological monitoring approach, different questionnaires were applied. At the beginning as well as at the end of the study, the State Anxiety Inventory (STAI-S) , developed by Spielberger, Gorsuch and Lushene (1970, revised 1983), was used. The STAI-S is a psychological inventory based on a 4-point Likert scale with 20 questions on a self-report basis, concerning the relation between state anxiety/fear as characteristic in due consideration of situational influences and intra-psychological processes. The aim was a before and after comparison of changes in the test peoples mental state. In order to get a more precise image of the participant Five-Inventory-10 (BFI-10) (Rammstedt et al., 2012) was applied. The five personality tr openness to experience, conscientiousness, extraversion, agreeableness and neuroticism. Nowadays, it is the most established and accepted reference model for the description of personality (Rammstedt et al., 2012, p.7). Furthermore, a general questionnaire with questions to event affinity, perceived sense of safety and social basic data should give insights, if the participants represent the general characteristics and perceptions of the other event attendees at the Back to the Woods Open Air. The test people also had the chance to give self-assessment regarding stressing situations at the event via tape recorders.

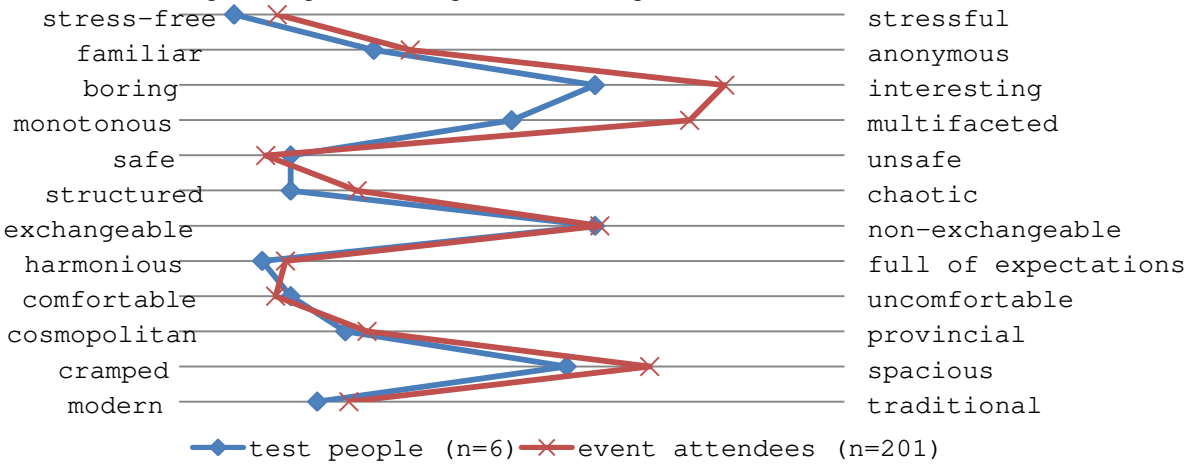
Within the context of this paper the authors utilize the GeoVisualizer application to visualize multivariate spatio-temporal physiological data from multiple users (challenge (d)). The GeoVisualizer application provides even non-visualization-experts interactive tools to produce meaningful visualizations based on state of the art techniques in order to provide a better insight in the underlying georeferenced data (Michel et al., 2013). GeoVisualizer is based on the Open-Source NASA World Wind SDK which provides a three-dimensional virtual globe and various plugins to import georeferenced data (e.g., Shapefile, GeoTiff, Web Map Service, Web Feature Service, Sensor Observation Service). The GeoVisualizer is implemented with the Java Web Start Technology, which allows starting the application on every computer connected to the Internet. Once installed, the GeoVisualizer application resides on the hard disk of the computer and can be also run in offline mode. However, if the computer is connected to the Internet a check for updates will be executed to ensure that the user always has the latest, up to date components.

Based on Nold s Bio Mapping , the approach of psychophysiological monitorin geo-referencing was tested and improved in different own studies, primarily in environmental planning context (e.g. accessibility and barrier-free design for impaired people (Bergner et al., 2011), impact of noise in urban areas (Bergner et al., 2012), orientation in open space (Exner et al., 2012) but also in other fields of research, like stress management of emergency rescue services (Steinitz et al., 2014)). This study is based on these insights and counts as the most up-to-date work by the authors.

## 6. Analysis and Discussion of Results/Findings

At the same time of the study, a general survey (n=201) with the visitors of the Back to the Woods Open Air took place within the research project MultikOSi (see chapter 2). Figure 2 shows the overall perception of the event by the event attendees as well as the test people in a semantic differential. The only difference is that the study test people experienced the event a bit more boring and monotonous. The chosen test people represent the general social structure (gender, age, social data) of the other event attendees. This is an important fact for the evaluation of the resulting data. The study test people pose no exception.

Figure 2: Open Air Perception of Test People and Event Attendees



The analyses of the test people questionnaires and data sets are carried out in a simple profile analysis, because an aggregation is inappropriate due to the small number of cases. To exemplify and discuss the results and findings, later visualizations are made available in simple profile analyses in comparison to an aggregation of all six test data sets.

### 6.1 Simple Profile Analyses Questionnaires and Psychophysiological Monitoring

The data of the six test people is anonymized and coded (e.g. HA29 represents one certain test person). The STAI-S shows that four of the test people (HA29, MA23, SA17, GA23) had a higher anxiety value at the end of the study in comparison to the beginning, whereas HA29 s anxiety value was significantly higher. The test people SE23 and EA09 had almost no change (Table 1). The increase of state anxiety is presumably connected with the abrupt break off of the Open Air because of the massive thunderstorm, which also ended the execution of the study.

Table 1: Results of State-Anxiety-Inventory (STAI-S)*

| test person | study begin | study end | difference |
|---|---|---|---|
| **HA29** | 42 | 65 | + 23 |
| **MA23** | 30 | 46 | + 16 |
| **SA17** | 29 | 40 | + 11 |
| **GA23** | 32 | 42 | + 10 |
| **SE23** | 40 | 39 | - 1 |
| **EA09** | 42 | 39 | - 3 |

* A resulting value of 20 means no anxiety, 80 the highest anxiety value.

The Big-Five-Inventory-10 (BFI-10) indicates that the test people are very different regarding their personality traits (Table 2). HA29 is more a conscientious type, but rather suspicious and less compassionate and cooperative. MA23 is characterized as a highly outgoing, energetic and compassionate, cooperative person, and less sensitive or nervous. SA17 has a tendency to be a conscientious type. GA23 is highly open to experiences, an inventive and curious person, like SE23. A tendency to extraversion and openness to experiences is shown by EA09. In case of neuroticism, none of the six test people has a high parameter value towards experiencing unpleasant emotions (like anger or anxiety/fear) easily.

Table 2: Results of Big-Five-Inventory-10 (BFI-10)*

| test person | extraversion | neuroticism | openness | conscientiousness | agreeableness |
|---|---|---|---|---|---|
| **HA29** | 3 | 3,5 | 3 | 4 | 2 |
| **MA23** | 5 | 2 | 3 | 4,5 | 2,5 |
| **SA17** | 3 | 2,5 | 3 | 4 | 3,5 |
| **GA23** | 3,5 | 3 | 5 | 3 | 3 |
| **SE23** | 3 | 3 | 4,5 | 3,5 | 3,5 |
| **EA09** | 4 | 2,5 | 4 | 2,5 | 3,5 |

* A resulting value of 1 means no parameter value, a value of 5 means highest parameter value (5-point-scale)

The psychophysiological monitoring results indicate a wide ranged percentage of being stressed between 2,00 % (HA29) and 13,00 % (SA17). The duration per stress event is nearly equal (between 4,3 and 4,9 seconds) with the exception of SA17 (7,7 seconds), who has also the highest percentage of being stressed (Table 3). The study had a duration about 3,5 to 4,5 hours. The self-assessments via tape recorder indicate that stress was experienced in dense crowds, especially while getting drinks or food. Here, the synchronized tape recorder data is reflected in the physiological indicated stress events.

Table 3: Results of psychophysiological monitoring stress parameter values

| test person | total time data set (in sec.) | number of stress events* | total time of stress events (in sec.) | average duration per stress event (in sec.) | Percentage test people were stressed |
|---|---|---|---|---|---|
| **HA29** | 13324 | 57 | 266 | **4,7** | **02,00%** |
| **MA23** | 16507 | 190 | 851 | **4,5** | **05,00%** |
| **SA17** | 16484 | 439 | 2145 | **7,7** | **13,00%** |
| **GA23** | 13246 | 233 | 1069 | **4,6** | **08,00%** |
| **SE23** | 16498 | 170 | 738 | **4,3** | **04,50%** |
| **EA09** | 16462 | 256 | 1248 | **4,9** | **07,50%** |

* Minimum duration of three seconds

In the following, HA29 (least percentage of being stressed) and SA17 (highest percentage and highest average duration per stress event) are exemplarily analyzed in comparison to the quantitative questionnaires STAI-S and BFI-10.

According to STAI-S, HA29 s anxiety level clearly increased at the end of the study in comparison to the beginning, but had the lowest percentage of being stressed, continuously measured during the study. On the other hand, HA29 has only the slightest tendency to neuroticism (value 3,5). SA17 as the most stressed person during the event shows also an increase in anxiety level at the end, but no

tendency to a high parameter value in neuroticism. As a result, no indication of an interdependency between the different dimensions (surveys and psychophysiological monitoring) can be found in the case study.

## 6.2 Simple Profile and Aggregated Visualization

Figure 3 illustrates a two-dimensional stress heat map from all users who visited the Woods Open Air within the GeoVisualizer application. In addition, the visualization shows tracked GPS coordinates of test person HA29 by using three-dimensional pins. The head of the pins is colored according to its emotional state during stress (pink pins) or non-stress phases (cyan pins). Using the third dimension allows to compare and analyze the results of one test person with regard to the data of all test people, e.g. the tracked study participant did not spend time in the stress-hotspot area depicted in the lower right corner of Figure 3. In order to easily grasp the stress hotspots of the test person, the pins have been extruded more when a stress event was detected.

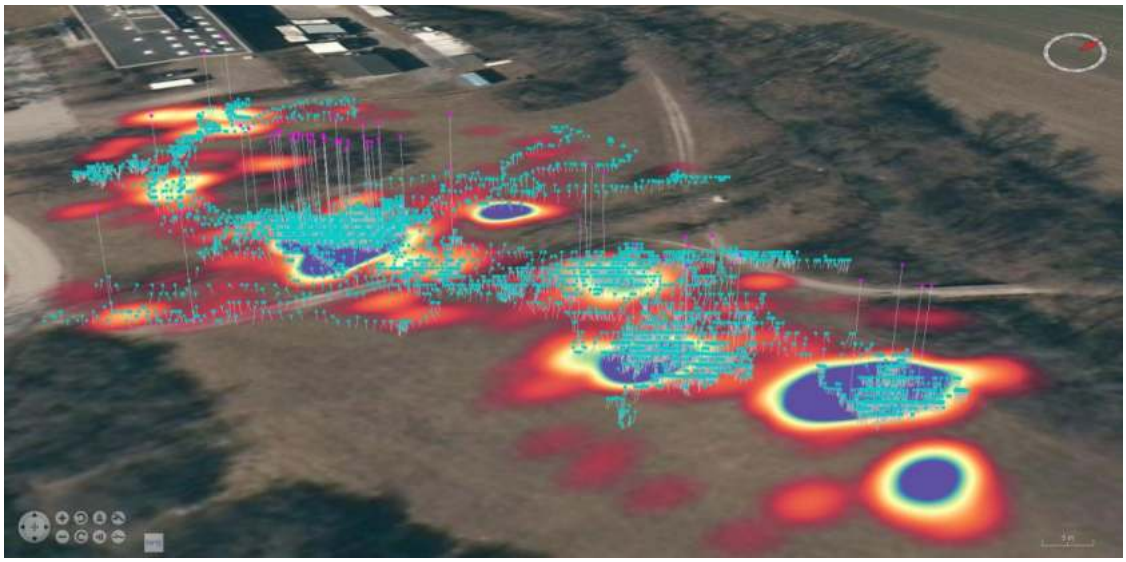


Figure 3: Visualization of the stress heatmap of all test people and the stress spots (pink pins) of test person HA29, using the GeoVisualizer

When especially interested in the relation of different attributes of spatio-temoporal time series, the two-dimensional visualization is not sufficient any more. As described above, 2D maps mostly use colours, contours or heatmaps to convey the information, e.g. river, terrain, land usage, etc. However, this kind of visual representation is limited by the number of colours that can be easily distinguished and perceived by planners and decision-makers. Furthermore, the amount of data items or layers can overlap in the visual display, whereupon information of layers beneath get lost. The GeoVisualizer application provides also a layer viewer for easy selection and comparison of the needed information.
As a consequence the usage of a third dimension is necessary in order to provide user-friendly and easily understandable visualizations. This would tackle the problems described previously. The GeoVisualizer application enables the user in a fast and easy way to feed the needed information in to the system and to get appropriate visualizations in an interactive open source tool. And as possible demonstrative, reduced to elementary functions information tool it is helpful to process the many different information channels an environmental planner as well as an event planner have to consider.
In case of the presented study, the visualizations helped to identify the most crucial areas where stress was experienced by the test people. As seen in Figure 4, the authors made the decision to exemplarily visualize and analyze an aggregated stress heatmap of all study participants, as it would have been

done if a higher number of test people had been available. As result, especially the food and drink zones as well as the dancing area are documented with a high density of stress events. On-site observations have shown, that in these areas dense crowds were present. The queuing also triggered many stress events (tape recordings). Open to discussion are the stress events in the dance floor area. Furthermore, the toilet area was very stressful for the study participants. This fact was confirmed by the participants and other event attendees. Queuing and the condition of the toilets itself were problematic.

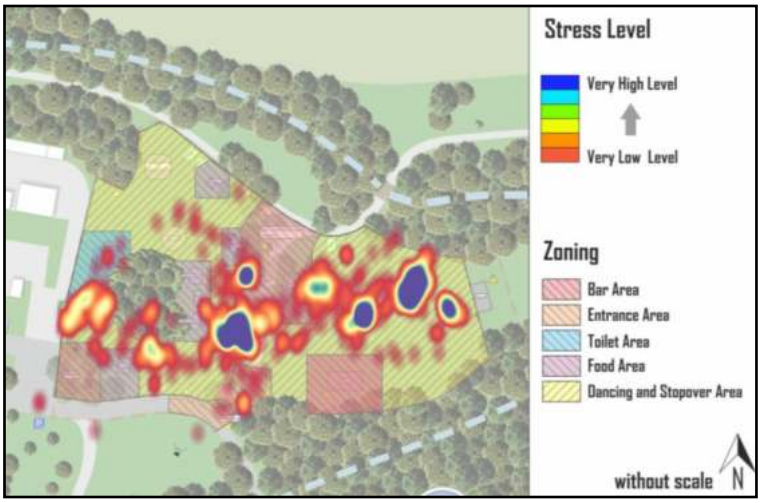

Figure 4: Aggregated heatmap and zoning of the event area

## 7. Conclusions

User-generated emotion data in the context of environmental as well as event planning shows very high potentials in delivering completely new insights into perception and experience of humans in their immediate environment. If visualized in an adequate, easy to handle and information reduced way, this data offers new perspectives across disciplines. The here presented study has met the methodical challenges, defined in the beginning. But the point of the matter is that the results, concerning this study and the mentioned former studies, are only exemplary. A lot of interdisciplinary basic research has yet to be done. Especially the identification beyond doubt of stress inducing stimuli is the biggest challenge for further studies. Data extracted from questionnaires, self-assessment, the location and visualizations can help to understand to which stimuli people are exposed. At this point, the authors basically recommend a higher number of test people, an exact defined target group or object of investigation, observations on-site, more data of the study participants personality tra not to forget, the evaluation of experts in the specific field of research. Still, there is gap between continuously, objectively measured indications of emotions by psychophysiological monitoring and retrospective recall, self-assessment methods and quantitative questionnaires which face each other and have their individual short-comings. A mixed-method approach turns out to be reasonable. Also the application of other sensor data, like crowd sensors, can help to get more objective data of the immediate environment. The analyses and validation of the gathered data is still highly complex and not completely to be automated. At this moment, the authors regard it as a high risk to give recommendations for decision-makers based on user-generated emotion data.

The experiences made at the Back to the Woods Open Air were valuable though very special, because of the abrupt end of the study due to the incoming thunderstorm. The data gathered up to that point already gave specific involved groups of players indications where problematic hotspots could be in the future. On-site observations have supported the fact, that queuing, dense crowds and the toilet situation is not only stressful for the event attendees, but also a matter of safety aspects. The study will be repeated in 2015, adding participating observations of the test people.

## 8. Acknowledgements

The research at hand is part of the research project Support Systems for Urban Events Integration for Openness and Safety (MultikOSi), research programme Research for Civil 2012 - 2017, topic Urban Safety and Security, funded by the German Federal Education and Research.

**From Victims to Sensors: An Overview of PPGIS Applications in Emergency Planning and Management**

Hsiu-Tzu Chang[1], I-Hsin Chen[2]

[1]Assistant Professor, National Cheng-Kung University, hsiutzuchang@mail.ncku.edu.tw
[2]Master Candidate, National Cheng-Kung University, jollyalison@hotmail.com

Keywords: Public Participation, Emergency Planning, Volunteer Geographic Information

*The term public participation geographic information systems (PPGIS) was bo
National Center for Geographic Information and Analysis (NCGIA), meaning to bring GIS technology to a local level in order to increase the data access and allow stakeholders to participate in the knowledge building and decision making process. With the growing popularity of personal computers and electronic personal devises, the contribution from public via the internet has also grown significantly based on the appearance of volunteered geography information (VGI). With the lack of immediate authoritative data, it has applied increasingly to emergency response as citizen became the sensors to report the unknown situations at the disaster area. With the growing amount of sensing and new information source, to what extent PPGIS has engaged in the planning process and changed the ways we defined data and knowledge in emergency planning and management is the core inquiry of this research. This paper takes an overview of the development of PPGIS applications in emergency management mostly in the United States, identifying its roles and functions in the four steps of emergency management mitigation, preparedness, response and recovery- in relationship to types of disaster and level of participation. A classification of PPGIS applications in emergency management is established through reviews of existing literatures, professional magazines and websites. This paper will facilitate further understanding of PPGIS, its trend, and identify new possibility in emergency management from the perspective of spatial planning discipline.*

## 1 Introduction

Public participation is a form of collaboration among public, private and civic sectors, which is also an important process in spatial planning that enables stakeholders to express their views and opinions in the decision making process. Locals are not only the main users of space but also the one with most understanding of local environment. With the contribution from public, professionals and government officials can make a more accurate and relevant spatial plan with the detailed information and advices from locals. Therefore, the communication from bottom to top has been an emphasis in participatory planning process.

Enabled by Web 2.0 which is promoted by the spirit of interaction and sharing, PPGIS (Public Participation Geographic Information System) is presented as a more people-centered GIS (Geographic Information System) compared to traditional rational planning methods, where planners control the majority of data collections, analyses and decision making process. As the new technology enable a new interface of information sharing and public dialogue, PPGIS has become one of the important methods of public participation, attributing to the instant interactions between governments and citizens. As this new field emerges, substantial PPGIS applications have grown in different types of planning process, including most technocratic-led emergencies planning and management.

Emergency planning is aimed to reduce the vulnerability to hazards and adapt with disasters, including both human accidents to natural disasters such as flood, earthquake. The needed information consists of disaster related spatial data such as hydrogeology, topological properties, soil and other geological layers to help analysis and predict where the location of disaster and the needed responses at different geographic scales. GIS has been an essential tool that for data collection, display and analyzes in emergency planning, and it has applied in avoiding damage from climate change as issue of the global warming heightens. In order to acquire the accurate geospatial data and advices from locals, PPGIS has also applied in emergency planning to aid the efforts. Websites with on-line map are provided for public

to achieve and provide the information about disaster planning, acknowledging the location of evacuate areas and routes. The managers can also gain more detailed information in a smaller scale, making the result of plans more reliable.

In recent years, on-line disaster response communities have grown and promoted as a more efficient method compared to traditional planning methods as residents face the immediacy to response to the pre-and post-disaster conditions. The contribution from public via the internet has also changed significantly due to the appearance of volunteered geography information. (VGI) Residents to establish an on-line evacuation maps by using web mapping services. Sites such as Google Map or Yahoo! Maps have created web-based mapping applications more accessible to users. The interfaces of these websites are easy to use and provide achievable, editable content. Take Kaohsiung explosion (2014) in Taiwan as an example, local volunteered residents built an on-line map at once, tagging explosion spots, hazardous area and aid distribution stations one the Google Map. The on-line map not only helps the emergency evacuation but also displays the current situation to relief workers or other people.

This paper intends to document the growing popularity of PPGIS in emergency management in relation to the four steps of emergency management - mitigation, preparedness, response and recovery. Current case studies of PPGIS applying in emergency management are drawn from the United States and some other countries. We will identify its roles and the relationship to types of disaster and level of participation. With this review, the current state of PPGIS function in emergency planning will be conclude, bringing out the new possibility in emergency management with this new technological development available.

## 2 Literature Review

### *2.1 Public Participation*

Public participation, also referred to as public involvement, can be defined as a process of allowing people to influence the outcome of plans and working processes. Public participation is the process consulting with the public before making decisions. In order to produce the best possible results, collaborative problems with the goal of achieving more acceptable decisions require adequate discussion with the public. The two-way communication is regarded as a way of empowerment and democratic governance.

The public means an open and unlimited circle of persons. It consists of the affected individuals or groups of people, like residents, house owners and stakeholders. The broad public is everybody. Public participation usually involves those potentially affected by or interested in a decision. The principle of public participation is that those who are affected by a decision have a right to be involved in the decision-making process. The term stakeholder is used for individuals or groups with term goal, like professionals and the non-governmental organizations (NGOs), representing specific interests. Stakeholders and the public can be both involved in public participation projects, but not necessarily at all stages of the project and in the same intensity (EU IPA, 2010).

After identifying the public, participation can be thought of as the specific activities that individu or groups engage in and tend to achieve a suitable and reasonable result. The discussion about participation usually focuses on the approaches of participatory and the depth of involvement. Participation can be done with different degrees of intensity: ranging from information broadcasting to consultation activities up to an active involvement, participating in decision-making process. (Firus et al, 2011) (Figure 1) Overall, understanding who the public is and defining how much the participation works would help operate a public participation project at an appropriate position.

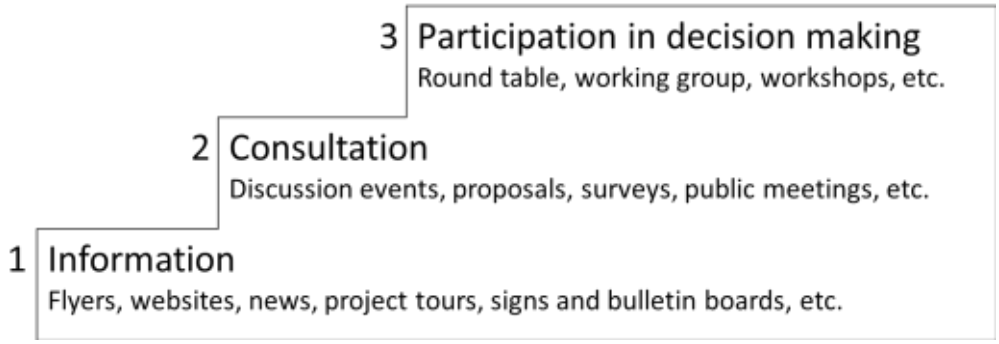

Figure 1. Intensity Degrees of Participation Processes
Source: Arbter et al., 2005

*2.2 PPGIS*

The term public participation geographic information system (PPGIS) was brought out in 1996 at the meeting of the National Center for Geographic Information and Analysis (NCGIA) in the United States. Same as the literal meaning, PPGIS is utilizing GIS technology to achieve the concept of public participation, in order to include and empower the entirety of population, and avoid marginalization. Among the societal issues, concerns that all voices should be heard in a democracy have sparked these researches in PPGIS. (Obermeyer, 1998) It can be applied to many aspects, as spatial planning is the major applied area that PPGIS provides a bottom-up system for public to join the process of discuss and decision making.

Since the 1990s, the applications of PPGIS has been extensive, ranging from community and neighborhood planning, environmental and natural resource management, mapping traditional ecological knowledge of indigenous people, to measuring change in place value (Brown, 2012). Two formats of PPGIS exist, including workshop PPGIS and web-based PPGIS (Chen and Ding, 2012). Workshop PPGIS is holding workshops for a specific issue one-time or on a regular base. It operates at planning in a smaller scale, like community planning or indigenous living area search. It is a common method in civil panel, start-up workshop, scenario workshop, and annual conference, etc. Using paper map or online map to display layers of information not only inspire the thoughts of locals but also explore issues and identify the problems.

The second type of PPGIS is web-based PPGIS. The emergence of Web 2.0 improves the implement of PPGIS, providing a new pattern of public participation. Web 2.0 s facilitate a new online participatory platform, where people not only consume content (via downloading) but also contribute and produce new content (via uploading), breaking the barriers between users and data-providers. (Bugs et al, 2010) Web-based PPGIS were developed later on and merged the idea of Web 2.0 technologies which are innovative, collaborative to provide simplified services. Different from the workshop PPGIS taking place in an actual space, most of the web-based PPGIS use internet as a virtual interaction space. With the character of asynchronous, anonymous, open-data, information conservation and etc., web-based PPGIS bring the traditional GIS to the internet surface, making the information sharing more conveniently. Citizens can get the information at once and participate in the public affairs without time and space limits. For example, FEMA (Federal Emergency Management Agency, US) established a Flood Map Service Center website, containing flood risk area map of the US. Residents can type in an address to get the flood risk area map near the site. If they discover a controversy or have some questions about the map, they can send an email to the center to confirm.

Owing to the rapid transmission of internet, the interaction of PPGIS between locals, government and the third party has become instant and transparent. However, there are two main disadvantages about web-based PPGIS, which are identity issues and information accuracy respectively. To avoid these

problems, some projects apply both kinds of PPGIS. Do a local survey by workshop PPGIS and set up all database by professionals on the internet, then establish a website to inform public.

Technically, the application of both kinds of PPGIS needs supplement data updating and data analysis. Take emergency planning and management as an example, before a disaster happens, locals can check the risk area and work on the mitigation or avoid living there. Locals should check the affected area to make a safe escape route and record the first-hand information at once when a disaster happens. Governments and emergency managers should possess the abilities to update data, integrate data, publish information, and make the spatial plan with the local knowledge.

### *2.3 Emergency Planning and Management*

There are three types emergencies divided by its causing factors, which are natural disaster, man-made disaster and both in combined, like fire disaster. According to FEMA (Federal Emergency Management Agency, USA), the definition of emergency is any occasion or instance that warrants acti lives and to protect property, public health and safety, such as a hurricane, tornado, storm, flood, tidal wave, tsunami, earthquake, volcanic eruption, landslide, mudslide, snowstorm, fire, explosion, nuclear accident, or any other natural or man-made catastrophe. After the 911terrorist attacks in 2001, the US revised the context of emergency and started to emphasize the acts of terrorism. Therefore, the content of emergency planning and management has changed, moving from the focus of natural disaster to concluding more and more aspects.

Emergency planning is a continual cycle of planning, training, practicing, and revising, which are referred to a four-phase cycle --preparedness, response, recovery, and mitigation (Haddow and Bullock, 2003). The cutoff points form these phases are not always clear. Some may measure the process into five phases. Due to the need of different expertise and broad area/local knowledge, emergency planning requires collaboration with personnels from locals and other agencies. As for emergency management, it is the process of preparing for emergencies and disasters, mitigates their effects, and responds to and recovers from them. (FEMA, 2002) In short, emergency planning is a systematically method to minor the effect of disaster, and emergency management is to make sure the functions of emergency planning. In order to decrease the damage, both of them should be considered as an integrated project.

The four phases of emergency planning are illustrated in the circle of emergency management. (Figure 2) Mitigation and preparedness are implemented before the disasters happen. Response and recovery are actioned after the damage. Emergency planning and management is linked up by the four phases sequentially and cyclically. The explanation and actual content are in the following table. (Table 1)

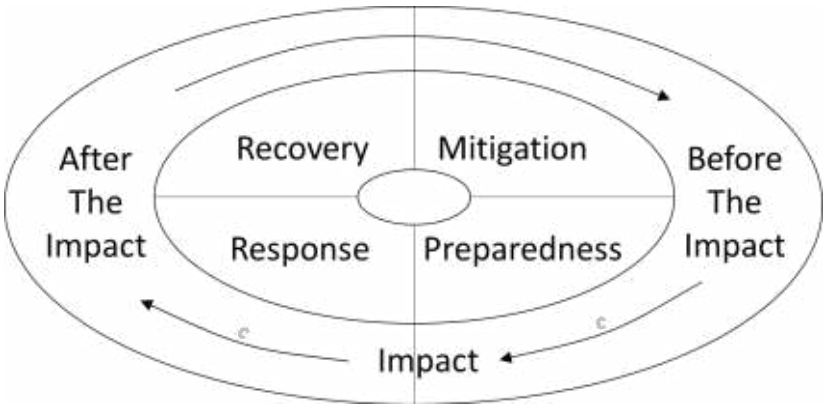

Figure 2. The Process Image of Emergency Planning and Management

Table 1. The Four Phases of Emergency Management
Source: Cova, 1999

| Phase | Explanation | Content |
|---|---|---|
| Mitigation | Prevent future emergencies or minimize the effects. | To avoid or to decrease the damage of disaster, governments draw up and implement emergency plans through policies, usually designed as long-termed plans or procedures. Mitigation measures can present in two types, structural and nonstructural respectively. For example, in earthquake risk areas, the structural measures might include changing the materials and structure of buildings and installing securing facilities. The nonstructural might include comprehensive plans and land use zoning. |
| Preparedness | Prepare to handle the occurrence of emergency before it happens. | Preparedness is to take a prevention action in case an emergency occurs, including training, planning and warning. Training maintains the ability of resilience. Preparedness plans ensure that when a disaster strikes, emergency managers will be able to provide the best response possible. Warning provides a longer time to prepare and face the disaster. |
| Response | Respond to an emergency safely during or after it happens. | Response activities take place during an emergency. Response is to put the preparedness plans into action, including saving lives, preventing further property damage and adjust the plans based on the instant emergency situation. |
| Recovery | Recover from an emergency. | After an emergency, recovery activities are taken to return the area to a normal or safer situation. The sort-term goal is to conduct lifeline systems and get assistance to help maintain the basic needs of life. The long-term goal is to recover economic activities, rebuild public infrastructure and living environment. |

## 3 Current Status of PPGIS in Emergency Planning and Management

### *3.1 Public Participation in Emergency Planning and Management*

The reflections in this paper derive from seven selected PPGIS case studies which are related to emergency planning and management in the United States, Haiti, Philippines and Vanuatu (see Table 1). Among them, four cases were applied in USA which represents the development in the past decades because USA is the country with the longest history in PPGIS. The other cases are from different countries which stand for the critical evolution of PPGIS in recent years. All of the application name were identified and divided into three degrees of public participation inform, consult and participation in decision making.

Numbers of websites applying PPGIS are presented on the internet and open to public. Most of the cases were searched via on the internet, including OnTheMap for Emergency Planning, Flood Map Service Center, NYC open data and Vanuatu disaster response. OpenStreetMap of Earthquake in Haiti and Micro Mappers of Typhoon Ruby not only take the internet browser as a surface but also applied the app technology on the personal devices. Geocollaboration Software Architecture was the only case capturing from existing literature.

OnTheMap for Emergency Planning and Flood Map Service Center are both national websites. OnTheMap is an integrated platform with various resources. Among them, emergency management is one of the public data tools that provides a web-based interface for viewing the potential effects of disasters on the U.S. workforce and population. The website lists the hazard event areas and sorted by different kinds of disaster. Then, users can click the area and see the map with optional layers and information to view the detailed workforce, population, and housing characteristics for hurricanes,

floods, wildfires, winter storms, and federal disaster declaration areas. This application of PPGIS is functioned with inform. Users can only get the information but can t reply by the syste

Flood Map Service Center (MSC) contributed by FEMA (Federal Emergency Management Agency) is an official public source for flood hazard information. Users can type in their address to get the official flood map and receive a better understanding flood risk. The whole country map was divided into same size of grids with numbers. The information is presented on each grid map. If anyone has question about the flood area, he can send emails to MSC to confirm the information. The function extend the concept of public participation from inform to consult, accepting the corrective and advisory forms of its users.

In addition to the national official website, some states or administrative areas set up their own web-resources with more detailed data. Take New York City as an example, NYC Open Data collected different types of public data generated by various New York City agencies and other City organizations available for public use. The data are presented by different machine-readable formats, such as datasets, charts, maps, documents and etc. Descriptions of the data, the collection method, and other contextual material, called metadata, are recorded and make the data sets easier to understand and use. All of them are arranged by types, category and reference city agency. Among these classifications, the maps have applied the concept of PPGIS, providing the datasets about public safety, including population, tornado, hurricane and fire disaster. The website is full of basic and advanced datasets, also possesses the function of discussion, so users can leave messages corresponding to each dataset. When citizens review the map, they can select different kinds of layers and even add new dataset on the map, then export the map. The application of PPGIS not only reaches the degree of consult but also enhances the convenience of spatial analysis. Anyone can use these datasets to participate in and improve environment by conducting research and analysis or creating applications.

Except for the official application of PPGIS with matured technology and rich data mentioned above, there are some case studies from other areas which were contributed by NGOs with different participation process. OpenStreetMap of Earthquake in Haiti was contributed by Community OpenStreetMap Haiti (COSMHA) and Humanitarian OpenStreetMap Team (HOT). Due to the serious damage from the earthquake, roads and landscapes had a radical change. To complete a functional map, the organization collected the scanned historic map and the satellite imagery from UN, GeoEye and Digital Globe which was released to the public. The largely empty and incomplete map gathered thousands of volunteers, developers, and organizers to generate the most complete map of the country of Haiti currently. They also used cell phones or devices with GPS to record the extant roads and rivers, building a new on-line map according to the current landscapes. In addition to marking roads and transit information, there was analysis of damaged buildings, displacement camps, and emergency service centers. The free and open on-line map serves more than merely a digital, web-based map for viewing the decimated region. It not only provides accurate road information for citizens calling for aid, but also make numerous contribution to the actions of rescue and recover to the response organizations and government agencies.

Vanuatu disaster response faced a similar situation with Haiti and also only reach the phase of inform, but they applied PPGIS in another method. On March 2015, cyclone Pam hit Vanuatu, left a path of destruction. The disaster response in Vanuatu was led by UNICEF Pacific, trying to provide clean water, sanitation and basic infrastructure, so the need of open data emerges. They combined existing data sets which were conducted by Akvo before the disaster happened, to help the teams to allocate their assistance accordingly. The datasets was collected from public and contained the proportion of households with no toilet, proportion household with water sealed and flush latrines, Vanuatu household size and water point functionality and etc. These combined datasets present useful information to relief teams and emergency managers to hand out in the field.

For the purpose of aiding data collections, smart phone APPs are invented and applied in emergency planning. Take Micro Mappers of Typhoon Ruby in Philippines for instance, digital humanitarian volunteers tagged images on the map by using Micro Mappers Image Clicker and rated the level of damage they saw in each location. Those that are tagged as Mild and Severe c

geocoded by members of the Standby Volunteer Task Force (SBTF). The application shows the current situation immediately and offers images to social media, applying the step of inform in public participation.

According to the aforementioned cases, PPGIS applications perform in different kinds of format but the majority only reach the degree of inform in public participation. The last case is an academic research about Geocollaboration Software Architecture conducted by The Pennsylvania State University. Through the study in Lower Swatara Township and Centre Region, the concept of community emergency management planning is exemplified, explaining how emergency planning is a community activity with local area stakeholders, resources, and threats. They held the emergency planning meetings to bring all of the emergency-related stakeholders together in the region. After setting scenarios, applying geospatial representations and providing information about infrastructure and land use, they provide a forum for the citizens and agency leaders to reflect on how to improve their coordination and communication, based on past experiences, in order to be prepared for a large-scale emergency event in the future. Later on, Geocollaboration Software Architecture was proposed, using GIS interface to generate a geospatial representation. Every individual data layers are reusable and can be combined to produce multiple representations, and linked to other online content. The software is open to everyone and the information will be transmitted to the emergency planning and management. In their demonstration of the Geocollaboration Software Architecture, it allows public participate in decision making, which reached the ideal goal. The creation of the PPGIS software is based on the opinion from possible users. However, the application still just an experiment in the academics research so far.

### *3.2 PPGIS Applications in Four Phases of Emergency Planning*

Geographic information system has played an important role in emergency planning for decades. If the concept of public participation is integrated into the technic of GIS, how will it be presented in emergency planning? Carrying on the discussion of PPGIS case studies, PPGIS application can appear in diverse forms and contributed in different phases of emergency planning, including mitigation, preparedness, response, and recovery. After case studies, we array the cases into the matrix of public participation and emergency planning. (see Table 2)

Table 3. The Case Studies Matrix of Emergency Planning and Public Participation

<table>
<tr><th>Emergency planning / Public Participation</th><th>Mitigation</th><th>Preparedness</th><th>Response</th><th>Response</th></tr>
<tr><td rowspan="3">Inform</td><td colspan="2" rowspan="3">On The Map for Emergency Planning</td><td colspan="2">Vanuatu disaster response</td></tr>
<tr><td colspan="2">OpenStreetMap of Earthquake in Haiti</td></tr>
<tr><td colspan="2">Micro Mappers of Typhoon Ruby</td></tr>
<tr><td rowspan="2">Consult</td><td colspan="2">Flood Map Service Center</td><td colspan="2" rowspan="2">Only volunteers (broad public) involved.</td></tr>
<tr><td colspan="2">NYC open data</td></tr>
<tr><td>Participation in decision making</td><td colspan="2">Geocollaboration Software Architecture</td><td colspan="2">None<br>Website<br>Website and App<br>Academic Essay</td></tr>
</table>

In most cases, PPGIS is applied in the phases of mitigation and preparedness before the disaster happens. On The Map, Flood Map Service Center and NYC open data take the internet as a surface to present the information by online interactive mapping. Sufficient data related to emergency planning are collected for public to acquire accurate information conveniently. These websites have established for a few years. Citizens can surf on them and acknowledge the information about emergency planning in their daily life. However, if the websites haven t been well-promoted, the interaction process would be passive because not every citizen obtains the passion to learn the knowledge of emergency planning initiative. Though Flood Map Service Center and NYC open data obtain the function of consultation, the usage rate and effect is still not notable.

Geocollaboration Software Architecture has an integral and mature process of applying PPGIS, beginning from awareness presentations, to staging area planning, to software conducting. The Geocollaboration Software Architecture is not just software but include a complete process with different methods of public participation. It reached the degree of participation in decision making, applying PPGIS in the phases of mitigation and preparedness of emergency planning. The software collects the advices from public in order to organize the spatial planning. Although the paper didn t mention the possibility of applying the same concept after disaster happens, the software architecture may be a great helper in the action of response and recovery as well.

Vanuatu disaster response, OpenStreetMap of Earthquake in Haiti and Micro Mappers of Typhoon Ruby are the PPGIS application after disaster happens. No matter what kind of emergency, disasters may cause the rapid destruction of landscape and physical environment. One of the important points of response is to collect the instant information. So as to control the damage and help the victims to settle down, relief workers need to arrive in the distress area immediately. The correct status about traffic, basic facility, natural resources and other needed information would contribute great favor to the agencies. Vanuatu disaster response and OpenStreetMap of Earthquake in Haiti collected data by internet and independent devices then established a functional on-line map. To take it up a notch for the convenience, Micro Mappers of Typhoon Ruby and used cell phone app to record the situation and rate the damage as Mild or Severe . The combination of cell phone and internet bring a better flexibility and convenience to building the database. When the users arrive in the distress area, they can open the GPS to record the location, even tag photos to spread out the current images. Though most victims didn t possess adequate equipment to build the dataset, volunteers from other places can be the sensors to facilitate the data collection. These cases consult the broad public in public participation without local residents.

OpenStreetMap is an openly licensed map of the world being created by volunteers using local knowledge, GPS tracks and donated sources. Its app makes use of the smart phone owners, recording the moving routine by GPS and turning the highly-used paths into roads. OpenStreetMap not only can be applied in daily life but also catastrophe. Except for the earthquake in Haiti, the system was also applied in the earthquake of Nepal. In serious unprecedented events, the maps and information that are needed for doing the groundwork at the local scale immediately after the event are often not available. (Laituri & Kodrich, 2008) So volunteers in worldwide started to draw the map on the internet according to the satellite image. This gain a great attribute to disaster response because others can know the new terrain by updating on-line map and making the rescue action become more efficient. Because of the different conducting process, the result of map would be more close to the local users and the traffic can be calculated according to the actual usage rate of each road as well.

### *3.3 PPGIS Applications in Emergency Planning and Management*

According to the case studies, present PPGIS applications are well-functioned to inform the public before disaster happens. The GIS technology is applied fully well in emergency planning in most of the developed countries. The information is provided on the websites and open to everyone. In recent years, applying PPGIS during or after disasters are more and more common. After the experiences of Indian Ocean tsunami (2004), Hurricane Katrina (2005), Haiti earthquake (2010) and etc., the on-line disaster response operation systems have improved over these years.

Most of the PPGIS applications in emergency planning and management haven t reac participation in decision making. Some websites possess the function in the phases of mitigation and preparedness but the appliance is still unformed. So far most applications consult the volunteers with proper devices but there is still no application about consulting the advices of local residents after disaster happens. However, the action of response and recovery truly need the information from victims because they are the first responders who know the best of the local situation of that time. The spatial planning should accede to their opinion because they may also be the people who will continue to live in the environment.

On the whole, the PPGIS application in emergency planning and management is lack of two-way communication. The most common form of interaction is that the public collects and provides data to managers. Then the data managers will confirm, arrange and publish the data. (Figure 3) When different people upload data in the same location but with different description, the managers need to correct the mistakes and judge the accuracy. (Chen and Ding, 2012) Afterwards, the public not only can use the information but also be the role of supervisor and corrector if the information got mistakes. Take OpenStreetMap as an example, the map is divided into grids for users to choose the area they want to edit. The grids are colored into three colors, which mean complete, verification, verify invalid, high priority and currently worked on. The users can know the integrity of the map by different colors.

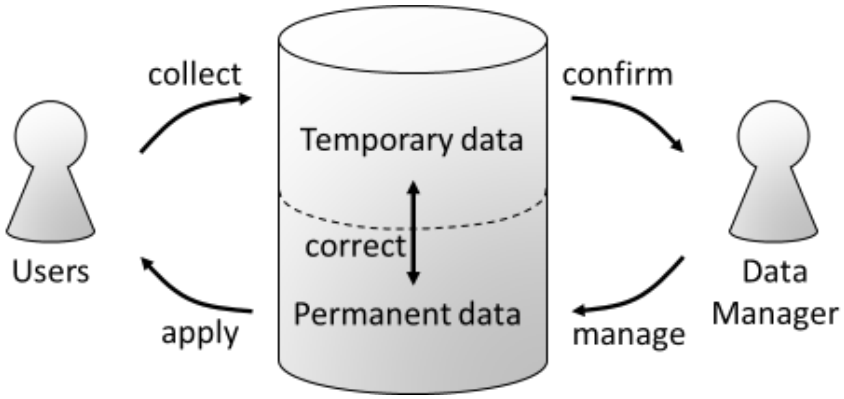

Figure 3. The process of current web-based PPGIS application
Source: Chen and Ding, 2012

The reason of lacking PPGIS application in consult and participation may be the necessary to identify users and arranging diverse data. The broad public should involve in the planning process when the emergency planning implements a spatial plan. Though the environment belongs to everyone, but if taking all the advices from everyone into consideration, it will take a long time and cost more money for sure. Therefore, identifying the participants turns important in reality, especially when governments need to select the proper public and stakeholders.

## 4 Conclusions

Emergency planning and management requires a visualization of detail information from roadways, bridges, buildings, and even parking lots of a local community. GIS is the system which is suitable to present a huge amount of information to everyone. As a result, GIS has been applied in emergency planning for decades. PPGIS applications merge the public participation into GIS, mostly functioning in spatial information collection and display. Though the current PPGIS applications are lack of consultation and decision making, the technics in information delivery is well-developed, especially in mitigation and preparedness phases. Most of the countries establish the internet GIS platform to present the spatial information. Until now, there are some GIS websites providing free platform and easy surface for public to edit information on the map or produce their own maps, like Google Map and Yahoo! Maps, allowing everyone to achieve and manage the spatial knowledge.

PPGIS can be applied in every phases of emergency planning, no matter before or after disaster happens. The applications in mitigation and preparedness usually perform the information on websites and have less interaction with public. Due to the increasing penetration of private internet device, the PPGIS technic applied in response and recovery are thriving in recent years. More and more apps are invented for emergency planning and management by government agencies (e.g. FEMA App), nonprofits (Disaster Alert, Your Plan) and donation partners (Esri ArcGIS app, HelpBridge), making the local become the sensor of various data. Some of these apps collect user general content and manage the information methodically. Some of these apps provide instant information before disaster occurs to improve the preparedness of individuals. For instance, FEMA created several GeoPlatform to provide geospatial data and analytics in support of emergency management. The GeoPlatform has seven main subjects, which are hurricanes, floods, tornadoes, winter storms, earthquakes, biohazards and man-made disaster. Users can obtain the weather report, set the disaster alarm and follow the new FEMA news. When a disaster occurs, users can also upload photos and tag them on the map through the app by GPS to spread out the image of current situation in local.

However, when most of the PPGIS applications are web-based PPGIS, the limitation of possessing devices appears. Some cases like Micro Mappers of Typhoon Ruby require using smart phone and install the specific app to collect data. In another word, the limited of devices restrict the user range. People without smart devices or computer are excluded, such as people from developing countries, elderly people and the poor. Disasters often include relocation and movement of large numbers of people to another area, the establishment of refugee camps, and the infusion of different groups of people into new areas that may not have the necessary infrastructure to support them. (Laituri and Kodrich, 2008) However, in the most of time, they are the vulnerable groups that need help and be heard in emergency planning and management. The information asymmetry and shortage situation may be a problem during the emergency planning and management. That may also be the reason why the users of PPGIS applications in response and recovery mostly are volunteers, not local residents, turning the PPGIS concept into VGI (volunteer geographic information).

To respond the unbalance problems, workshop PPGIS should be implemented in the process of PPGIS, avoid relying on the web-based PPGIS. Workshop PPGIS not only can fix the accuracy and reality during the process but also build the trust among the locals. With a coming disaster, local users can provide the updated data and opinion for spatial planning by their daily experience and observation in local through the workshops. Emergency managers can help to manage the data. The information gathered from the public will help to make the decisions more accurate at different phases of emergency planning and management. Future research should pay attention to the information gap in every related individual and group. When the technology of cell phone apps is improving rapidly, the whole public

should be considered completely as well. The concept of public participation c
PPGIS applications in emergency planning and management, continuing to bring the technology into play to decrease the damage of disasters in the coming future.

# GEO-ICT SERVICES IN SPATIAL PLANNING: DEFINING A CONTEXTUAL FRAMEWORK FOR OPERATIONALISING PUBLIC LAND POLICY

Pietro Elisei[1], Wendy-Laura C n [1], Radu-Matei Cocheci[2]

[1] Smart Cities Concepts and Project Management, Urbasofia, Bucharest, Romania, wendy.cinta@urbasofia.eu
[2]Department of Urban Planning and Territorial Development "Ion Mincu" University of Architecture and Urban Planning Bucharest, matei.cocheci@gmail.com

*Fragmented, inefficient institutional arrangements, layered on top of the weak reliability of statistical information across both the developed and developing world, and the subsequent low degree of awareness concerning the management of public property / public land rule out the effectiveness of traditional planning instruments.*

*To what extent may a Planning System incorporate geoICT (geographic Information Communication Technology) services to the mutual benefit of the planning profession, communities and policy-makers in their attempt to optimize the development processes? An open and responsive government seems more likely to encourage an aggregated view of new planning models rather than obstructing them, subsequently propelling effective public service delivery.*

*The contemporary ICT era triggers the need for masterplanning as a dynamic collaborative process / output, allowing on the integration of end-user requirements through means of a crowdsourced inflow of data, having thus modelled the pre-existing regulatory planning framework.*

*Through this paper, we aim to define a possible framework for connecting ICT models with normative and strategic planning processes at local level, starting from a comparison between different EU planning systems and how geo-data can be used in both facilitating the implementation of planning regulations and building local governance capacity.*

*Addressing the challenges and inconsistencies of spatial planning norms in relation to the real-time developments / evolutionary trends, by mapping the gaps between different planning levels, may pave the way for geoICT services as innovative binder between the co-dependencies generated at various planning scales.*

**Keywords**: Planning Systems, Digital Spatial Plans, City-Services

## 1. Introduction

Until recently, the problem of geographic analysis for public administrations was the lack of spatial data availability. The more recent over-abundance coming from various sources, such as volunteered GI activities (e.g. Wikimapia, OpenStreetMap OSM), public initiatives (e.g. Spatial Data Infrastructures SDI, Geo-portals) and private projects (e.g. Google Earth, Microsoft Virtual Earth, NASA World Wind and other 3D models), has not yet been aptly put in use, enacting planning policies in (public) land use management for a wider range of urban governance models. Weighting the costs and benefits of these policies requires both data accessibility as well as data storage capabilities to be provided by the use of geoICT.

Maps in spatial planning are often reduced to their role in evaluating the normative content of spatial plans – unlike ordinary maps, governments issue spatial plans not to describe the existing situation, but to illustrate different regulations often associated with geospatial objects (MetaLex, 2009).

Established as a policy infrastructure for sharing geospatial information in Europe in order to support Community policies (EC, 2007), the INSPIRE (Infrastructure for Spatial Information in the European Community) directive, as well as other Spatial Data Infrastructure (SDI) programmes depend on standards such as the ones provided by the Open Geospatial Consortium (OGC). As the large volumes of information collected by various public authorities become *a gold mine* for Europe's public administrations (EC, 2011), the further development of geoICT services are considered to be a factor enabling better public policy and scientific decision making, while also producing significant benefits to society as a whole (Stoter et al, 2011).

However, around the world there are significant differences in the way SDI is explained. On the one hand, in the USA the focus is on re-engineering projects, duplicate data reduction, data sharing promotion or standards and metadata revision, while in Africa SDI is used just as a decision-support tool in enhancing sustainable development, social and economic transformation or environmental conservation (Navarra, 2010). As national SDI initiatives also include the existence of a national government policy for SDI (e.g.: in Romania, the efforts of the National Cadastre and Real Estate Publicity Agency – ANCPI), with different institutional arrangements in acquiring and providing spatial information (Crompvoets et al, 2006), it is often difficult to evaluate these initiatives through the use of measurable variables.

Consequently, the aim of this article is to identify to what extent may a Planning System incorporate geoICT services to the mutual benefit of the planning profession, communities and policy-makers in their search for optimized development processes. Besides explaining the state-of-the-art in using geoICT services in spatial planning, the article presents initiatives from the Netherlands, Italy and Romania in an attempt to identify common paths that can be taken in the creation of a contextual, geoICT driven framework in operationalising public land policy.

## 2. Background

GeoICT is the end result of the combination between geographic (or spatial, geologic, geodetic, geometric, etc.) information and Information and Communication Technology (ICT), increasing the availability and accessibility of government's services by improving general planning, coordination and cooperation (Akingbade et al, 2009). As highlighted by Navarra (2010), geoICT can be perceived from three perspectives: urban and regional economics, 'techno/legal/managerial' perspective and GIS sciences perspective.

Table 1. Perspectives in defining geoICT services

| **Urban and Regional Economics**' perspective | **'Techno/Legal/Managerial'** perspective | **GIS Sciences**' perspective |
|---|---|---|
| - **public good**, used to discipline the spatial structure of the urban economics, 'optimizing' the spatial distribution of natural, economic and social activities. | - **standardisable**, formal and quantitative way, not necessarily mediating spatial knowledge, in its attempt of making space controllable and measurable. | - contingent, informal, qualitative and prone to manipulation by humans, displaying diverse values and interests. |

The first perspective analyses the provision of geoICT by achieving maximum possible output from a given set of inputs (Worthington and Dollery, 2000), as spatial and economic data define financial and strategy decisions in state governance. This concentrates upon the spatial management of cities as an administrative unit for state governance, covering for regional and urban spatial policies (transportation infrastructure, bio-diversity, local taxation), managing urban change / regeneration (rising / declining areas) and steering land use policy to act as blueprint for population behavior and development.

The succesful applicability of geoICT services in public sector governance requires the existence of comprehensive evaluation methods (DeLone and Mclean, 1992), taking into account not only the overall benefits, but also the societal and economic impacts, the latter including operational efficiency and effectiveness, as well as program efectiveness (Clapp et al, 1989).

The supply of general information is critically different from the support of real planning processes, as encountered in a survey by Campagna and Deplano (2006) on GI provision within public administration in Italian websites presenting mixed impacts on the effectiveness of geoICT to support spatial planning and decision making processes. The various forms (tourism, location of government services, online planning) were not consistently addressed, failing to provide substance to the actual planning domain.

Another example in supporting this theory is reflected in the analysis deployed by Karikari et. al. (2005) concerning the application of GIS for land administration in Ghana, finding that nearly all cadastral and land registration systems focused on record management rather than information exploitation. No GIS was used for analytical purposes by the Lands Commission Secretariat in Accra - the leading agency on land administration - but only for static map displays, leading, in turn, to limited research attention in terms of the societal benefit of resorting to dedicated geoICT services.

In the case of the Netherlands, Koomen and Groen (2004) studied the current and expected development on supply (agriculture) and demand (urbanization) side and then discussed government intervention. To this instance, STEPP - a GIS-based Strategic Tool for integrating Environmental aspects in Planning Procedures - was found to stimulate the exchange of relevant information among various stakeholders including decision-makers, providing means of navigation to explore planning scenario alternatives, thus aiding the less-equipped actors to be able to perceive land use change for achieving a more participatory process of governance and decision-making. As we will see further, an added value of such service provision will be addressed by the Legal Atlas (MetaLex standard) incorporating the legislative part of land use management.

The operational level of service delivery based on inputs (such as geo-data, geo-information and monetary resources) is directly linked to the effectiveness of the programmes using geoICT to provide such services, resulting, in turn, into a quicker decision-making process. Another aspect is the value of geo-information and how this is actually used as input for the delivery of public services. Eventually, geoICT can contribute to the making of smaller cities more fertile grounds, by providing agglomeration benefits to firms, government services and otherwise unavailable social activities in such contexts (Navarra 2010).

According to Acharya (2009), the wise use of geoICT could be the prime instrument to support the overall objective of the envisaged Land Administration System (LAS) of the nation, admitting that adopting geoICT in land administration is a problem and a solution in itself, especially acknowledging the huge investments to be allocated for mind-set revolution.

From a Spatial Data management point of view, geoICT includes: data acquisition, data assimilation, data analysis, information extraction, decisions support and data/ information dissemination. Out of

these prospects, our current focus relies on decision-support, whilst the main issue to be addressed is the integration of various information extraction processes in the scope of providing relevant and reliable interoperable public services.

Land Administration - as defined by the UN - is the process of determining, recording and disseminating information on ownership, value and use of land when implementing land management policies, focusing on the accurate boundary survey of the land parcel and the registration of rights over that parcel, whilst Land (Use) Management perceived the land as a resource from both the environmental, as well as the economical perspective. Land Reforms come to alter the pattern of land tenure and land use in specific areas.

Identifying users with information requirements into the integration of survey records information addresses an operational model of a dedicated public-enabled land administration portal (Lee 1995). Such a tool has been defined by the International Federation of Surveyors (FIG) in the form of a database containing spatial referenced land-related data for a defined area, also covering for procedures and techniques for the semantic collection, updating, processing and distribution of data (FIG, 1995) - the Land Information Systems (LIS). Within such framework, specific software development languages and methodologies have to be addressed in order to provide for geoICT related services. The Unified Modeling Language (UML) has been rapidly perceived as a de facto standard software design language, based on its capabilities of visualising the modeling language into specifying, constructing and documenting the artefacts of a software system (Rumbaugh et al, 1999).

Also, from this perspective, geoICT services for e-land administration fundament government infrastructure, in their primary scope of recording legally recognized interests of land (ownership and use) including the technical, legal and managerial issues concerning the legal situation of defined units of land. In turn, these provisions reflect upon the real estate market, and further, handling the quantitative analysis of historical states, the continuous monitoring of comparable metrics and indices in time series can scope for the optimization of future landscape development.

Safeguarding the reliability, availability, access and use of spatial information can quantify for the societal objectives of geoICT services, developing new social and organizational capacity, whilst ensuring a high degree of awareness within modern governments, which need to address a highly efficient management of land use in retrieving significant value out of the land. Under such auspices, a possibility to seamlessly handle spatial data contained in each administrative unit can be considered, assuming that the political and economic frameworks remain constant not changing over time, in clear antagonistic view with the GIS sciences' perspective. According to Georgiadou (2009), the environment to use and apply geoICT relies on the provision of rules, legally prescribed in influential text (such as regulations, policies, principles and declarations).

The following sections will provide an insight into the planning system structure of three EU-countries the Netherlands, Italy and Romania with the aim of connecting this structure to the possible use of geoICT in support of daily government operations. The highly connected world, in which international key-players emerge in the geoICT sector in the context of globalisation, requires an increased awareness on innovative trends and possible technology transfers that can be used for designing new provisions in the aid of planning processes.

## 3. Planning System Analysis

Table 1 Administrative levels in The Netherlands, Italy and Romania

| EU | THE NETHERLANDS | ITALY | ROMANIA | |
|---|---|---|---|---|
| **Central Government** (-al system) | State level (unitary,centralised decentralisation ) | State level (regional, centrally rooted) | State level (unitary, highly centralised) | |
| NUTS1 Macro-Regions | - | - | 4 | no legal / administrative statute |
| NUTS2 Regions | 12 Provinces | 21 Regions (*Regioni*) | 8 | |
| NUTS3 Micro-Regions | 12 COROP regions | 107 Provinces (*Provincie*) | 41 Counties Bucharest (+1) | |
| LAU1 (NUTS4) | inter-communal level (joint approaches) | | | |
| LAU2 (NUTS5) | 443 Communes (*Gemeenten*) | 8101 Communes (*Comuni*) | 103 Cities, 217 Towns, 2856 Communes, 6 Sectors (Capital) | |

*3.1. Netherlands*

The main responsible body, at national scale, is the former Directorate-General of Spatial Policy inside the **VROM** (the Ministry of Housing, Spatial Planning and the Environment, since 2010, the Ministry for Infrastructure and Environment, **I & M**), which became a weaker form after the recent reform in e.g. relation to coordinating central government funding, under the name of the **National Spatial Planning Agency**.

The **National Spatial Strategy** (Nota Ruimte, 2005), formerly based on the Fifth National Policy Document on Spatial Planning and the Second National Structure Plan for the Rural Areas, has is radically rescaled and reformed the Dutch Spatial Planning approach, from the imposin stage towards promoting developments . It is characterised by less detailed r the central government, fewer barriers and greater latitude for other levels of government, members of the public and market parties, in order to promote more effective local land use policies; still, besides entrusting the lower hierarchical levels of governance with such responsibilities, a clear lack of national comprehensibility is to be faced as downturn of these new provisions.

Only in the case of major infrastructure projects, energy supply and city-regions development, the Central Government takes responsibility: within each envisioned area (i.e. complex nation-wide spatial issues in the N and S wings of the Randstad the highly urbanised western part of the Netherlands in the country s Green Heart and in S-E Brabant.), the Cabinet is producing a programme that bring together the principal issues and couples them to investments by local governments and private sector parties.

One central theme inside the implementing agenda of the National Spatial Strategy the basis for developing spatial policy is the integral development of supra-local areas, which must be developed through development planning , thus development-oriented instead of plan-led. In support of approach, improving decision-making on projects relies also on measures such as the integration of permits etc.

Under the new **Dutch Spatial Planning Act** (Wet ruimtelijke ordening **Wro**, 2008) the province can include a vision for a regional area development project in a structure vision. This is a policy-oriented document and thus not legally binding upon municipalities. If the province wants to issue binding regulation, the Act provides for a competence to establish generally applicable land-use regulations which municipalities must translate into local land-use plans. But the exclusion of certain land uses is more likely to follow (for example, building in areas of outstanding ecological value) than the stimulation of a certain sort of land use, as is the case in an area development project. (Spaans, 2007)

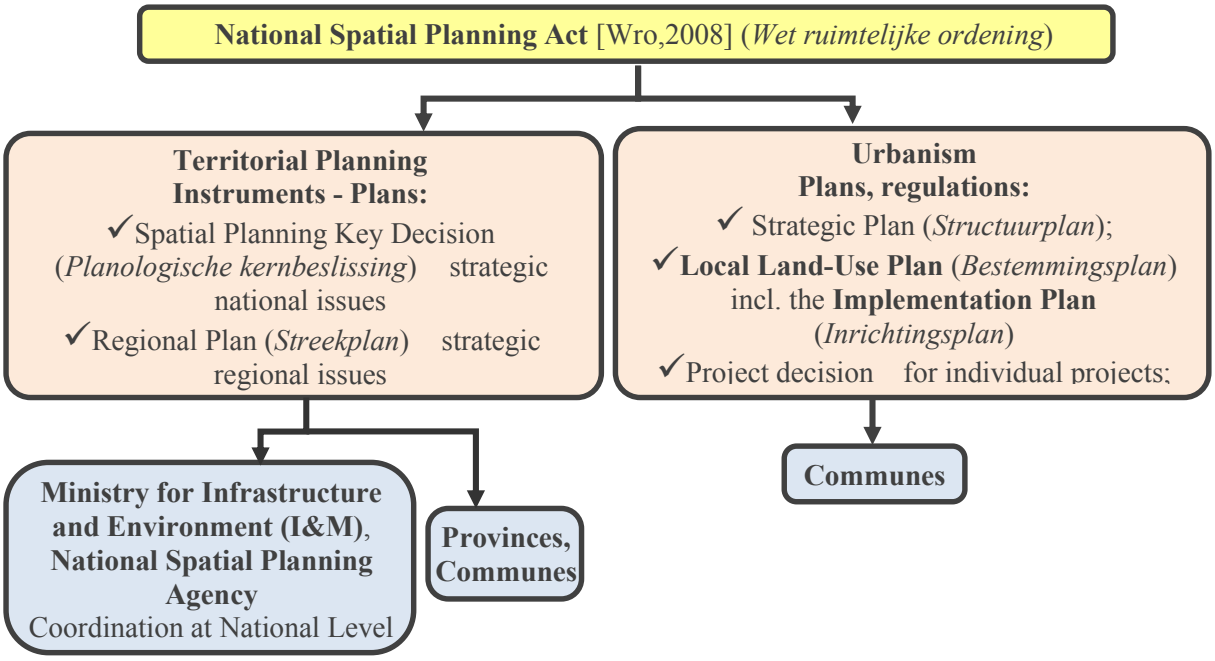

Fig. 2 Planning System in The Netherlands: main legislation, system of plans, administrative competences

The Act defines a partly mandatory set of plans (Fig. 2) specific for each hierarchical level, including the possibility to make exempt of, in some situations. Elements of each plan can be binding on lower authorities. **The land-use plan** (*bestemmingsplan*) **is the only plan that is legally binding** on citizens through the regulation of land use and prescriptions related to land use. This comes with an integrated **implementation plan** (*inrichtingsplan*). A building permit can only be granted if the proposal conforms to the land use and building prescriptions in the land-use plan. (Spaans, 2007) Besides this, local authorities can also formulate a **project decision** for individual projects. Such a plan is less comprehensive, but also legally binding. Upper levels can counterargue through means of **intervention procedures**. Still, such mechanisms are seldom used, due to time-consuming considerations. The secret of successful planning is in extensive intra-governmental negotiation and consultation, entrusting the lower-level apparatus in proceeding with their local issues. As such, the provinces do not have the competence to determine land use regulations on their own. They do provide directions - through i.e. the **regional plan** (*streekplan*) - and approve **local land-use plans** (*bestemmingsplan*), an often simultaneously combined approach. Their influence on local spatial policy is made through **verification**; through **notice of change**, undesirable land use changes can be opposed, yet usually avoided in practice due to again bureaucratic constraints.

By Wro, **the government is bound to make available all spatial plans in digital format through means of the RO-Online portal**. These are displayed as one image to allow the broad perception upon all re/developments of a specific area at once.

Related legislation provides considerations also to the geo-spatialisation processes, such as the alignment with SDI provisions and geo-spatial infrastructure standards. GIDEON, the National Spatial Data Infrastructure (NSDI) adoption was considered through the Geo-Information Geo-Information Council (*GI-beraad*) as an advisory Council of VROM, and the National Mapping Agency (Cadastre). The 2 embodiments addresed were the Space for Geo-Information (RGI) between 2004 2009 and the Geonovum since 2007, the latter as an established knowledge centre for geo-standards and geo-architecture in e-governance. The use of the Standards by municipalities, provinces and the central government itself is enforced by law in a separate governmental Regulation, for which the imposed standards are appended to. Furthermore, the innovation program space for Geo-Information , with the scope to improve the Dutch SDI, made **the framework mandatory for all projects carried out**. This was released in June 2006 as a dynamic document, extendable and improvable in time.

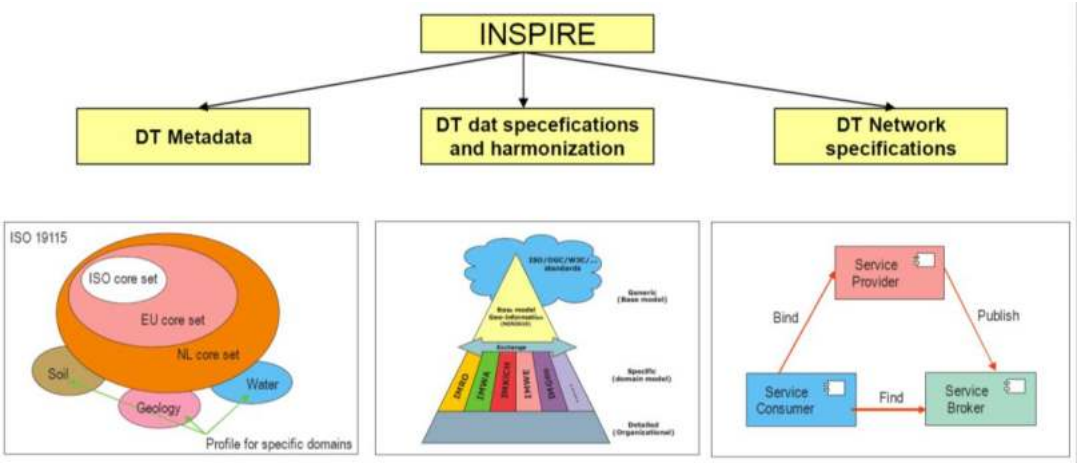

Fig. 3 Standardisation according to EU expectations e.g. INSPIRE (Bulens, J., Vullings, W., Crompvoets, J., Reuvers, M., 2007)

Other ICT relevant initiatives are few **Public Services on the map**, the **National Georegistry** and the number of central government SDI integrated initiatives, such as the **National Geo Data Infrastructure for Disaster and Emergency response management: GDI R&C** (*Rampen & Crisis*) since 2009, the EduGIS project, in which **geoinformation and GIS tools from different sources are made available for educational purposes** (www.edugis.nl) and even e-gov initiatives beyond borders, such as the **joint program X-border-GDI** with running examples including **Spatial planning, Water management, Nature and Tourism, Traffic and Disaster management** (e.g. the Geo viewer for animal disease, the Tourism project eRIGG providing hiking maps, etc. http://www.x-border-gdi.org/en/index.html)

Although only few experiences in applying the Dutch standards in the different profiles are registered, it is expected that it will result in time in an increase in operability in exchanging information over different domains.

*3.2. Italy*

The territorial fragmentation and lack of coordination between the various planning instruments have been in the past probably one of the biggest obstacles to be faced by the Italian planning profession,

since any action planned could have been extended only within the legal framework of the plan (usually municipal), and also since the effects of the intervention, with the advent of the latest regulations, have regulated the planning profession that attempted to harmonize the classification of the planning instruments, in order to set up an address for all the municipalities that fall in a given area and, overall, to regional level between the individual provinces. (Salzano, 2004)

Law 1150 of 17 August 1942 is still the fundamental law concerning urbanism, in a regulatory framework suffocated by an overlapping of norms not always of an exclusively urban planning character, which have modified but not substituted the previous ones. the need o been constantly postponed since its first considerations back in the 60s. The main planning responsibles are the national government (and in particular the Ministry of Public Works) and the municipalities.

All settlements included in the lists which the Ministry of Public Works is required to train and upgrade, are obliged to do the **PRG** (*Piano Regolatore Generale*), the General Regulatory Master Plan (Fig. 4). Settlements that do not come with PRG must still adopt a **Building Code**, which is more than the minimum of regulation of transformations, and that contains a cartographic attachment called "**Manufacturing program**" (**Pdf**). The PRG is implemented, according to the law, or for direct intervention (planning permission, building permit today), or - for certain areas or parts - by means of a "**detailed plan of implementation**" (**PPE**). The detailed plan is extended to a part of the township, and precise for it the rules provided for in PRG-level detail. It can come to indicate the plannimetric outlines and the elevation of individual buildings (*planovolumetrico*). The **territorial plan of coordination PTCP** has force indefinitely. The municipalities whose territory is included in whole or in part within a territorial plan of coordination PTCP, are required to conform to this the relevant municipal plan.

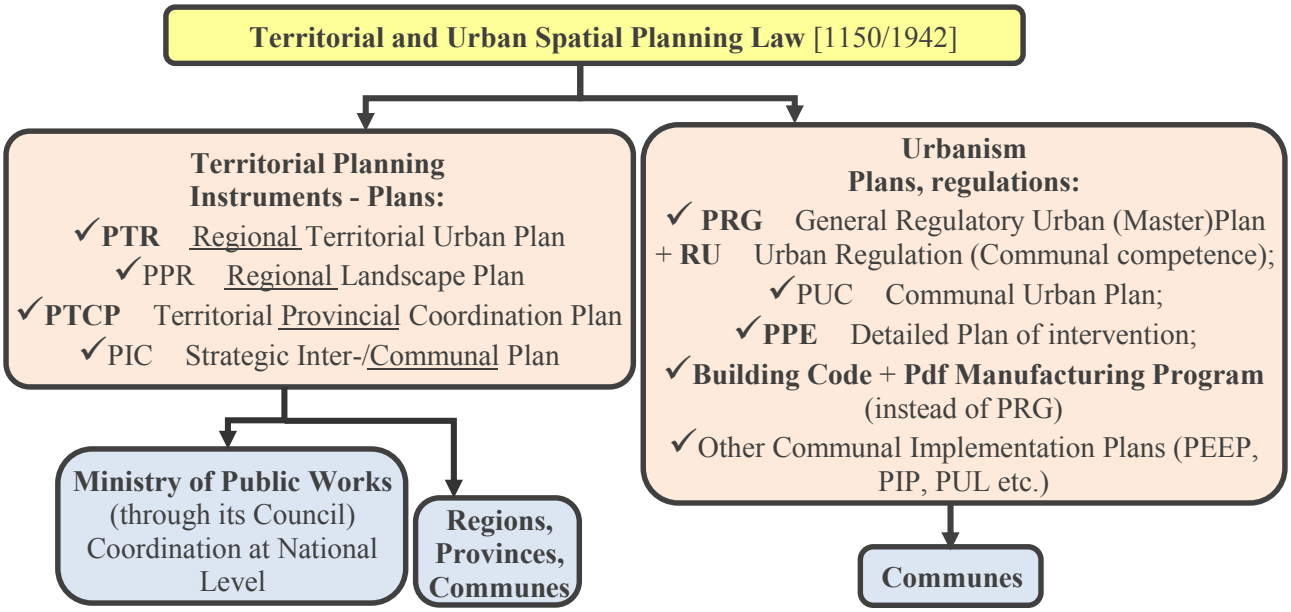

Fig. 4 Planning System in Italy: main legislation, system of plans, administrative competences

The Italian Communes have a central role in the Italian territorial planning processes, by outreaching the possibility of taking initiative and responsibility when coming to territorial planning. Other hierarchically superior entities have only a stimulating role, of guidance and control. The Communes in Italy are a highly variegated reality, with dimensions ranging from 2.5 million inhabitants in Rome to at most 100 inhabitants. This implies the fact that the Communes have absolutely diverse technical

structures and capacities. Some of them, which managed to publicize online their regulatory plans, such as the public oriented service towards the citizens comprising the community, have solved the planning informatisation, but when confronted with the problem of data model provision, even under a pragmatic approach, was generally perceived as scarcely generalizable.

*3.3. Romania*

Romania still suffers from *a rather widespread reluctance to accept planning as a democratic discipline, mainly because of its strong tradition during socialist times* (Florescu and Mitrea, 2015). After 4 decades of communist regime, characterized by an excessive centralization of the state and a planned economic regime, with an inherited taste for realising fixed general urban plans from the inter-war period, planning in Romania is still undergoing alignment in scope of assuring a greater transparency of planning processes and easing the involvement of local communities and other stakeholders. The current administrative competences for planning are established in Romania by the Law for Urban and Territorial Planning (no. 350/2001, with its subsequent modifications).

There are two main areas where planning activities take place without it being a subject of the national planning law. The first one is the environmental legislation, which stipulates the necessity to realize Management Plans for certain types of natural protected areas, containing provisions regarding land use. The second one is the regional development area, where certain plans are made at regional level (Regional Development Plans PDR) or even at local level (Integrated Urban Development Plans PIDU) in order to motivate the use of structural funds for different priority projects.

Territorial Plans (PATN national level, PATZ regional and sub-regional level, PATJ county level), the General Urban Plan (PUG) and specific Zonal Urban Plans (like the ones for central areas and protected built areas) are initiated by a competent administrative authority and are afterwards drafted by a designer/consultant which is attested by the Romanian Registry of Urban Planners (RUR - http://www.rur.ro/). The selection of the consultant is subject to public procurement regulations. For the other Zonal Urban Plans (PUZ) and for all Detailed Urban Plans (PUD), the command is issued by a private party who can choose to work with any designer attested by the Romanian Registry of Urban Planners.

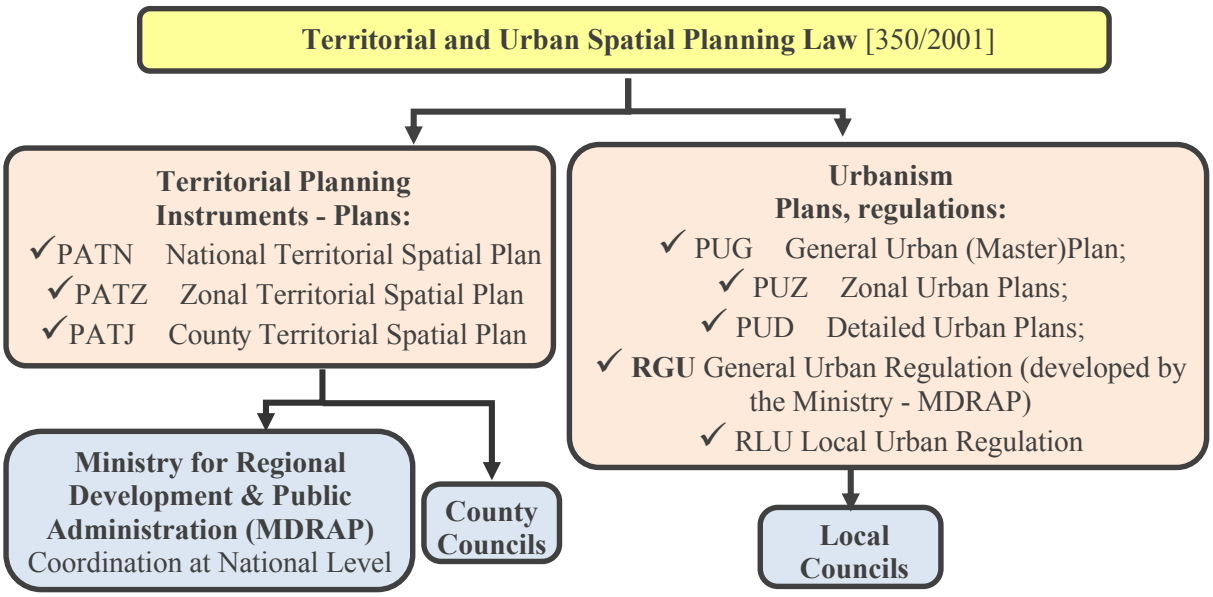

Fig. 7 Planning System in Romania: main legislation, system of plans, administrative competences

The enforcing of all plan provisions is assured through the release of Urban Planning Certificates, overseen by the Chief Architects at local level. Furthermore, the application of these provisions is supervised by the State Building Inspectorate and County Chief Architects.

The application of the planning system in practice in Romania suffers from certain legislative gaps that haven t been covered yet by the successive changes in the planning legislation. Elements regarding the operationalization of different law provisions remain unclear, but it is also worthy to note the lack of correlation between legislative provisions in different domains, especially concerning property rights (Ian i, 2008). Moreover, planning becomes more and more associated with the ab structural funds (Florescu and Mitrea, 2015), which eventually determines a submission of the national planning system to EU- level guidelines, often ignoring the need to focus on urgent local issues such as demographic decline or de-industrialised areas.

Furthermore, an analysis of policies and planning documentations in post-communist Romania highglights the territory s excessive fragmentation at all levels. This fragmented k territory, also caused by a lack of integrated data collection and analysis system, determines a lower impact of planning interventions (Groza, 2009). In this context, although there are some breakthroughs in using GeoICT services to support planning processes (Section 4.1), there is currently a lack of correlation between the planning sector and the ICT sector, with the latter only seen as a tool for decision support in some planning areas.

## 4. GeoICT services in support of planning processes

*3.1. Netherlands*

In the case of the Netherlands, IMRO is set as a compulsory standard since 2006 by the Dutch Ministry of Spatial Planning and Environment, for the definition of all land use types. This had been addressed in accordance with the GEMET thesaurus (General Multilingual Environmental Thesaurus coming in the form of a SKOS vocabulary http://www.eionet.europa.eu/gemet), covering for 40 themes of relevance to all levels of government (Hopkins et al. 2003)

An example of geoICT service is the **3D Pilot NL CityGML ADE IMGeo 2.0** a national 3D standard set up by the NSDI ExCo - Geonovum together with the Dutch Kadaster, the Netherlands Geodetic Commission and the Dutch Ministry of Infrastructure and Environment, under an ongoing national programme reaching multiple targets: harmonising the semantics of various representation of classes, attributes, code lists etc.; reaching an agreement on profiles and versions of interface standards such as the OGC Web Map Service (WMS) and Web Feature Service (WFS); coordinating reference systems, image formats, etc. in order to improve interoperability.

Related to public land management, 3D Pilot NL presents its added value covering for 3D cadastre - e.g. describing the properties owned in high rise condominium developments and integrated planning and management of underground and aboveground municipal assets. The integration of surface and subsurface data, the 3D virtual spatial planning environments (e.g. calculating soil volumes of planned tunnels), along with the recording of properties located above and below each other covering for the 3D cadastre, plus a 4D change detection are some of the use cases addressed through this initiative in its attempt to provide solutions within the spatial planning professions. (Trakas et al. 2012)

The 3D Pilot NL shares a dependency on open access to a rich infrastructure of 3D data provision and services. Such model advanced the use of geoICT services to be addressed by the planning community wherever European governments - national, sub-national or local - choose to promote such use. As ICT advances, such best practices of institutional team building and enhanced working policies need to be embedded in nation-wide incentives. (Trakas et al. 2012)

Another best practice example is the **Legal ATLAS**: a new type of corroborated service, in which legal provisions are aligned with the spatial mapping of land use regulations. Working in the form of an internet portal, the Legal ATLAS combines existing technology for disclosing legal texts with GIS. (Quote) Its main asset is the fact that it provides a map-based *normative reasoning* by checking the consistency of two sets of spatial norms for example if a zoning plan at city level fits the overall zoning plan of the province or whether a particular plan is allowed at a specific location.

*3.2. Italy*

The **Urban-GIS** project initiated as a mosaique of communal urban planning instruments (addressed at local scale) by Lazio Region - Sistema Informativo Territoriale Regionale SITR Area inside the Regional Directorate for Territory, Urban Planning, Mobility and Waste Management - with the primary scope of creating an information system compatible with the Territorial Data Infrastructure (IDT) at Regional level. (Merola, 2014)

Urban-GIS is a GIS tool thought for the harmonisation of all existing urban planning instruments enforced at regional level, with the purpose of creating a single framework alltogether. The purpose of this initiative concerns the multiuse of a facilitated and accessible consultation for all information related to urban plans. An unified legend will ensure the comprehensibility of various destinations provided by the planning instruments enforced. The project is defined in synergy with the other territorial entities (Provinces and Communes), beyond the data provisions of related competence, which consent for continuous updates within the acknowledged framework. This geoICT service performs an efficient monitoring of the current state-of-the-art in Lazio regional planning. In a first phase, the platform will run for internal utility between the sectorial operators and main providers. Afterwards, all citizens will be invited to use the regional Geoportal and provide further considerations towards the utility in consulting planning instruments. For future developments, Urban-GIS considers the insertion of specific protocols in terms of real-time (4D) provisions of wider and more reliable platform dissemination, as long as the continuous upkeeping in terms of data updating is ensured. (Merola, 2014)

**NEWPLAN** an award-winning geoICT service tackling the disparities at geospatial scale within the planning domain presents the concept of Paperless Urban Planning based on geospatial technologies targeting Workflow Management, while getting the civil society involved as co-designer. NEWPLAN started as a geoICT service based on GIS designed by Trilogis for the Autonomous Province of Bolzano, aiming to aid the central level of the territorial government, merging the urban plans of each municipality onto the provisions of the province, in line with the levels of the planning system addressed (Conti, 2013).

The problem faced by such service was the inconsistency and discrepancies inside the Italian Planning System, when trying to export its use for the neighboring Province of Trento, characterized by different land use policies.

The **Plan4All** project concerned the interoperability and the harmonisation of spatial data in scope of territorial planning. It addressed the synthesis of existing standards at the moment of implementation (2010 - 2013), the metadata profiling for territorial planning, shared data models and the harmonisation

process, relying on a database of existing best practices in Europe at regional and communal levels, taking into consideration also ongoing research initiatives at the moment of implementation, covering for the 7 themes addressed by INSPIRE.

One of the first international workshops (held in Rome in 2010) addressing these issues has managed to consolidate dialogues with the professional orders (architects', planners', landscapers', e cultural associations (i.e. INU, the Italian National Institute of Urbanism) and other interested institutions interested by these topics, evidencing the difficulty in reaching a common dialogue / language between various approaches and cultures in need of interaction. Matters of particular interest in the project focused on: (Vico et al. 2010).
1. Harmonised Data concerning Regional Laws
2. Operativity concerning various Scales and various Types of Plans

All in all, the Plan4All workshop concluded that a Territorial Coordination Plan (PTCP) would clearly establish the role of the Province and the contribution to its main tasks (e.g. provisions of the Communal Structural Plan would be addressed by provisions of the Regional Structural Plan through means of the Provincial Territorial Coordination Plan). In ensuring this, a Compatibility Plan would be consisted as a mosaique of Communal Plans. As such, with time, the Province will properly confront the hierarchical harmonisation and normalisation of the plans at various levels (vertical). To achieve this, a "telescopic" data model and an unified legend (shared dictionary) for addressing geographical objects and norms at various cartographic levels and scales have been defined and tested. The primary scope is to favor data fluxes through various hierarchical levels, whilst ensuring the preservation of certain autonomy at communal level and the integrated management of additional information of specific interests, in an extendable and exportable model (Vico et al. 2010).

The peculiarity (and the difficulty) of the Italian situation resides in the existence of 20 different Urban Laws, which are directly derived from a single national legislative node, albeit oriented in similar directions, giving form to a fragmentation of processes, procedures and cultures which render in a highly complex mode the way towards achieving data interoperability in the same national context. The necessity in proceeding towards the data and metadata models common in Europe must therefore firstly overcome the non-indifferent obstacle of the national level.

*3.3. Romania*

According to the provisions of Law no. 350/2001 with its subsequent modification, all urban planning documentations have to be realized in digital or analogic format, on topographical support which is revised using satellite images or terrain measurements. The electronic form of a documentation is very important as the law clearly stipulates the need to send the electronic data to the National Agency of Cadastre in order for it to be published on the INSPIRE Geoportal. The ICT impact is even greater on the dissemination of plans, as many local authorities publish intermediary forms of the plans on their websites for the public consultation procedures. In recent years, the development of GIS technologies has led many local authorities to command the realization of urban plans in GIS format, in order to help their management of spatial planning data (permit procedures etc.) after the ratification of the plan.

Breakthroughs in the use of geoICT services in Romania have often been funded through structural funds, including pre-accession instruments. An example is the two Geoportals (one for the discovery of spatial information at national level and the other granting access to geo-products) set upt by the Romanian National Agency for Cadastre and Land Registration (ANCPI) and the Duttch Kadaster International within the PHARE Twinning project *Geodetic network modernization and spatial data inftastructure framework* (Bulens et al, 2009).

GeoICT web services have developed at local level due to the involvement of local public administrations (Bucharest, Galati, Oradea), while at national level they were determined by the need to implement EU Directives, with the creation of portals in domain such as agriculture, biodiversity or water management (Ioni et al, 2006).

The lack of an integrated data collection platform to support planning processes is currently being addressed through the Territorial Observatory project (started April 2015). A subject widely addressed by planning professionals for years, the functioning of such a system has two main objectives: providing support to planning policy, by improving the knowledge on territorial reality and its dynamic, and dissemination of territorial information to the population in order to increase participation in implementing and sustaining planning and development policies (Groza, 2009).

The new Dynamic Master Plan for Bucharest, the capital city s General Urban Plan which is c being drafted, is an innovative example of using geoICT in an urban planning documentation from the analysis of the existing situation (using an integrated, city and metropolitan level database) to the drafting of a set of dynamic planning regulations (Florescu, 2012). The new Dynamic Master Plan aims, through the use of geoICT, to reduce spatial disparities by pursuing flexible mixes of amenities, thus pro-actively engaging with the changing structure of the city (Florescu and Mitrea, 2015).

All in all, while there is progress made in the domain of geoICT services supporting planning processes in Romania, this progress is only partially sustained at central level, with no framework being provided on the use of geospatial data in territorial and urban plans. Moreover, except from some central government initiatives including initiatives of the National Cadastre Agency -, most advances in geoICT service provision in planning have been the result of local initiatives from city halls.

## 5. Conclusions

Using plans requires the representation of the content of plans in relation to possible decisions so as to choose among alternatives knowing the expected consequences (Hopkins et al, 2003). Consequently, there is a need for decisions about urban development to be based on both analytical models of urban development processes and forecasting (Hopkins et al, 2003). While the authors above consider the implementation of a Planning Markup Language as a step in the standardisation of geoICT services supporting spatial planning, the differences highlighted in this article between different planning systems and cultures underline the difficulty of such an attempt.

A further challenge comes in tackling overlapping jurisdiction from different government bodies empowering a multitude of different regulations applied. The Metalex developers (2009) reached the conclusion that land use regulations issued by adjoining municipalities categorised differently, determine the land use `regime' in these municipalities as uncomparable. More than anything else in the world, in this era of globalisation governed by commerce and consumerism, planning also needs to go global. The interoperability of planning instruments and services is the process to be ensured so that all the related professions are able to address similar issues in similar ways. A unified *legend*, together with aligning part of the planning processes addressed by different administrations, should ensure a better outcome in the 4D attempt on Smart Planning Processes.

As we have seen in the case of NEWPLAN, systems must be designed in such a way that once a service model is available it can be reused and/or cope with ever ever-changing requirements of the geo-information users, thus ensuring some degree of sustainability and resilience (Acharya 2009). Basic provisions, such as the ownership concerning Land Administration rights held based on statutory law,

common law, customary traditions and informal use, should be a value input clearly addressed by geoICT services such as Legal ATLAS' MetaLEX (NL) or NEWPLAN (IT). Although constant efforts are made in geo-technology diverse applications, the absence of the actual reliance of harmonized planning systems in which to make use of these (see the case of NEWPLAN) is clearly noticed; hence, a further question to be addressed is: How would a Smart Planning System look like be defined?

# FLOOD RECOVERY IN THE SOCIAL MEDIA ERA.AN ASSESSMENT OF SOCIAL NETWORK INFORMATION IN BUILDING SOCIAL FLOOD RESILIENCE

Angela Esposito[1], Giustino Emilio Piccolo[2]
[1]University of Naples "Federico II", angela.esposito@unina.it
[2]giustinopiccolo@gmail.com

Keywords: *Resilience*, *Social Media*, *Urban Flood*

## Abstract

*In the face of the social technological revolution the sharing of information has led cities evolving towards always more complex systems. Social media have indeed a strong capacity of connecting people, and several urban self-organized initiatives have been emerging from virtual communities impacting on urban activities organisation. By enhancing communication opportunities, social media could be taken into account to improve urban planning decision making processes, and so they can also play a significant role in flood risk management.*
*In dealing with urban flooding it is important to know how quickly and efficiently a city can recover from a flood event. Before the event, social media can help increasing awareness by enabling wider risk communication. During and after the calamity, creating easily accessible information sharing platforms, social media are able to increase the disaster recovery capacity of the affected urban system, as a sort of social recovery rate.*
*Many sets of indicators have been proposed in the literature analysing the social perspective of flood vulnerability and urban resilience. Nevertheless, in these it is not easy to include the impact of using social media coping with floods.*
*In June 2013 during the flood of the river Elbe, citizens of Dresden (Germany) created a spontaneous Facebook network to require offer aids and assistance.*
*Building on the experience, we propose a methodological approach aiming at evaluating how the use of social media can affect social flood resilience, and in this way assessing the effectively social function of the media.*

## 1. Introduction

In the today s society, social media -such as blogs, Twitter, Facebook-and other information portals have emerged as dominant communication mechanisms, overcoming any other previous technology.
Sharing information, forming connection, communicate interesting contents (Chui et al., 2012), these media mainly operate in a similar way to traditional human community and they are transforming dynamics, behaviours, and structures of our society (Kaewkitipong et al., 2012). Hence, they are significantly becoming powerful drivers in the current social technological transition. These digital platforms are effective and efficient communication channels (Palen et al., 2009), they are affecting how citizens communicate, collaborate, and coordinate with each other. Social media have indeed the capacity of linking individuals beyond geographical proximity, increasing their ability of instant connectivity for ideas, knowledge and information sharing. Moreover, these communications can be mostly realized with a minimum or non-existing cost. As such, social media can be also considered as a powerful democratization force (Lai and Turban, 2008).
In the last few years social media have been used more and more during disasters, and in particular during extreme flood events. Being powerful instruments for immediate communications and easily accessible information, social media represent a key tool during all disaster phases, from risk communication to recovery. In other words, they have been used as an instrument to increase the

ability of a system to cope and to reorganise itself after the perturbations generated by the flood, hence the system resilience. The need of quantitatively measure such system property has led over the time to several indicators able to reproduce and evaluate social resilience main parameters. However, few works have been found regarding the role played by new digital communication ways during flood disasters.

This paper presents an analysis of the use of Facebook during extreme flood events. Established in February 2004, Facebook currently has more than 800 million users globally, it is available in 70 languages and is growing at around 150% per year. It is a web-based social networking service, allowing registered users the ability to connect and share contents with friends, family and co-workers.

An assessment of the use of Facebook regarding to flood events is presented using an explorative case study. In this paper we try to give an answer to the question: how the use of Facebook can influence the social resilience of a urban system affected by an extreme flood event? The paper is organised as follow: in section 2 the conceptual framework is illustrated; a review of the concept of social resilience and the state of the art of the literature about social media and flood resilience is presented. In section 3 the method and outcomes of the case study analysis are described and discussed. In section 4 the conclusions are described.

## 2. Conceptual framework

### 2.1 Social flood resilience

Natural calamities, such as floods, earthquakes and hurricanes, often affect the stability of urban settlements. Cities are defined as complex adaptive system, where physical elements, activities and city users interact one with others in different ways. As complex adaptive systems, cities are not linear cause-and-effect systems, but rather dynamic systems: Variables, the different system s compone and the elements of each component (e.g. people, businesses, governments), are constantly interacting and changing, for better or worse, in response to each other, creating non- linear feedback loops that either promote or deplete the energy upon which their futures depend(Sanders, 2008).This complexity makes extremely difficult the evaluation of the effects critical events could have on the urban system. In fact, both extreme natural events and disasters linked to human activities (e.g. nuclear incidents), can affect a urban system in several respects, determining significant changes in its structure and organisation. Focusing on flood events in urban areas, presence of flooded areas can result into a wide range of related impacts: infrastructural damages, urban functionalities and space perception. A multi-sectorial approach, to be applied to a well defined study area, is needed to achieve an adequately complete overview of flood effects and city's behaviour once affected (Esposito and Di Pinto, 2014).

Social dynamics influence all flood disaster phases, from risk perception and preparedness up to recovery. Social phenomena represent inherent communities' features or long term dynamics, often slowly developing. This circumstance leads to consider that flood duration - on the basis of flood related impacts- actually lasts beyond the time period during which urban areas are flooded.

Even not claiming to fully analyse related impacts, it needs to be asserted that calamitous events affect cities not only in their physical elements (causing damages in infrastructures or buildings), but also in the social structure made up by city users and human activities.

As adaptive systems, cities have the ability to adapt to changes and learn f co-evolve, self-organize and give rise to emergent patterns (Frantzeskaki, 2011). Hence, they show the ability to cope with a perturbation by properly re-organising themselves. UNISDR (2009, p. 24)

defines resilience as *the ability of a system, community or society exposed to hazards to resist, absorb, accommodate to and recover from the effects of a hazard in a timely and efficient manner, including through the preservation and restoration of its essential basic structures and functions*. In the field of urban flood the term resilience is often also to define the capacity of the urban system to absorb disturbances and perform changes without fundamentally altering its functional structure (Walker et al., 2004). Reflecting the several components that set up a urban system, resilience can be evaluated from different perspectives: social and economic resilience (Cutter et al., 2010; Boon et al.,2012; Adger, 2000); infrastructural resilience (de Bruijin, 2004; Cutter et al., 2010); ecological resilience (Holling, 1973, Adger, 2000).Social resilience is closely linked to community and social vulnerability concepts. Social vulnerability can be defined as a characteristic of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impact of a natural hazard (Blaikie et al., 2014). As such, it is one aspect of what is meant with the term community resilience, which has been described previously starting from analysing four primary sets of networked resources: economic development; social capital; information and communication; community competence(Norris et al., 2008).

Social resilience can be assessed on different levels of analysis: individuals, human communities, larger societies (Norris et al., 2008). Even remaining unchanged the main general features of social resilience concept, a certain reference level of analysis has to be set. The literature presents several works aimed at analyse the multiple factors which contribute to a proper assessment of social structure reorganisation after an event. Table 1 reports a framework of some significant variables proposed in the literature as indicators of resilience and recovery ability in relation to natural disasters.

| Author(s) | Indicator |
|---|---|
| Tapsell et al. (2002) | "Social Flood Vulnerability Index"<br>(SFVI, based on different social groups and financial deprivation indicators) |
| Cutter et al. (2003) | "Social Vulnerability Index" (SoVI), based on:<br>-economy (income, rents, median house values; percentage of employers in extractive industries)<br>- demography (age, ethnicity, race)<br>- buildings and infrastructures |

Table 1. Social resilience indicators

The need of evaluating social resilience has led to point out indicators as representative measures. The variety of indicators reported in technical literature reflects the effort to define and measure this broad (un-measurable) issue. The main challenges when evaluating social resilience indicators can be that there is no right and no wrong methodology. According to the need of the study, it is important to set the scale on which applying the indicators (e.g. Household, neighbourhood, community, region, nations), and choose the approach (e.g. national indices taxonomic approach , or household surv situative approach ) (Schröter et al., 2005).

### 2.2 Social media and flood resilience

A number of studies about communication and information sharing during extreme events, including floods, has been emerging in the scientific community in the last few years. The literature focuses on three main issues (Ryan, 2013): studies on agency communication (Waymer and Heath, 2007); studies on information seeking as part of a wider aim (Cohen et al., 2007; Hughes et al., 2007); and studies about the use of social media (Kaewkitipong et al., 2012; Kongthon et al., 2014; Vieweg et al., 2010). Social media, defined as internet-based applications that enable people to communicate and share resources and information, are an always increasingly used instrument to ensure communication schemes during flood events. More specifically the term *social media* is used to refer to the broadcasting strategy used by different individuals, institutions and companies to communicate with various stakeholders(Chui et al., 2012; Haegeman et al., 2012; Nielsen, 2012). Such strategies are implemented by using tools know as *social network sites* (SNSs). SNSs are *web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system*(Boyd and Ellison, 2007, p.211). SNSs have been used by billions of people all around the world (Hutton and Fosdick, 2011) for a wide variety of purposes, including personal, community, business, politics, and public affairs (Hoffman

and Novak, 2012). The use of SNSs emphasises the relations and the communication of an individual within his existing extended social network. Using hastag form of keywords in the contents published, SNSs make the shared messages searchable. As a result, SNSs become able to form online communities, networking people who share similar interests (Lai and Turban, 2008). SNSs are also being used as platforms where people talk about current environmental challenges and give environmental tips (Haider, 2012). Raising awareness around current environmental challenges, such as climate change and increasing urbanization, SNSs are also used to trigger citizens to actively participate in civil environmental activities that are immersed in the everyday life (Bakardjieva, 2009).

Providing new sources of information and rapid communications, increasing social participation and forming new networks, SNSs are also becoming a useful tool for victims, humanitarians, volunteers, and the general public to communicate during disasters, especially during extreme flood events (Kongthon et al., 2014; Starbird et al., 2010; Vieweg et al., 2010). One of the major issues in extreme flood events is the inability to know on a real time base where help is really needed. The use of SNSs as communication channel could be the answer to this need. SNSs have the characteristic of being accessible via smartphones, which makes them available also when traditional communication channels, such as radio, television but also phone calls and texts, are not able to cope with a higher amount of data processed at the same time (Bird et al., 2012).

During extreme flood events good communication schemes could play a significant role to ensure that the public will behave in a way where appropriate and effective steps to reduce and mitigate the risk are taken(Yamada et al., 2011).

An emerging trend in the emergency management literature indicates the use of SNSs as a way to help building a more resilient community. The basic concept of this tendency can be sought assuming that improvements in communications, risk awareness and preparedness can lead to an improved social resilience (Cutter, 2008). According to White (2011)community resilience should include a grassroots effort where social media is utilized in a number of ways to support the safety of the community. Dufty (2012)states that the use of social media by emergency agencies could assist in learning for disaster resilient communities . The contribution of social media to community resilience lies in the capacity of SNSs in forming the so called community of practices , defined as g share a concern or passion for something they do and learn how to do it better as they interact regularly (Wenger, 2011). According to Dufty (2012)the development of such communities of practices through SNSs helps in building a more resilient community in different ways. SNSs can help in developing social capital (e.g. networks, leadership, support systems) for disaster resilience learning communities; SNSs can be powerful instruments for informing others of the flood risks in their community, discussing and planning what is being done to manage the risks and what they can do; they can be used to provide support to people during and after the flood by communicating warnings and other information to affected communities. In this way, SNSs contribute to coordinate community response and recovery.

SNSs represent a platform to raise spontaneous networks useful in facing a disaster, disseminating information and warning messages. Furthermore, the large ease of access of these platforms makes them a powerful tool also during the recovery phase, as a collector of aid requests as well as to organise relief distribution. As a consequence, they contribute to make the distribution of support both based on the "rule of relative advantage" and inspired by the desirable "rule of relative needs". "Relative advantage" refers to the advantage which could be connected to being part of a community, having political connections and accessibility to resource; "relative needs" is more oriented to distributing support proportionately to the requests(Norris et al., 2008).

Acting *across* and *within* an affected community, these tools permit to share knowledge, information and also to receive/give psychological support. Norris et al. (2008) pointed out three social dimensions of "social capital": "sense of community", "place attachment" and "citizen participation". Structuring aids-network using SNSs improves all them and, in turn, the capacity of collectively react to disaster induced perturbations. It actually means put up a community and lean on community resilience.

## 3. Case study: the Elbe Flood in the city of Dresden. Methodology and analysis.

Between the 30th of May and the 3rd of June 2013 extreme heavy rains affected large parts of Eastern and Central Europe. The distribution of precipitations in the basin of the rivers Elbe, Moldau and Saale reached values two to three times higher than the normal average of June. The heavy rain resulted in surface runoff causing a severe flood situation. The city of Dresden was one of the flooded urban areas. With some 500.000 inhabitants, Dresden is the capital city of Saxony. The city was already flooded in 2002, when the whole city centre was invaded by the water. Different structural measures taken after the 2002 flood helped the city to better cope with the 2013 flood. Although these circumstances, the2013 flood determined significant impacts.

While the city was flooded, a spontaneous network of helpers was created using a Facebook page called *Fluthilfe Dresden*. This work aims at investigating the effectiveness of *Fluthilfe Dresden* page, aiming at estimating how it served in improving city' ability to arrange available resources in respect to the needs, and how it helped in improving the resilience of the flood affected community.

The analysis can be summarised in the following steps:

1. data collection;
2. post processing;
3. dataset elaboration.

### 3.1 Data collection

In order to collect data to be elaborated, a survey has been carried out pointing out the total number of *posts*, which represent the set of on-line published messages of *Fluthilfe Dresden* page. The dissemination of each post has been analysed on the basis of three basic Facebook functions: "*likes*", "*sharing*" and "*comments*". These functions allow Facebook users to show their support to published messages by approving the contents ("*likes*"), by posting the said messages on the own Facebook profile page ("*sharing*") or by adding comments giving reply and opinions ("*comments"*).

The page has been liked by ca. 43.000 users, who used it to ask, to provide help or to be updated about the flood. Data survey has led to observe that in the time frame from the 3rd of June to the11st of June 2013, 158 posts have been published on the page, with a total of 74652 sharing, 19602 likes and 4632 comments. The time frame has been chosen considering that it corresponds to the main operative period of the page, and it corresponds to the days the city was flooded.

A further analysis has been performed regarding the content of all published messages, distinguishing three main categories of contents: help requests, helping offers and communications. Although a wide variety of posts contents has been founded, requests and offers have been also organised depending on the typology of requested/offered resources (willingness/need to help or assist affected people as a volunteer; material aid offers or requests, e.g.: food, accommodations, blades, blankets).

The whole set of 158 post has resulted being made up by 59 help requests, 41 helping offers and 58 general communications.

Leaving aside communications, the set of offers and requests is resulted composed as follows:

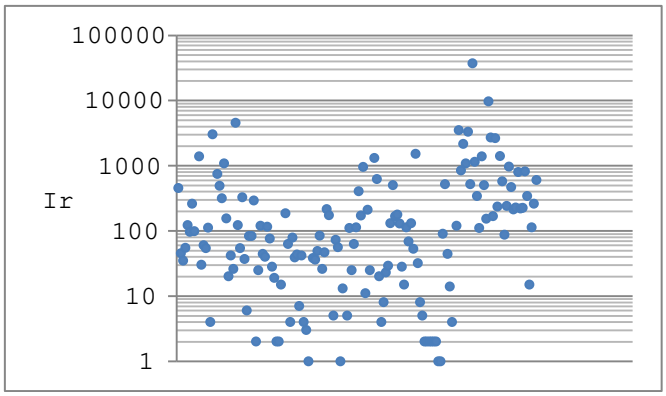
- volunteers help: requests,28.7%; offers, 22.2%;
- material needs: requests, 30.6%; offers, 18.5%

### 3.2 Post processing

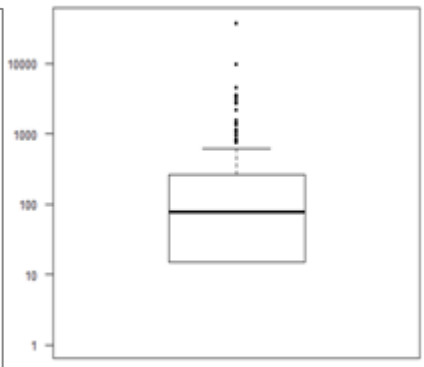
Likes, sharing and comments represent a way to virtually support, deal with and disseminate post contents. In accordance with this consideration, during post processing operations ithas been assumed that the more a post received likes, sharing, and comments, the more its contents were disseminated on line. And hence, more likely the offer/request could be satisfied.

For each post, a *response index* ($I_R$)has been defined as the sum of relative likes, sharing and comments. The $I_R$ value has been assumed as a measure of the efficacy of a certain post in terms of its spread within the Facebook users' community.

Dataset has resulted to hold both a large set of elements similar in their values and some others significantly different from the previous regarding to $I_R$ order of magnitude (Graph 1).



Graph 1.Scatter plot of "*Response index*" ($\mathbf{I_R}$) values



Graph2.Boxplot of $\mathbf{I_R}$ values in logarithmic scale

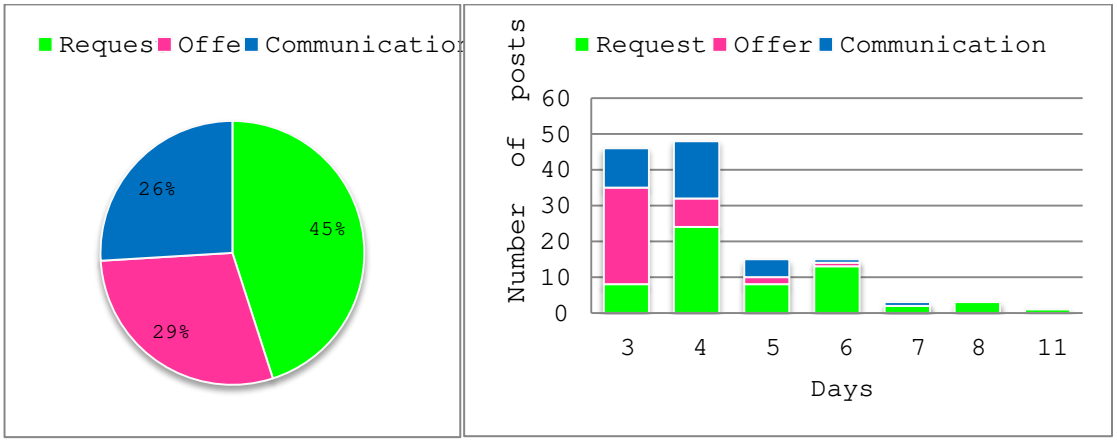
In order to substantiate the analyses, statistical based evaluations have been carried out. $I_R$ has been assumed as an observed variable and the set of its numerical value as a sample. Values dispersion has been investigated starting from quartiles, using boxplot representation. More in details, defining $q_1$ and $q_3$ respectively the first and the third quartiles, interquartile range $h$ can be obtained ($h= q_3 - q_1$). Outliers have been identified as values exceeding the range [$q_1$ -1.5 $h$; $q_3$+ 1.5 $h$] (Graph 2).

### 3.3 Data elaboration and outcomes

Once identified the outliers, they have been kept out from the reference dataset. Having pointed out 23 outliers, the original set of 158 posts has been reduced to 132 posts. The updated dataset has allowed not to taking into account outliers in all the following evaluations, ensuring an adequate significance to processed values. Main statistical moments of $I_R$ values for revised dataset have been evaluated (Table 2).

| | |
|---|---|
| Minimum value | 0 |
| Maximum value | 520 |
| Average value | 83.1 |
| Mode | 2 |
| Standard deviation | 128.2 |

Table 2. Main $I_R$ statistical moments



Graph 3.(a) Percentage of requests, offers and communication; (b) Posts by day classified in requests, offers and communications

The outliers' elimination has made the whole dataset composed by: 59 help requests, 38 helping offers and 33 general communications (table 4 and graph 3 (a)).Help requests represents a large part of the whole dataset, higher than the two comparable quantities of help offers and communications.

Further consideration can be deduced from deeply examining how posts are geographically distributed as well as within the chosen time frame.

Based on the posts' publishing date on *Fluthilfe Dresden* page, time trends have been deduced (Graph 3 (b)).Globally, the highest number of activities on the page has been registered on the 4th of June. As regards the Elbe River, the maximum water level was reached on the 6th of June. This matching shows that several factors determine the number of page users, such as: hydraulic levels and flooded zones localisation, number of affected people and their ability to be connected to Internet (as regards help requests), fame and knowledge of *Fluthilfe Dresden* page within Facebook users (as regards help offers and communications).

The distribution of these three categories through the different days is resulted to be not homogenous. On the 3rd of June the number of registered helping offers is much higher, while in the other days the number or requests is more relevant (Graph 3(b)).Help requests have resulted to be generally the most significant rate of posts' contents.

Some posts included the exact location of the concerned request, offer or communications. Thus, data collection has led to register the geographical position for the said posts. More in details, 82 posts have been geographically placed according to Dresden city districts divisions ("*Ortsamtsbereich*") (Table 3; Fig 1).

| Ortsamtsbereich | Requests | Offers | Communications |
|---|---|---|---|
| Schönfeld-Weißig | 0 | 1 | 0 |
| Radebeul | 2 | 1 | 0 |
| Leuben | 12 | 3 | 0 |
| Neustadt | 10 | 5 | 2 |
| Plauen | 1 | 1 | 0 |
| Loschwitz | 4 | 1 | 0 |
| Pieschen | 10 | 3 | 5 |
| Cossebaude | 2 | 0 | 1 |
| Altstadt | 7 | 2 | 2 |
| Freital | 1 | 1 | 0 |
| Altfranken und Gompitz | 0 | 1 | 0 |
| Cotta | 2 | 0 | 0 |
| Pirna | 0 | 1 | 0 |
| Blasewitz | 0 | 1 | 0 |
| Total value | 51 | 21 | 10 |

Table 3. Summary table on the basis of geographical available locations

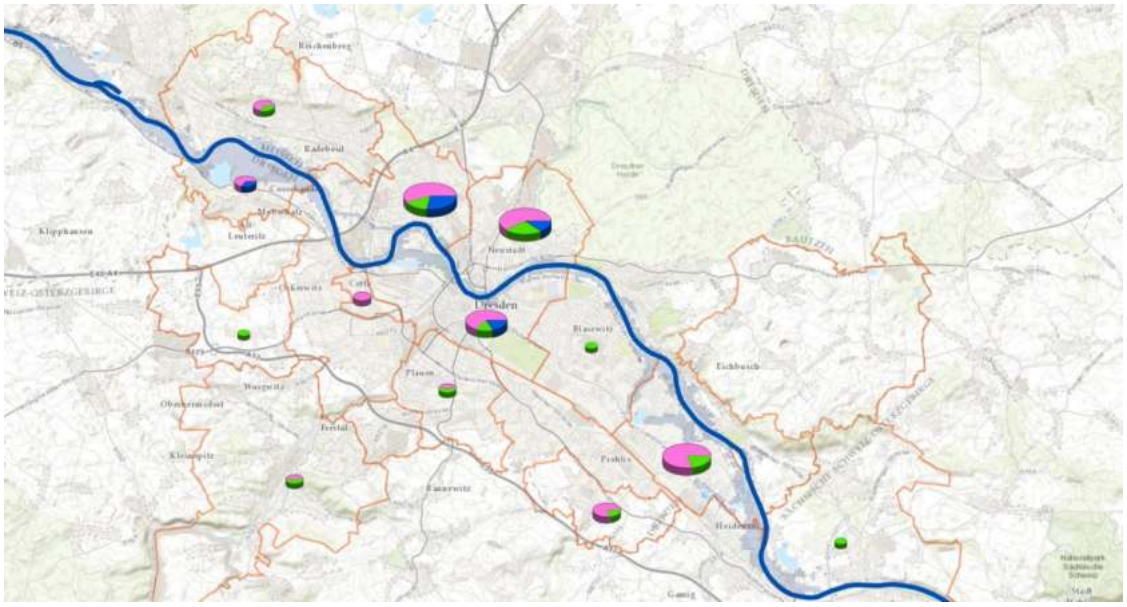


Figure 1: Thematic map (Scale: 1:150000). Dresden city districts administrative boundaries ("*Ortsamtsbereich*") (orange lines). Pie charts dimensions increasing with number of posts, representing help requests (pink), help offers (green) and communications (blue); maximum flooded area in June 2013 (light blue) based on PERILS data.

Being not possible to associate the exact place referring to all *Fluthilfe* registered posts, the cartographic representation of dataset values has resulted limited. However, data allow to point out that the webpage was especially used in the northern part of Dresden city (Pieschen and Neustadt districts). This circumstance could be related to the characteristics of this district to be mostly residential areas, easily accessible with public transport (e.g. Train station Bahnhof Neustadt and several tram stops), and to their location very close to the city centre.

A first measure of *Fluthilfe Dresden* page efficacy can be assumed as the response index average value, equal to 83.1. Therefore, each post has resulted to be read by 83 Facebook users on average. It has to be specified that this $I_R$ average value is just an approximate estimate. Due to characteristics of dataset values, $I_R$ considers only likes, sharing and comments reported on *Fluthilfe Dresden* page, not also all Facebook users that became aware of a certain post after the latter has been shared on users' profile pages. It is clear that this observation not necessarily means that each help request or offer received 83 replies. However, $I_R$ mean value helps in highlight the high potentiality of a tool such as *Fluthilfe Dresden* page in disseminating information and needs.

The response index has been calculated for each day (Table 4). Having defined $I_R$ as indicative of the web page global efficiency, the latter results more significant in the time frame from the 3rd of June till the 5th. Registering an $I_R$ value of ca. 40 %, the 4th of June can be identified as the most page efficiency day (graph 3).

The response index has been also calculated for each of the three categories requests, offers and communications (Table 4). The most efficient posts result those classified as communications, with a $I_R$ of ca. 60%.

| | Requests | Offers | Communications | **Tot.** | **$I_R$** (%) |
|---|---|---|---|---|---|
| June, 3 | 8 | 28 | 11 | 47 | 29.2 |
| June, 4 | 24 | 8 | 16 | 48 | 41.6 |
| June, 5 | 8 | 2 | 5 | 15 | 13.6 |
| June, 6 | 13 | 1 | 1 | 15 | 10.6 |
| June, 7 | 2 | 0 | 1 | 3 | 4.3 |
| June, 8 | 3 | 0 | 0 | 3 | 0.7 |
| June, 11 | 1 | 0 | 0 | 1 | 0.0 |
| **Tot.** | 59 | 39 | 34 | | |
| **$I_R$** (%) | 26.9 | 16.5 | 56.6 | | |

Table 4. Response index per day and per post category

## 4. Conclusions

Besides economic losses and damage in infrastructures and buildings, flood events and related effects act as a stressor for affected people in regard to psychological and social issues. Individuals can better face a perturbation leaning on help and support that can come from the communities they are member of. Being able to create virtual communities, SNSs holds a strong potent instrument for disaster management.

This paper seeks to understand how the use of SNSs, such as Facebook, can influence the social resilience during extreme flood events. More in details, the case of *Fluthilfe Dresden* Facebook page has been deeply investigated. During 2013 Elbe River flood, this web page created a spontaneous virtual network of helpers which turned into a real and effective aids network requests, offers and disseminating useful information, *Fluthilfe Dresden* page served to coordinate aids network and to provide a better and easily accessible communication network. The page has resulted to have reached a large popularity among the Facebook users community. This fame has been in this work estimated through a survey of all published posts, and defining a "response index" as a measure of page effectiveness.

Even being an explorative case study, *Fluthilfe Dresden* page demonstrates that the creation of social virtual communities via SNSs can generate effective platforms for informa knowledge building. Both these aspects play a significant role during calamitous events. In fact, the spontaneous *Fluthilfe Dresden* aggregation of people sharing problem/needs/opportunities turned into a useful tool, serving to coordinate aids network and provide a better and easily accessible communication network. As the case of Dresden shows, it can be stated that such virtual communities, created form the spontaneous aggregation of people sharing the problem/needs, can contribute to provide support and give assistance to the real community during and after flo

These observations lead to extend the already known wide potential of SNSs, as supporting instruments for disaster management, they are able to contribute to globally improve recovery and resilience of affected communities.

Optimising use and allocation of available resources (both materials and not) and contributing to making the city system globally capable of responding to the emerging needs (acting as a community), SNSs can represent a strategic element during and after the event. *Fluthilfe Dresden* page was spontaneously created during the event recognising the considerable entity of the event and its impacts. With reference to settlements located within flood prone areas, aids networks based on SNSs could be properly arranged also before the event. Organising a web based platform able to collect help's offers -before the event- and SOS messages and requests -during and after the event- results considerable in defining community behaviour facing with the disaster.

SNSs based tools create bottom up aid networks which could integrate institutional measures. Advantages could interest all actors involved in disaster management as well as affected people: institution, organisation and bodies in the area of Civil Protection obtain a structured useful collection of "helpers" availability and their location; affected people can communicate their needs and, at the same time, receive support and help as well as real time information about the flood event and operative issues.

Improving both efficiency and efficacy of aids networks, structuring SNSs based tools help in improving community readiness to the risks they have to cope with, contributing to building flood resilience communities. This view descends from and has its roots in considering community resilience as a process to be suitably made up before the perturbation occurs, ready to be performed during emergency situation.

# QUALITATIVE GIS AND SOCIAL JUSTICE IN THE URBAN MANAGEMENT

Elena Giannola[1]

[1]Dipartimento di Architettura, Università degli Studi di Palermo, elenagiannola@libero.it

Keywords: participation, GIS, social justice

## 1. Introduction

*Multiculturalism and multi-ethnicity are increasingly transforming European cities: in this complexity, making right policies to guarantee the social justice and the quality of life is really difficult.*
*More generally it s an ethical problem. Society isn t uniform, and to safeguard the multi*
*giving all the citizens (women, children, strangers, young or old people) the same rights, we must change the way of making knowledge. Planners should adopt mixed methods (quantitative and qualitative) to analyse the urban context, and also representations should include all points of view, through new mapping systems. Traditional maps could be integrated with new typologies of drawings, like mental maps or similar, to be more inclusive and more representative of the reality.*
*ICT and digital mapping systems like Geographical Information Systems (GIS) can represent a valid support for this new geographical vision: for example, touch screen devices could be used in the participatory processes to draw collective digital maps, as an interactive document for the local governments and for planners.*
*The citizens needs can be expressed with the map s language, as well as the decisions are drawn on the master plan.*
*International researches about this theme have produced some interesting experiences of qualitative GIS , forced the traditional instrument s limits, using mixed me multi-level interpretation of spatial context. In this way it s possible to bu image, influencing the spatial perception and the hypothesis of future about the urban and regional development.*

## 2. Social inclusion in the territorial analysis: a new method for a new urban democracy

Cities are evolving: in this complexity, making right policies for guarantee the social justice and the quality of life is really difficult. Consequently is necessary improve the management of a social texture composed by different cultures, questions, opinions.
It s an ethical problem (Forester, 1989; Lo Piccolo and Thomas, 2009) that determines subs consequences on the urban management, from different points of view (political, economic, social and cultural).
The traditional analysis of the urban context follows a rigid scheme: the planner observes the physical and the social aspects of the city, he analyses the urban connections and the economical-social dynamics, he finally expresses evaluations and opinions and anticipates future developments. In this way there is an unique way of knowing: the scientific point of view of the planner is the reference for the data interpretation.
However the increasing complexity of the social and cultural context of the contemporary cities needs another way to analysis and evaluation. Usually the urban policies are referred to a hypothetical person: an adult man, born in the same city where he lives, who has an average level of education (a frequent model is a person White Anglo-Saxon Protestant, WASP). The urban population are really more fragmented: there are many ages ranges, different sexual identities, different cultures, different opinions about the common services and the use of collective resources. In the city there are many rhythms, different uses of the same spaces in different times.

It s not possible to define a single point of view to represent the urban co
analysis. We need a multilevel knowledge, and an integrated system to analysis. The two-dimensional representation of the city or territory is too constrictive: there are many important elements to represent in the city map, but often they are immeasurable and we cannot compare them. This determines a representation problem: if we can t have a common s
factors, we will choose a particular and specific parameter to select references and to draw consequently the other elements. The representation of the city, and generally the management of the urban dynamics, should be more democratic and inclusive (Lo Piccolo and Picone, 2014).
In the Seventies the researchers started to introduced a critical interpretation of the scientific method to analysing: if we change the criteria of measure, we will change the results of the research. In this mutation of the scientific method s approach, especially in the human and geographical sciences related with the city, a great role has been represented by feminist critic to the theory of a universally valid knowledge, based on the principle of «eye s
2002, p.274). So we need a way to compare the different information we collect from the urban analysis, but this is very difficult because of their ontological difference (material and immaterial issues, quantitative and qualitative data). To this aim, we can utilize a mixed method, composed by qualitative and quantitative analysis, in various phases, to reach at the last a knowledge more complete.
Sara Elwood writes: «If all knowledge is partial, then incorporating multiple forms of knowledge is a fundamental practice of good science. So-called "expert knowledge" is but one of many valid forms of knowledge that may be brought to bear upon a research question, and experiential forms of knowledge be equally appropriate» (2011, p.383)
At this moment in the scientific community there is a debate about the fundaments of mixed methods: some researchers (England, 1993; Hanson and Pratt, 1995; 2003) think that is correct to conduct separately different typologies of analysis, and then express an overall assessment; others researchers (Jiang 2003; Nightingale, 2003; Knigge and Cope, 2006) think that is correct utilize a mixed method in all the phases of the research, integrating different methodologies to analysis, to achieve a complex mix of results (Elwood, 2010).
Therefore the multiplicity of the urban contexts determines the necessity of a multilevel and integrated methodology of analysis and action.

## 3. Overview of the new ICT tools: e-participation and web interactive mapping

There are various technical instruments to enhance public participation in decision making processes: surely the ICT are really a great resource in this context. In my PhD thesis I analysed some of this application: in all the cases, the main objective was to improve the communication between people and administrator, or between different social groups in the city. The communication is the most important aspect in the participatory dynamic.

### 3.1 ETM and DEMOS-plan: PARTERRE project

The PARTERRE project (Electronic Participation Tools for Spatial Planning and Territorial Development) involves the following partners: the Tuscany Region, Sector Innovation and Research in ICT, University of Palermo and the company Urban Adventure Ltd in Italy; the company TuTech Innovation GmbH and the city of Hamburg in Germany; the University of Applied Sciences in Turku in Finland; the University of Ulster in the United Kingdom; the Community Council of Voroklini in Cyprus (Table 1).This project has been developed as part of the two strategic tools of interaction between users and information exchange, DEMOS-Plan (product from TuTech Innovation GmbH of Hamburg) and ETM-Electronic Town Meeting (produced by Urban Adventure Ltd), then applied to local circumstances.

| PROJECT | TYPOLOGY | ACTORS | |
|---|---|---|---|
| PARTERRE | **European project**, focused on territorial management by ICT and innovative technologies. | ITALY | ✓ Regione Toscana;<br>✓ University of Palermo<br>✓ Avventura Urbana s.r.l. |
| | | GERMANY | ✓ TuTech Innovation GmbH<br>✓ City State of Hamburg. |
| | | FINLAND | ✓ Turku University of Applied Sciences |
| | | UNITED KINGDOM | ✓ Ulster University |
| | | CYPRUS | ✓ Voroklini Community<br>✓ ANETEL society |

Table 1. PARTERRE project

In the website of PARTERRE project we can read:
«The PARTERRE Consortium a public/private partnership consists of a balanced mix of academia, public authorities, SMEs and NGOs covering the breadth of Europe and is designed to provide a wide range of expertise on business, technical, government and scientific issues related to spatial planning, environmental assessment, Living Labs, public administration and eParticipation topics» (http://www.parterre-project.eu/?consortium=1).
In this context, the partners used two technologies to realize public participation related to discussion about local territorial topics: the Electronic Town Meeting (ETM) and DemosPlan (DP).
I would focus the discussion on ETM, because it s the typology of technology th project s context, by the University of Palermo. It was an experiences totally for many reasons, especially for the building of a new social, collective image of the city (Lynch, 1960; Memoli, 2005).
«With the Electronic Town Meeting, not only are the citizens directly involved in a public decision making process, but the issues discussed are also prioritized in a way that is immediately visible to policy designers. Recently, the Regional Government of Tuscany has imported the Electronic Town Meeting into its own policy practice, by organizing about ten initiatives of such a kind since 2006.
Over time, this has led to the creation of an Open Source, web-based application for collective discussion and voting support, which is integrated with a streaming server to host the participants who may be localised remotely» (http://www.parterre-project.eu/?electronic_town_meeting=1).
ETM (Garramone and Aicardi, 2011) it s a good method to simplify the discussions, voting and to synthesize results: often people discussions are difficult to moderat compare different points of view. Another benefit of ETM is the feedback of the users: the participants to the project feel themselves like a really authorities.
Registering their opinions and their point of view is important to confer them the appropriate importance: they really see that the computerized system has registered their votes and their ideas, and consequently this fact produces confidence in the stately institutions, because it s verified t the govern hears the people s voice.
This is the most important result of the project that we can observe in Palermo: people was proud to collaborate with University and with Europe, and consequently the participation was successfully.
In Palermo there were a lot of other topics related to the project: one of these is that the location of the ETM was in a historical building, the Maredolce s Castle, that is a symbol part of the city. Maredolce s Castle is in a neighbourhood of Palermo called Brancacci famous for its high level of criminality and for the neglect by public administration for a very long

time: people who live there would a change, a new image of their city, and the historical buildings are for they a possibility to show their cultural and artistic value.
So, the PARTERRE project was for Palermo an opportunity to recuperate values and identity, to dialogue with people, to improve civic knowledge, to confer meaning and importance to the citizen participation. In the 2014 the city s major, Leoluca Orlando, organized a cycle constituted by five different ET Meetings, to improve citizen awareness about city and territory.

3.2 Participated webGIS: local platforms

In the UK there are many experimentations about participation tools, especially about participative GIS. There are local platforms, or also regional or national instruments to m requests, the territorial needs and the political choices.
One significant example is made by Neighbourhood Initiatives Foundation (http://www.planningforreal.org.uk/) for the master plan of Slaithwaite, and is a tool to engage the community in local problems of environmental planning. In this case the base map was made by technicians in scale 1: 1000, and exhibited at the event planning group organized on the day of the local fair, crowded with many participants (Carver et al., 2001; Kingston et al., 2000).
The use of a computerized system rather than paper for the map display has allowed, among other things, to control the visibility of comments (made accessible only to the conclusion of the discussion, so as to stimulate the participants ideas and original proposals and creative ), and the recording of many more contributions at the same time of similar experiences of Planning for Real.
The end result of this process, managed through the web platform (available at: http://www.ppgis.manchester.ac.uk/projects/.html), was a new plan of the village that brings together most of the comments from people who live and work in that community.
With this project we have tried to minimize the conflict and to reach decisions acceptable to most stakeholders through consensus-building approaches based on the achievement, by an increasingly large component of the urban population, of a better understanding of spatial implications of the decision making process.
On the web platform http://www.ppgis.manchester.ac.uk/projects.html are several projects of this type, such as IntelCities, project funded by the European Community (Kingston, 2007), designed to support and make more open and transparent debate on the theme of space.
This type of system is based on flexible technology of Web Map Server of the Open Geospatial Consortium (OGC), from which provide the base maps (basemap), and supports a variety of spatial data formats including ESRI shapefiles and various raster data formats such as GeoTIFF. It also has functions for the inclusion of additional layers to show geospatial data and significant information relating to territorial policy, which means that you can deploy and change, albeit limited, depending on the particular local needs.

## 4. Participative GIS: structure, working and potential applications

The focus of my PhD thesis is the participative GIS: the question of mixed methods could be applied to the technical tool, as a GIS, so we can imagine a GIS more flexible and more adapt to describe the social and cultural component of the urban contest.
Actually there are many experimental trials: the researchers are trying to overcome the conflict between the mathematical and quantitative structure of the traditional GIS and the necessity to represent also qualitative social data.
Critical GIS and qualitative GIS are possible (Cope and Elwood, 2009; Knigge and Cope, 2006; Kwan, 2002).
The first trials to realize a GIS more inclusive in relation of qualitative information have produced a multimedia GIS: the map was conceived as an hypertext, linked to photographs, mental maps and other materials. However in this way we have the qualitative information like a later addition, not as a constitutive part of the system.
We need a GIS really inclusive in its structural paradigm, from its original design and not only in the final utilize.

The idea of a participative GIS (also defined Public Participation GIS, PPGIS) is based on the assumption that the data stored in the GIS and spatial analysis tools can give the different groups in society, including various minorities (ethnic, gender), the ability to claim their rights in decision making and planning in the redistribution of land resources.
The idea of a PPGIS could be interpreted as a reaction to the perception of GIS technology as a top-down, technocratic and not inclusive of the interests of social groups involved in decision-making.
The PPGIS is thus basically designed as a tool that works with a bottom-up mechanism, a facilitated technology, strongly characterized in a social sense. It allows users to combine their knowledge, ideas, perceptions, informal and qualitative data, with the official (but not most important) knowledge of the territory about the physical description. So we can have a different interpretation of the value and of the effective location of the geographical elements, because they aren t related only to the coordinates stored in the GIS database, but also to referencing system.
The idea of a PPGIS is not very recent, dating back to the Nineties, but since then it has expanded considerably and now it constitutes a large and consistent stream of research in the field of geographic information science (Nyerges, et al., 2011, p.350). The fundamental concept is to provide a cartography "deformable" depending on the variables you want to highlight, identifying a display adapted to each typology of variable. In this way the representation of the physical context will not be realized in the same way as that of quantitative variables of social type, and will be different from the mapping of qualitative information.
The process is reminiscent of the old system of overlapping transparencies of McHarg, in which the scholar, aware of the impossibility of reducing to the same numerical scale evaluation different typologies of variables (economical, historical, artistic, environmental, social), attempted to operate comparing, on an experimental basis, restricting himself to draw backgrounds that showed where that variable was more or less expressed, then overlaying transparencies between them, identifying where there was a higher concentration of "value" in a broad sense and where it was this minimum (McHarg, 1989).
Although the experiments in this direction are made for about 20 years, the literature on the evaluation of the real effects of PPGIS in planning practice is not very la fundamental to define exactly what we mean when we talk about PPGIS.
The concept of GIS in public participation is based on the assumption that the geographic data stored in GIS and spatial analysis tools can give to different social groups the ability to represent their interests in the democratic decision-making about the distribution of land resources.
In my PhD thesis I have applied this methodology to an urban context in the city of Palermo, comparing the theoretical issues whit the practical context.

## 5. Case of study: mapping the neighborhood

5.1 The urban context: two neighborhoods in comparison

I have chosen two neighborhood really different for many aspects: Arenella-Vergine Maria and Albergheria.
The first context, Arenella-Vergine Maria, is an urban district delimitated from an administrative point of view: it s the district number 25 in the city of Palermo. It s a periphera the sea, and the social composition of the population are quite homogeneous, because there are almost exclusively native residents. The condition of the buildings is between good and mediocre, there are only a few examples of evident degradation.
There are some monumental and significant urban buildings, like the Rotoli s ancient tuna fisheries, a decommissioned chemical industry; there are also natural references like the sea and the beach. These elements are really important at the neighborhood scale.
There are some services, but not enough in relation to the normative standards.
The second context, Albergheria, isn t corresponding to an administrative district, but part of the historical centre of Palermo. It s a neighborhood in a social sens

the population is very heterogeneous: there are many foreigners, especially people who came from Africa and Asia. There are also European immigrates, principally they come from East-Europe, but Indians, Nigerians, Kenyans, Ivorians and North Africans are the majority.
The condition of the buildings is really bad, and the public spaces are utilized by residents like an extension of their own houses: there aren t really a public control, so thi considered a social shade zone .
The aim of the experiment was analyse the sense of identity and belonging of the inhabitants in this two urban contexts, and mapping it to express, through the figurative language, the social perception of these places. At the last, the experimental process was repeated using the master plan of these two urban districts, showing the real points of interest for the urban communities, and reading in correspondence the master plan previsions for that places.

5.2 Two different representing methods: manual stretched or automatic deformed GIS maps

To represent the social perception of the urban context, I have utilized the software ArcGIS and I have applied two different methods: a manual stretching of the basemap, in order to a mental map of the same urban area, and then an automatic deformation of the map, using the tool Cartogram.
In the first case, I have realized both an urbanistic analysis of the urban context (size of the area, building typologies, services distribution, and more) and a social analysi methods like interviews and mental maps (Corbetta, 1999). Then, I have synthetized all the mental maps and the other information in a general mental map, and I have transformed it in a digital map using a common scanner. Finally, I have uploaded it in the GIS software and I stretched the original basemap (raster format) trying to match the points of reference (monumental buildings, landmarks) of the basemap with the same points drawn on the mental map. I have used the tool georeferencing to this aim: in this way I have changed not only the position of each p also the whole referencing system. I have passed from a quantitative referencing system to a qualitative elements frame. The use of the georeferencing tool is theoretically significant in this operation (fig.1).

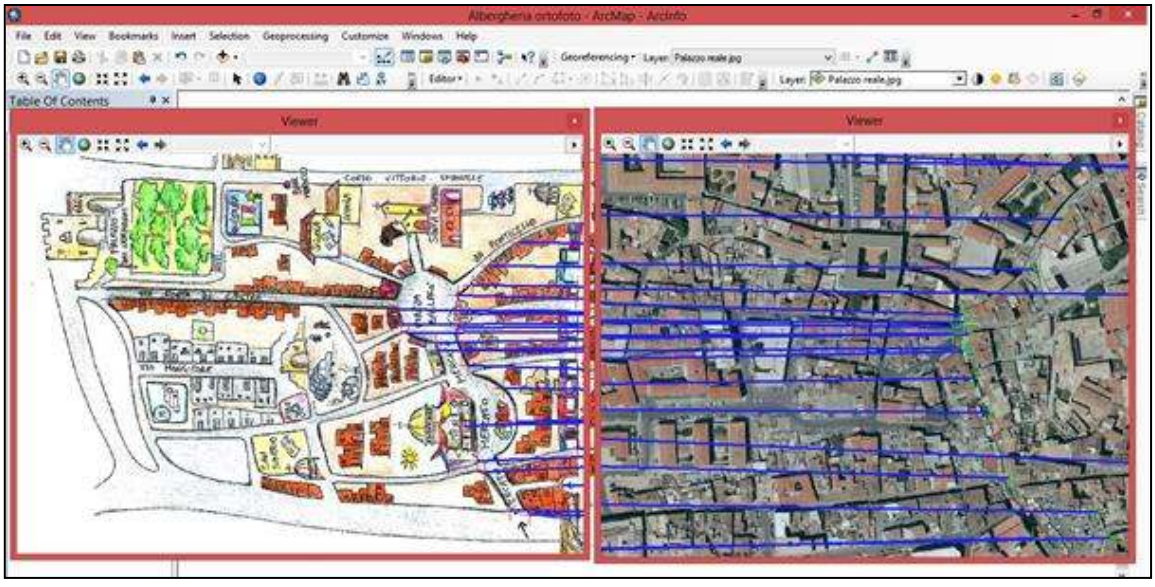

Figure 1. Georeferencing of basemap in relation to corresponding mental map.

The second method has a different process: after a qualitative survey about the social context, I have categorized the information in a table, and I have determined a value scale based on the frequency of the people s answers about the public spaces, the neighborhoo landmarks and more. After this operation, I have attributed a numeric value to each important

spatial element of the urban area, and I have selected a vectorial basemap (a shapefile of the urban area), because the applicative tool works changing the areal size of polygons.
Cartogram has been realized by two researchers, Gastner and Newman (U.S.A substantially an algorithm finalised to resize the States of the world in relation to their population and not for their areal extension, like in the fig.2

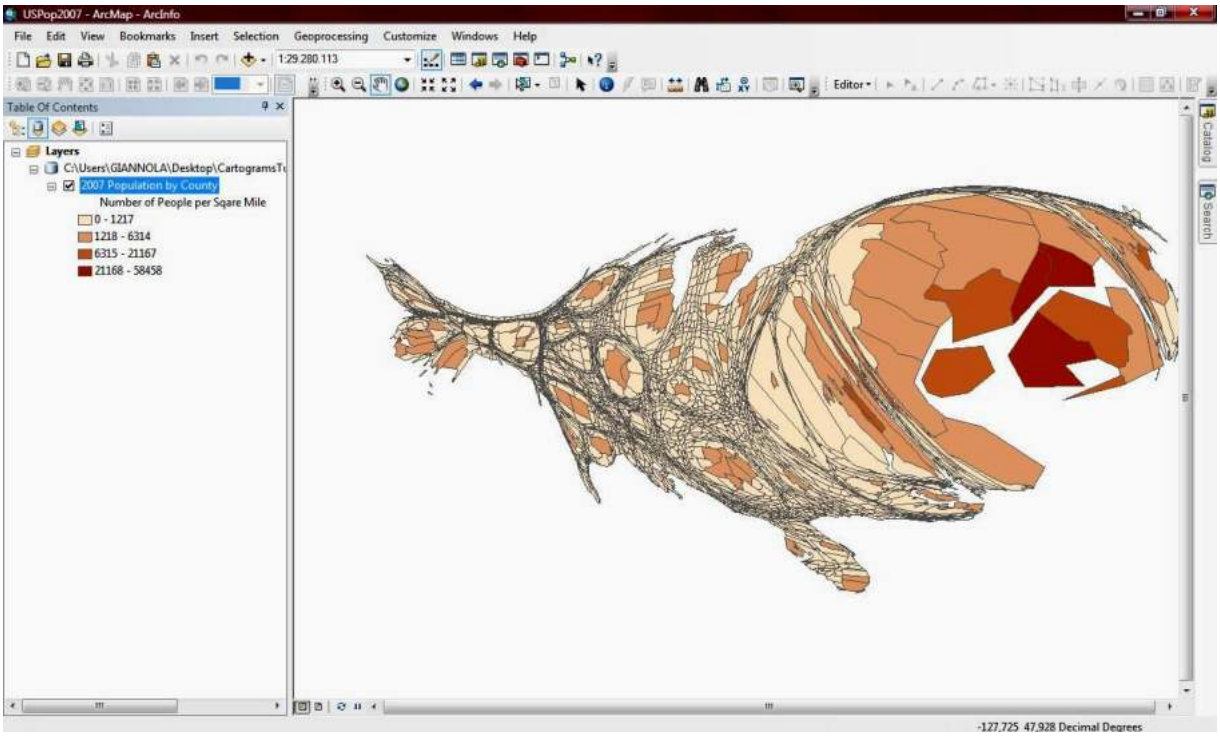

Figure 2. Demonstrative example of the Gastner and Newman s method

Cartogram it is designed to represent an approach to geography less physical and more social. It intends to enhance in the representation not the size of the territories in terms of area but the amount of people living there. In this way, as the data is still considered quantitative, scholars software authors have drawn attention to the "human" component of the territories studied, emphasizing that the presence of the inhabitants is the key element of a territory (Nyerges et al., 2011). It is certainly a big step forward in the relationship between geography, technical planning and human sciences, but it is still a partial point of view: for example, it environmental ecosystem in which man lives at the same level of importance of the amount of people who focus in it.
The definition of the fundamental criteria of a similar system of representation is therefore subject to the particular type of analysis to perform, and certainly a system of representation does not exclude the other, in view of a study as much as possible inclusive and integrated.
Comparing the two methods, the first (manual stretching) result more adapt to represent our objective: the automatic method presents some technical difficulties to appli projected for very extended geographical areas and not for little subdivisions of an urban district. Another problem is the necessity to force the qualitative information to became a quantitative datum: the choice of the value scale in that case present some critical points about the propriety of the method.

5.3 Results

At the end of the GIS processing the map has been deformed: the points of interest are more extended, some areas are stretched and some others are compressed.

This deformation has been applied in the same way to the master plan: the extension of some specific urban areas corresponds to a more deep perception of them by the inhabitants. In the fig.3 we can observe the deformation of a crossroad, called Ballarò square : in the perception it s really a large squares, because is a very important point of referer residents know.

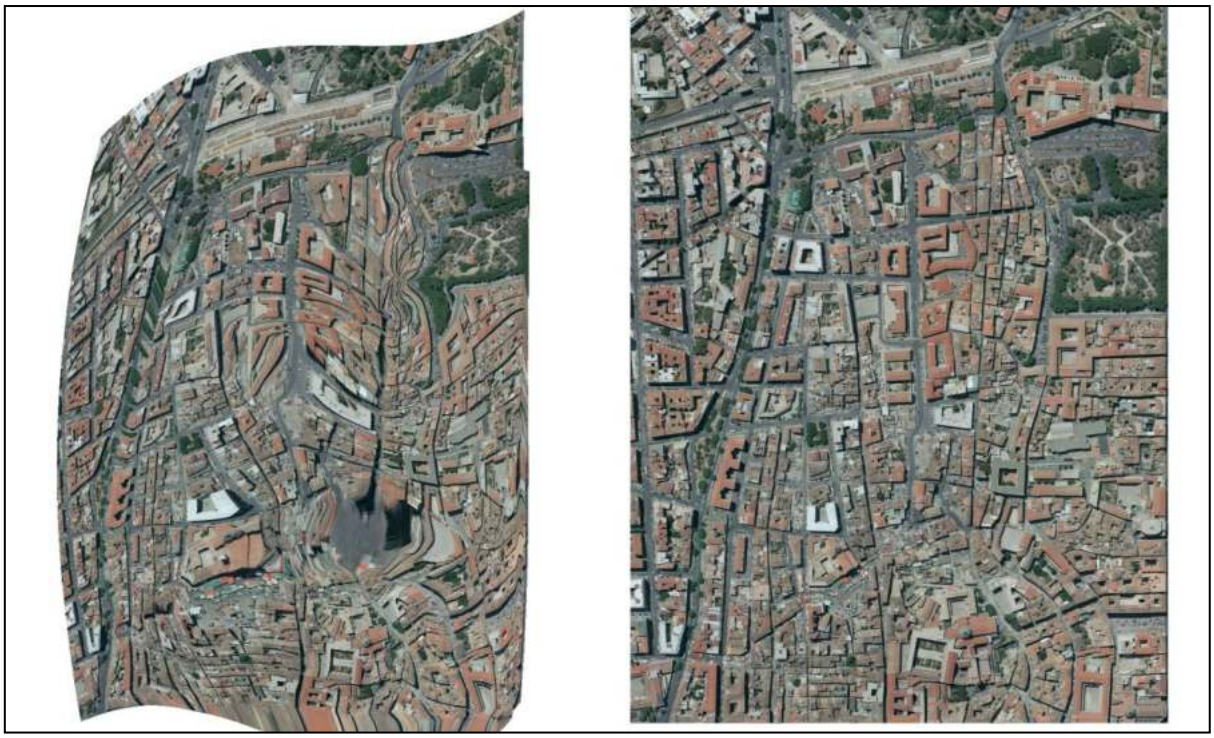

Figure 3. Comparison between deformed and original map of the Albergheria neighborhood.

The importance of this place derives from the fact that it is a place crossed to go through several directions, in each of which there is a reason of interest. To the left (south) there is the market of Ballarò; always in the same direction, the central train station; down (to the east) there is Via Maqueda, a very important commercial urban axis, where the services are focused on education (Faculty of Law) and the city administration (Piazza Pretoria and the Town hall of Palermo); on the right (north) we find the accommodation centre of Santa Chiara, and subsequently Piazza Bologni, until you get to the axis of Corso Vittorio Emanuele. Finally, on the top of the map (west) there is the Norman Palace, the police station, the public garden of Villa Bonanno, the connection to the railway station Orleans, the University campus. We can define the square Ballarò as a centralizing element of movement. We can see clearly the non-linear paths, except for a few main lines. We can note the high building density of the Porta di Castro street, where the buildings seem to thicken, and the spaciousness of via Mongitore (both in East-West direction), which also ends in a square just before Ballarò square (really it s now an empty space used for parking, where children play football and where they accumulate bags of uncollected rubbish).
In the masterplan, this focus point corresponds to a lack of planning. The master plan for this area in fact provides only that the streets are driveways: it doesn t consider pedestrians, is not given the right importance of this point as a landmark and as a sign of identity and recognition of the district.

## 6. Conclusions

The integration between the computerized map and the intuitive representation of mental map, and then the integration between the quantitative data and the qualitative ones, has determined a hybrid representation, a computerized map "deformed", expressive of both points of view.
The product obtained is an example of what could be accomplished by applying a mixed methodology of analysis (Elwood, 2010; 2011).
The fact that the deformation is made through georeferencing assumes an important meaning: working in this way we force the system of geographical coordinates in which are located the points we have moved manually on the map. We use a command that has already another specific function, that belongs to a logical system completely different. The points have a position in the space, as well as physical objects have a shape, but there is a big difference between the position detected by instruments and the position that is perceived by the people, and it s the same for the shape. The GIS is an instrument designed to represent and calculate points and coordinates referred to a geometric grid recognized globally as valid, so doesn t have tools that allow to track other types of representation.
We can interpret the use of geo-referencing as a tool for "deny" the officially recognized position of each point in different ways: it s a forcing, denoting the need to further d the instrument; it s also an innovation to enable GIS to contain more cartographic records, to make GIS a multidimensional instrument; Finally, it s a provocation, finalis the ethical question related to the choice of a single system of representation and to the consequent exclusion of other systems that could instead be recognized as equally valid.
The disciplines involved in this work are at least three: Planning, Social Sciences and Geomatic. For the Social sciences the topic more interesting to develop is the social justice, which concerns the democratic nature of the instruments of government (in this territorial governance), the transparency of operations carried out (the accessibility of web platforms encourages the social control on policies that are implemented by decision makers) and the inclusion of all elements of society in the territorial context. The social justice encourages a dialogue, moderates the conflicting, takes account of the needs, expectations, collective wishes without discrimination or marginalization. To do this it is clear that the digital tools are not enough, because Internet and ICT have limitations related C: however PPGIS can be a valuable support to the participatory process, properly used and integrated with the traditional practices of participation offline.

# TECHNOLOGY, INFORMATION AND ACTORS: CONNECTING THE SMART CITY PARTS

**Author: Alexandre Hojda**

PhD. Student in Urban Management at PPGTU PUCPR Brazil[1],

E-mail: profalexhojda@gmail.com

## Abstract:

*Smart City is the sum of the parts that involve technologies, information and actors. Information and Communication Technologies (ICTs) are given great prominence, but are only one of the parties to the smart cities development (non-exclusive, nor the most relevant). The information needs to be dynamic, available, with quality and organized, to be better offered and demanded. Finally, the actors, whether government, private or civil society are extremely importance for the realization of smart city.*

*ICTs are essential, but the investment in human capital must occur for the smart city success. Perhaps this is a gap in the literature (and in practice) of smart cities, since, for the actor to act properly, this should be trained and encouraged in the actors relationship, with trust a unpreparedness, ignorance and discouraging of the actors involved can lead to a negative scenario of disinterest, discontinuity and, finally, make every project "smart city" lose its ability to integrate, to act and to contribute.*

*The aim of this study is to analyze the smart cities as the result of the group from different parts: technology, information and actors, because, above all, the latter is often "placed in the background" when talking about smart city.*

**Keywords:** smart city, technology, actors.

[1] This PhD. Study is supported with scholarship from CAPES Foundation, Brazil.

## 1) Introduction

Characterized as complex, heterogeneous, with predominantly unplanned infrastructure and, in general, with short-term public policies, cities attended the worsening of their urban problems in mobility, pollution and public safety, resulting in reduced quality of life.

The challenges in urbe involve both governments, who are under pressure by increasing demands (versus tight budgets), as the society, that need to learn to live in the fiercest urban areas, whose public services are far from adequate.

Taurion (2011) points out that the expansion of urban problems requires a new attitude of the public administration, both in planning and acting, as in partnerships (between different government levels and with the private sector) and in the citizen empowerment.

The cities are dynamic, offer and demand information, and the adoption of technology for their management is not something new. Concepts such as Informational City (CASTELLS, 2003), Augmented City (FIRMINO, 2004), Cybercity (LEMOS, 2005) are already established in the literature.

Against the backdrop of urban difficulties, the relationship between city and technology can be a way to improve the cities responsiveness and resilience. This relationship materializes in the phenomenon "informational city", whose emphasis is on the use of Information and Communications Technology (ICTs) for urban management.

Currently seeking to expand the use of these technologies in urbe, in an attempt to improve the decision making process. Therefore, it is vital to be fast, accurate and be connected. Thus, the discourse of "smart city", which involves more than just the adoption of digital technologies, arises, but the perception of "smart" as vigilant, snapshot, efficient, connected, integrated, etc.

In the smart city each part is relevant and interferes with each other. Technology should be modern, connected and interconnected; information needs to be available, with quality and organized. Finally, the man, whether governmental actor, private or connected to the society (offering or demanding information and services) should be included in the process, getting attention for improving their integration and their role in the set. Thus, all parts are extremely importance for the realization of intelligence in the city.

The aim of this work is to show the smart cities as the result of a set of different parts: technology, information and actors. However, these actors are often left in the background when i about smart cities.

Besides this introduction, the paper presents four items: the second part details the smart city; the third text component addresses the technology and information; the fourth item highlights the actors and the relevance of their activities in this context. The fifth text component characterizes the relationship of parts to the whole in smart city and finally presents the conclusions.

## 2) Smart City

The term smart city is comprehensive and abstract, and in the literature presents different descriptions for smart city, which often play concepts such as: digital city, information city, connected city, teletopia , cybercity, city knowledge-based, smart communities, electronic community, e-commun space, etc. Smart city is a concept closely connected with technology and information, but there is no single definition that clearly establish what is and what are its characteristics (QUESADA and PULIDO, 2012).

Sometimes the term digital city is used as "first step" in the direction of being a smart city, as part of a new way of flow distribution of people and information on the city. The digital city is not necessarily intelligent, but all the "smart cities" have the digital associated with them (FERNANDES & GAMA, 2005/2006).

In the 2000s, the term "smart city" came to be used widely by private technology companies such as IBM, Cisco and Siemens, associating this product as a solution to the cities. Their packages "pre-drawn" are offered to local governments with the "promise" that "technology will solve their problems" and it is sold as the 'future of the city' (LAZAROIU & ROSCIA, 2002) e (CÂMARA et al., 2012).

Under private influence (and in attempt to minimize their problems), various cities around the world have adopted the discourse of informational city, specifically the "smart city" as something by itself "solve" all the problems of the city (mobility, connection information, monitoring and surveillance, public safety, among others). There is a wide range of characterizations in the literature about smart city projects, can be found projects who call themselves smart cities, with approaches such as: governance, environmental, economics, citizenship, Wi-Fi, smart energy, information and services on the Internet, monitoring and surveillance, etc.

To facilitate the understanding, adopts the concept of smart city :

> "... The city is smart when investments in human and social capital (smart people), transport (smart mobility), digital infrastructure (ICTs), sustainable economy (smart economy) and a high quality of life (intelligent life), adding the sound management of natural resources (intelligent environment), through a participatory governance (intelligent governance)" (STEENBRUGGEN, 2014, pp. 3).

The smart city should be viewed as a system where the parties (transport, energy, education, health, water, public safety, etc.) are inseparable, forming an interconnected system. In practice, attempts to generate a balance to improve the efficiency of the systems that make up the city, and the planning can

be based on information separated by sectors (problematic or not) or by geographical area (QUESADA & PULIDO, 2012).

The literature is imprecise, but commonly stands as relevant points for the smart cities organization the integration of different systems and public policies, as well as factors related to (CÂMARA et al, 2012, pp. 6; LAZAROIU & ROSCIA, 2012):

- Smart economy**:** innovative spirit, entrepreneurship, productivity and flexibility in the labor market, international insertion, ability to turn, etc.;
- **Smart people:** skills, creativity, participation, social and ethnic pluralism, adaptation to cosmopolitan, participation in the collective, etc.;
- **Smart governance**: encouraging to social participation, quality of public services, government transparency, strategies and long-term planning, etc.;
- **Smart mobility:** accessibility, sustainable transport systems, ICTs available on infrastructure, innovation and safety in sustainable transport system, etc.;
- **Smart environment:** stimulus to urban sustainability, combating pollution, environmental protection, natural resource management, etc.;
- **Smart live:** life quality for citizens, cultural and educational facilities, health, security, tourist attractions, social cohesion, etc.

Taurion (2011) states that two points are needed in order to become a "smart" city. The first is the long-term planning, define how wants the city to in 15 or 20 years in terms of: infrastructure, attractiveness for business, efficient management, quality of life, etc.

The second point is the organization of the stages of implementation of the smart city project: I) determine the most relevant systems; identify the most problematic and the most impact; II) quantify the inefficiencies; III) analyze the inefficiencies causes and who are the stakeholders for the solutions definition; IV) identify and estimate the benefits and the role of each actor; and, finally, V) implement the solution, and the vast majority of the solutions involve more than one actor. For this, the empowerment, trust and cooperation should be seen as essential.

A smart city can be designed as an environment that integrates ICTs, information, physical infrastructure, government and society, seeking to improve the efficiency in the management of the urbe, and the city can be considered smart when ICTs become "invisible" (as these are embedded in the physical artifacts and day to day environments). Thus, the society shall not see the technology in their daily lives, just feel your benefit.

## 3) Technology and the information on the Smart City

The technology now allows to measure and control things previously unimaginable, as well as providing connections between different objects (eg, the Internet of Things), enabling the exchange of information with each other and may result in autonomous, preventive and corrective actions.

Data are relevant to the development of diagnosis and prognosis. These, when aggregates value are transformed into information which, in turn, can result in knowledge benefiting urban management faster, accurate and appropriate (KLAUSER & ALBRECHTSLUND, 2014; KANASHIRO, 2013).

Modern cities offer many data: people, mobile, public and private vehicles, displacements, offered and demanded public services, etc. Mostly, are available data, but their collection and organization are not simple. However, with the available technology it is extremely feasible and accessible. The information s analysis can help municipal urban management to know more and to identify patterns and relationships that help in the search for solutions to urban problems.

Lemos (2013 & 2010) emphasizes that people produce and use information. With Big Data, people can offer and have access to information more broadly, which, by the government side, improves the management of the city, and, on the citizen side, not only improves the use of urban structure, but its empowerment on the urbe.

Remember that "knowledge is power" and not all actors are willing to share their power. Thus, often ends up predominating the individual rather than the collective (STRAUHS, 2012).

## 4) An actor prepared for a smart city

Smart city is more than just the sum of technologies to the available information, but involves decision making, which must be fast and accurate, based on information. Therefore, this circuit is complete only with people (governmental, private and society).

Strauhs (2012) corroborates the argument that smart city necessarily involves the actors in the organization of information and training of knowledge, because it is generated by people and the human being plays a key role, since the most important inputs are not the tangible elements, but intangible. Cardoso (2013, pp. 15) points out that people are not only essential to the functioning of the systems (be "smart" or not), but are, in imbricated form, the elements of the system itself.

Here is possible observe a gap in the literature (and practice) of smart cities, regarding the actors training to act in a more appropriate manner, including by, encouraging trust and cooperation.

## 4.1) Human capital

Anderle and Freitas Jr. (2013) highlighted that ICTs are important to the existence of the smartest cities, but the investment in human capital is essential. Fernandes and Gamma (2005/2006) argues that to a location being intelligent, beyond physical infrastructure that must go in this direction, the human and intellectual capital by education and culture systems are essential to encourage the "intelligence" of the actors and institutions, facilitating the adjustments facing the challenges.

Strauhs (2012) points out that in the knowledge society, education and social relations acquire great importance, because institutions require much more than technology, require people in permanent sharing ideas.

## 4.2) Trust

Another important point connected to the actors relationship is trust, which involves processes mutually developed face positive signs, the interactions, relationships and engagement between them. These positive signs encourage better attitudes and these, in turn, tend to favor better results (a virtuous cycle). Nascimento and Labiak Jr. (2011) argues that trust involves a set of actions established by actors, aiming gains and mutual security, in the present and for the future.

The trust can originate the relationship between ordinary people or professional relationships based on contracts. It is worth noting that confidence is influenced by three groups: 1) processes (long time relationship that proved to be stable, which is done in belief that the other will keep their usual behavior); 2) characteristics in common (family, religion, ethnicity); 3) institutional: the existence of formal structures in society (legal system, government, organizations) (NASCIMENTO & LABIAK, 2011).

Regardless of the nature and context, the decision of an actor trust the other requires a positive assessment of points, such as: interpretation of the intention and the possible behavior of the other actor; the belief that the other will act to improve the current situation of those involved (and not deteriorate it); and, finally, the most important, which is to know the other's behavior front of situations is expected from it acceptable behavior in unforeseen circumstances.

Trust relates to cooperation (virtuous circle), since before "positive signs" the actor engages more and it raises the relations level. In a second moment, ensures better attitudes that will end up favoring better results (NASCIMENTO & LABIAK, 2011, pp. 18).

## 4.3) Cooperation and collaboration

Trust exists as a function of the sum of institutional factors, skills, cultural proximity and favorable assessment of the intention of the different actors, and may result in the establishment of cooperation.

Thus, every actor (individual or organization, consciously or not), is a node of a cooperation network which, to a greater or lesser degree, has an impact or is impacted by other (NASCIMENTO & LABIAK, 2011).

Komninos (2007, pp. 1) extends the argument about the smart cities regarding people:

> [ ] the smart city must be the result of combinations of human capacities, educational institutions and digital technology (this sum results in new city functions, such as strategic intelligence, technology transfer, obtaining innovation through collaboration and the provision of digital services).

Cooperation involves actions established by actors who have a common interest and, therefore, trust each other, aim at some future gain (shared or individual), which strengthens cooperation as a dynamic and interactive process, because it cooperates to survive, to win, to overcome. The cooperation involves interest and this may be based on: need (alone do not get what I want or the law does not allow me); safety (lowers the risk, increases control, reduces the failures possibility); ease (cooperating is easier); and, finally, cooperates for pleasure (alone is not pleasant) (NASCIMENTO & LABIAK, 2011).

## 5) Connecting smart parts of town

Worth emphasizing the difficulty of conceptualizing what is a smart city in a "single recipe". But, in this scenario it is clear that technology is just one of the catalysts tools that solves (or softens) some points of urban problems, impacting positively on the citizens life quality.

Of the parties to the smart city, the man is one of the most relevant points and perhaps the least worked, because it gives great prominence to the millions spent on the purchase of a given technology, but little emphasis to training, involvement, and to man motivation in this process. The unpreparedness, ignorance and discouraging can lead to disinterest, the discontinuity and, finally, make all "smart city" coming down soon.

Specifically, considering management of Brazilian cities, is even clearer that relevance of actors, due to problems with the public low-quality services (and the lack of capacity to reverse this scenario), because public institutions have chronic cases of inefficiency, legal rigidity, excessive bureaucracy, credibility issues, limited budgets, meager investment capacity and absence of long-term planning, which reflects in fall of citizens' well-being (BATISTA, 2013).

The human capital involved in the management of Brazilian cities, in addition to presenting quality difficulties, has shortage in professional s number, training problems, func institutional overlapping (two or more institutions provide the same public service), creating power and resources contention problems for investments (BATISTA, 2013).

The prevailing view in the smart cities literature is that the technology and information are the smart city supporting components and this view is reinforced by Mitchell (2007), whose emphasis is given on the new intelligence of cities, supported on the combination of telecommunication, sensors and software:

> [ ] digital telecommunication networks (nerves), integrated intellige
> (brains), sensors and indicators (are the sensory organs) and the
> knowledge and cognitive competence) (MITCHELL, 2007, pp. 4).

Make even smarter cities through new uses of information and communication technologies, can lead to offer more knowledge for and by the people. Technological development is only part of the smart city process. Still must take into account that actors are the key parts, which must be trained and receive due attention and encouragement, to no longer be the faint rings of the smart city system.

## 6) Conclusion

The text ventures out in getting the idea that the discourse of smart cities is relevant to the cities towards their problems and challenges. Governments have stepped in order to understand that investment in technology and information can generate increasing scale gains before the deficiencies and, in turn, the society is already realizing that with the technology can even live better.

Technology presents a far from simple linear relationship with the municipal administration: the technology evolves and changes very fast, which requires public administration afford dynamic and streamlined way. However, the widespread practice of public management is to be slow and bureaucratic, hindering the city s relationship with what is latest in technolo good projects are implemented incompletely, if not reduced (cutting some parts initially planned) or simply abandoned.

The information must not only be fast, accurate and affordable, as should feed the communication channel between the government (among actors) and society. ICTs are a reality that help empower the society to be more present in public administration and assist in the inspection, as in the case of mobile application (APP for mobile) COLAB.RE (http://www.colab.re/), which allows citizens to post city's problems and track the resolution thereof.

Smart cities are a mix of human capital, technology and information and their practice involves cities with very different realities to each other, which prevents think of standards or rigid models. In developing countries is stark and urgent need to improve the training of actors, because the inefficiency, lack of long-term planning and the discontinuity of public policies prevail in everyday life of cities. Strengthen training, collaboration and cooperation between actors is vital to improve the engagement of them, the continuity and increasing efficiency of projects and their public policies.

A smart city project without attention to the actors can result in very expensive technological tools of city management, which will be underutilized or even abandoned by political pressure, economic,

institutional or impossibility of building partnerships, resulting in a large expenditure of scarce resources public and little or no benefit being created for citizens.

After visiting smart cities experiences in Brazil, the author of this paper would like to leave as text contribution some points not found in the literature, but widely discussed among actors in charge of projects:

1) Need for good protocols: the creation of detailed work protocols helps determine who does what and what should be done in each action, taking into account the specific features of each reality. Having good described protocols help in the performance of the institutions and actors, reduces conflict and even is a developer factor of trust and cooperation. But, in practice, have these good protocols is not the rule, is the exception

2) Training and education: the actors should receive training, good and proper, but sometimes the training is flawed. For example, in the case of an institution that operates in conjunction with other institutions at a given smart city project. This institution receives training by their professional A, but for some reason, the department has just selecting another professional to act on the spot, i.e, this new professional B will act in smart city, but did not receive adequate information and will have to interact, often unprepared, generating delays, losses and wear.

3) How to reconcile on the smart city the use of tacit knowledge (experience, habits and customs). Despite the tacit knowledge escape the formal knowledge, its use should be recognized as an important point in the management of smart cities

4) In places that have public services provided by private companies (concession or public private partnership - PPP), private institutions often are afraid to expose their data and information for fear of prejudice or punishment. However, when private institutions collaborate offering their data, it helps to increase the management capacity of the actors. The partnership process between the public and private should be one focus-base to strengthen the smart city.

5) The governance of large cities in developing countries (eg, São Paulo - Brazil) is a great challenge because the public structures doesn t realize the problems, and the actors face diff from the point of view of the ability of reversal of urban problems. In this scenario, the smart city can be a hope because it costs much less to invest in technology than destroy and rebuild the whole city.

6) Smart city projects can be opportunity for a common cultural change in the Brazilian public management: is traditional Brazilian public management "deny the problem" or "postpone the problem." It should pass to go against the problem, confront and seek ways and alternatives to solve it.

7) Finally, it is important to make a placement of an employee of the Rio de Janeiro City Hall (involved in the smart city project), when asked about the use of technology in urban management: "... the city has the equipment, Big Data, employees and projects, but it all depends

on the citizen! Both in behavior, "no littering", as in "participate". Every citizen today has a cell phone pocket, then must close the gap between the government and society (by technology that's possible). We must participate in the problem and take part of the solution! By technology, the solution of the city is the citizen 'hand', which is a major player in this system!

Acknowledgements: I want to express my gratitude to the advisor Professor Dr. Rodrigo Firmino for the academic support in the PhD Study and the possibility to participate in this congress AESOP 2015.

# MAKING SMART CITIES SUSTAINABLE: EXPLORING ATTITUDES OF SOUTH KOREA S SMART CITY PRACTITIONERS USING Q METHODOLOGY

Joon Sik Kim[1]

[1]Xi an Jiaotong-Liverpool University, joon.kim@xjtlu.edu.cn

Keywords (maximum 3): smart cities, sustainability, Q methodology

*With regard to the applications of intelligent technologies in urban development, the concept of smart cities has spread widely and been applied to many empirical projects around the globe. In recent years, smart cities have employed the notions of the sustainable urban development with a great concern on global climate change. Although the current smart sustainable city model has particularly emphasised on energy optimisation and low-carbon management, the sustainability strategy of smart cities should go beyond the technological aspects of intelligent solutions. In order to address this emerging issue, planners have faced the complex challenge of how to develop smart cities in a wider sustainability context considering the city s economic dynamics, social di complexity. This research draws attention to perspectives and attitudes of the practitioners in association with sustainable strategies in the development process of smart cities, and Q methodology has been used for this purpose. To define the wider range of issues under study, the research explores lessons-learnt from the context of long-standing debates around collaborative planning practice towards sustainable urban development. Relevant stakeholders for Q analysis have been identified using author s earlier contacts and snowball-sampling technique. The research aims to demonstrate an overview of the subjective perspectives and attitudes on sustainability in the smart city development, especially from the standing point of the observed practitioners. The results may show how the smart city practitioners interact with very controversial and complex issues on environmentally-sustainable development in South Korea and around the world.*

## 1. Introduction

New patterns of urban development with the uses of ICT (information and communication technology) have often described as smart cities . The concept of smart cities has be to urban development and management practices around the globe. Urban planners have also recognised smart cities as a potential tool to solve urban problems using innovative solutions, which might differ from the traditional methods of urban planning and development. There is a wider acknowledgement that smart cities can add value to urban environments and improve the quality of life of the city s inhabitants. In many urban development projects, the smart city model has been increasingly applied in order to optimise resource management and improve public services by integrating different urban systems, such as urban infrastructure, environment, transport, energy, healthcare, security, e-government, and so on.

In recent years, smart cities have employed the concept of sustainability. The combination of green and smart technology is notable in the contemporary eco-city developments (Joss et. al. development of smart cities has been seen as a catalyst to transform economic and social environments of the city to be more knowledge-based and eco-friendly (Kim and Wang, 2014). This new development style has been also considered as a valuable tool to reform the city s industrial network by attracting diverse ICT industries that could enable a low-carbon economy, and ultimately drive the city s sustainable growth (Steinert, et al., 2011). Although the adoption of intelligent technologies is now commonly accepted in sustainable urbanisation projects, there is a widely held view that this new practice has operational difficulties. One criticism of much of the literature on sustainability in the development of smart cities is that the current practice is narrowly focused on technological innovation on energy optimisation and renewable energy generation (Joss, et al., 2013). According to Kramers et al. (2014), the concept of a smart city does not fully involve issues of sustainability, and there is a lack of a connection between the notions of a smart city and sustainable development. The key argument here is that the existing accounts fail to achieve sustainability in a wider context of the

city s economic dynamics, social diversity and spatial complexity. Although there is little analys evaluation on how smart cities can be developed sustainably in practice, many smart city projects around the world have been keen to closely associate with the city s sustainability v environmental concerns. This is because the language of smart and sustainability was appealin politicians and developers for a self-promotion purpose by creating positive place branding of the technology-led innovation in a sustainable way.

This research, therefore, draws attention to the practical consideration in the development process of smart sustainable cities. This article aims to investigate the practitioner s perspective and attitude in dealing with sustainability aspects in the smart city development, and highlight lessons from their experience. The study of practitioner s attitudes is important because the attitu policy makers and researchers may have an impact on the development strategies and directions of smart sustainable cities, especially when there is no clear consensus built on this emerging issue. Barry and Proops (1999) also argue that identifying how individuals think about environmen significant element to judge whether relevant environmental policies are socially acceptable, and therefore able to be implemented. Similarly, unravelling subjective opinions of professionals in delivering the sustainability goal in the smart city practice requires data experiences and practices. The research uses Q methodology to measure attitudes and subjective opinions of practitioners. Q methodology is one of most effective tools of investigating perspectives, attitudes and subjective structures from the standing point of the person, in this case, observed practitioners (Peritore, 1989; Zraick and Boone, 1991; Brown, 1996).

In the following section, firstly, the principles and implementation process of Q methodology will be introduced. This is to provide an overview of the research structure and process, because the research methodology used in this study, Q methodology, is little known in the field of social science and urban planning (Barry and Proops, 1999; Previte, J. et al., 2007). Secondly, the next section will move on to conceptualising smart sustainable cities by bringing the notions of smart cities and sustainability together. The major concern here is that the current practice of smart and sustainable cities is limited on the energy-related issues, and it is, therefore, important to explore the sustainability issues in a wider context. For this purpose, lessons-learnt from the long-standing collaborative planning debates in delivering the city s sustainable vision will be discussed. A key task in this section is to iden common structures (so called Q statements ) of the smart city practitioner s att sustainability issues. Thirdly, by analysing the participant s responds on Q statements, the findings and the principal issues which have arisen in this Q analysis will be provided. This paper will be concluded by proposing a strategic direction for the development of smart sustainable cities based on the analysis results drawn from the practitioner s perspectives.

## 2. Understanding Q methodology

Q methodology was originally developed by a psychologist, William Stephenson, in 1935 in order to examine individuals subjectivity systematically in a scientific way (Stephenson, 1935; Brown, 1996). This research method has been developed further based on factor analytic theory, although there was a considerable peer criticism on Q methodology (Brown, 1997). However, it is now widely accepted as a scientific research method (Cross, 2005), and most frequently used method in studying attitudes (Petit dit Dariel et al., 2010). While the method was initially applied to the academic field of psychology, it has recently been used in a wide range of disciplines, such as agriculture (Brodt et al. 2006; Davies and Hodge, 2012), public health (Kraak et al., 2014), rural planning (Previte et al., 2007), transportation (Rajé, 2007; Van Exel et al., 2011), e-learning (Petit dit Dariel et al., 2013), tourism (Stergiou and Airey, 2011), sustainability (Barry and Proops, 1999), and energy (Cuppen et al., 2010), to list a few. Despite the fact that Q methodology is little used in the field of urban planning, it is a well-structured and increasingly-used research method of measuring the different perspectives, attitudes or subjective opinions (Cross, 2005; Watts and Stenner, 2012; Zabala, 2014), and developing new ideas with a capturing of the human practice (Simons, 2013). Therefore, this research method has a potential in the investigation of planning practice by identifying planning

professionals particular perspectives that could pass on to relevant planning actions, such as the development of strategies, plans, and guidelines, in response to the real-life practice.

Q methodology is recognised as a combination of the qualitative and quantitative research techniques (Stenner et al., 2008). From the qualitative point of view, this emphasises on the subjective opinions and understandings of individuals. In contrast, this method employs quantitative tool of factor analysis in order to examine the statistical correlation between the different views of individuals. This can be explained in the following five stages of the Q methodology implementation (for more extensive information, see Barry and Proops, 1999; Davis and Michelle, 2011; Simons, 2013):

- *Identification* of the concourse : this stage is to develop a wide range of discussion and discourse under investigation. The concourse is commonly described as a set of views, ideas, values, opinions, or beliefs that shared by a population under study in relation to the research question. In order to collect the concourse, many researchers have generally used the multiple survey methods of interviews, focus groups, or literature and media reviews.
- *Definition of Q statements*: the broader discourse collected from the above stage needs to be summarised and reduced to a manageable number of the concourse, which is often referred to Q statements. The number of Q statements is usually no more than sixty, although it varies in different studies. The most important of this stage is that Q statements should reflect the full range of the concourse.
- *Implementation of Q sorting*: this stage involves the survey participants to ask them to rank all Q statements on a scale from disagree (-4) to agree (+4) using a Q table (Figure 1). The range, such as -4 to +4, will be used to sort the statements in the later stages.
- *Factor analysis*: when Q sorting is completed, the correlations between Q sorts are calculated by using the factor analysis methods. This statistical analysis is to identify and classify a distinctive group of Q sorts that shares a similar subjective opinion or position.
- *Interpretation of the factors*: the final stage is to interpret the results of the factor analysis. Typically, the researcher gives a name to the statistically calculated factors in order to describe the meaning of factors. Those categorised Q sorts can represent distinct characteristics of shared perspectives in the study topic.

DISAGREE AGREE

| -4 | -3 | -2 | -1 | 0 | +1 | +2 | +3 | +4 |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| | | | | | | | | |
| | | | | | | | | |
| | | | | | | | | |
| | | | | | | | | |

Figure 1. Example of a Q table

The qualitative and quantitative features of Q methodology provide an empirical framework to translate a particular individual s dialogue into a systematic analysis. methodology are emerged from that fact that the sorting activities are self-organised by participants, therefore, no built-in assumption has been applied into the method. This enables the results of Q sorting to be formative and emergent, and consequently, the method has the power to surprise (Cross,

2005). The greatest concern over the disadvantages of Q methodology is perhaps the lack of reliability that may provide little basis for systematic generalisation. The primary argument is that the results of Q sorting may not be the same even if it is repeated on the same individual. Taking this into account, Cross (2005) emphasises the importance the participant s responses in the limited ac determined statements. In order to represent the view on the research subject more accurately, it is necessary to derive Q statements from various sources and employ a number of different data collection techniques. Moreover, the wording of statements should be carefully designed to allow participants to think about the issue, rather than make them confused (Simons, 2013). Given the importance of defining Q statements, the following section will conceptualise smart sustainable cities in a wider context. As explained earlier, the current practice is narrowly focused on energy-related perspectives. Therefore, before proceeding to collect concourses, it will be necessary to develop a framework to capture the full range of views involved in the issues of smart sustainable cities.

## 3. Conceptualising smart sustainable cities

The city is at the heart of both carbon emission problems and solutions. The mitigating problems associated with climate change given the critical mass of people and resources at the city s disposal. New innovative technology is already used to make the city s living environme more convenient and comfortable. Ironically, these new comforts can requir produce more carbon emissions than the older ways of living. Bearing in mind that there is a potential conflict between the two concepts, smart cities and sustainability, this section addresses the key aspects of sustainability delivery in the development process of smart sustainable cities, by reflecting lessons-learnt from the collaborative planning practice.

### *3.1 Definition of a smart sustainable city*

There is no single model for the correct form of smart cities, and many cities around the world have translated the concept of smart cities differently in order to mirror their particular economic, political and cultural environments (Neirotti, et al., 2014; Kim, forthcoming). It has commonly been assumed that not all elements of smart cities have equal weighting in the planning and development processes of smart cities (Hollands, 2008). Not surprisingly, the same principle might be applied to when smart cities adapt the concept of sustainability. For example, the concept of smart cities in South Korea has been transformed to the idea of U-Eco City (Ubiquitous-Eco City) by mirroring the national of Low Carbon Green Growth (Kim et al., 2012). Chinese government has launched its national low carbon pilot programme based on the National 12th Five Year Plan, which emphasises a great importance of low-carbon city construction. This influences the recent development of the term low carbon smart cities in China. The language of green smart city has been collaboration on the development of smart cities between Chinese government and European Commission (Yanrong et al., 2014). In an international context, International Telecommunication Union, which is the United Nations specialized agency, defined a smart sustainable city as:

> "an innovative city that uses information and communication technologies (ICTs) and other means to improve quality of life, efficiency of urban operation and services, and competitiveness, while ensuring that it meets the needs of present and future generations with respect to economic, social and environmental aspects (ITU-T Focus Group on Smart Sustainable Cities, 2014:13) ."

Although there is a degree of uncertainty around the terminology in this area, the term smart sustainable city is used here. The primary concern on the definition of smart sustainable cities is the capability of coving wider-ranging sustainability issues. While the current practice has not tackled a wider range of issues than merely energy-related aspects, this research aims to address the complexity of smart sustainable cities which is impossible to separate from the economic, social, environmental and political contexts. This raises questions about the conflict interests and issues involved in smart sustainable cities which will be discussed in the next section.

*3.2 Smart city implementation and sustainability delivery*

Although sustainability issues are emphasised in the field of smart cities, little is known about its implementation in a real-life context. The apparent nature of smart sustainable cities must be seen in line with the dynamics in political, economic and social environments in the development process. There are two arguable issues in applying the sustainability concept to the smart city practice, and vice versa.

Firstly, sustainability issues are not the top priority of all key stakeholders involved in the smart city development. As sustainability issues are related to the global concerns on climate change, the shared consensus on sustainability can be readily built between smart city stakeholders. However, the implementation issue is another potential concern. Although most stakeholders may understand the importance of sustainability in smart cities, it is difficult to generate tangible commitments from stakeholders. There is also a concern that the most polluted cities are located in developing countries where the smart city concept is not fully established (Neirotti et al., 2014). The issues of sustainability may create a consensus on the need of comprehensive interactions between participants in the development process of smart cities. However, sustainability does not generate obvious tensions between players to compete for limited resources for the immediate gains. The high costs of taking no action can be the incentive to collaborate (Gary, 1989), but sustainability may not stress threat or scarcity of resource loss among participants. This lack of tension between stakeholders around smart sustainable cities makes it difficult to encourage them to put their extra time, money and effort into the project. Barry and Proops (1999) also argue that there is a shared perception that environmental problems have not been very important comparing with other social ills, such as unemployment, being far more prioritized. Moreover, comparing with other urban problems, such as housing supply and basic infrastructure, smart cities have been seen as an added-value and not been a top priority for all interest groups. Kim (forthcoming) has reported that developers have seemed uninterested in implementing the task of smart cities in meaningful ways once the initial excitement of smart cities has died away after being used for marketing and publicity purposes at the early stage of the urban development project.

Secondly, compartmental approach to the development of smart sustainable cities may be another obstacle to achieve effective collaborative efforts in delivering smart and sustainable goals for the project. While the core concept of smart cities emphasises the integration of a cit
(Ebrahim and Irani, 2005; Dirks and Keeling, 2009; Kitchin and Dodge, 2011), it is evident that smart city practitioners have faced practical difficulties in an effort to incorporate the fragmented working process with the engagement of many organisations and individuals not directly connected each other previously (Kim, forthcoming). This becomes more problematic when sustainability issues are involved. The wide-ranging sustainability challenges cannot be tackled by any single organisations, and should allow open, collaborative and innovative approaches (Steinert, et al., 2011). The complex and compartmental operations in the practice of smart sustainable cities have become a barrier to facilitating active involvement from all actors to achieve the sustainability vison of a smart city in practice.

Despite the arguments above, there is also an advantage in engaging the concept of sustainability to smart city practice. A certain work scope of smart cities, such as tasks related to intelligent technology, may promote more focused efforts, comparting with wide-ranging sustainability issues in the general urban development projects. However, it is necessary to overview the existing practice of smart sustainable cities in order to develop an overarching framework to evaluate wider-ranging sustainability issues in the practice of smart sustainable cities.

*3.3 Evaluation framework for smart sustainable cities*

A smart sustainable city is a relatively new concept and its theoretical and empirical frameworks have not been clearly developed. Consequently, some operational problems have been identified with particular reference to the idealism of smart sustainable cities itself. However, the arguments on how

to accommodate multiple processes in planning practice to draw those complexities and dynamics of delivering sustainability are not new. Viewed from a collaborative planning perspective, there has been a concerted effort among planning professionals and academics to achieve benefits for sustainability by means of collaborative actions for the last three decades (Forester, 1989; Healey, 1997; Susskind, et al., 1999). There are relatively extensive literatures on collaborative planning for sustainability. In a systematic approach to explaining an empirical framework of delivering collaborative actions in planning practice, Kim (2002) has identified three key aspects of sustainability delivery based on the notion of collaborative planning: consensus building, facilitation and open participation.

- *Consensus building* (Let s work together): consensus building has been recognised as a primary tool for implementing collaborative efforts. This focuses on a process of face-to-face dialogue to seek agreed outcomes, such as policies and action plans. The consensus building process would be able to make stakeholders reach shared statements for common goals on sustainability.
- *Facilitation* (Let s make it work): this emphasises a way of collaborative working by encouraging individual stakeholders to deliver the sustainability vision by taking action for themselves. Facilitation is to encourage participants to implement focused issues or projects on sustainability.
- *Open participation* (Let s bring all): this is a broad definition of involvement to consider a wider range of alternatives including multi-level co-operations. This would allow wider involvement of all interest groups willing to participate various aspects of sustainability delivery.

In a similar way, smart sustainable cities require a multiplicity of implementation processes in order to deal with complexity and dynamics of multiple issues involved in sustainability. Some processes such as providing supporting regulations for the development demand continuity of leadership from the public sector, but others require community participation approaches. This is because smart sustainable cities need collaborative working processes that emphasise both top-down and bottom-up approaches.

## 4. Implementation of Q methodology

This research explores smart city practitioners perception towards sustainability, and Q meth is used to examine the subjectivity of interests, especially from the standing point of the observed participants. The results of Q analysis presented here are derived from an on-going research of investigating the subjective perspectives and attitudes on sustainability in the smart city development around the world. In this paper, participants of Q sorting are mainly from ICT firms in South Korea. Although some of them have international experience working in multiple countries, the particular participant group here may hold a different view from the global professional population at large. The unravelled perspectives of smart city practitioners in this paper cannot be translated as a general discourse, as there are great differences among the political traditions and economic conditions in different countries. However, the results may provide representative features and critical arguments in the current practice around the world, as South Korea is one of countries in which the smart city practice is firmly developed in urban development process.

### *4.1* Identification of the concourse

As the first step of implementing Q methodology in this research, the existing discourses in the relevant areas of smart sustainable cities have been explored using a number of different research techniques. The initial concourses have been identified based on the insights of th experience as a smart city practitioner in Asia and the Middle East. In order to represent the views on the study subject more accurately and widely, a series of interviews with three smart city professionals were conducted. Even broader subject issues were collected from academic literatures and media publications such as internet news and blogs. Stainton Rogers (1995) reports that the number of

concourses at this stage could be usually around three times more than the size of the final number of Q statements.

*4.2 Definition of Q statements*

The next stage in the Q methodology process is to select a manageable numbers of statements for Q sorting, derived from over one hundred concourses identified in the previous stage. There is variation in the size of the final Q statements in the literature, although the typical number of Q statements seems to be in between 30 and 60. Drawn from initial tests and pilot Q sorting, the research has found that 33 statements are suitable for this study. In this selection process of the final statements, a concourse matrix has been used. The previous studies (Dryzek, J. S. and Berejikian, 1993; Barry and Proops, 1999) reported that this matrix could be useful in several ways:

- the matrix could filter the statements to reflect more precise and essential arguments in the subject area; and,
- it could also enable an independent selection process by minimising the investigator s influence.

The concourse matrix was necessary in this research because Q statements should: (1) represent wider perspectives of sustainability, rather than energy-related issues; and, (2) mirror the quintessential discourse from the broader practice of smart and sustainable cities, rather than solely from the researcher s insights gained from one s empirical experience. Applying the three key a delivering collaborative actions for sustainability (consensus building, facilitation and open participation), this research developed and employed a concourse matrix illustrated in Table 1. In order to echo multiple processes of delivering the smart sustainable city practice, the categories of two different project types, strategy making and project implementation, were also applied. The use of this matrix may allow collecting much richer and more widely shared views and attitudes of the smart city practitioners towards sustainability. Based on this concourse matrix, thirty-three Q statements of the smart city practitioner s perception towards the sustainability issues were statements have been allocated in each cell of the matrix (9 cells in total), and the full set of Q statements is listed in Table 4.

Table 1. Concourse Matrix of Smart Sustainable Cities

| Key Aspects of Sustainability Delivery | Project Types | |
|---|---|---|
| | [Strategy Making] *Vision and Strategy* | [Project Implementation] *Development Project* |
| [Consensus Building] Let s work together | *Q Statement No.1 to No.6* | *Q Statement No.7 to No.12* |
| [Facilitation] Let s make it work | *Q Statement No.13 to No.18* | *Q Statement No.19 to No.24* |
| [Open Participation] Let s bring all | *Q Statement No.25 to No.29* | *Q Statement No.30 to No.33* |

* For the full sentences of Q statements, see Table 4.

*4.3 Implementation of Q sorting*

This stage of Q methodology involves the survey participants for Q sorting. Participants were asked to use an inverted pyramidal table (Figure 1) in order to rank the 33 statements in a nine-relative scale (-4, -3, -2, -1, 0, +1, +2, +3, +4), based on how strongly they agree or disagree with the particular statement. Whether or not participants may agree or disagree on all statements, they are forced to rank the statements in the given structure. This process (so called, forced choice method) enables participants to consider the sorting process more carefully, and consequently, reveal their true feelings in response (Prasad, 2001).

In order to conduct Q sorting survey, an online survey tool has been established. The research used FlashQ (Rick Hoodenpyle s version, available at http://qmethod.org/links), which is a free application originally developed by Christian Hackert and Gernot Braehler (2007). The online version of FlashQ was set up on a HTTP server with PHP by modifying FlashQ s XML and the PHP-bac codes (available at http://qmethod.org/links and http://www.hackert.biz/flashq/downloads/). When participants start Q sorting using this online tool, firstly, FlashQ displays 33 Q statements one by one randomly and asks the participant to split them up into three categories: disagree; agree; and, neutral. Then, the participant is required to place all statements into the Q table in a ranked-order according to the forced distribution. At the last stage of Q sorting, the participants are required to complete an online questionnaire for their personal details.

For this survey, relevant stakeholders in the field of smart sustainable cities have been identified using author s earlier contacts and snowball-sampling technique. However, due to the complexity and time-consuming process of Q sorting, it was difficult to attract many voluntary participants to get involved in the survey. Therefore, the personal contact of the author in South Korea was useful at the earlier stage of the survey. There were 10 participants in this analysis. As Akhtar-Danesh et al. (2008) pointed out, it is more important to represent different opinions in the study subject precisely in Q methodology, rather than the number of the participants. Although most participants are in the private sector of ICT industries, the participants were selected on the basis of their work experiences and the areas of their expertise. This may mirror different viewpoints in the practice of smart sustainable cities. The details of the participants background can be shown in Table 2. Among 10 part participants have worked in the field of smart sustainable cities for more than 9 years, and four of them have work experience less than five years. There are five consultants and two marketing professionals in the participant pool, but the rest varies. Six participants have worked solely in South Korea, but four of them have the international work experiences in different counties.

Table 2. Participants Background for Q sorting

| Q Sort ID | | Work Period | Affiliation | Job Description* | Work Location |
|---|---|---|---|---|---|
| 1 | 9ITCsK | More than 9 years | ICT | Consultancy | South Korea |
| 2 | 7ELCsK | 6-8 years | Manufacturing | Consultancy | South Korea |
| 3 | 4ITPMK | 3-5 years | ICT | Management | South Korea |
| 4 | 4ITCsK1 | 3-5 years | ICT | Consultancy | South Korea |
| 5 | 4ITCsK2 | 3-5 years | ICT | Consultancy | South Korea |
| 6 | 9ITEgK | More than 9 years | ICT | ICT Engineering | South Korea |
| 7 | 9ITMaMt | More than 9 years | ICT | Marketing | South Korea, China, Middle East, Europe |
| 8 | 4ITMaKC | 3-5 years | ICT | Marketing | South Korea, China |
| 9 | 9ITCsKC | More than 9 years | ICT | Consultancy | South Korea, China |
| 10 | 9ITCnMt | More than 9 years | ICT | Urban Development | South Korea, Middle East |

## 5. Q analysis and research findings

### *5.1 Factor analysis*

The PQMethod software (Schmolck, 2014) has been used in analysing the data of Q sorting, which is available online freely. PQMethod has been seen as one of the most frequently used statistical programmes, which is customised particularly for Q analysis (Simons, 2013). Using the Q sorting data provided by participants, the software created a correlation matrix from Q sorts, and then factor-analysed. For this purpose, Principal Component Analysis (QPCA), which is the most popular method of factor extraction, was used. In this factor analysis process, three factors with eigenvalues greater than 1.00 have been considered significant statistically. After a varimax rotation (QVARIMAX) on the factors, QANALYSIS was performed in order to differentiate the factors based on the participants Q sorting. The results of factor analysis are shown in Table 3.

Table 3. The Results of Factor Analysis (Factor Matrix)

| Q Sort ID | | [Factor 1] *Korea-specific Perspectives* | [Factor 2] *Marketing-specific Perspectives* | [Factor 3] *Conflicted Views* |
|---|---|---|---|---|
| 1 | 9ITCsK | **0.7848X** | -0.2255 | -0.0405 |
| 2 | 7ELCsK | **0.6915X** | -0.0191 | -0.4547 |
| 3 | 4ITPMK | **0.5605X** | 0.1365 | 0.3376 |
| 4 | 4ITCsK1 | **0.5805X** | 0.1746 | 0.3298 |
| 5 | 4ITCsK2 | **0.7413X** | -0.1932 | -0.0707 |
| 6 | 9ITEgK | **0.7726X** | -0.5481 | 0.3501 |
| 7 | 9ITMaMt | 0.2986 | **0.5474X** | -0.0357 |
| 8 | 4ITMaKC | -0.2216 | **0.8674X** | 0.1137 |
| 9 | 9ITCsKC | 0.1611 | 0.0300 | **-0.6937X** |
| 10 | 9ITCnMt | 0.2714 | 0.0177 | **0.6620X** |

X indicates a defining sort (resulted from automatic pre-flagging of PQROT)

Six of the participants are identified as significant relations on Factor 1; two on Factor 2; and, two on Factor 3. Considering the participants profile backgrounds, Factor 1 can be described a specific perspectives , because the factor analysis result shows a strong distinction on t work locations. All six participants who are loaded on Factor 1 have mainly worked in South Korea and the rest participants have work experiences internationally in different countries. Based on the participants profile information, Factor 2 may be related to the participants jo participants loaded in Factor 2 are working in the area of marketing and sales in the development of smart sustainable cities. Therefore, Factor 2 is named as Marketing-specific perspectives . W Factor 1 and 2 seem to have profile-based relations, Factor 3 is rather related to the personal viewpoints of the two participants. Factor 3 shows conflicted views between two particular respondents on the domain of smart sustainable cities, although both participants have worked in the field of smart cities more than 9 years and internationally. It was found that the only difference on the participants profile is the job description as one has a consultancy background, but th urban development (construction) background.

*5.2 Interpretation of the factors*

Drawn from the factorised analysis, the detailed discourses will be investigated in this section in order to explore the subjective landscape of the ten practitioners in the development of smart sustainable cities. For this purpose, the above three factors have been represented by the four operant types of discourses: Discourse A (Korea-specific perspectives, Factor 1); Discourse B (Marketing-specific perspectives, Factor 2); and, Discourse C (Conflict views, Factor 3). Table 4 shows each discourse representing the distinct perspectives and attitudes from the standing point of the practitioners in the field of smart sustainable cities. For Discourse A and B, factor arrays that were produced by PQMethod are used. This is because a set of factor arrays represents ideal type Q sorts by calculating a weighted average of the scores (Barry and Proops, 1999; Addams and Proops, 2000). However, Discourse C employs actual Q sort scores from the two particular participants (C1 and C2) in order to compare their conflict views on each statement.

Table 4. Q Statements and Scores on the Four Extracted Discourses

| | Q Statements | Discourses | | | |
|---|---|---|---|---|---|
| | | A | B | C1 | C2 |
| 1 | Government should lead the development of smart sustainable cities. | -1 | -1 | -3 | 3 |
| 2 | Smart sustainable cities should build up a city s resilience to natural disasters, all linked to climate change. | -1 | 0 | 0 | 1 |
| 3 | Green and renewable energy technologies are at the heart of many smart sustainable city developments. | -1 | -3 | -2 | 3 |
| 4 | Generally speaking, smart cities are not sustainable because they use more energy than before. | -4 | -2 | -2 | -3 |
| 5 | A key aspect of smart cities should be a new way of living sustainably, rather than conveniently. | -2 | 3 | -1 | -1 |
| 6 | There is the lack of an understanding of stakeholders roles and responsibilities in the development of smart sustainable cities. | -1 | -1 | -1 | 2 |
| 7 | Smart city projects should be implemented under the sustainability vision. | | 2 | 3 | -4 1 |
| 8 | The majority of people on smart cities prioritise the sustainability issues. | -1 | -2 | -3 | 1 |
| 9 | It is necessary to organise a steering body involving wider stakeholders in the development of smart sustainable cities. | 4 | 1 | 1 | 2 |
| 10 | Making smart cities more sustainable needs more resources and therefore money. | -2 | 2 | 1 | 2 |
| 11 | There is no dominant model for smart sustainable cities. | 0 | 4 | 2 | 0 |
| 12 | I am not very concerned about the sustainable development in smart cities. | -4 | -2 | -2 | -3 |
| 13 | Technical specifications for smart sustainable cities can be standardized. | 1 | -1 | -2 | -1 |
| 14 | It is necessary to develop an evaluation framework related to the sustainability impacts of ICTs in smart sustainable cities. | 0 | 0 | -4 | 1 |
| 15 | For a successful smart sustainable city, the integration of the city s diverse systems i essential. | -1 | -4 | 4 | -2 |
| 16 | The notion of cyber-security (risk of hack) is becoming extremely important in a smart sustainable city context. | 3 | 2 | -1 | 1 |
| 17 | The development of smart sustainable cities must be able to contribute to the city s economy e.g. jobs, growth, and finance. | 2 | 0 | -1 | 2 |
| 18 | A smart sustainable city needs a wow factor : it should show something new and innovative. | -3 | -1 | 0 | -3 |
| 19 | A lack of legislation framework on smart sustainable cities is one of significant obstacles in its implementation process. | 1 | 2 | -1 | 4 |
| 20 | It is difficult to secure full benefits of smart sustainable cities if there are robust regulations on privacy and data protection. | -2 | -2 | 0 | -2 |
| 21 | I think most future environmental problems can be solved by intelligent technology. | -2 | -3 | 2 | -4 |
| 22 | I believe intelligent technology can be used to change people s behaviour to be more sustainable in their everyday lives. | 2 | 0 | 3 | 1 |
| 23 | Wireless network infrastructure is more vital in the development of smart sustainable cities than one of smart cities. | 0 | -2 | 4 | 4 |
| 24 | People would not be willing to pay extra money for intelligent services making their lives more sustainable. | -3 | 4 | 2 | 0 |
| 25 | The current practice of smart sustainable cities does not involve public participation as much as it should. | 2 | 2 | 1 | -2 |
| 26 | The users of smart sustainable cities are not only municipal governments, but also enterprises and citizens. | 4 | 2 | -3 | 0 |
| 27 | The sustainability strategy of smart cities should go beyond the technological aspects of intelligent solutions. | 3 | 0 | 2 | -1 |
| 28 | Smart sustainable cities should act as a platform to learn sustainable practices. | | | 3 | -3 0 0 |
| 29 | A smart sustainable city is a very good instrument to link people, and therefore increase local democracy participation. | 0 | -4 | 3 | -4 |
| 30 | Smart sustainable cities can strengthen community engagements by recognizing the citizen as a sensor. | 0 | -1 | 1 | 0 |
| 31 | I see smart cities as a development tool of putting sustainable ideas into practice. | 1 | 0 | 3 | 3 |
| 32 | It is difficult to cooperate with private sectors in developing smart sustainable cities, as they take a short-term view. | -3 | 1 | 1 | -1 |
| 33 | Smart sustainable cities should make a great amount of public data available to users and software developers. | 1 | 1 | 0 | -2 |

*5.2.1 Discourse A: Korea-specific perspectives*

Drawn from the results of the statistical analysis, the respondents in this discourse have particularly: agreed on Statement [9], [16], [26], [27], and [28]; however, disagreed on Statement [4], [10], [12], [18], [24], and [32]. In analysing the Q sorts, this discourse expresses a primary concern on collaborative efforts in the development of smart sustainable cities. This discourse emphasises strongly on the need of: an institutional arrangement for the wider stakeholder involvement (+4 for Statement [9]); and a consideration for wider users including public, private and community sectors (+4 for Statement [26]). The importance of integration shared by the respondents in this dis may reflect the particular interests in the South Korea s practice of smart sustainable cities because the evidence from the participants profile suggests that all six participants in had solely worked in South Korea without international work experiences in the other countries. Kim (forthcoming) reported that South Korea has developed in a standardised form of the smart city development as a series of U-City projects. While U-City projects focuses on the system in of public services provided by local authorities, the practice of smart cities in South Korea experiences a complicated challenge in managing diverse and conflicted interested involved in the development of U-City projects. This echoes a strong support in this discourse for the idea that smart sustainable cities can only be achievable by collaborative efforts from diverse stakeholders and the urban system integration is critical in the development of smart sustainable cities. This shared view on the integration of the city s core systems can have an effect on Statement [16] that is also highly-ranke this discourse, by emphasising the importance of the cyber-security in the development of smart sustainable cities. Additionally, because the Korea s smart city practice is mainly focused on p sector services and systems, it seems possible that this discourse expresses disagreement (scored -3) on the need of a wow factor to show something new and innovative in the deve sustainable cities [18], comparing with other discourses.

Another strong agreement of Discourse A is that the sustainability issues in smart cities must be considered from wider perspectives, rather than focused narrowly on the technology-led solutions. The respondents have strongly agreed (scored +3) that a smart sustainable city should: go beyond the technological aspects of intelligent solutions [27]; and, act as a platform sustainable practice [28]. The respondents in this discourse are very concerned about the importance of sustainability issues in the smart city practice [12], and optimistic about engaging the two concepts of smart city and sustainability in practice (see Statement [4] and [10]). The data reported here appear to show a different view on the earlier argument made by Joss, et al. (2013) that the current practice of smart sustainable cities has narrowly focused on technological aspects of energy-related issues. However, ironically, this discourse has also reported that the majority of people of smart cities may not prioritise the sustainable issues [8]. It seems that practitioners, at least in South Korea, have a clear understanding on the wider definition of sustainability, although they might feel that it would be difficult to implement sustainability in practice as it requires collaborative actions with wider stakeholders.

The findings in this discourse would seem to suggest that the practitioners in the same geographical area might have similar views on smart sustainable cities, as they are from the common political, economic, social, and cultural backgrounds. This might suggest that it would be possible to establish an area-based development strategy for smart sustainable cities, but might not be feasible to develop a common model of smart sustainable cities globally. Speaking from the South Korea s context, t development smart sustainable cities requires institutional and political instruments to facilitate collaborative efforts in practice. It seems that there is a potential to facilitate the collaborative practice in South Korea, as there are common understandings on a wider perspective of sustainability and the need of holistic approach in the development of smart sustainable cities. Those mutual understandings among practitioners may act as a catalyst in establishing a suitable institutional arrangement for further collaborations and prevent many difficulties that may arise later.

*5.2.2 Discourse B: Marketing-specific perspectives*

The statistical analysis shows that, in this discourse, the respondents have particularly: agreed on Statement [5], [7], [11], and [24]; however, disagreed on Statement [3], [15], [21], [28], and [29]. There are two respondents who have been loaded in this discourse, and they are working in the ICT business area of marketing and sales in the development of smart sustainable cities. Both respondents have global work experiences in different countries. One possible implication of this is that their views could differ from Discourse A, as the respondents in Discourse B are more business-minded and working globally. As the marketing and sales professionals often face their clients closely, this discourse may also reflect the perspectives of their clients, public and private developers of smart sustainable cities. This may explain the reason why this discourse has strongly emphasised the linkage between smart cities and the city s sustainability vision [7]. The marketing background of th respondents might be also influential in Statement [11]. This discourse has most strongly agreed that there is no dominant model for smart sustainable cities, while Discourse A has expressed a neutral view on this. This is because South Korea has developed a uniform U-City domain, although the respondents in this discourse may stress the diverse approaches for smart sustainable cities by reflecting the city s particular economic dynamic, political priority, and cultural legacy. These results would also seem to support the idea that it is possible to define a specific model of smart sustainable cities in a domestic practice, however, impossible to create a worldwide standardised model. However, this discourse also shares the same view with Discourse A that green and renewable energy technologies may not be at the heart of many smart sustainable city developments [3].

Comparing with Discourse A, this discourse shows different opinions in the following five statements in particular ([5], [15], [24], [28], and [29]). Although Discourse A disagrees (scored -2) on Statement [5], A key aspect of smart cities should be a new way of living sustainably, rather than conveniently , Discourse B agrees (scored +3) on this. This may mirror the global trend on smart sustainable cities emphasising more on sustainability in everyday life, although the South Korea s practice may prioritise on the aspect of people s convenience. Similarly, Statement [15] for a succe sustainable city, the integration of the city s diverse systems is essential is agreed b respondents in Discourse A, while Discourse B expresses strong disagreement on this statement (scored -4). As discussed earlier, despite the fact that South Korea has developed the integration-oriented approach in the development of smart sustainable cities, it seems South Korea s U-City model is not applicable to many other countries. Another strong disagreement (scored -4) in this discourse is on Statement [29], a smart sustainable city is a very good instrument to link people, an therefore increase local democracy participation . Considering this discourse marketing-specific perspectives, the local democracy participation issues may not be seen as an important value in promoting smart sustainable cities comparing with other values such as improving sustainable living environments [5] and delivering the city s sustainable visi interesting view on the people s willingness of paying for the smart sustainable services. discourse has strongly agreed (scored +4) on Statement [24], people would not be willing to pay extra money for intelligent services making their lives more sustainable , while Disco (scored -3). A possible explanation for this might be that citizens in South Korea are more willing to pay for the smart sustainable services, than those in other countries. However, from the marketing professionals point of view, the paid-services may not be easy to implement in practice.

*5.2.3 Discourse C: Conflict views*

Unlike the previous discourses, the statistical analysis of Q sorts has identified that there are two respondents who expresses conflicted views distinctively on the statements presented. The analysis result on this discourse shows that the conflict opinions between the two respondents are stressed particularly on Statement [1], [3], [6], [8], [14], and [25]. Those are related to the issues of: the government leadership [1]; primary work scope [3]; stakeholder s roles [6]; priority on su [8]; outcome evaluation [14]; and public participation [25]. As Q methodology deals with the subjectivity of individual s perspectives, it is expected that people may have statements. However, what stands out from this discourse is that the conflicted views of the two

respondents are mainly from the consensus building aspect in the development of smart sustainable cities. As explained earlier, this research developed a concourse matrix (Table 1) to reflect wider perspectives of smart sustainable cities using the three key aspects of sustainability delivery: consensus building; facilitation; and open participation. Four out of the above six statements are mapped on the consensus building aspect (Statements [1] to [12]), and the three are particularly on the strategic making category of the consensus building aspect (Statements [1] to [6]). This result may show that there are more significant conflicts and tensions between stakeholders in building consensus in the strategy making process, particularly on the issues of: who should lead; what should be prioritised; and who should do what.

## 6. Conclusion

Learning from the participants in this research, the practitioners on smart sustainable cities have shown particular attitudes and perspectives based on their work backgrounds. It seems that the practitioners share common views if they work in the same geographical or business areas. This subjective landscape on smart sustainable cities can be valuable to understand the existing debates in practice and implement projects more efficiently by mapping possible conflicts in advance. Initial observations in this study suggest that it would be practically difficult to define a dominant model for smart sustainable cities. There would therefore seem to be a definite need for an area-based approach in the development of smart sustainable cities by reflecting local political landscapes, economic dynamics, and cultural identities. The evidence of this can be clearly seen in the case of South Korea. The results of Q analysis suggest that the development strategies of smart sustainable cities in South Korea should pay more attention to the institutional arrangement for collaborative efforts in order to integrate not only the city s core systems but also wider stakeholders involvements research may have limitations in terms of a narrowed range of the participants, Q methodology has demonstrated great potentials in investigating the views and attitudes of the practitioners that may influence on the implementation of smart sustainable cities significantly. However, the results of Q analysis must be interpreted with caution because the methodology is to measure the individuals subjective opinions and attitudes from the particular standing point of the observed participants, rather than generalise the results of the statistical aggregation from the anonymous data.

# Eco-intelligent Technology Integrated Planning—Application of ZZAEPZ General Planning

KUANG Xiaoming[1], DENG Xueyuan[2], WANG Lu[3]

[1]KUANG Xiaoming, Lecturer of Tongji University, Director of Shanghai Tongji Urban Planning& Design Institute.

[2]DENG Xueyuan, Corresponding author , PHD, Shanghai Tongji Urban Planning & Design Institute, Urban Space and Ecological Research Institute, Collaborative Innovation Center of Intelligent Urbanization of High Density Area of Tongji University.

[3]WANG Lu, Shanghai Tongji Urban Planning & Design Institute, Urban Space and Ecological Research Institute

**Keywords:** Eco- intelligent Technology Integrated Planning (ESIP), Material Flow Analysis of Urban Metabolism, ZZAEPZ

## 1. The integration of Eco- intellegent technology to meet the challenge of urban planning

According to the system theory put forward by Qian Xuesen, the city is a typical open complex giant system. The system has exchange of material, energy and information, etc. with the surrounding environment, at the same time includes a large number of subsystems[1]. Smart city and ecological city achieve efficient and reasonable operation of the whole urban in the aspect of the exchange of information, material and energy.

### *1.1. From ecological city[2] to positive ecological city[3] and to the urban metabolism*

Since Ecological City was clearly put forward by UNESCO in the "Man and the Biosphere" plan in 1971, the thought of harmonious development of man and environment has gradually won support among the people. The countries of the world are carrying out Ecological City planning and construction practice one after another.

However, "Ecology" was defined as minimum damage to nature (Register, 1982) in the 20th century, which was far from enough for the future development of city. An ecological city in the future will not be the enemy of the nature, instead it should be blessed by the nature and become the doctor and friend of the destroyed nature. The ecological city in the future is a positive ecological city, which is not to consume the ecology but to supply the ecology. In the city level, it includes such concepts as increasing green area, cold islands, capacity and water purification (Wu Zhiqiang, 2004). The positive ecological city is supported by green and ecological technology.

The theory of urban metabolism turns from the ecological-system perspective to research perspective centering on human activities. The theory of urban metabolism researches urban social economic activities, and the flow of material and energy in the regional and global biogeochemical process. The

characteristic of the material and energy flow and the relationship between the urban activities and natural process define the production and consumption behaviors in the city. Therefore, the urban metabolism system becomes a multi-disciplinary research field, and in order to realize the mutual response between human and ecology in the future, it focuses on analyzing all kinds of human behavior and material flow in the city. In *The Changing Urban Metabolism*, C. Kennedy points out that urban metabolism is that all social economic and technological process synthesize in the city. It should bring the growth and production of energy and the reduction of waste (C. Kennedy, 2007). [4]With the climate change and the atmospheric degeneration, the urban metabolism system model has increasingly become a key element for sustainability and human health. The urban metabolism system helps to integrate all the activities of the city in a model.

### *1.2. Intelligent City*

The Intelligent City has become the new idea and new practice of future urban development expanded in the global since the beginning of the 21st century, which mix together numerous concepts such as smart city, digital city and information city, etc. The smart city is based on the information and communication technology (ICT). The integration and development of ICT promote the formation and development of information society and knowledge society, profoundly changing people's living and working way, organization form, social formation and innovation pattern. Until the beginning of 2013, several cities in the world have carried out a variety of smart city practices. Dozens of cities in China as well enter this rank and put forward to build smart city. "Creating the future-oriented smart city" has become the strategic measure of future innovation drive and transformation development for the city. [5]

### *1.3. The integration of Eco-Smart technology to optimize urban metabolism process*

At the present stage, when planning the urban metabolism system, a major challenge is the problem of incomplete information. In the urban planning and management, the planners and planning governors don't know the data such as how many energies are consumed in the city, how many water resources, how much sewage is discharged, and how much waste is produced, etc. And they don't clearly know how large the land area those resources and energy can support and how many human activities it can bear, etc. When the planners cannot judge objective problems of the city, the planning and compiling work are lack of logic supports. Changing the status quo needs ability of information acquisition, information understanding and information response.

Therefore, the planning and construction of Eco-Smart city should be integrated. Three core steps of construction of Eco-Smart city are perception, judgment and response. In ecological city, the construction of intelligent technology and intelligent system can make ecological city become measurable and more acute. The first step is to perceive, that is to know the changes of the city. The second step is to identify and judge the data information through reasonable analysis model. The third step is to forewarn, respond and give feedback to the emerging condition according to reasonable standard.

According to the statistic analysis of 225 smart city projects carried out in Europe, 153 smart city projects take up a proportion of 68 percent (others are architecture, block, regional scale) in respect of urban scale; 83 projects target the energy conservation and emission reduction, and 83 projects are focused on people's livelihood, occupying a proportion of 76 percent (the other projects are focused on justice & clarity, resource intensivism, development transformation, and advertising and marketing). This shows that the planning and construction of smart city are very suitable for ecological goals of urban scale. [6]

The synthesis of ecological city and the smart city concept as well as the integration of ecological and intelligent technology will contribute to raising the qualitative problems of ecological city to quantitative level. Meanwhile, it also helps to track the material and energy flow in urban complex system in form of information and give feedback so as to provide information support for planning formulation and plan implementation,.

## 2. Eco-intelligent technology integrated planning framework based on UM&MFA

### *2.1 Urban metabolic system and material flow analysis*[7]

The urban ecological study divides ecological factors into abiotic factors and biological factors. The abiotic factors include: solar radiation, temperature, wind, atmospheric moisture, soil, rainfall and hydrology of the city. In urban planning in recent years, the analysis and research for abiotic factors gradually increased, but few were involved with biological factors and biological diversity. [8]

Compared with the theory of ecological city, the emergence of urban metabolism (UM) theory further focuses on the research on all kinds of energy and material flows in urban artificial material environment and it is more suitable for urban planning. The theory of urban metabolism considers the main flow system in urban environment as: energy, water circulation, land resources, atmosphere, matter, pollution and traffic flow, etc. (Paulo, 2013).

Material flow analysis (MFA, Baccinni and Brunner in the 1990's) 9 is the analysis method of urban metabolism. It's used to measure how matter enter the city system, flow and gather in the city and ultimately discharge from the urban system in the form of pollutants, wastes and output. Material flow analysis provides a framework for researching the metabolism between nature and artificial system.

Urban planners and design use UM and MFA in the following four aspects: 1. Sustainable assessment report; 2. Emission measurements of urban greenhouse gas; 3. Mechanism modeling used for policy analysis and urban design; 4. Design tool: design tool is on the basis of the previous three. Urban metabolism analysis also can be used as a design tool to create more green and sustainable infrastructures. It is not end treatment but starts from the preliminary planning and design. Designing a closed-loop, recycling the resources and reducing the amount of the final wastes by tracking the urban energy, material and waste in the whole process of the urban system. Now they are using all kinds of technologies to make it easier for green buildings to reach their goals. Model use is not limited to functional analysis. It can also be used to examine and weigh the relationship between humans and infrastructures. [10]

### *2.2 Eco-intelligent technology integrated planning framework*

The overall conceptual planning scheme of ZZAEPZ plans and formulates by using the planning framework of comprehensive integration of Eco-Smart.

As the fifth shock wave of transportation technology development, the air transport industry promotes the growth of new urban form -- aerotropolis (John Kasarda, 1992)[11], and it is the projection of global economic integration trend in the city. In spatial form, aerotropolis is shown as: a large complex centered on the airport, and integrated with multiple functions such as air transportation, logistics, commerce&trade, shopping, travel and leisure and industrial development, etc. (Mckinley Conway, 1993)[12]. On March 7th, 2013, the State Council formally approved T*he Development Planning of Zhengzhou Economic Practice Zone (2013-2025)*, proposed to construct the Zhengzhou airport area to

be the going-first area of economic development of the national aerial port (hereinafter referred to as "aerial port zone"), which covers an area of 415 sq. km.. The scale of the core area of aerial port (hereinafter referred to as "aerial port") is 27.6 sq. km. The annual cargo throughput in near term is 3 million tons and the reserved is 5 million tons. The annual passenger transportation is 50 million and will reach 70 million in the near future. On the basis of *Development Planning*, the formulation of conceptual planning is made. We put forward and use the planning framework of comprehensive integration of Eco-Smart in the formulation. In the meantime, we think and explore the specific ecological characteristics and characteristics of information enrichment of the aerotropolis.

The horizontal direction of this planning framework consists of four steps: the definition of urban metabolism subsystem, the setting of ecological intelligent target, ecological simulation and planning response layer, intelligence platform building. In the analysis and planning response of each vertical subsystem, in order to reach ecological goal of urban development, we use material flow analysis through integration of smart technology in planning such as simulation technique, intelligent platform construction and the overall arrangement of intelligent infrastructure, etc.

The first step is the definition of urban metabolism subsystem. Through analyzing the urban metabolism of aerotropolis economic practice zone, we confirm the integrated planning consists of the following 6 subsystems: energy, transportation, solid waste, noise, hydrographic net and vegetation.[13]

The second step is the setting of ecological objective and index. The planning establishes the basic index of six dimensionalities to establish the direction for planning.

The third step is ecological simulation and planning response. We carry out the modeling and simulation of the system input and output for the ecological elements previously confirmed. The special aspects of aerial port are noise and restricted space, so this time we simulate the noise and restricted space. The planning response is to put forward the corresponding solutions for six subsystems such as energy, transportation and solid waste, etc. after the system simulation.

The fourth step is the intelligent platform building. It consists of perception, transmission and WEB-based 3DGIS system. Aiming at a variety of ecological technologies used by ecological elements, we carry through integrated systematic planning and design and we reach the intelligent monitoring of ecological goals through equipment system construction of three steps of perception, judgment as well as response.

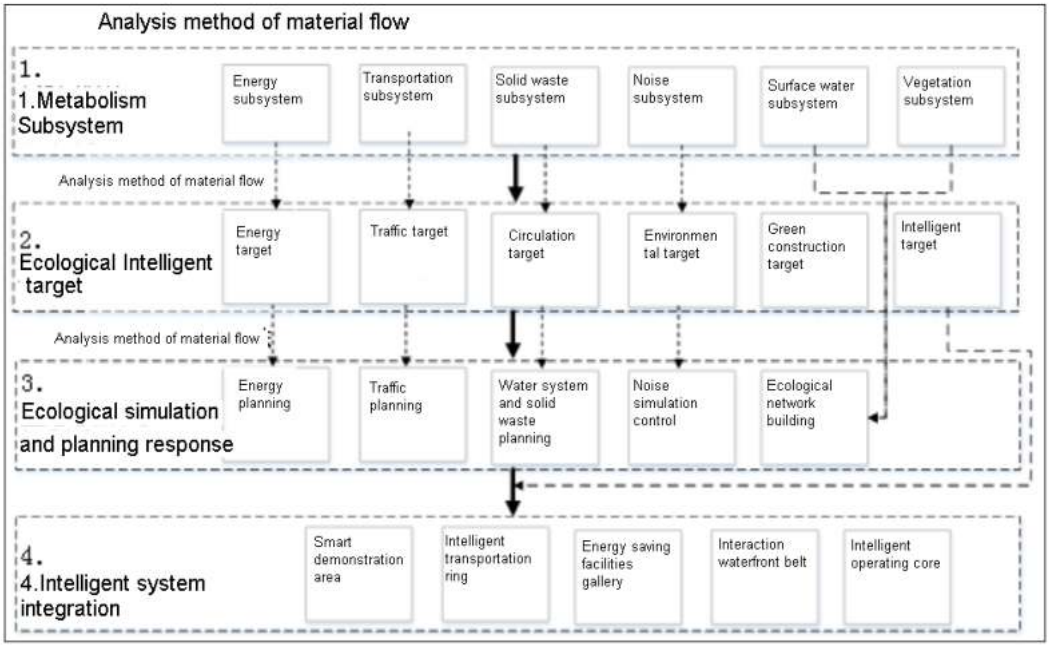

Figure 1 the planning framework of Eco-Smart technology integration of ZZAEPZ

## 3. Conceptual overall planning of ESIP applied to Zhengzhou airport zone

Based on the above framework of Eco-Smart Technology Integrated Planning (ESIP), we have finished the planning research of Eco-Smart integration in conceptual planning of ZZAEPZ. Now, we combine the second, third and fourth steps in the frame to briefly introduce six parts of the planning research achievement: objectives and indicators, noise simulation and control, energy planning, ecological network building, intelligent transportation system planning and intelligent inspection system.

### *3.1 Ecological intelligent goal and index*

Figure 2 Ecological intelligent goal and index system of five dimensions and one core

The setting of ecological intelligent target system of the aerial port zone learns from the intelligent city evaluation system in European Union [14] put forward by Giffinger and the *Eco-City Index System* [15] formulated by Chinese Society for Urban Studies. Integrating the main content of the goal level and combining the actual demand of Zhengzhou aerial port zone, it puts forward the ecological intelligent target system of one core and five dimensions through the target of five ecological dimensions of energy, transportation, circulation, environment and building as well as various types of control center to realize the intelligent integrated monitoring operations of ecological goals.

We set an index respectively for target of five dimensions and one core on the basis of target, a total of six groups of indexes to monitor and implement easily. Energy index: the proportion of clean energy saving shall reach 30 percent in 2020 and 70 percent in 2040. Transportation index: the proportion of transit trip shall reach 20 percent in 2020 and 60 percent in 2040. Circulation index: the consumption of tap water shall reduce by 40 percent in 2040 and the reuse rate of recycled water shall reach 60 percent; in solid waste treatment, the proportion of waste recycling, composting and electricity generation shall be maximized and the proportion of landfill shall reach 3 percent. Environment index: the proportion of carbon emission per GDP shall reduce 25 percent in 2020 and 55 percent in 2040 and the urban noise shall be up to standard. Construction index: the energy-saving standard of all new buildings shall reach 50 percent in 2040. Intelligent operation index: the coverage rate of intelligent facilities shall reach 20 percent in 2020 and 60 percent in 2040.

## *3.2 The simulation and control of noise*

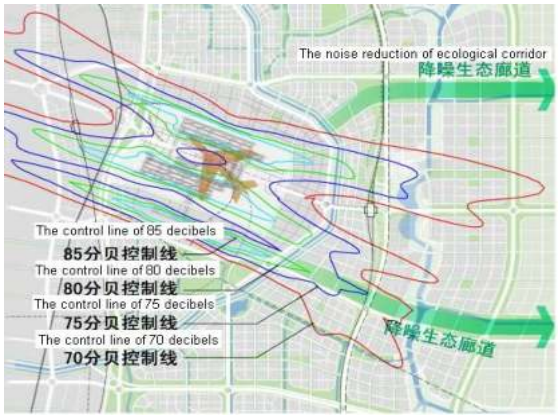

Figure 3 The noise simulation of aerial port

Noise impact is a specific ecological environment factor in aerotropolis and we plan to simulate the noise that 5 tracks do to airport space. According to the simulation, the noise in most of the land within the planning scope is lower than 70dB. The planning takes a full consideration of the influence of airport noise and arranges production land near the two sides of the airport and settles all kinds of living, culture and education, health, services, commercial and recreational activities in the distance of the airport, and sets noise reduction green corridor in the direction of freight runway.[1]

### *3.3 The ecological network construction*

Currently, the planning area is mainly the cultivated and woody land, featured with about 23 sq. km of jujube orchards,, with high greening rate and good ecological benefits. The middle line of the south-to-north water transfer project passes through the planning region. The blue line of control is 90 meters. There are green belts of 200 meters left along the SNWD Main Canal. The river systems in the planning region are rich. Many rivers flow through the planning region, such as Zhangba River, Xiaoqing River, Mei He, Gaolu River, Liming River and Zhelong River, etc. Some parts of the rivers have flow cutoff.

Plan to construct the basic ecological network of ecological city by using water system and linear green buffer. The basic function units of urban development are just like cells inlaid in the ecological network, inarching natural water system and green space and forming the ecological network pattern of **ecological wet formation** and **cell inlay**.

The planning reserves the existing river system and dredges parts of dried-up rivers and enhances the mutual connection between the rivers, reinforces the ecological effects of rivers in the city and retains the ecological embankment and original vegetation. Meanwhile, the planning combines with urban rivers and ponds to build artificial lake to form the main park node of the city. The plan integrates the south-to-north water diversion canal and Xiaoqing River to form X type surface drainage of aerotropolis, on the basis of which the rest of the north-south water systems are cleared and connected in network.

The ecological green space of planning can be divided into two levels: urban green space and ecological green land; the ecological vegetation consists of various of elements such as forest ring corridor, ecological water system, waterfront shoreline and urban farmland, etc. with a total planning area of about 44.7 sq. km; urban green space includes urban public green area and road green buffer, etc. with a total area of 56.9 sq. km and the per capita public green land area is 21.9 square meters per person. Two levels of ecological elements system get rid of the drawback of simple controlling over the urban internal greening system indicators, and highlight the important role that the city peripheral ecosystem plays in ecological city construction.

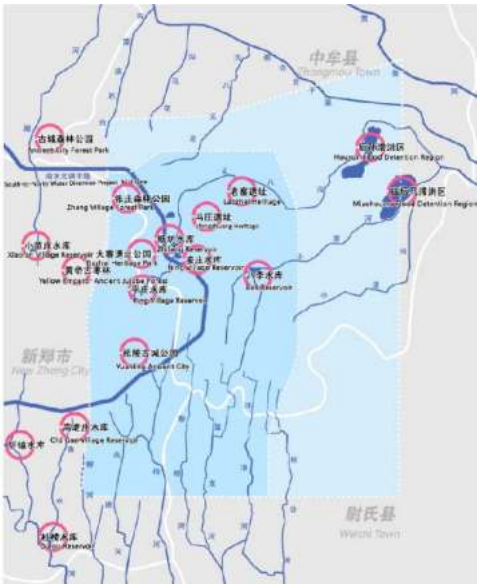

Figure 4 The current situation and planning of ecological system in aerotropolis

### *3.4 Energy planning*

In the aspects of new energy and clean energy, by using six kinds of new energy such as natural gas, solar energy, biological energy source, wind energy, geothermal energy and solid waste power generation in the planning area, the proportion of clean energy reaches 70 percent, the use of electric power reaches 30 percent and the carbon emission reduces by 55 percent in the year of 2040.

In the aspect of energy intelligent management system, set energy monitoring center in major public buildings and establish a city level energy center to implement networking and monitor and allocate the energy consumption of the city, building and municipal administration. By using WEB -based 3DGIS, realize the real-time monitoring of energy consumption of all departments and the condition of underground energy facilities and early warning of equipment accidents through the pipe sensors and equipment management systems lying underground.

Figure 5 Intelligent energy management system planning in the aerotropolis

### *3.5 Transportation system planning*

Transportation planning is divided into three levels: the first is passenger transport - how to ship out 3 million tons per year; the second is freight transport - how to transport 50 million people; the third is the transportation inside the aerotropolis.

Relying on airport, the planning area builds the multi-modal transport system with high speed rail, interurban railway, rail transit, expressway and fast road as the backbones. Passenger traffic system planning: in the core area of Zhengzhou Xinzheng International Airport, using the join of interurban

railway, rail transit, BRT and conventional public traffic to form three-dimensional seamless transfer hub. Freight system building: in Zhengzhou urban area, realize the joint of three ports - the logistic harbor of arterial road as road port, the international multi-modal transportation center as rail port and the airport logistic park as aerial port, efficiently connected through the interlaced rapid commodity transport passage.

Plan an airport logistic zone around airport, build a set of intelligent logistics management system through the construction and integration of intelligent settings in seven aspects such as security airport, E-port, rapid logistics, seamless outsourcing, efficient commerce, intuitive information and safe farm, realizing the transfer of aerial port from logistics center to information center.

Figure 6 Intelligent logistic park planning in the airport

In the airport economic zone, as a demonstration project, plan an intelligent transportation ring road with a length of 43 kilometers, set 18 base stations covering a width of 1 kilometer on both sides of the road respectively. The traffic replacement is composed by information indicating, intelligent monitoring and integrated control center, providing information such as route guidance, parking guidance, deceleration prompt, peccancy detection, accident pretreatment, bus information, real-time control of traffic signals and emergency rescue, etc.

Figure 7 Intelligent road system planning in the aerotropolis

*3.6 Intelligent monitoring system planning*

Figure8 Intelligent monitoring and control system planning in the aerotropolis

At last, the intelligent integrated planning integrates such subsystems of urban metabolism as energy, transportation, building energy efficiency, noise control, atmospheric monitoring and water quality monitoring with the intellectual technology used in environmental ecological factors, making the information acquired can be connected and integrated to reach the ultimate goal of ecological city through intelligent integration. The planning integration forms one area, one ring, one region, four galleries and four cores, all of which act as the outcomes of intelligent integration. One area: one airport intelligent demonstration area. It manages the aviation, passenger flow and logistics through intelligent technology, stores and analyzes the laden huge amounts of high-grade passenger flow logistics information to make airport transfer from logistic harbor to information port. One ring: intelligent transportation ring. One belt: dynamically monitoring the water quality of Xiaoqing River, and setting a large number of interactive experience devices in the waterfront belt, making it a demonstration area of water ecological education, exhibition and recreation. Four galleries: setting energy saving facilities galleries along Yingbin road, connecting line of Daguang expressway, Wansan road and S102, using solar street lamp and breeze electric generator to supply electricity for urban lighting, adopting moderate LED nightscape lighting. Four cores: setting an intelligent integrated operation monitoring center in airport, northern, eastern and southern area respectively, monitoring and evaluating the ecological efficiency in the overall urban operations to make ecology and intelligence predictable, evaluable and adjustable.

## 4. Conclusion

Regarding the ecological environmental impact probably caused in the large-scale and rapid development and construction of ZZAEPZ and problems such as incomplete information and the inter-departmental information isolated island existing in each subsystem of urban metabolism, the

research uses MFA to build an ecological intelligent integrated planning framework and apply it to overall planning of experimental area, which achieves preliminary planning results.

Through the planning formulation process we can see that about the six subsystems defined in this planning, the research and planning for transportation, light green subsystem and noise factors are sufficient. The coordination of department is relatively successful because the planners have a certain stock of knowledge on these aspects. However, energy subsystem is a new problem emerging in recent years, so there are several attempts, but cross-functional coordination is not very successful. For recycling, because of absence of communication mechanism among planners, environmental protection, and sanitation departments, the planning result is difficult to implement.

## Abstract

With China's fast economic development in the past decade, China now has more than 350 ov er 200 meters high-rise buildings and seven of them are in the present highest skyscrapers. Ult ra high-rise building projects plays an important role in economic growth of China as the urban area development space is becoming more limited and also other resources. Ultra high rise buildings are the substantial and spiritual symbol for the region which can push forward development of different areas.

Therefore, with the development of information technologies used in fields in urban planning, architectural design and property management, problems like safety, cost,energy saving, and optimization of the structure have been continually thrown out and focused by world's leading experts.

Wuhan Greenland Center (606 meters height) ,the 2nd tallest structure in China and 4th in the world. The 300,000 m2 urban complex consists of cultural spots, residential apartment, hotel, offices, shopping center and tertiary sectors like finance, creative studio, etc. The project aim to generate a new city sub-centre as well as the revitalization of this area. And Being a key participant in the Wuhan Greenland Center project, this article will share details during the pre-stages of decision making, site selection, environmental evaluation and social economic effects, functional compound, etc. By the means of modern information technologies and cutting edge tools, which benefits in settle the public needs and shorten the processing period.

## 1. Introduction

In the past decades, hundreds of ultra high rise buildings have arise China. It s not only the spiritual symbol of a city but also beco economics and revitalizing some downgrading region.

Being one of the world s ultra high rises building properties owner, July 18th 1992 with its headquarters in Shanghai China, Greenland enterprise tenet of Greenland, create better life in the past 22 years and f government advocates and what the market calls for, forming the curren which features highlight on the real estate, integrated development of rele including business, finance and metro through a two pronged development meth management and capital management and ranking the 268th place in 2014 the 40th place of the Chinese mainland enterprises on the list. In income amounted to 402.1 billion RMB(1USD=6.1RMB), total pre tax profit total assets 478.4 billion RMB at the year end, of which the real area of 21.15 million square meters and a sum of 240.8 billion RMB industry champion.

The real estate business of Greenland Group is taking the lead natio development scale, product type, quality and brand. It is also far ah rise buildings, large urban complex projects, high speed rail station industrial park development. Of the present 23 ultra high rise urban still under construction), 4 enters the world top ten in terms of development projects have covered 29 provinces and 80 odd cities with construction up to 82.33 million square meters. Closely following t globalization, Greenland Group expands its business overseas in a st covering 4 continents, 9 countries including USA, Canada, UK and Aust becoming the top runner of global operations of China s real estate industry.

In addition to ensuring its leading position in the real estate indu develops secondary pillar industries including finance, business, hot investment and energy resource, acquires Greenland Hong Kong Holdings (00337) company in Hong Kong Stock Exchange, and fulfils its strategic layout resources. It accelerates the overall pace of going public, propelli internationalization of itself.

Greenland Group will drive growth at a higher starting point, strive t operating income and over 50 billion profit by 2020, ranking among the Meanwhile, Greenland Group will build itself into a respectable transna sustainable development, outstanding benefit, global operation, pluralis continuous innovation, and complete the significant transformation from China s the World s Greenland .

Well experienced in building ultra high rises and leading in project s Greenland Group constantly refreshes the city skyline with its corporat leading operator in developing ultra high rises in China. There are buildings completed or under construction by Greenland, four of which highest buildings in the world. All of them have become the new la around the world.

# A Spatial Study on Creative Community around Tongji University in Shanghai Based on the Data Analysis of Professional Social Network

Sicheng WANG[1], Keke LE[2], Jiaying LIN[2]

[1,2]Tongji University, Shanghai, China
[1]yingzaofashi@foxmail.com, [2]leonardokeke@live.cn

## Abstract

*Creative city is the current hotspot in urban planning against the background of urbanization and economic transition in China. The urban zone around Tongji University in Shanghai is a typical creative community, which has undergone more than 20 years of development, from the spontaneous clustering of creative industries to organized planning and managing led by local authorities.*

*This study focuses on the history and future trend of this community. People, as the element of a creative city, for that University and Company would function. University is the institution for educating people, while Company provides for the working of People. Consequently, the links among People, University, Company reflect the creativity performance of a community. This study visualizes this relevance with methods of data analysis. The famous international professional social network LinkedIn is taken as the data source, and the general information of personal identity, education and employment of individuals in creative industries within Tongji Rim are collected from users homepages. Through analysis of the intrinsic link between the research objects by data quantification and statistical distribution observation, characteristics and internal factors of development of a university-oriented creative industries area has been observed.*

**Keywords:** Creative community, Career track, Professional social network

## 1. Introduction

### 1.1 *Tongji Rim: A University-oriented Creative Community in A Creative City*

Tongji economic zone is a collection of neighborhoods surrounding Tongji University (Figure 1), as the concept of an economic geography, it has nearly 10 years of history, and its development process is almost 30 years. According to the 2007 "Overall Plan of Tongji Economic Zone in Yangpu District", Tongji Rim is defined as "a economic activity circle with knowledge service as a link, and a creativity industrial cluster with creativity, innovation and entrepreneurship as feature". As a famous Chinese Engineering University, Tongji University has strong strength in architectural design, urban planning, landscape gardens, civil engineering, art and design and other disciplines.

From the early 1980s, inside and outside Tongji University have been a few design business and technology consulting services company (such as Tongji Urban Planning and Architecture Research Institute established in 1982). In the early 1990s, with a large-scale urban construction of Shanghai Pudong New Area, and the first real estate development boom in China, market demand of design industry increases, in Tongji University, teachers and graduates with relevant professional backgrounds opened a large number of design studios or companies in and outside the campus. And the emergence of these companies has prompted the gathering of downstream service industries such as computer renderings companies, models production companies, printing companies. By 2002, on the 860 meters long, 20 meters wide Chifeng Road on the south side of the campus has accumulated spontaneously more than 500 design and construction-related businesses. And Chifeng Road "street of architectural design" is formed in 2004. Around campus and this street preliminarily constitutes a complete design-oriented industrial chain supported with the graphic production, architectural models, decoration, design and consulting enterprises, which forms industrial clusters of design and plays a role as a venture incubator as well.

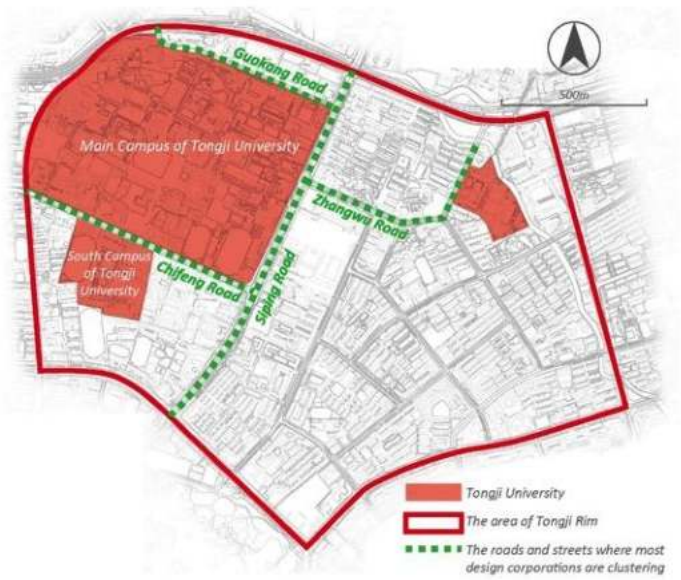

Figure 1. The area of Tongji Rim

By 2014, a total of 2,200 design firms and creative agencies have settled in the surrounding communities around Tongji University, employment ups to nearly 30,000, the annual output value nearly ups to 30 billion yuan that is over 20 times to $ 1 billion of 2002 (Figure 2). In terms of Yangpu District that Tongji University is located in, 95% of design firms accumulate in this region. As a result, Tongji Rim becomes one of the first modern service-oriented industrial base and the most influential gathering area design industry in China.

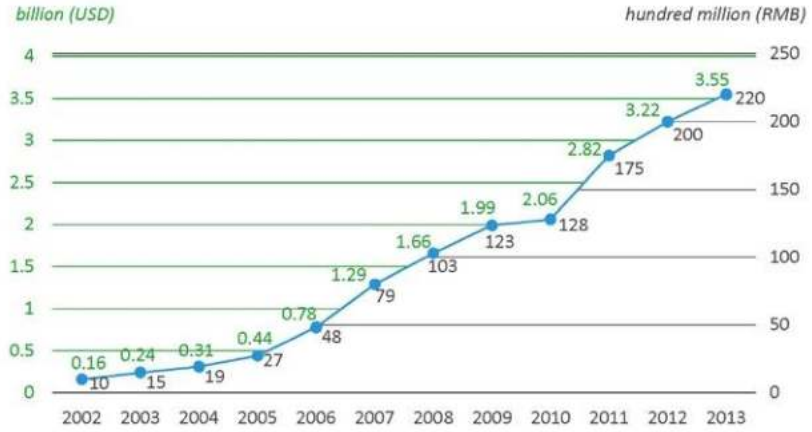

Figure 2. Total Value of Out-put of Tongji Rim from 2002-2013

Shown in Figure 1, the core area of Tongji Rim covers about 2.6 km$^2$ (area of Tongji University covers about 0.7 km$^2$, accounting for about 27% of its total area). In this region, most entrepreneurs and employees of design industry-related companies have close relation with Tongji University (faculty or graduate), while the names of these companies often contains the "Tong", as if to prove their links with Tongji University. Therefore, Tongji Rim is a typical university-led and oriented creative community. It has many similarities to the other university-oriented creative community such as Stanford University-oriented California's Silicon Valley, Harvard and MIT-oriented Massachusetts Route 128, and Tsinghua University-oriented Beijing's Zhong Guan Cun, etc.. As Edward Roberts (2009) points out, the estimated 6,900 MIT alumni firms headquartered in Massachusetts generate worldwide sales of about $ 164 billion. More than 38 percent of the software, biotech, and electronics companies founded by MIT graduates are located in Massachusetts. And these industries are precisely the leading disciplines in MIT. Thus, the spillover of leading discipline of a university often bring about a high accumulation of related people and businesses, and the formation of these disciplines-led industries cluster, to burst out an amazing innovation. Therefore, we hope to explore the main features of university-oriented creative community and the gathering track of business and people through the analysis of Tongji Rim.

### *1.2 People, University and Company, Three key elements of Creative Community*

The direct characterization of Tongji Rim is the continuous gathering of design industry-related businesses around Tongji University, resulting in huge economic benefits. As Paul Krugman (1991) points out, remarkable concentration of production in the space is the most striking feature of the geography of economic activity. As a University-oriented creative industries area such as Tongji Rim performs is the phenomenon that a large number of leading discipline and university-related industries and enterprises gather around the campus and bring about creative production activities.

Company settle near the university in order to transfer and take advantage of resources generated in the university more easily, but the university itself does not have the resources

company need, instead, the real source is the "people" and what they carry, Maryann P. Feldman (2014) states, "Person" (human agency who construct system and make all kinds of decisions in the public and private sectors) is the decisive factor for the success of a place. Therefore, people related to the university (teachers, researchers, graduates or students) are the carrier of resource shift and energy exchange between university and company. Zhang Xisheng et al. (2009) points out that human resource (trained talent, its own teachers, introduced talent, etc.) is overflowed from the university, and directly participates in the company s development process, while improving company s culture. Among these people, some may set up new creative enterprises with their own knowledge and skills; some may become a partner or employee in other companies. They are the joints linking company and university organically, and gather in a relatively concentrated space and produce a large number of innovative products, so as to form the city's creative industries area.

In other words, a university with unique leading discipline is the material premise of rapid development of such creative industries areas in urban, and gathering of large numbers of creative enterprises is a direct promoter of creative industries, and people active between universities and company is not only the necessary carrier of realizing technology resource shift from university to company, but also the key ring linking university and company. People, university and company constitute the three core elements of university-oriented creative industries area, and "people" are the most core element.

Although the people, university and company are the three core elements of university-oriented creative industry area, but it is not to say that the presence of these three elements will be able to nurture the creative industry area in the city. They might form a sustainable "creative ecosystem" due to coupling of features under certain conditions and trigger coordination and interaction as "chemistry" university continuously develop cutting-edge theoretical knowledge and technological achievements, and cultivate entrepreneurial and innovative talent, while a lot of companies gather and incubate, and finally the "creative production " is formed in a large-scale, resulting in considerable economic benefits.

In this paper, Tongji Rim is taken as example, the three core elements "people", "university", "company" is listed as three sources of indicators of university-oriented creative industries urban area. By collecting open data from the "LinkedIn" a professional social network, the coupling relationship between the three sources indicators is analyzed to reveal the main features of coordination between them, and quantify these characteristics to each sub-index for further research.

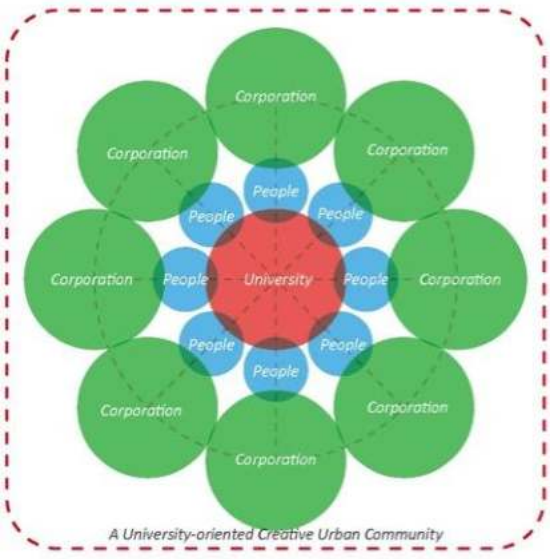

Figure 3. Three key elements of a university-oriented creative urban community

### *1.3 To Informationize the Relevance between Three Elements*

How to define the relationship between "People", "university" and "company"? As mentioned above, "people" is the most core element of the university-oriented urban creative industries area. The coupling relationship between "university" and "company" is realized through every independent "person". As Torsten Hägerstrand (1969) proposed two concepts: (1) the study of the individual can understand the development of social and groups; (2) A link between space and time should be developed.

Therefore, in this paper, people who are related to those companies in Tongji Rim are defined as the research object to analyze their correlation with Tongji University and its surrounding companies. This correlation can be displayed by certain information of individual characteristics. Among them, the correlation between "university" and people can be reflected through individual educational information (graduate schools, academic, major, etc.); and the one between company" and "people" can be done through individual work background information (work units, headline, projects, etc.). These two aspects of a person's information constitute the individual complete career information library under definition of two dimensions time (age, school year, working years) and space (location). With this information base, the relationship between "people", "university" and "enterprise" is transformed into information.

Therefore, by collecting and analyzing personal career information database of "creative people" in Tongji Rim, some characteristics of a personal career information can be found, which might be reflect the comprehensive feature of Tongji Rim.

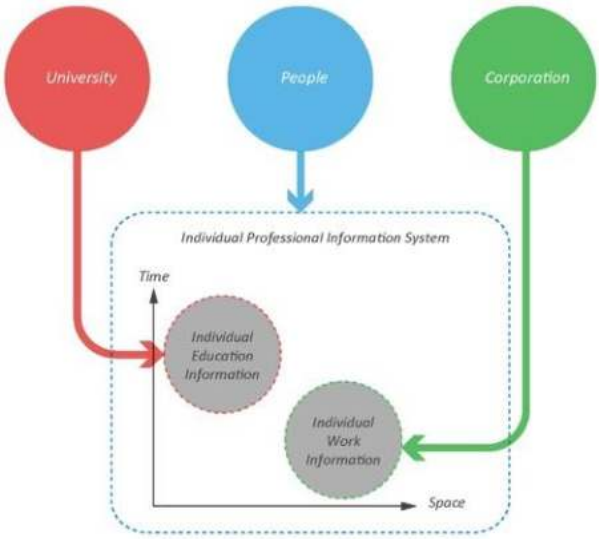

Figure 4. To Informationize the Relevance between Three Elements by the individual professional information system

### *1.4 LinkedIn s Database*

LinkedIn offers the possibility of observing "university" and "enterprise" two dependent variables through "people" as independent variables. Firstly, as a global, wide-used professional social network tools, LinkedIn has a large number of individual users, each individual user has a comprehensive education information and work background information; secondly, as a semi-open social platform, most information of the users is public and available easily to some extent; LinkedIn also has considerable business users, the overall information associated with these businesses crowd can be found. Therefore, by the collection sorting and visualization of user information on LinkedIn, it is possible to describe group career information for further description of features of university-oriented creative industries area.

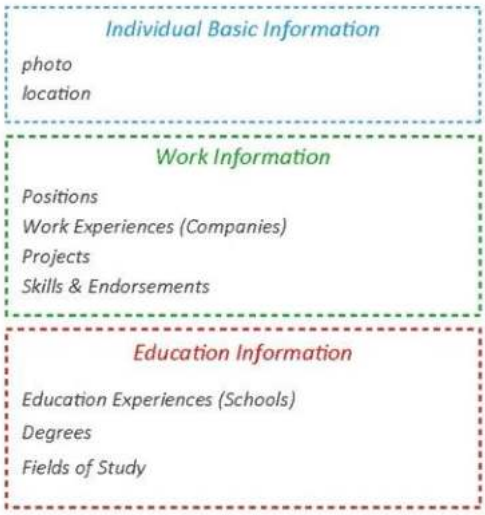

Figure 5. The basic structure of an individual user s profile

## 2 Methodology

### *2.1 Quantification and Graph of People, University and Company*

Based on every user profile on LinkedIn, a single individual is described and defined by classification of the three categories that profession, contacts and education, and which respectively involves a total of eight tags that company, previous company, experience, industry (profession), connections (contacts) and education, major, skills (education), the following is formula:

$$Person_n = \{I_{an}, I_{bn}, I_{cn}, I_{dn}, I_{xn}, I_{mn}, I_{nn}, I_{on}\}$$

$Person_n$ represents the n individual (Figure 6);

$I_{an}, I_{bn}, I_{cn}, I_{dn}$ belong to profession category, respectively represents company, previous company, experience and industry of the n individual (Figure 7);

$I_{xn}$ belongs to contact category, represents connections of the n individual (Figure 8);

$I_{mn}, I_{nn}, I_{on}$ belong education category, respectively represents education, major, skills of the n individual (Figure 9).

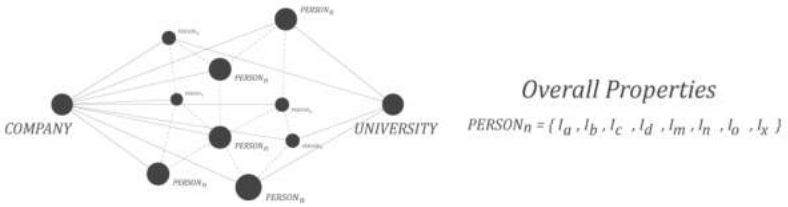

Figure 6. The graph of Personal Properties

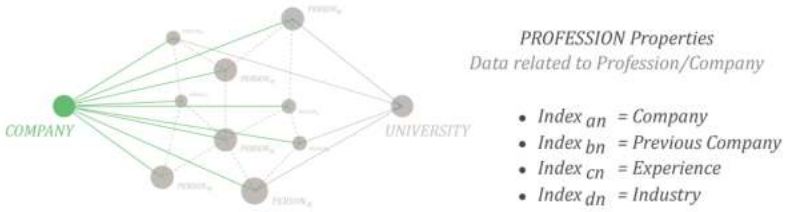

Figure 7. The graph of Professional Properties

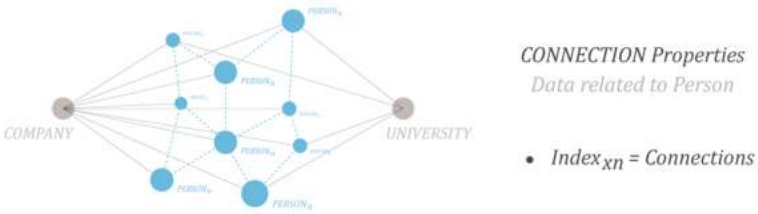

Figure 8. The graph of Connection Properties

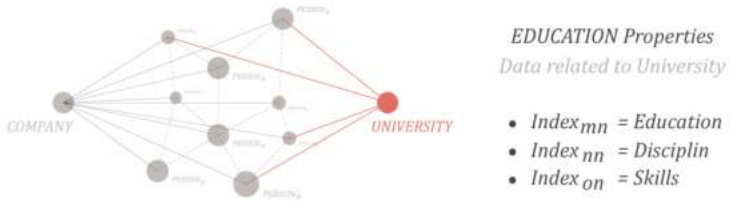

Figure 9. The graph of Education Properties

For a research on a university-oriented creative industry cluster, the object are the companies, people and university, and personal information contains companies and university, so it is the first thing to do that filtering and determining the study sample people active in the region, obviously, "in the region" is the qualification, and only $I_{an}$ (company) has spatial attributes in the eight individual tags, so $I_{an}$ is defined as the qualification to filter out all the people information which contains $I_{an}$ in use of Advanced Search on LinkedIn (the features include keyword, name, title, company, graduate schools, location and many other information) (Figure 10). It needs to be emphasized that the company information (company's name used in this research) as the filter keyword is not to limit its timing, which means both cases that the company is the one people currently or once work in. Taking such a filter condition is to remain the dynamic attributes on time-line of personal data, so as to analyze the track of creative talent more completely.

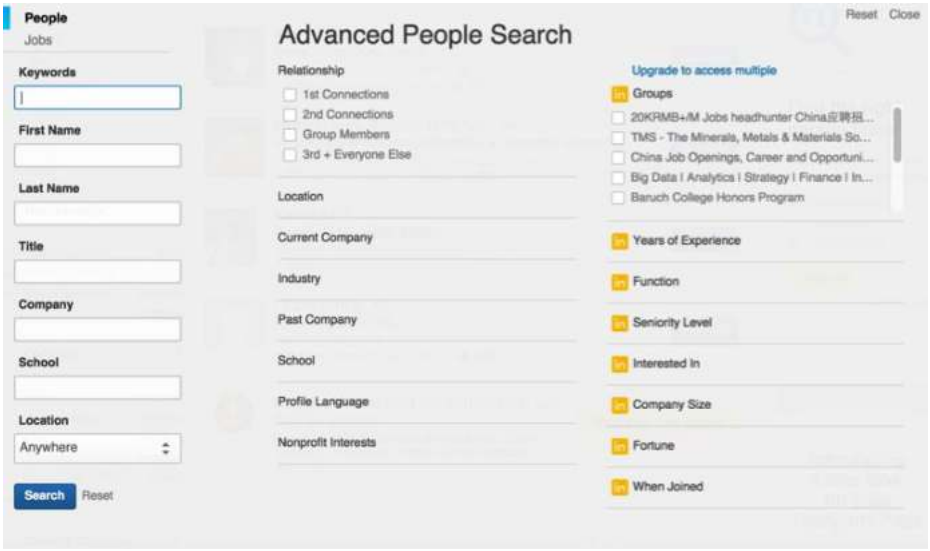

Figure 10. The advanced people search panel on LinkedIn

A user list that meets the condition will be shown after filter, each of the personal information contains three categories of information, career, contacts and education. When data is adequate and objective, after classification and statistics, it can be the quantized evidence to analyze the intrinsic relationship between company and the university (Figure 11). So analyzing the intrinsic link between the research objects by data quantification and statistical distribution observation is the core methods in this study.

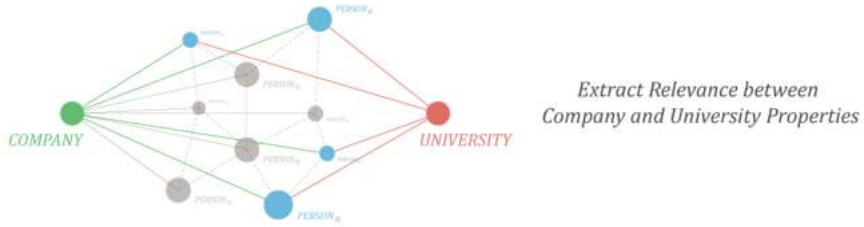

Figure 11. The graph of relation to be extracted between company, people and college

*2.2 The Framework and Flow of Research Method*

In this paper, the research object is Tongji Rim. On the basis of statistical methodology described in Section 2.1 above, the feasibility of data collection is evaluated in advanced to ensure a certain scale of users who relate to the company in LinkedIn database (> 100, based on consideration of a single company size, constraints on LinkedIn site, user incomplete information and other factors). The final selection are the following four companies in Tongji Rim as the qualification $I_a$: a. Architecture Design & Research Institute of Tongji University, sample size is 170; b. Shanghai Municipal Engineering Design Institute (Group), sample size is 115; c. Tongji urban planning & design research institute, sample size is 115; d. CCDI GROUP, sample size is 177. After collection, the corresponding personal data is classified into eight tags for mass distribution statistics respectively

This paper focuses on the following four data Stats: 1. Statistics of $I_{nn}$ education situation of users who relate to $I_a$ company; 2 Statistics of $_{dn}I$industry situation of users who relate to $_a I$ company; 3 Statistics of annual number change of related people who work in $I_a$ company as graduation (the data comes from experience $_{cn}I$the earliest years of employment with the company information); 4. Statistics of annual number change of related people who transfer in $I_a$ company (the data comes from experience $_{cn}I$the years of transferring with the company information).

From statistics of the four companies (a,b,c,d), the resulting mass distribution (histogram) and their distribution characteristic come to determine analysis of relations between company, people and university in Tongji Rim as well as the cause of development of a university-oriented creative industry cluster. The following is the specific research method flow (Figure 12):

Figure 12. The framework and flow of research method

## 3 Results and Discussions

### *3.1 The Results of Statistic*

After the statistics of related groups in four companies, based on four focus mentioned in Section 2.2, the four mass distributions (histogram) are obtained.

(1) Mass distribution of education situation of people who relate to the four companies:

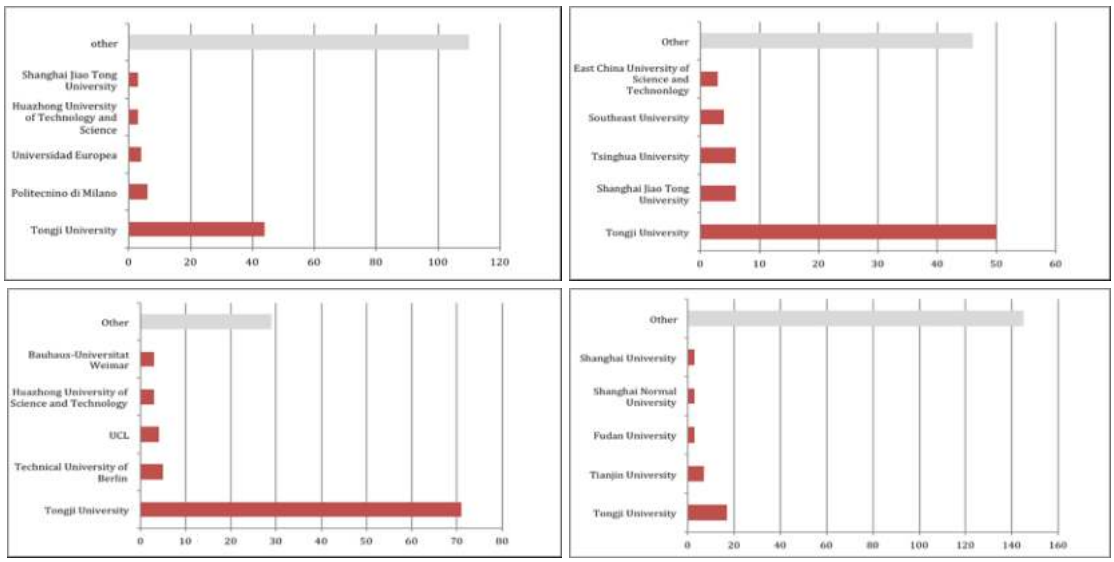

Figure 13. Mass distribution of education situation of people who relate to the four companies

The figure shows that Tongji University (among other things) has the highest occupation in education situation in all of the four companies, which accounts for 73%, 72%, 83%, 52%, respectively in a, b, c, d company, its average occupation ups to 70%, which means that 70 percent of the related people of the four companies in Tongji Rim graduated from Tongji University.

(2) Mass distribution of industry situation of people who relate to the four companies:

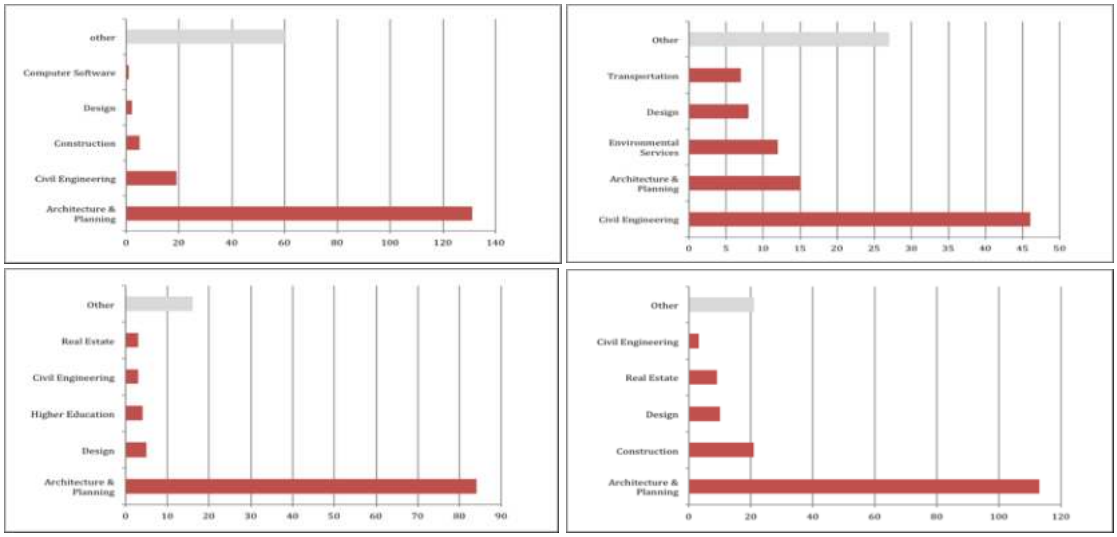

Figure 14. Mass distribution of industry situation of people who relate to the four companies

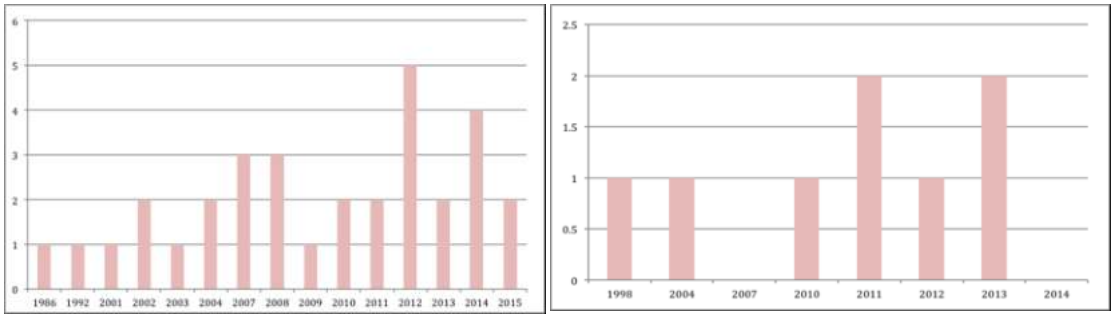
The figure shows that the industry of people who relate to the four companies are involved in the following three areas: architecture and planning, civil engineering, design. In a, b, c, d companies, architecture and planning (among other things) accounts for 83%, 17%, 85%, 72% respectively, and 64.25% on average; civil engineering (among other things) accounts for 12%, 52%, 3%, 2% respectively, and 17.25% on average; design (among other things) accounts for 1%, 6%, 5%, 6%, and 4.5% on average. The three industry average occupation reaches 86% in sum, which means that an average 86% of people in any one of the four companies come from architecture and planning, civil engineering or design, and the most come from architecture and planning.

(3) Mass distribution of annual number change of related people who work in $I_a$ company as graduation:



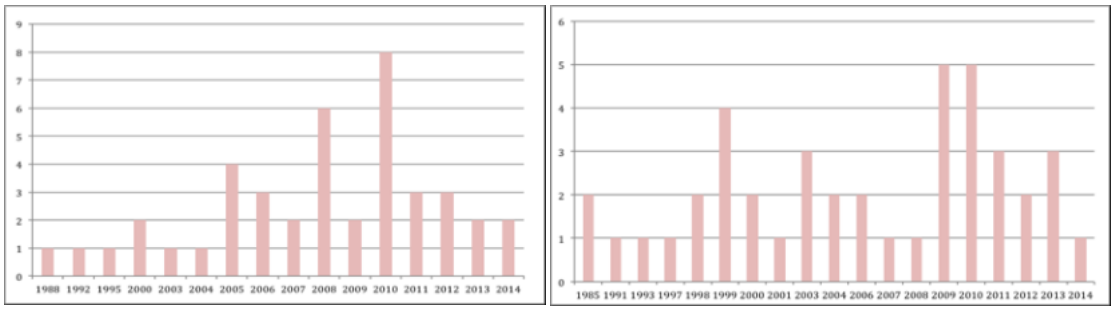


Figure 15. Mass distribution of annual number change of related people who work in $I_a$ company as graduation

The figure shows that the number of people who work directly in the four companies as graduation has fluctuate growth in 2000-2014. The peak respectively appears in 2012, 2010, 2011 and 2010. For further analysis of number change of talents the four companies attract between the 15 years (2000-2015), it is necessary that statistical analysis of annual number change of related people who transfer in the four companies.

(4) Mass distribution of annual number change of related people who transfer in the four companies:

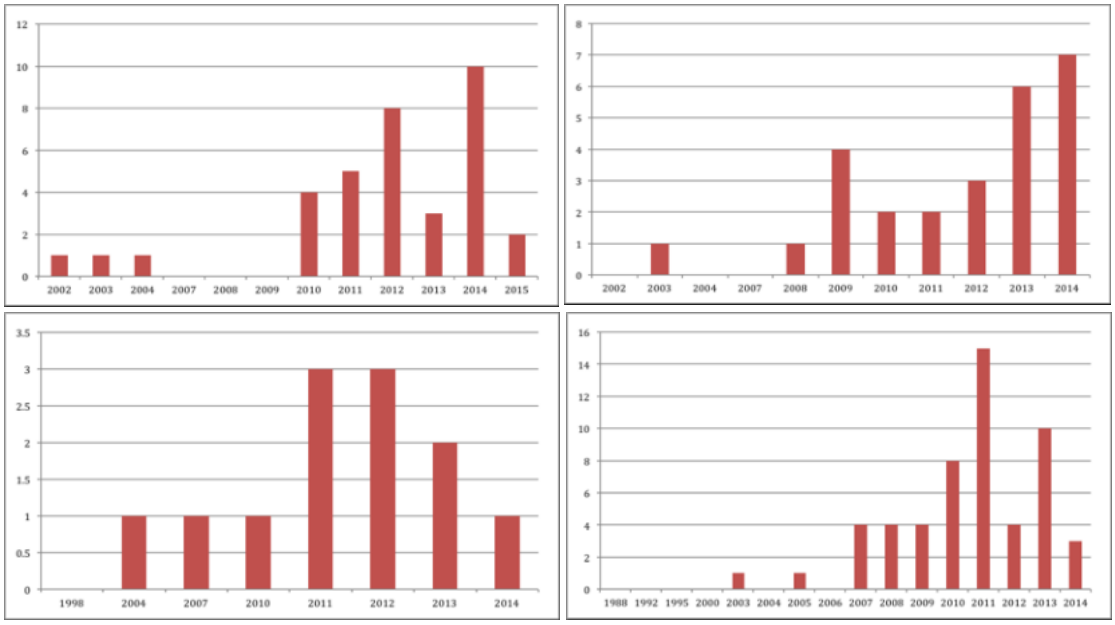

Figure 16. Mass distribution of annual number change of related people who transfer in the four companies

The figure shows that the number of people who transfer in the four companies also has fluctuate growth in 2000-2014. The peak respectively appears in 2014, 2014, 2012 and 2011. By accumulation of the (3) and (4) mass distribution, annual overall distribution of people who relate to the four companies will be obtained for the next discussion on internal factors of development of a university-oriented creative industry cluster. The mass distribution of overall

number of people who relate to the four companies is as follows:

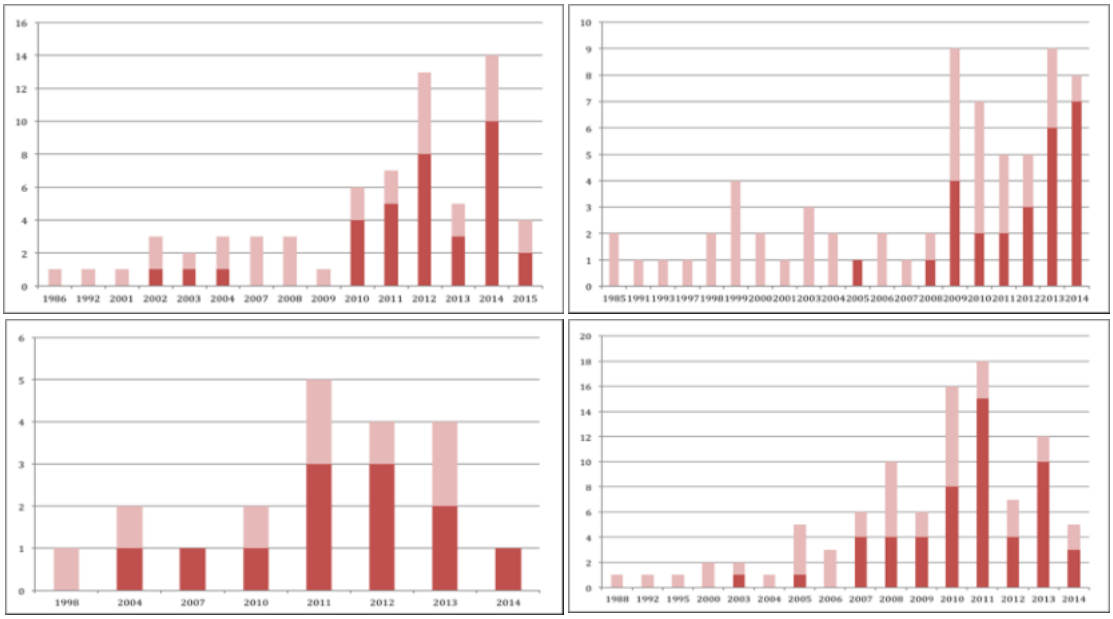

Figure 17. Mass distribution of overall number of people who relate to the four companies

The figure shows that the overall number of people who relate to the four companies still has fluctuate growth in 2000-2014, while it has a greatly increase between 2009 and 2011. The peak respectively appears in 2014, 2009, 2011 and 2011.

### *3.2 The Sustainable forces for A University-oriented Community Development*

According to the result of 3.1 (1) statistics, it shows that spillover university talents provides a stable of human and intellectual resources for industrial concentration and development around the university; according to the result of 3.1 (2), it shows that the overflow of a university s leading disciplines forms characteristics of its surrounding industry (in the 2012 National Assessment of Universities Leading Discipline, Tongji University s architecture and planning, civil engineering, design ranks second, first, sixth respectively of all universities in China); according to the result of 3.1 (3) (4) statistics, it shows that once industrial clusters with characteristics and advantages forms, it will be able to attract more relevant people, including graduates and transfer talent, and gradually forms internal productivity and external attractive force for sustainable development.

From this paper, the research results achieved by means of LinkedIn database and conclusion mentioned above, to some extended, coincide the points purposed by Reid Hoffman (2013), the CEO of LinkedIn: (1) Evaluation of a group depends on the individuals that make up this group; (2) Each group has some common characteristics; (3) Geographic density is also very important. Cooperation would be maximized when information and ideas spread among all groups which have common interest, if which happens in the same geographic region.

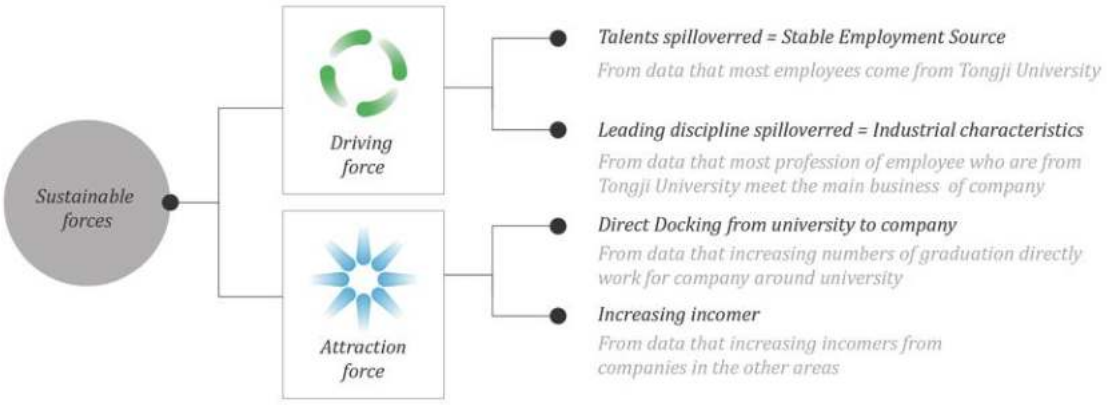

Figure 18. The Sustainable forces for A University-oriented Community Development

### *3.3 Future Application*

In summary, by LinkedIn s user information statistics and analysis, certain characteristics in a university-oriented creative industries area has been observed from the perspective of social networks. These features are shown through the quantitative relationship between people, university and company, which in turn is based on each individual education and profession background. In this study, the relevant conclusion is drawn after preliminary exploration to Tongji Rim as a study case. Studies have shown that in result of directly or indirectly talent output, the spillover leading disciplines and professional technology and attraction from the outside, a university-oriented creative industry cluster can be able to gather a lot of talent, and these talent is the driving force behind the development of this kind of creative industries cluster. Therefore, this study provides empirical evidence of creative function layout and element configuration to urban managers and planners. Meanwhile, thanks to LinkedIn s wide application and huge amount of users in various regions and industries, based on preliminary results of this study, the quantitative analysis can be applied in other similar cities and regions for further analysis and follow-up survey, such as Beijing Zhong Guan Cun, Route 128 in Boston and San Francisco Bay Area and other places. As the amount of data on the LinkedIn platform increases, the accuracy of quantitative analysis will be greatly enhanced, and it is possible to combine with geographic information systems for more accurate visual expression of space gathering of creative industries and people.

Keywords: Global Urban Network, Information Flow, Google Trends

*Abstract:*
*Network of City under the impact of globalization and information technology is an active direction for the last decade of Urban and Regional Studies. Based upon the search interest statistics provided by Google Trends, this article gets* people s online attention *data among cities in 2012, maps the main linkage among world cities, and ranks cities according to their international connectedness. Main results confirm that 1) Europe has the largest number of higher-ranking cities in the new global urban network, the next is North America, and the least is South America as well as Africa; 2) Southeast Asian cities except Singapore and Hong Kong all perform poorly under the new criteria; 3) Two types of cities, info-flow-in and info-flow-out, nearly distribute evenly across the main continents; 4) Connection within and between Europe and North America is of the most density and frequency among other intercontinental links. Overall, significant differences exist between the new networks based upon inter-city concern on the Internet and the traditional urban system based on the producer service firms. Interconnectedness of cities to a large extent is influenced by the real geographic location and distance. The research does a beneficial attempt on mining information flow data and provides new insights into city network studies.*

## 1. Introduction

World Cities is always a key issue in the field of urban and regional studies. A series of changes have taken place over time in the research methods and ideas. Generally, the mainstream researches can be divided into three stages: stage of world cities with attributes but without relations, stage of world cities in network society, new stage of world city network in global environment (Yang, 2011).

In the first stage (1960s-1990s), most research literatures are about the comparison of the city's comprehensive index (e.g. the concentration of headquarters of multinational companies, controlling rate of financial assets, etc.). The cities ranking in front according to these attributes are defined as world cities. In this period, World Cities study has obtained a great deal of information about urban nodes, but mainly focused on characteristics of cities in and by themselves, n among world cities. (Hall, 1966; Friedmann s world city hypotheses , 1986; Sassen's triad of world cities, 1991; 1994; 1996)

In the second stage (1990s), the development of information technology had a more and more profound impact on the global urban system organized by world cities. Cities were involved into global urban system through the information network, and their operation is increasingly affected by globalization. Castells (1996) proposed the famous theory of "space of flows", revolutionarily distinguished from the traditional "space of place", and defined the concept of nodes and hubs. Manuel Castells' *Global Spaces of Flows* describes the world city from the spatial perspective of global flows as the nodes and hubs with the "most direct influence" on a global scale. He believes that global city s concept is not a static place, but a process of connecting. Global city in world network is the centre in the connecting process of advanced services production and consumption. Castells has built a research framework based on relations of world cities, but the empirical data is lacking at that time. So it s necessary to strengthen the collecting of the relation dat system.

In the third stage (Since 2000), academic studies of world cities has changed from the traditional approaches to a new empirical phase. In this period, there are two main types in the analysis of relational data between cities: two-mode dataset and one-mode dataset:

For the two-mode dataset, researches mainly analyse producer services from the diversity of urban serving function and make use of hierarchical information flow between multinationals instead of the real connection between cities. Liu and Derudder (2013) systematically summarized three existing calculating approaches of urban network (the ownership linkage model, the interlocking network model, and the two-mode city-by-firm network model). By interlocking network model method, Taylor (2001) measured the strength of the force in global urban network through a large number of case studies, pointed out the key elements in the formation process of global urban system, and built the bridge from enterprise s linkage to cities linkage, which has become the theo foundation stone of global urban network studies by corporation. Nevertheless, the relational data of Taylor s interlocking network model is unable to express directional link betwee different connecting characteristics resulted from enterprise s various industries, sizes and strategies might bring biases. To solve this problem, the two-mode city-by-firm network model is applied to evaluate firms and cities positions in corporate networks simultaneously. But t approach and the associated computational burden deters urban scholars from using it.

For the one-mode dataset, researches reflect urban network from some measurable aspects of economic activity between cities, such as the infrastructure s connections, e.g. air flow (Derudder and Witlox, 2008; Smith and Timberlake, 1995; 2001), telecommunications streaming, internet connections etc. (Malecki, 2002; Tranos and Gillespie, 2009), the number of co-author papers and patents (Maggioni et al., 2007; Sonn and Storper, 2008; Matthiessen and Schwarz, 2010), the population of international migration (usually the business elite and senior) (Beaverstock et al., 2000), etc., and then builds a world city network system with the tools of graph theory and social network analysis method. However, nearly all the researchers acknowledged that the limitations of statistical data directly affected the accuracy and depth of the study.

In general, the two-mode dataset is characterized by connections between two separate sets of nodes (cities and firms, respectively) while actors in the one-mode dataset are directly interlinked. The essence of all corporate-based analyses of urban networks is a city-by-firm data matrix rather than a city-to-city adjacency matrix. Such researches have to face the transformation of the two-mode data into a one-mode data, and the transforming almost inevitably leads to a loss of information because certain network structures disappear after transforming.

Nowadays, the Internet has become an integral part of human economic and social life. The popularity of the Internet has made it possible to collect more detailed data, and greatly reduced the cost of data collection. With the arrival of the eras of cloud computing and big data, theoretical research about global urban network will break the past constraint of lacking connecting data, and embrace the new time where we have the ability to pay attention to each indivic microscopically.

In the Internet era, people s online searching interest data of cities, to a certain extent, ca comprehensively reflect the economy, image, openness, creativity and social vitality of cities., and has generated a growing impact on economic and social development. As a start for most users surfing online, web searching engine can find the desired content on the internet through a keyword. Therefore, the total number and frequency of keywords in the search engine can be a direct indicator of the degree of the concerned word.

In this paper, we take the one-mode dataset method and utilize the users concern data based on the world s largest search engine, Google, to characterize and reflect the mutual att We expect to build a directed-weighted network of global cities based on the online inter-concern

data, and compare the final results with GaWC in order to reveal new features of urban network in the Information Age, also provide guidance for promoting the development of urban network.

## 2. Design of research methods

### *2.1 Data acquisition*

To make it easier to compare our outcomes of with the predecessors' research achievements we take the 182 cities of three levels (Alpha, Beta, Gamma) according to GaWC 2012 as study subjects. With the key words index tool provided by Google Trends (Figure 1), we get the Google users search interest data of year 2012 among all 182 cities. Google Trends analyses a percentage of Google web searches to determine how many searches have been done for the terms users entered compared to the total number of Google searches done during that time. Trends results are normalized by the total searches from each region so that data from two regions with significant differences in search volumes can be compared equally. By writing scripts for batch query and file analysis, we build up an intercity concern matrix formed by 32,942 Trends data (see Table 1).

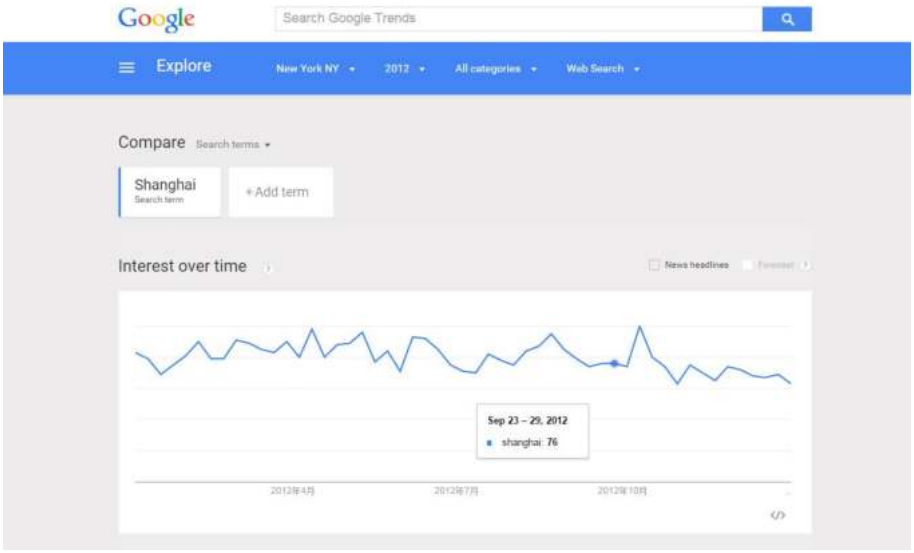

Figure 1. The screenshot of Google Trends page

Table 1. Pedagogical Matrix of Google Intra-searching Interest for Major World Cities

| | City A | City B | City C | City D | Outdegree |
|---|---|---|---|---|---|
| City A | | $W_{AB}$ | $W_{AC}$ | $W_{AD}$ | $OD_A$ |
| City B | $W_{BA}$ | | $W_{BC}$ | $W_{BD}$ | $OD_B$ |
| City C | $W_{CA}$ | $W_{CB}$ | | $W_{CD}$ | $OD_C$ |
| City D | $W_{DA}$ | $W_{DB}$ | $W_{DC}$ | | $OD_D$ |
| Indegree | $ID_A$ | $ID_B$ | $ID_C$ | $ID_D$ | |

To demonstrate the matrix, we take four cities A, B, C and D as an example (see Figure 2). There are two pieces of information link between each two cities. is the interest index of searching terms "city B" from users in city A. reflects to what extent people in city A concern about city B. Analogously, is the interest index of searching terms "city A" from users in city B. shows city A s popularity in city B. Thus, the matrix actually corresponds to the giant network of mutual searching links among world cities.

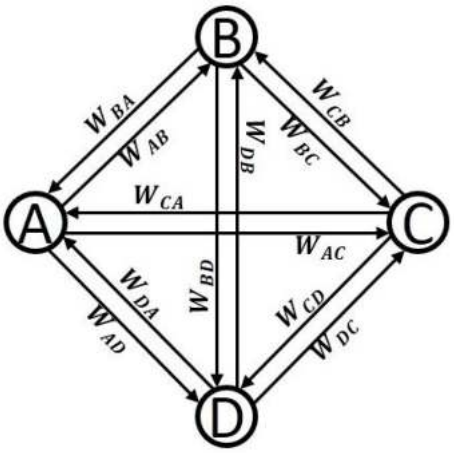

Figure 2. The Graphical Representation of Intra-searching Network

*2.2 Data processing*

Global urban network system can be studied from three aspects--**city nodes, information links, and urban networks.** This study starts from the data capture of the information links. Evaluation of the city nodes and the urban networks is conducted after processing the links.

*2.2.1 Link*

*(1) Link strength*

Each two cities has two reversed links between them (city A to city B and city B to city A). Using Taylor (2001) s model for reference, we define the strength of the link betwee multiplication of the two directional links. It is measured as follows:

$$= \quad = \tag{1}$$

The link strength index indicates the mutual concern degree between two cities. It is a comprehensive reflection of the strength of connectedness between the two cities. However, there is a problem with this algorithm: when the value of or is 0, the link strength index therefore equals 0, which is not consistent with the reality that there exists a one-way link between the two cities. To solve the problem, we learn from the method of calculating geometric mean, and improved the equation as follows:

$$= \quad = \quad \sqrt{(\quad)^2 + (\quad)^2} \tag{2}$$

*(2) Link symmetry*

At present, the majority of the existing research literature of the global urban network focus on the non-directional weighted network. The importance of node and the directionality of flow are less clear and need to be taken into account. In this regard, Limtanakool et al. (2007) sets up a three S-dimensions framework for identifying and classifying the pattern of the urban systems from an interaction perspective. Limtanakool brings forward the concept of link symmetry index LSI to describe the degree of difference in both directions of the flow. For the link between cities A and B, LSI is measured as follows:

$$LSI_{AB} = \quad LSI_{BA} = \quad [\frac{f \ \ln(f\ ) \quad f \ln(f\ )}{\ln 2}] \tag{3}$$

$$_{AB} = \frac{W}{W \quad W} \tag{4}$$

$$_{BA} = \frac{W}{W \quad W} \tag{5}$$

Here, $_{AB}$ is the proportion of flow volume from nodes A to B in relation to the sum of volumes on links A to B and B to A. Similarly; $_{BA}$ is the proportion of flow volume from nodes B to A in relation to the sum of volumes on link A to B and B to A. When the value of $LST_{AB}$ is 0, the link between nodes A and B is a one-way flow which means completely asymmetric. When the value of $LST_{AB}$ is 1, the link between nodes A and B is an equivalent bi-directional flow, which means completely symmetric. Liu et al. (2013) thinks that Limtanakool s formula is inadequate in describing the vector nature of network links, because the index LST itself does not have directionality. LST is just limited to quantifying the symmetry level of the whole network. Furthermore, in the vicinity of 0.5 (where links A to B and B to A are close) LST does not have the sensitivity to reflect differences of the vectors. In order to realize the visual quantitative measurement of the symmetry of the two-way flow, Liu et al. make additions to the formula that when the volumes in both directions of the link have non-magnitude differences, the following formula can be used:

$$LST_{AB} = \frac{W \quad W}{W \quad W} \tag{6}$$

With Eq. (4), the formula can be evolved as follows

$$LST_{AB} = \quad _{AB} \quad 1 \tag{7}$$

When $LST_{AB} < 0$, $_{AB} < \quad _{BA}$, which means that node A s inflows are greater than outflows while node B s inflows are less than outflows. In the same way, when $LST_{AB} > 0$, $_{AB} > \quad _{BA}$, which means that node A s inflows are less than outflows while node B s inflows are greater than outflows. LST can distinguish the directionality of the flow by the positive and negative signs of the value, but the result is contrary to conventional understanding. Therefore, we further improve the formula as:

$$RLST_{AB} = 1 \quad _{AB} \tag{8}$$

When $RLST_{AB} = \quad 1$, flows completely goes towards node B from node A. When $RLST_{AB} = 0$, flows are equivalent on both directions between nodes A and B.

According to Eq. (2), (6) and (7), function diagrams are drawn to illustrate the relations of $LSI_{AB}$, $LST_{AB}$, $RLST_{AB}$ along with $_{AB}$ so that their differences in measuring city links are seen directly.

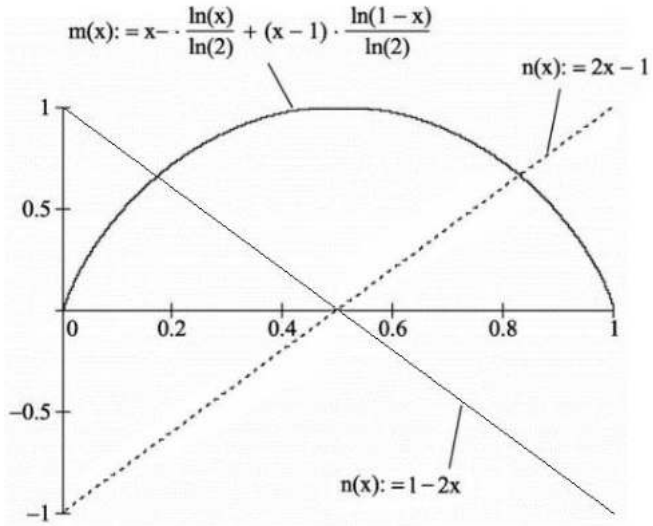

Figure 3. The Comparison of LSI, LST and revised LST index

*2.2.2 Node*

*(1) Node strength*

Node strength describes the sum of all link strength connected with a node. On the basis of Eq. (1), the node strength index of city A is measured as follows:

$$= \quad + \quad + \quad +$$
$$= \quad + \quad + \quad + \tag{9}$$

reflects city A s total amount of information flow in the global urban network.

*(2) Node degree--indegree & outdegree*

The node indegree index describes the total amount of information flowing into a node to a certain extent reflects the centrality of a city node. The node outdegree index describes the total amount of information flowing out of a node. to a certain extent reflects the radioactivity of a city node. For city A, its node indegree index and outdegree index are measured as follows:

= + + + (10)

= + + + (11)

*(3) Node symmetry*

We carry on the concept of node symmetry index NSI proposed by Limtanakool et al. (2007) to describe the degree of differences between node indegree and outdegree in the directional network. For node A, its node symmetry is measured as follows:

$$NSI_A = \frac{\circ}{\circ} \quad (12)$$

When $NSI_A$ = 1, flows are completely going out of node A. When $NSI_A$ = 0, inflows and outflows of node A is equivalent. When $NSI_A$ = 1, flows are completely going into node A.

*(4) Node Clustering Analysis*

To compare with GaWC s study results, and identify differences and similarities of the world city hierarchies in various networks, this paper divides the 182 global cities into 3 classes and 10 sub-classes by K-means clustering taking the node strength index as variations. K-means clustering method is applicable to the case given a known number of categories. Its calculation principles are not discussed in this paper.

## 3. Empirical test

In this section, the proposed theoretical framework is illustrated by empirical data. The pattern of spatial interaction among 182 cities as constituted by Google Trends is characterized for a new world city network. Carrying out the test of these 182 cities enables us to assess whether our approach is feasible and effective.

*3.1 Calculation of the link and node indices*

Following the research methods above, we compute the values of all node and link indices of the network consisted of 182 world cities and their online inter-concern. Due to space limitations, detailed procedures are not included in this paper.

*3.2 Comparison of Google Trends network and GaWC network*

Does the new network based upon the web concern follow the old urban system? We make clustering analysis of the 182 cities, tabulate the outcomes along with GaWC s results (Table 2), and mark cities by classes on the world map (Figure 4).

Table 2. Values of Node Strength, Degree, Symmetry, Entropy and Class

| Class | | GaWC | Google Trends |
|---|---|---|---|
| | ++ | London; New York | Paris |
| | + | Hong Kong; Paris; Singapore; Shanghai; Tokyo; Beijing; Sydney; Dubai | Los Angeles; Chicago |

| | | | |

| | | |
|---|---|---|
| - | Nantes; Tianjin; Accra; Algiers; Gothenburg; Porto; Columbus; Utrecht; Orlando; Ahmedabad; Asuncion; Kansas City; Seville; Turin; Dar Es Salaam; Portland; Krakow; Managua; Pune; Leipzig; Malmo; La Paz | La Paz; Guayaquil; Houston; Baku; Tokyo; Managua; Nicosia; Tallinn; Guatemala City; Asuncion; Dar Es Salaam; Almaty; Algiers; Manama; George Town(CI); Helsinki Muscat; Valencia(SP); Bogota Amman; Riga; Tianjin; Port Louis |

From Table 3, we can see that:

1) In Class , 15 cities remain the same and 13 cities rank up compared with GaWC. Among them, the cities moving drastically up are Bristol, Charlotte, Phoenix, Glasgow, Edinburgh, Birmingham (UK) and San Diego. In addition, 4 cities--Paris, Singapore, Toronto and Hong Kong keep taking higher-ranking place in both two networks. Still more impressive, Paris climbs to the top from the 4th, Los Angeles soars to second from 18th, and Chicago leaps to third from 11th.

2) In Class , 30 cities remain the same; 14 cities rank up; 27 cities rank down. Among them, the cities moving drastically up are Portland, Orlando, San Jose (US), Pune, Leeds and Tampa, and the cities going largely down are London, Madrid, Barcelona, Johannesburg and Warsaw. Strikingly, London falls to 95th from the summit, and Madrid drops to 92th from 19th.

3) In Class , 14 cities remain the same and 42 cities rank down. Among them, the cities going largely down are Tokyo, Beijing, Bogota, Shanghai, Houston, Helsinki, Guangzhou and Ho Chi Minh City, most of which are located in the Asian regions. More prominently, Tokyo falls to 164th from 17th, Beijing drops to 143th from 8th and Shanghai slips to 107th from the 6th, which are the sharpest drop in all declines.

Thus, there exit significant differences between the new networks based upon inter-city concern on the Internet and the old urban system based on the producer service firms in cities.

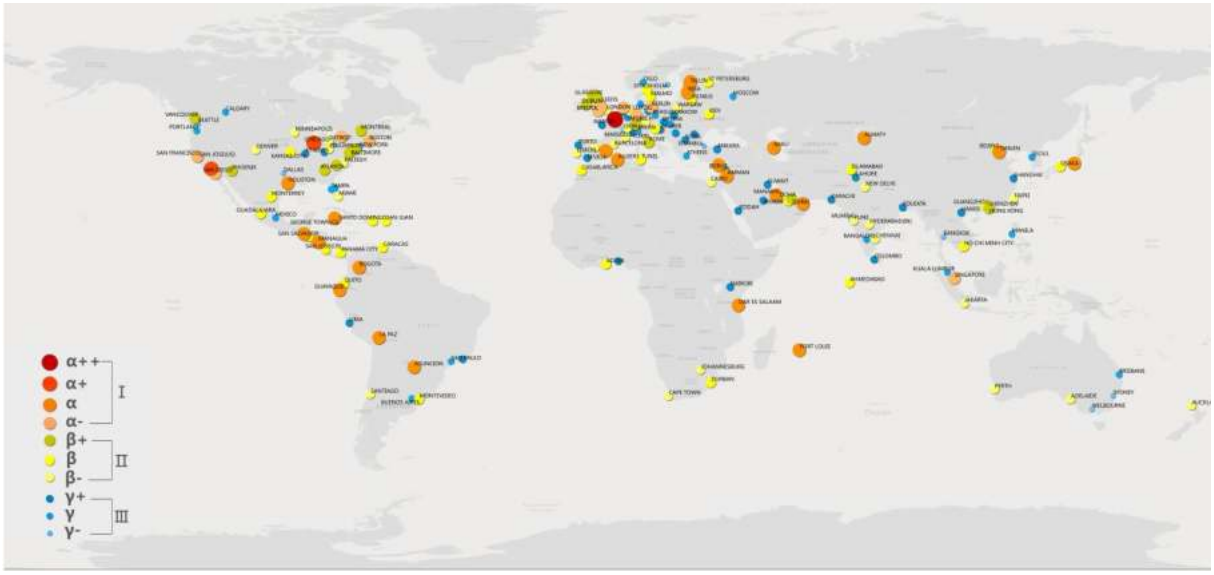

Figure 4. World cities in 3 classes and 10 subclasses according to web concern

*3.3 Visualization*

This study involves massive data with non-uniform structures, so the visual data analysis tools (ArcGIS) is employed to map out the directional weighted urban networks formed by 182 city nodes and their inter-connected links (Figure 5).

In Figure 6, the size of city node responds to the value of the node strength index , indicating the city s sum volumes of searching and being searched. The lines correspond to the in the network where the value of the link strength index is shown by the line thickness. Nodes are divided into two types distinguished by colour: the red nodes are info-flow-in cities ( NSI < 0 ) and the blue nodes are info-flow-out cities ( NSI > 0 ). Arrows indicate the direction of flow.

According to the node symmetry index NSI, the 182 cities can be divided into two types: concerned-city type and concerning-city type. Concerned-city type refers to cities whose indegree is bigger than outdegree, which means the volume of searching for other cities is smaller than that of being searched. On the other hand, concerning-city type refers to cities whose outdegree is bigger than indegree, which means the volume of searching for other cities is bigger than that of being searched. In this study, the volume of being searched and that of searching for other cities are nearly equal in the case of most cities (where the value of NSI hovers near 0). A minority of cities manifest obvious directionality: the indegree of Helsinki, Riga, Muscat, La Paz and George Town (CI) is much bigger than outdegree so these cities obviously belong to the concerned-city type, while the indegree of Manama, Tokyo and Houston is much smaller than outdegree so these cities apparently belong to the other type. Very few cities present an extreme directionality: Bogota, Amman, Tianjin and Port Louis have a net inflow while Valencia (SP) has a net outflow. All cities showing obvious or extreme directionality belong to those whose total number of information flows are small and rank in the lowest class.

We sort every link between all the cities according to the flow volume and draw the results as a scatter plot (Figure 6). As can be seen clearly from figure 7, the values of the link strength index vary continuously from the minimum to the maximum, and there are 4 obvious stages throughout the function curve: 1) the value of is 0 where no connection happens among cities; 2) the value of rises rapidly from 0 to about 50; 3) the growth of slows down and forms a long gradual slope, where the majority of links are within this range; 4) the increase of accelerates again and tends to climb straightly, where the most important links with large volume of inter-concern are located. They are backbones of the whole urban network.

In order to more clearly understand the network structure, we display the map separately by setting top 5%, 10% and 20% of the biggest flow volume as threshold (Figure 7, 8 and 9).

When the threshold is set to top 5%, 10 core links appear in the world map. Among them, Birmingham (UK), Bristol and Manchester together form a strong inter-concern circle in Britain. Besides, the links Edinburgh-Glasgow, Nantes-Paris and Dusseldorf-Gothenburg further establish the heart position of Europe in the world cities network. For North America, two links, Cleveland-Cincinnati in the middle area and San Jose (US)-Francisco in the west coast, make America the second active region in the core network. For Southeast Asia, there is just one link from Hong Kong to Singapore visible. For Inter-continental connection, only one link from Zagreb to Calgary is visible.

When the threshold is set to top 10%, 49 links appear in the world map (including 10 core links). Compared with the situation of top 5% threshold described above, there are 6 more links turning up within the British Isles (Leeds-Bristol, Leeds-Birmingham, Leeds-Manchester, Glasgow-Belfast, Edinburgh-Belfast and Bristol-Dublin), 3 more links coming forth among other European cities (Paris-Berlin, Rotterdam-Amsterdam and Birmingham (UK)-Prague), 6 more links springing up in North America (San Jose (US)-San Diego (US), Washington-Baltimore, Columbus-Cleveland, Raleigh-Charlotte, Charlotte-Cleveland and Charlotte-Los Angeles, San Jose (CR)-San Jose (US)), 3 more links showing up in India (Pune-Mumbai, Ahmedabad-Pune and Hyderabad-Bangalore) and 2 more links showing up among other Southeast Asian (Singapore-Jakarta and Mumbai-Singapore)

When the threshold is set to top 20%, more than 800 links emerge in the world map. The embryonic framework has formed and is very close to the fully formed global urban network (Figure 5).

## 4. Conclusions and the way forward

Studies on global urban network have experienced three major phases: stage of world cities with attributes but without relations, stage of world cities in network society, overly new stage of world city network in global environment. In the third phase, analysis based upon one-mode dataset and two-mode dataset are the two main types. The well-known interlocking network model designed by Taylor (2001) for producer service firms in cities is of the two-mode dataset type. It has been widely adopted in academia, but the inherent problem of information loss caused by the projection from two-mode to one-mode makes it defective. Unlike two-mode type, one-mode dataset can directly create the city-to-city-matrix without transformation, while the persuasive and massive city-related data is needed.

In general, despite different underlying assumptions and operations, all approaches look at ways to build up the city-by- something datasets to estimate how individual cities are connected th the something networks. The rise of cloud computing and big data technologies provides us new possibilities for the something . In this context, we cast our eyes over the vast data of Internet users.

In this paper, we have (1) proposed a new framework with improved methods for analyzing the directed weighted network of city based upon one-mode dataset; (2) collected the Google users search interest data of year 2012 among 182 cities of three levels (Alpha, Beta, Gamma) according to GaWC; (3) simulated the information flow by calculating the link and node indices; (4) visualized the city network on geographical entities; (5) observed the hierarchies and patterns in the global city network; (6) made comparisons with GaWC group s outcomes.

Main results are as follows:

For **node**, 1) Europe has the largest number of higher-ranking cities in the new global urban network based on Google Trends, where the node strength is also greater, the next is North America, and the least is South America as well as Africa; 2) Southeast Asian cities except Singapore and Hong Kong all perform poorly under the new criteria; 3) Two types of cities, info-flow-in and info-flow-out, nearly distribute evenly across the main continents.

For **link**, 1) Europe still takes the heart position of the world, then North America and Asia. 2) Connection between Europe and North America is of the most density and frequency among other intercontinental links.

Overall, significant differences exist between the new networks based upon inter-city concern on the Internet and the traditional urban system based on the producer service firms. Interconnectedness of cities to a large extent is influenced by the real geographic location and distance. Cities in the same region are more likely to show concerns to their surrounding areas (the top 5% links in Figure 7 prove this). The district-crossing connection comes at the next level.

The analysing method of weighted network based on people s online attention da flaws and advantages. The deficiencies and places might be improved of this article are as follows:

1) Although people s online attention data can comprehensively reflect the openness, creativity and social vitality of a city, etc., the data s validity recognized. The relationship between cities socioeconomic development and p searching interest data still need to be verified through other inter-relational data between representative cities.

2) Trends data is relative, not absolute, which makes our map may not reflect the real scale of searching flows in the global context. Google s web page says that sets of search data are divided by a common variable, like total searches, to cancel out the variable's effect on the data. Although Google assures the comparability of Trends data, it still does not clearly explain how the raw data is normalized so that the restoration is unable to be carried.

3) English language bias. As a keyword for searching in this paper, the English names of the city may cause that the searching interest data of non-English-speaking areas cannot be truly reflected, while English-speaking world cities are highlighted in the network.

4) Although Google is the world's largest search engine, its service is limited in some countries and regions, moreover, maybe it s not the mainstream search tool widely used by loca cause that the data of Google Trends cannot fully reflect the real online attention.

5) From the perspective of graph theory, the node-related links, except the inflows and the outflows, also include the link whose source and destination nodes are the same. This kind of links, more universal and to some extent associated with city size, can indicate the contact between the various urban elements within the city. This paper focuses on the research of inter-concern network between cities, ignoring the local people s search within the city itself, which may distort the netw structures, especially the size of the nodes.

6) The specific reasons for the flow s asymmetry between cities need to be furth

7) This paper selects totally 182 cities distributed at , , three levels of the GAWC group' results as study object, which has certain limitations. Besides, the distribution of these cities also cause some bias. For example, more European cities were selected compared to other regions and the online attention between these cities is far more than two distant cities, which makes these cities behave better than the actual situation.

The advantage lies in the analytical comprehensiveness of asymmetric links between cities and the technology of data collection and data processing, which saves us a lot of time.

1) As for analysis method, directional weighted network is an important supplement to the urban network research, which allows us to simultaneously analyse the directions and quantities of the complex city network through studying flows asymmetry. This method helps us dee the asymmetric of relationship between global cities and determine the true status of the various cities in the network more accurately. In the past, the research of global urban network can hardly go deep into the analysis level of directional weighted network because the data is difficult to obtain and handle. This study has provided technical support and empirical tests to remedy this defect.

2) As for analysing material, it s innovative to employ the statistical data ba
this research, which has enlarged the studying range of original cyberspace in urban geography. The object of this study is measurable online data of bi-directional links between cities. Compared to the data of air flow, telecommunication flow, immigration flow, capital flow, etc., the online data are less expensive to obtain, easy to operate and convenient to use for urban and regional researchers. In this article only the Google Trends keyword search interest has been used, an offers other user's search-related indicators, which makes it potential for further research. Besides, with the improving of Internet data s abundance (such as commerce, education, t data), this approach may continue to enhance its own adaptability, which is also an important aspect in the follow-up studying.

# Smarter Decision: an Intelligent Decision-Making Platform for City Mayor

WU Zhiqiang[1], XU Xingjing[2] and CAO Jing[3]

[1]Tongji University, wusres@163.com
[2]Shanghai Tongji Urban Planning and Design Institute, a_xuxinjing@hotmail.com
[3]College of Design and Innovation, Tongji University

Abstract:
Urban managers are eager to transform from tradition Empiricism mode to Rational urbanization, a vast amount of data is collected from aspects of urban planning, management and security. However, lack of connections between and effective mana categories of data leads to the phenomenon of data islands .

An intelligent smart city decision-making platform is structured on the base of an in and supported by ICTs. The platform addresses to the new demands of intelligent production in future urban China. Within the Chinese urban decision-making syste background of urbanization, this integrated supporting system will meet the need real-time decision transmission of decision-makers at all levels.

There are eight functional modules in support to intelligent decision-making. In information of the city and the visualized data analysis will serve decision-mak urban development. Also the indicators of the evaluation system can act as a dat The city-being sustainability-oriented indicator system is established as the so computation. Key data mining and the spatial visualization of data are applying operation data mining and display are conducted through diverse visualization to Model, a basis of advanced software platform, algorithms development and the urb Furthermore, rationalism decision-making is promoted to realize the new manageme decision-making.

Keywords: ICT, Decision Making, Rational Planning

## 1. Background Overview of the Intelligent Decision Support System

Decision-making has existed with the production and activities of people throug matter national policy formulation or enterprise operation and management, even decisions cannot leave without decision-makings. Due to the importance of deci stakeholders, how to make an effective decision is always a focus of attentio decision support system makes use of the computer, software and other technol provide people with ancillary support functions in the decision-making process an effective decision. The decision support system, which focuses on solving s structural problems and emphasizes the friendliness of man-machine interactio important role in enterprise management, macroeconomic planning and disaster p long time.

Western countries' study on modern decision theory started early and emerged an scientific management theory after the industrial revolution, especially since 1 decisions have become an important research field of western public administra the economic development of western developed countries and the deepening of reforms, the study on administrative decisions have received more and more atte number of theoretical achievements have emerged. The typical theoretical achi mainly: Simon's decision making theory in 1940s; Lindblom's theory of Incrementalism and decision-making in the 1950s; Drucker's effective decision-making theory

Anderson's public decision-making theory in the 1970s; Heidenheimer and Helco' public decision-making theory in the 1980s; and Hammer and Champy's team deci theory in the 1990s.

Along with the rapid development of information technology, especially the ma application of the Internet, e-government affairs have been quickly establis become mature in the United States, United Kingdom and other western develop Foreign experts and scholars started to turn their attention to researching g making models. In the Reinventing Local Governments and the E-Government Init United States, the traditional bureaucracy model was compared with the electr model, and the Internet was considered not only to provide a powerful instrumen local governments but also promote the transformation of the government manageme the traditional bureaucracy model which emphasizes standardization, department effectiveness to the e-government model which highlights harmonizing network external cooperation and customer services. With the advent of global informati marketization and economic times, the original bureaucracy model was impac theoretical fields placed their research emphasis on how to make use of e-gove technology, to redesign the organizational decision making process so as democratization and scientization of administrative decisions.

## 2. Theoretical System of Intelligent Decision Support Systems

### 2.1 Intelligent Decision Support System

An intelligent decision support system is an auxiliary decision system that intelligence (AI) and DSS together and applies the expert system technology t better make full use of human knowledge, such as descriptive knowledge on deci procedural knowledge during decision making and inferential knowledge for solvi help solve complex decision problems through logic inferences.

The concept of IDSS was first proposed by Bonczek and other American scholars i functions are to handle both quantitative and qualitative problems. Its core ic with other relevant scientific achievements to make DSS have artificial intellig Please make sure that every reference cited in the text is also present in the versa).

### 2.2 Structure of the Intelligent Decision Support System

A relatively perfect and typical DSS structure is a four-base system structure through providing a traditional three-base DSS with a knowledge base and an i adding a natural language processing system to the man-machine dialog subsystem, problem solving system between the four bases, as seen in the figure below:

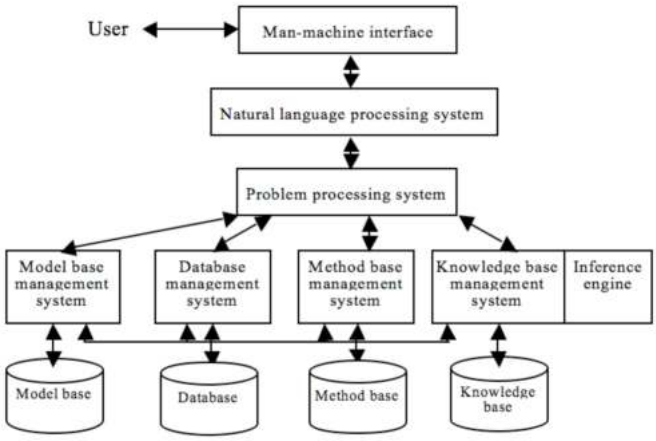

Figure 1. Structure Chart of Intelligent Decision Support System

2.3 Features of the Intelligent Decision Support System

1) Based on the mature technology, easy to construct practical systems.
2) Make full advantage of information resources at all levels.
3) Based on regular means of expression, easy for users to grasp and use.
4) Possess strong modularity characteristics, along with good reusability c development cost.
5) The system has a flexible combination of different parts, can realize a str to maintain.
6) The system can quickly adopt advanced supporting technologies, such as AI te

2.4 Operational Efficiency of the Intelligent Decision Support System

Because during the operating of IDSS, each module needs to repeatedly call the compared with the mode of directly adopting the lower-level call, its operatio However, considering that IDSS only runs when senior managers make a major operational efficiency is much lower compared with other information systems. operating environmental conditions for each run vary considerably, thus it is partial operational efficiency to get the efficiency of system maintenance in re

3. Key Problems Resolved by Intelligent Mayor Desk

As the world has entered into a critical stage of 50% urbanization rate, there challenges in terms of urban economic and social environment. Urban planning an operations management must be based on rational allocation of resources. The ke of new urbanization in China lies in changing the original extensive develo intelligent operations management and constructing a smart city. Under the sup science and technology, the positioning, planning, construction and management digitization, networking and intelligentization and critical problems like n ecological urban development.

Due to the complexity and chronicity of the large-scale construction of a smart city mayor plan the organization and implementation as a whole, which determine the mayor decision-making and command system in the smart city. However, there a barriers and challenges for the building of a command system in charge of the ci

1) Diverse sources of data. During the construction and operation of the city, departments may obtain completely different formats of data, including survey d texts, statistical figures, audio and video, real-time sensor data, etc. How to source codes of different system data formats through an integrated platform problem.

2) Unstructured data formats. Urban data volume is a massive data volume. T constructing a smart city is to complete the integration of traditional str unstructured data as well as the adding and updating of traditional yearbook d data so as to form a unified database. To transform from the traditional annuali real-time updating data processing stage is a technical difficulty for large ur academic circles try hard to tackle.

3) Secure and precise data. Large urban data involve different systems and levels of th what kind of data correspond to which urban management layer, and achieve reduc acceleration of the city mayor decision-making system while ensuring the safe decision-making system. During the application of multi-channel massive real-t safeguard the safe operation of the mayor decision-making system is a marking country s urban decision-making system.

Currently, there are giant gaps in real-time obtainment of urban data, int immediate feedback. It is a worldwide problem how to realize urban decision-mak a scientific and rational way. The smart city mayor decision-making system solv non-interoperability of urban management and delayed feedback of management inf integrating urban monitoring and management information data. Supported by logis platform and other ICT technologies, this system, specific to new demands a intelligent development of Chinese cities, realizes the analysis and expressi satisfy the urban decision makers at all levels and the real-time transmission and offers an integrated support platform for decision behaviors, in the cont decision-making system and urbanization development.

The mayor decision-making system builds a multisource, multi-scale and multi- database integrating social, cultural and economic fields based on space data database breaks through the traditional data acquisition methods and improves t acquisition to seconds. Meanwhile, it also uses for reference the data judgment for traditional data and applies them to the large data platform.

The mayor decision-making system sets up metadata exchange standards, breal traditional data processing mode, makes use of structured data to establish ex achieves precise description, rapid positioning, accurate search and value eval data.

The mayor decision-making system establishes multi-level data screening systems decision-making models. It integrates various data through all kinds of systems and pre-warns the identification and early warning of urban sustainable develop the dynamic 3D demonstration and accomplishes the automation of the whole urban decision-making process.

The above three points constitute the core technology system of the mayor deci The system, for the first time, realizes the unified data acquisition and exc overall urban level, integrates upward the information from different fields and p the method and technology support for the establishment of demonstration comprehensively, promptly and effectively copes with various demands of mayo improves the speed, level and quality of mayor decisions through using differe

resources and analytical tools, and makes urban administrator demands transform empiricism management model to the rationalism management model.

## 4. Framework of the Intelligent Decision-making Platform

Figure 2. Structure Chart of Intelligent Decision-making Platform

Intelligent decision-making platform has 4 major functions:

1) Intensive sense: to make decisions under the support of sufficient data;

2) Accurate judgment: to pre-judge the status and result;

3) Appropriate reaction: to mobilize resources for coping according to scenari minimum consumption of energies, resources, time and social mentality;

4) Continuous learning: to constantly improve the decision model and proces continuous progress.

Table 1. Smart city-leadership decision-making platform

| Serial No. | Function Module | Function Submodule |
|---|---|---|
| 1 | Development performance | Economic Subsystem |
| | | Social Subsystem |
| | | Ecological System |
| 2 | Resource pooling | Space resource pooling |
| | | Human resource pooling |
| | | Financial resource pooling |
| 3 | Bottom-up report | Document issuance |
| | | Communication with the Municipal Bureau |
| 8 | Major projects | World Expo project |
| | | Economically affordable housing |
| | | Disney project |

## 4.1 Development Performance Module

The execution of government programs includes various types of economic indexe protection indexes, security housing indexes and emission reduction inde performance assessment indicators are different in different provinces and citi divided into economic development, social development, environmental develop harmonization. Therefore, it is required to choose different indicators on the d of urban decision makers specific to different cities, and consult the gov evaluation weight for the comprehensive evaluation method. The module reflects part and happy livelihood part cared by urban decision makers and is the qua decomposition of the overall strategy and livelihood status.

Table 2. Framework of Development Performance

| Development Performance | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Economic System | | | Social System | | | | Environmental System | | |
| Economic Development Level | Comprehensive Economic Development Benefits | Income of Urban and Rural Residen | Basic Educatio | Urban Employment | Medica Health | Urban and Rural Cultura Life | Energy Conservati and Emissi Reduction | Resources Conservati | Science a Technology Input and Innovation |

## 4.2 Resource pooling module

Make an inventory of available resources within the city, including human resou and financial resources. Be clear available human, financial and material resou as to transform external resources and effectively use internal resources. Th overall and fractionized conditions of various resources available to urban d object of decision making.

Table 3. Framework of Resource Pooling

| Resource Pooling | | | | | | | |
|---|---|---|---|---|---|---|---|
| Human Resource | | Space Resource | | | | Financial Resour | |
| Organizat Structure | Task Assignment Status | Land Use Status | Land Planning Conditions | Land Gran Conditions | Investmen Promotion Progress | Riscal Revenuel Monitoring | Fiscal Expenditure Monitoring |

## 4.3 Bottom-up report module

An urban decision maker needs to keep up with the instructions and spirit of sup read all kinds of documents to be issued, thus making a separate module to sort the docum convenient to convey information in real time and inquire records at any time. T superior management and decision-making information of the city and is the guidi management and decision-making.

Table 4. Framework of Bottom-up Report

| Bottom-up Report | | | | | | |
|---|---|---|---|---|---|---|
| Document Issuance | | | | Communication with Departmen Bureaus | | |
| Decision Mak | Annoucement | Notice | Circula | Report | Request | Officially Re |

4.4 Major project module

An urban decision maker needs to make some major projects with highlights during office. The module includes major project objectives, implementation schedule, t accomplishment degree that an urban decision maker cares about, and can also upd in real time and control the project progress at any time. The module reflects t projects that the urban decision maker is concerned about and is the key to real goal.

Table 5. Framework of Major Projects

| Bottom-up Report | | | | | | |
|---|---|---|---|---|---|---|
| Project I | | | | | Project II | Project III |
| Goals | Implementation Schedule | Time Nodes | Completion Level | Onsite Pictures | Same as Project I | Same as Project I |

4.5 Emergency Responces module

The urban decision maker needs to make the fastest response to emergencies, and most appropriate way so as to minimize the losses of life and property of citize installed with an alarm system which directly connects to the weather bureau, pu the environmental protection agency, road transport bureau and other important d reports emergencies to the leadership at the first opportunity, and directly loc enable the whole leading group to start a contingency plan or directly hurry to issue. The modules reflects emergencies during the urban decision making process controllable methods to cope with relatively uncontrollable issues and serves as normal operation of urban management and decision making.

Table 6. Framework of Emergency Responces

| Emergency Responces | | | | | | | |
|---|---|---|---|---|---|---|---|
| Natural Disasters | | | | | Accider Disaste | Publi Hygiene | Social Security |
| Fire | Typhoon | Flood | Pollutant Leakage | | | | |

4.6 Daily management module

The module refers to the urban decision maker s daily work schedule and affairs including three parts: 1. Schedule arrangement: use Cloud calculation software t which can carry out real-time updating and facilitate to control his/her own iti upload daily important documents or conference introduction to be handled in adv Teleconferences: connected with video equipment which enables the urban decision maker

conference agenda that he cares about at the office and avoid the traffic time c
conference place and back. The module reflects the daily management work content
decision maker and pools all kinds of information to the informatization office

Table 7. Framework of Daily Management

| Daily Management | | |
|---|---|---|
| Schedule Arrangement | File Preview | Teleconferences |

4.7 Experience study module

The urban decision maker needs to follow closely the development footstep, learn
measures and practice projects by surrounding regions and benchmark cities and bring ex
enlightenment to the development of the city. It is required to set up a profess
case content of various sub-modules every day and conduct real-time update so as
decision maker see the latest events and excellent cases. The module reflects th
development of issues that the urban decision maker cares for are best practice
maker continuously learns.

Table 8. Framework of Experience Study

| Experience Study | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Economic Development Experience | | | Social Development Experience | | | Environmental Protection Experience | | | Urban Management Experience | | |
| Domesti Surround ng Cities | Domes tic Key Cities | Foreig Advanc ed Cities | Domesti Surround ng Cities | Domest ic Key Cities | Foreig Advanc ed Cities | Domesti Surround ng Cities | Domest ic Key Cities | Foreig Advanc ed Cities | Domesti Surround ng Cities | Domest ic Key Cities | Foreig Advanc ed Cities |

4.8 Comments summary module

The urban decision maker needs to keep real-time watch on the city s conditions
set of bottom-up information feedback mechanisms is required, including opinions
citizens, experts, NPC and the CPPCC and enterprise institutions, all of which s
adopted after the comprehensive study. The module reflects the pathways that mul
participate in urban management decision making and is a fast channel for the ur
hear the advices and suggestions of different parties.

Table 9. Framework of Comments Summary

| Comments Summary | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Citizen Inform Feedback | | Enterprise Institution Feed | | Organization Feedback | | | Intelligence Consultation Feedback | |
| Microbl Feedback | Urban Decisio Maker | Enterpr Alliance | Industry Associati | NPC | CPPCC | Party Committee | Indust | Agricult |

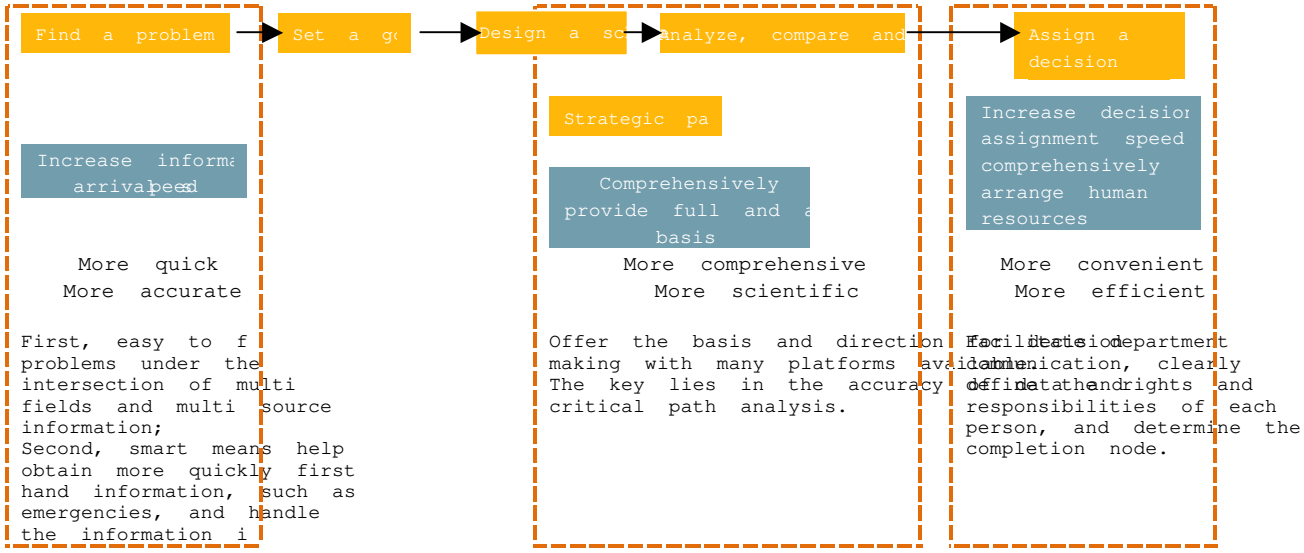

Figure 3. Decision-making Process

## 5. Development and Promotion of Intelligent Mayor Desk

Since its launch in November 2011, the Intelligent Mayor Desk project has ma network, cloud platform and other ICT technologies to exert itself to get throug barriers, realize the spring up and activation of information and enable the ma and wisely control the real time conditions of the city, thus making analysis decision response. Besides, with the help of the Intelligent Mayor Desk , the predict the future of the city and comprehensively master periodic problems duri

When a fire occurs unexpectedly in the city, the system can automatically give an alar mayor and his leading group able to start a contingency plan at the first op connects to the weather bureau, public security bureau, the environmental pro transport bureau and other important departments, directly locates the pla intelligently schedule the most appropriate disaster-relief resources and real condition of resources and the tracking and supervision of the responsible p integrates and analyzes the large data of different social media, pays close experiences of on-site citizens through the publishing of social media, and put direct train of opinion feedbacks between the mayor and citizens and restoring Besides, the system can intelligently search nearby major dangerous sources, disaste and other information, check erroneous ideas at the outset and predict and elimi

The smart city essentially features the spring up and activation of informat decisions, and serves the beautiful environment and life of the city as well a The Intelligent Mayor Desk adheres to giving play to the top-level design value makes use of information technology to achieve optimal social, economic an harmonization and minimum consumption of the city to meet the happy life of operation of the city and ecological vigor of the environment.

Keywords: Planning Knowledge, Network, United Kingdom, Sensible, Open Source Data

## Abstract

Planning knowledge network, as the agglomerations of academic outputs and scholars, guides practices to make a better city, educates younger planners and to supports decision making. The research focuses on the planning knowledge network in UK, aiming at making the network more sensible by visualizing, measuring, analysing and discovering the anchor cities of this network. This would be helpful to gain a better understanding of planning intelligence, and to benefit planning schools, scholars, organizations and even navigating young planners in such a planning knowledge ocean. In a word, the most immediate purpose of this research is to make such network sensible, and that is the beginning of a range of benefits.

Regarding planning knowledge society as a cooperative network, with planning scholars contribute academic outputs (publications) in a cooperative way, this research adopted the open source data as resources. Raised conceptual models for the network and methods for visualizing, measuring and analysing the network are innovative, which makes the planning knowledge network sensible for the first time. Additionally, the anchor cities, which represent knowledge produce, exchange and store agglomerations, are also been discussed.

By achieving this, the content is organized in six major parts. The main body is followed by the introduction part, which includes the open data resources introduction, the methods and tools, the visualization and analysis this network, and then the study on anchor cities to complement a more sensible network. Finally, the research draw the conclusion according to the results of important findings.

## 1 Introduction: A Sensible Network of Planning Knowledge

### *1.1 Planning Knowledge*

Urban Planning as a discipline have developed fast in the past 100 years. Since the first planning principles generated in UK 1909, urban practice, no matter the scale, have been supported by the planning knowledge (from planners, their academic outputs and proposals), along with other disciplines like engineering, Information technologies, politics, etc.

It is high time to discover the inside of the planning knowledge world itself. Such research could be beneficial to planning schools, scholars, organizations and young planners. Without doubt, it is an attempt to make a better understanding of the principles of planning, and the knowledge structure. Meanwhile, this would be instructive to regions like China, India, Southeast Asia, Middle Asia and the Arabic World, where the planning knowledge societies are still growing.

### *1.2 A Sensible Network*

AESOP, along with other organizations has contributed to diverted exchange platforms among different planning entities. This alludes that the planning knowledge society is a network. Planning knowledge network is not only the network of members, exchange students, visiting professors, but the academic intelligence cooperation. Though hard to be visible, since millions of publications bring every scholar into such network, certain approaches could be used to make the network sensible.

As information technology today help to solve problems we couldn't have ever imagined, more and more network become sensible. Through such process, one could gain deeper understanding of the network. The questions such as how the network looks like, what is the attributes, and whether it is location oriented are to answer.

## *1.3 Major Tasks and Structure*

### *1.3.1 Task 1: Visualize and Measure the Invisible Network: A Sensible Network*

In terms of sensible network, such network shall be visualized in the first place. Secondly, the network should have access to get measured through key parameters and proper methods. According to that, having the ideology and methods of networking, the tools to visualize the network shall be adopted. This attempt could be innovative in planning knowledge research or network research field.

### *1.3.2 Task 2: Discover Physical Anchors of the Network: the Anchor Cities*

As to make the network sensible, it is innovative to discover the relationship between invisible network and physical space. Anchor Cities , as a term we used in this research to cities that are outstanding in produce, exchange and store of planning knowledge, open a gate for deepening the sense of the planning knowledge network.

### *1.3.3 Structure of the Research*

The Research are composed by six major parts. First is the concept of planning knowledge network in the instruction phase (First Part).

The next three parts are aimed to achieve the first task. Followed by the data resources (Second Part) and the methods (Third Part) introduction, the UK Sensible Planning Knowledge Network (Forth Part) presents the results of visualization and analysis of the network.

For the second task, this research analyse the relationship between knowledge network and the anchor cities, as well as the clusters of anchor cities. This could be found in the five Anchor Cities of Planning Knowledge Network part (Fifth Part).

Finally, the conclusion (Sixth Part) summarized the findings and analysed results of the Planning Knowledge Network of UK.

## *1.4 Literature Review*

### *1.4.1 Networking of Planning Knowledge*

Planning knowledge had gained its cooperation among scholars global wide. Such kind of networking trends becomes the significant symbol in planning field. In 2001, when the first world planning school congress (WPSC) was held in Shanghai, it collected 600 hundred of papers (Urban Planning Review, 2001). Most importantly, the announcement of Global Planning Education Associations Network was made to enhance the exchange of planning knowledge (Zhiqiang WU, 2001). Such kind of network is not only consisted of the invisible knowledge exchange, but also embodied by massive exchange programs (Harvey A. Goldstein 2006). The globalization promotes the network to grow, and the urban planning knowledge network are changing more global-local at the same time (YuanYUAN, etc. 2004).

Bologna Declaration 1999 had been reached the agreement within 29 European eliminate the obstacle in education resources exchange (Andrea I. Frank, etc., 2014), in that way the knowledge could be shared in an active way. Moreover, as the urban development issues become acceptable worldwide, the knowledge for better life has trans borders (Henian LIANG, 2000).

However, there are some imbalance in planning education, which could be obstacle for knowledge exchanging. Like the incomplete evaluation system (Lei PANG, etc. 2006). 2007 when the AESOP annual conference was held in Napoli, the participants are mostly from the south part of Europe (Yi HUANG, 2007), such case implies that even the trend of networking of planning knowledge, there are still long way to go.

On the other hand, it shows the importance of this research in the perspective of planning knowledge globalization and regionalization.

#### *1.4.2 Development in Visualizing and Analysing*

The other important perspective of this research is the methods of visualizing and analysing based on open source data. Until recently, a method of EDEN had been introduced to visualize the simulated geographic data (Chad A.Steed, 2013). By using Hadoop, Song Gao had achieved to visualize the flow of employees in United State. Through the way of Medoids, the data of agglomeration of space could be analysed (Deepak Paramashivan Kaundinya, 2013).

Most importantly, Gephi as a useful social network analysing tool, helped Irene Eleta to cluster twitter customs according to the usage of language (Irene Eleta, 2012). It is obvious that there are many tools to visualize the data, as well as analysing.

For this research, we adopted Gephi as the major tool along with regular data analysis software. It is the model we design and the right research path we think that matters.

## 2 Data Resources: Open Resources of UK Planning Scholars Academic Data

### *2.1 Target Group: Academic Scholars as the Main Entities*

To establish such visualized knowledge network of UK, question of what kind of target group should be considered is to answer. The target group consists of two parts. First is the academic scholars from the planning schools (main entities), along with the related scholars (complementary entities).

Planning knowledge network, as the basic academic engine that generate intelligence to support practices like the decision making and design, remains the core value of academic outputs, such as articles, books, reports, etc. According to these criteria, the research choose academic scholars as the main entity of the target group. In total, this research focuses on 6 UK planning schools (Cardiff University, University of Manchester, University of Glasgow, University of Liverpool, University College London, and Birmingham City University) from AESOP membership list, which we believe have significant positions in planning knowledge field in UK.

Besides the main entities, the complementary entities should not be ignored. This includes independent scholars and scholars from planning schools out of the list.

### *2.2 Open Sources: Data of Scholars Academic Information*

One of the innovations is to take advantage of the open sources data from the Internet, which on one hand is easy and free to access. On the other hand, the massive information could help to complete or proofread information.

Open source data in this case mainly relies on three resources from the Internet. The first one is the basic information including names, abbreviation, title, and publications from the official website of each university. The second one is google scholar, which could be helpful when some modifications are needed and also the citing information of the publications (Articles, conference papers, reports, editorials, books, book chapters, etc.). The last one is other free publication search engine such as the ResearchGate or ScienceDirect, etc.

In fact, the process of data collection is difficult, especially when some information is not complete on the official website of the planning school. Therefore, it is quite important to have massive open source data to complement each other.

### *2.3 Raw Data for Measuring the Network*

The planning knowledge network is built upon knowledge exchange among the target groups and beyond. In order to capture knowledge exchange , the observation of academic outputs cooperation is essential. Some important factors listed below (more information are captured beyond the items listed). As this research is still ongoing, some raw data is still under testing for this phase, as the research is still on going.

**Academic Outputs Cooperation.** As the most important indicator in this research, the cooperation of academic outputs contains implies the academic relationship among authors in each article.

**Location.** The location of the publication shows how the planning knowledge network has an interaction with different places around the globe. With the help of this indicator, the knowledge network would never been floated and untouchable.

**Publication Year.** The planning knowledge network is never static. Publication year reflects how the knowledge network changing through.

**Cited Value.** This indicator reflects contribute a certain publication made to the planning knowledge network. If the cited value is high, then it means such publication is more active inside the network.

## 3 Model, Methods and Tools: Data Mining, Visualizing and Analysing Principles

### *3.1 Conceptual Model*

By visualizing and analysing planning knowledge network of UK, we constructed the conceptual model to set up the rules and also organize the algorithms. Figure 1. The Conceptual Model for Planning Knowledge Network of UK, illustrates the key items.

**Scholars** (as Node in the Figure 1): Inside the model, each node represents a single scholar (no matter the scholar is main entity or the complementary entity).

**Cooperation** (as link in the Figure 1): Each link represents the cooperative relationship according to one journal article, one conference paper, one book, one report, etc. The cooperative relationship has no direction, therefore the undirected way of algorithms are chosen. As been put, each link just represent a single cooperative activity, then the model adopt multiple lines if there are more than one cooperative activities between two certain scholars. For example, Scholar 1 and Scholar 2 have 3 cooperative activities, Scholar 3 and Scholar 4 have 2 cooperative activities. Scholar 2 gains totally 9 degrees of cooperation, while scholar 6 just got 1.

**Cluster** (as modularity): As also showed in the model, the network is consists of diverted groups. However, the main focus is on the major modularity rather than those absolute isolated ones (without any link to major modularity). Furthermore, the research would analyse different groups inside the major modularity.

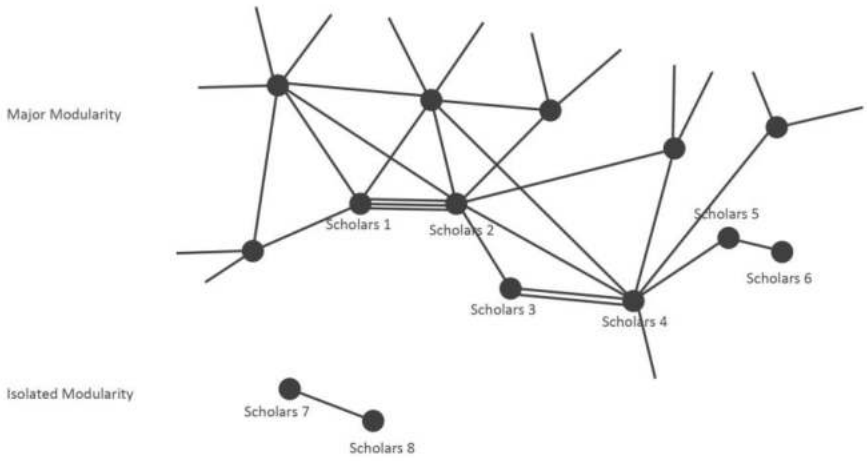

Figure 1. The Conceptual Model for Planning Knowledge Network of UK

### *3.2 Data Mining and Organizing*

During the process of data mining, we adopted a software called Bazhuayu D Machine to assist with the mining process. However, as mentioned before, due to data structural among so many official website, the programing work shall be individually created according to each site structure. Some of the structural data are easy to capture and classify, while the text data could only be filtered afterwards. The final structural of the data pool contains the key factors of each publication.

### *3.3 Visualizing*

To translate data into visualized language, the ideology is to regard each individual scholar as a node in the network, while links between nodes the cooperative academic outputs. The higher value of cooperative degree one node gets, the more cooperation a scholar earns. Similarly, if a link is bolder than others, then the academic relationship between scholars on both sides tighter.

With the help of Gephi, an open source platform of data visualizing software, the planning knowledge network could be visible. Different Force Models were tried to make the layout clearer and defined. Finally, we adopted the Force Atlas2 model which could present the hubs and the centralities of the hubs by the meantime, as showed in Figure 2. Three Stages of Force Atlas2 Models for Visualization.

Force Atlas2 Model obeys the basic algorithm of graph drawing, known as the Force-directed graph drawing. It is originally derived from the physical principle of Hooke s law as be outcome shows the multiple force balanced results among the node connections.

Figure 2. Three Stages of Force Atlas2 Models for Visualization: (a). Raw Stage, (b).Processing Stage, (c). Final Layout (Source: Graph generated through Gephi, 2015)

### *3.4 Analysing*

In this research, some vital indicators for analysis are chosen, including the average degree, the modularity of the network, the local clustering coefficient, the average path length, the graph density, and the connected components. The characteristics and principle for each indicator has been explained below.

#### *3.4.1 Average Degree*

Average Degree reflects the entire cooperative degree of each scholar. The higher the value of the average degree get, the more cooperative relationship the network get.

$$a = \frac{1}{N} \sum_{i=1..N} Degree(V_i)$$

a, value of average degree. N, the number of scholars. V, the set of scholars

### *3.4.2 Modularity*

The indicator of Modularity is raised (in 2004) and optimized (in 2006) by Newman, which is used to describe the strength of division of a network into modules (Newman, M. E. J., 2006). According to the indicator of modularity, it could be clear to measure the community structure in large scaled network. (Svr to be 1 if scholar v belongs to group r and 0 otherwise)

$$\delta(v_r, c_i) = \sum_{r} s_{vr} s_{wr}$$

$$Q = \frac{1}{2m} \sum_{vw} \sum_{r} \left[ A_{vw} - \frac{k_v k_w}{2m} \right] s_{vr} s_{wr} = \frac{1}{2m} \mathrm{Tr}(S^T B S)$$

$$B_{vw} = A_{vw} - \frac{k_v k_w}{2m}$$

Q, value of modularity of the network. S, Non-square matrix having elements Svr. B, Modularity matrix, which has elements. 2m, Total number of degree among all scholars

### *3.4.3 Average Clustering Coefficient*

This indicator measures the degree of which scholars in a network tend to cluster together. Duncan J. Watts and Steven Strogatz introduced the indicator of local clustering coefficient (both directed and undirected) to determine whether a graph is a small-world network (Duncan J. Watts and Steven Strogatz, 1998). And as for the relationship between scholars has no direction, we adopted the undirected local clustering coefficient to be calculated. Finally an average value of the overall local clustering coefficient values are studied to know the general clustering situation of the whole network.

$$C_i = \frac{2 \left| \{ e_{jk} : v_j, v_k \in N_i, e_{jk} \in E \} \right|}{k_i (k_i - 1)}$$

Ci, value of local clustering coefficient for a certain scholars. V, the set of scholars. E, the set of edges between all the scholars. Ki(Ki-1), possible links exists between all neighborhood scholars

### *3.4.4 Average Path Length*

The average path length is to calculate all paths among scholars, and then dividing by the total number of pairs. It shows the number of steps it takes to get from one scholar to another on average.

### *3.4.5 Connected Components*

This indicator describes how many scholars are strongly connected and weakly connected.

## 4 UK Planning Knowledge Network

### *4.1 Visualized Planning Knowledge Network of UK*

According to the model and the rules we set up, under the help of Gephi, we achieved the final visualizing work shows in Figure 3. Planning Knowledge Network of UK.

Figure 4. Planning Knowledge Network of UK shows the overview of the planning knowledge network based on the publication cooperation of UK. By using different colours, it is clear to distinguish major clusters. The spatial distance reflects the affinity between clusters in academic relationship, while the links between scholars explain the cooperative attractions.

Statistically, UK s planning knowledge network includes 2169 researchers, with 252 as the counted main entities of the target group. Cardiff University(56 entities scholars), University of Manchester(20), University of Glasgow(33), University of Liverpool(65), University College London(45), Birmingham City University(33).

While, 1917 scholars as the complementary part are discovered by visualizing process. Though been regarded as the complementary one, they also been unveiled in the final visualized work, which on one hand shows their strong impact and active connection in this network. On the other hand it proves that such network is quite tolerant and open.

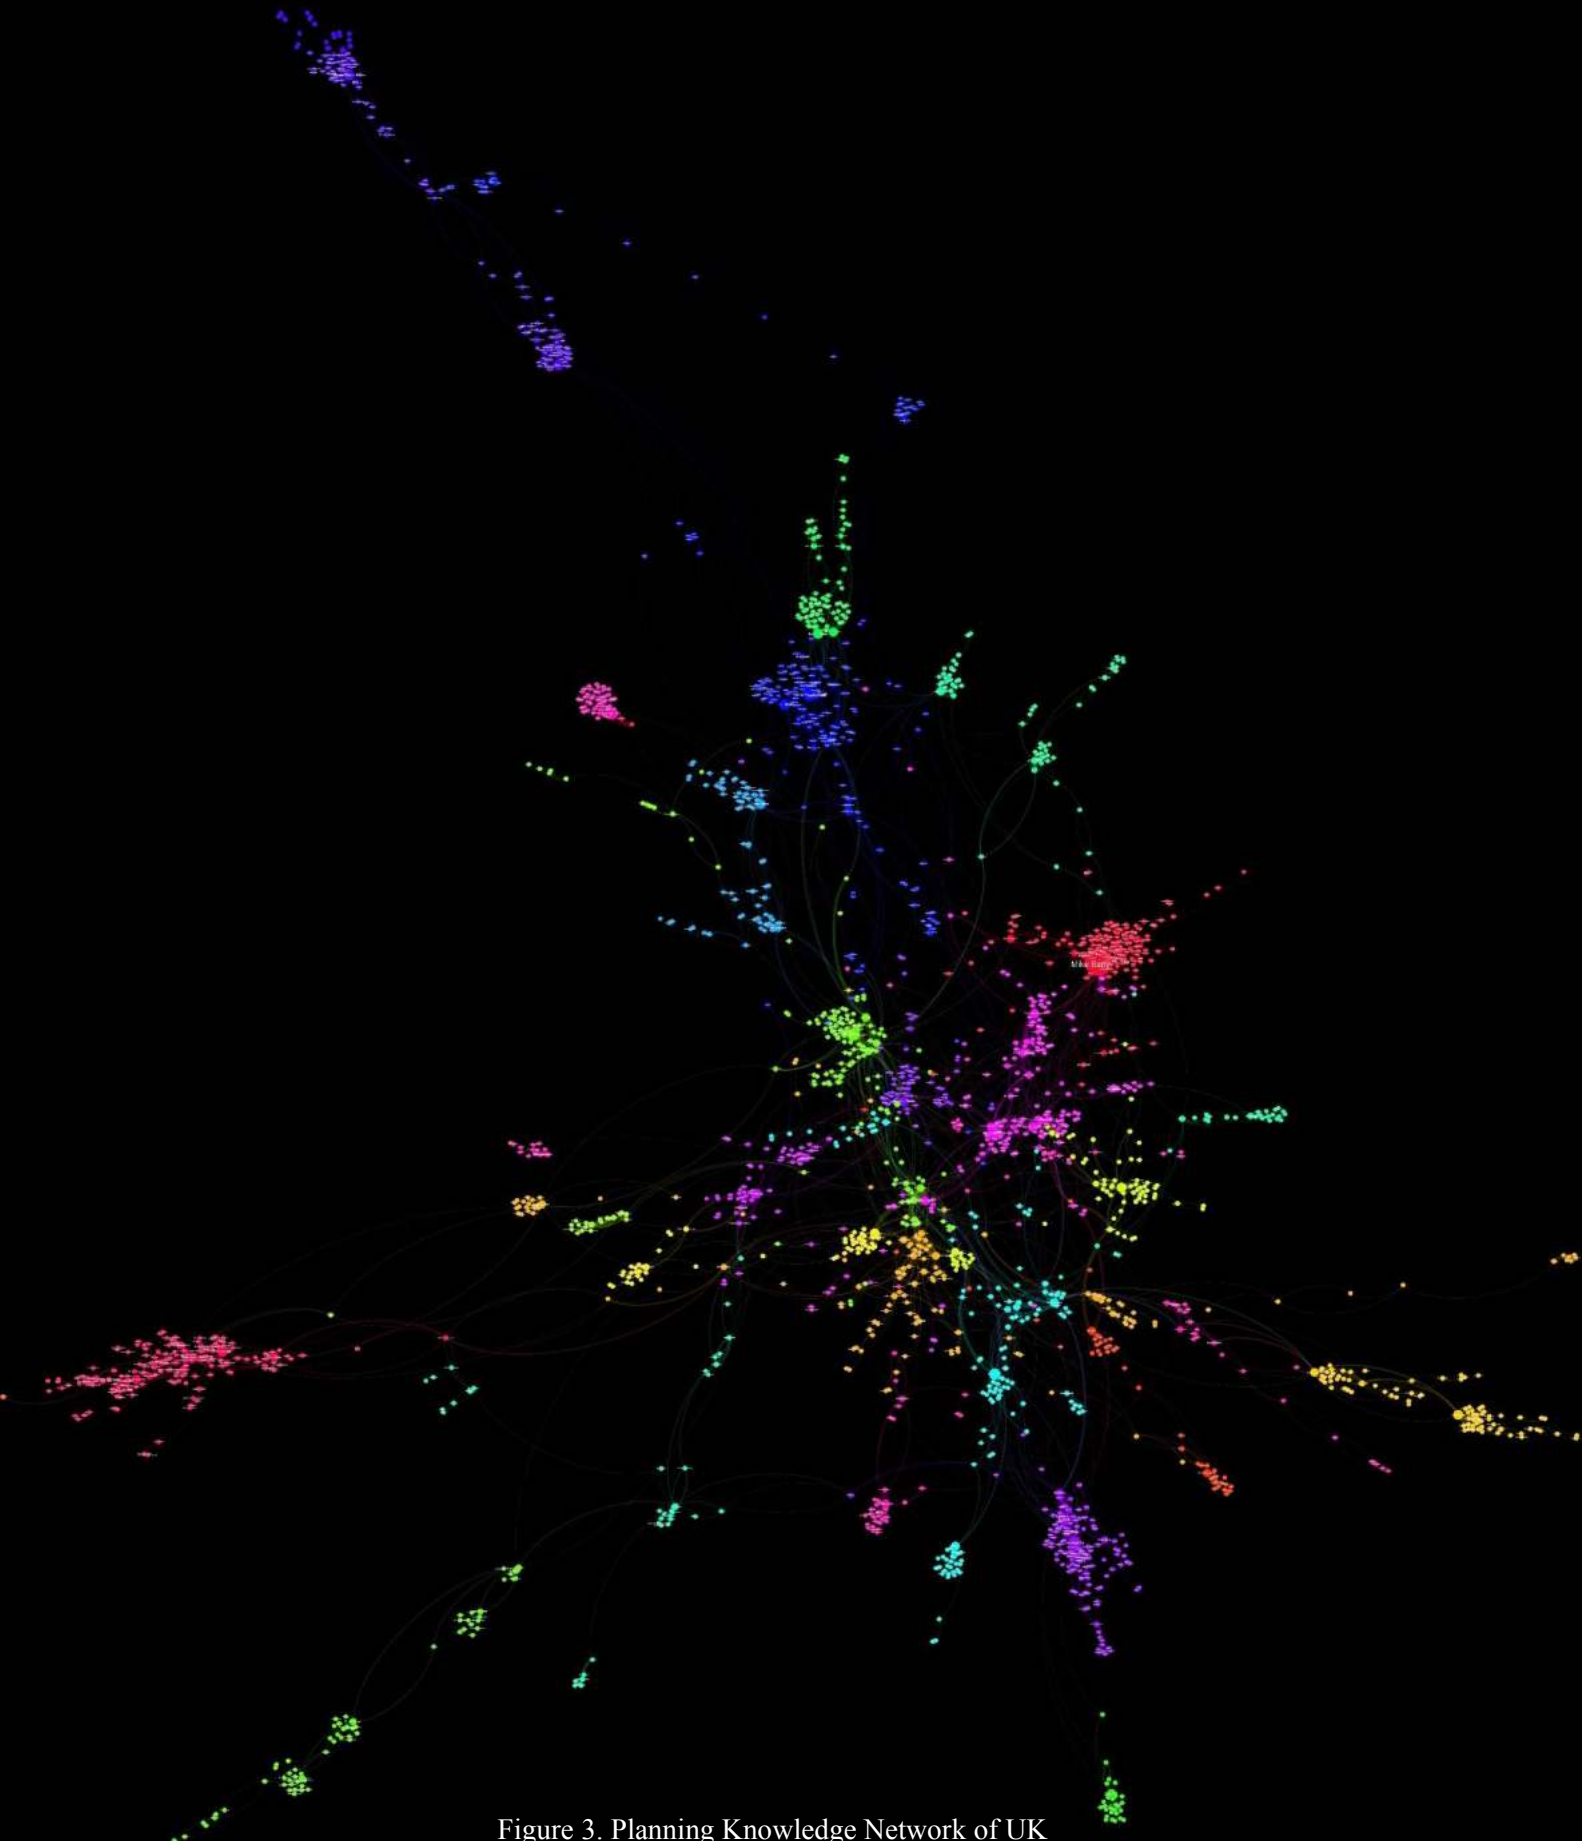

Figure 3. Planning Knowledge Network of UK
(Source: Graph generated through Gephi, 2015)

## *4.2 Analysis Results of Planning Knowledge Network of UK*

### *4.2.1 High Degree of Involvement in Network (Connected Components, Average Degree)*

The degree of involvement in the whole network could be measured according to the indicator of connected components. It implies that the 2055 scholars are highly involved in this network with a strongly connection, while only 114 nodes are less involved with weakly connection. (Robert Tarjan , 1972).

Those who are less involved in UK s planning knowledge network, with less devotion in acade cooperation, might have devoted more into urban practice, or software development, etc. Or because their majority academic outputs belongs other networks. However, this group of scholar are not belong to the 252 main entities we targeted.

### *4.2.2 Closeness of Scholars (Average Path Length)*

Scholars inside the network build the connection through cooperation on publications. While such connectivity could be sensed through the indicator of average path length. And such value for this network is 7.82 with total 1493783 shortest paths. The total diameter for the network is 19 units.

The closeness centrality distribution figure shows all the distances from a given starting node to each other scholars. 1 to 12 extra scholars are needed to build up a connection between two given targeted scholars in majority. According to the algorithms mentioned before (Ulrik Brandes, 2001).

### *4.2.3 Tendency of Clustering (Clustering Coefficient)*

The tendency to form a cluster varies from scholars. Among the relationships, 1789 triangles are created, which implies the tendency to join a cluster for each certain scholar is 0.815 (more than two thirds of total completion), according to the algorithms (Matthieu Latapy, 2008). In general, we could draw a conclusion that, a scholar is relatively close to a certain inside the cluster. On the other hand, it means scholars inside the network have less chance to fight alone.

### *4.2.4 Modularity of Whole (Modularity)*

Under the help of modularity tools, the research found out there are 143 clusters according to the modularity algorithms, while the total modularity is 0.899. Considering the modularity has the default range between [-0.5, 1), it is significantly high in modularity. In other words, it means the entire network shares the same culture of modularity in general. Technically, 4 clusters have the number of more than 150 scholars, while 9 clusters have the number of above 100 scholars.

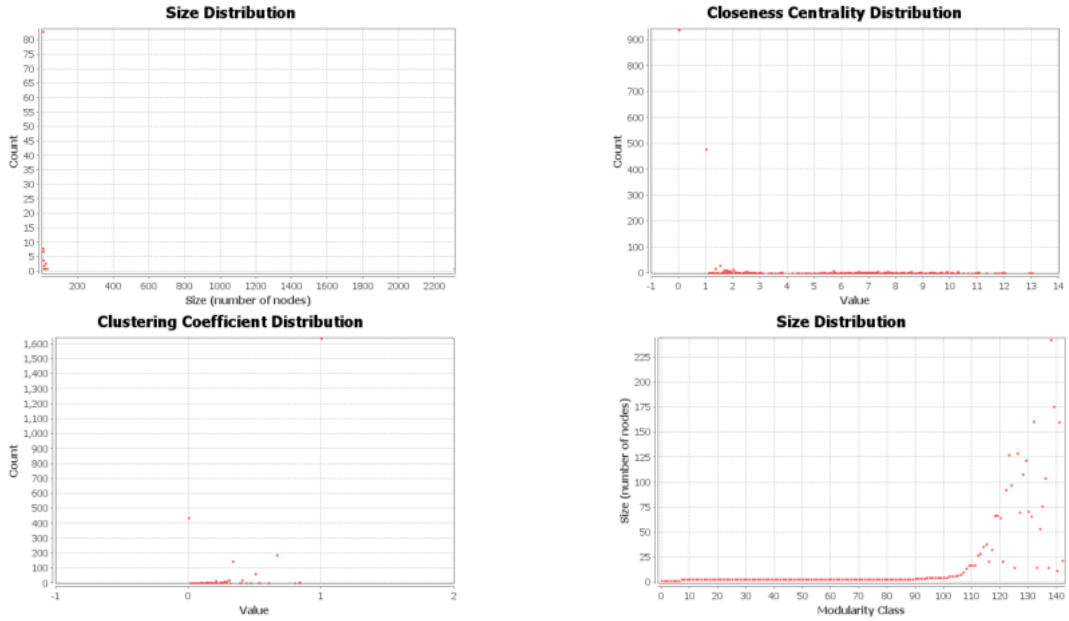

Figure 4. Results of Measuring the Network: (a).Nodes Size Distribution, (b) Closeness Centrality Distribution, (c).Clustering Coefficient Distribution, (d). Cluster Size Distribution (Source: Graph generated through Gephi, 2015)

## *4.3 Comparison*

### *4.3.1 Ten Major Clusters in UK Planning Knowledge Network*

Ten major clusters contribute over half of the cooperative degrees through the entire network, as well as they involve over half of the scholars. The Richard Chiverrell-John Boyle-Andy Plater s cluster ranks the first place, with the total degree of 974 (9.68% in proportion) and 244 scholars (8.78% in proportion).

As implies in Table 1. Ten Major Clusters in UK Planning Knowledge Network implies, all of the ten groups share higher value of degree proportion than scholars number proportion. This means i general, the scholars inside those clusters are more active in cooperation than those outside of these clusters. No matter how many pieces inside each cluster, it is always the degrees that matters.

Table 1. Ten Major Clusters in UK Planning Knowledge Network

| Rank | Gephi Code | Total Scholars | Proportion Scholars | Total Degrees | Proportion of Degree | Number of Pieces | Key Figure | Major Background |
|---|---|---|---|---|---|---|---|---|
| 1 | 138 | 244 | 8.78% | 974 | 9.68% | 4 | Richard Chiverrell, John Boyle, Andy Plater, Barbara Mauz, Janet Hooke, Neil Macdonald | University of Liverpool |
| 2 | 139 | 176 | 6.36% | 729 | 7.24% | 1 | Terry Masden, Kevin Morgan, Gillian Bristwo, Mara Miele | Cardiff University |
| 3 | 132 | 161 | 5.82% | 638 | 6.34% | 5 | Graham Haughton, Mark W Baker, Cecilia Wong,Michael Hebbert, Iain Deas, Ken Gibb | University of Manchester |
| 4 | 141 | 160 | 5.78% | 617 | 6.13% | 1 | Mike Batty, Alex Singleton | University College London |
| 5 | 126 | 130 | 4.66% | 449 | 4.46% | 4 | Mark Reed, David Adams, Peter Larkham, Alister Scott | Birmingham City University |
| 6 | 123 | 128 | 4.62% | 477 | 4.74% | 2 | Richard Bradshaw, Fabienne Marret Davies | University of Liverpool |
| 7 | 129 | 122 | 4.41% | 585 | 5.81% | 1 | Ade Kearns, Bailey,N, Hastings,A. | University of Glasgow |
| 8 | 128 | 108 | 3.90% | 449 | 4.46% | 1 | Thomas B Fischer, Sue Kidd, Olivier Sykes | University of Liverpool |
| 9 | 136 | 104 | 3.76% | 468 | 4.65% | 3 | Nick Gallent, Sir Peter hall, Robin Hickman, Stephen Marshell | University College London |
| 10 | 124 | 96 | 3.50% | 359 | 3.57% | 1 | Andy Morse | University of Liverpool |
| **Sum** | | 1429 | 51.59% | 5745 | 57.07% | | | |
| **Rest** | | 1339 | 48.41% | 4321 | 42.93% | | | |
| **Total** | | 2768 | 100.00% | 10066 | 100.00% | | | |

#### *4.3.2 Typical Typologies of Clusters*

To gain better understanding of the clusters that formed the whole network, we choose Mike Batty s and Richard Chiverrell-John Boyle-Andy Plate s Cluster to discuss. Representing the one typical typology of clusters, Mike Batty s shows more centrality, while the Richard Chiverrell-John Boyle-Andy Plate s represent the dispersible types. Both of them shows a higher proportion in cooperative degree and the scholar s numbers. The structures and typologies could be found i Typology of Mike Batty s and Richard Chiverrell-John Boyle-Andy Plate s Cluster.

The typology of Mike Batty s cluster implies a strong and attractive academic personality, with over 150 scholars directly owns the cooperation with him. The average degree reaches 3.86, while Batty gains his own degree of 177, which is 45 times of the average value in the cluster. On the other hand, Batty created 91 completed cooperative triangles (Mike Batty - Scholar A - Scholar B), such firm structure guaranteed Mike Batty to have a concrete first degree.

Furthermore, we believe such structure with the growing triangles contribute the development of this cluster. Beyond that, the personality and the openness of this cluster could have contributed to this without doubt.

Richard Chiverrell-John Boyle-Andy Plate s cluster, however, shows another possibility of organizing the cooperative academic relationship. The average cooperative degree among scholars is 3.99, a bit higher that Mike Batty s. While the three major figures inside degree and completed triangles of 70, 54(Richard Chiverrell), 49, 42(John Boyle), 41, 28(Andy Plate). The relative ratio of triangle cooperation among total cooperation is lower. Also the first degree is not relatively high compared with Mike Batty s. However, all the results imply that Ric Chiverrell, John Boyle and Andy Plate together plays the role of Mike Batty s in the cluste

Although the concentration is not that impressive, Richard Chiverrell-John Boyle-Andy Plate s cluster shows the attraction and stability either. The research take a close look at the topics of those two clusters, Both Mike Batty and Richard Chiverrell-John Boyle-Andy Plate are not constrained on few topics, on the contrary, they are open minded and accept different topics in cooperation.

To draw a conclusion, according to the study on the two typical cluster, it is not clear what kind of typology is more sustainable for clusters. However, two things are obviously certain. First, the completed triangle cooperation is the fundamental stabile element for a cluster. Secondly, the wider topic orientation, the more opportunities for clusters to grow, no matter in which typology they adopted.

### *4.4 Summary of Planning Knowledge Network*

In this phase, we visualized the planning knowledge network in UK, which appears the tolerance and openness to scholars knowledge. By adopting five important parameters, we measured the whole network, to have a general understanding of the entire cooperation and the modularity.

Later on, the comparison between major 10 clusters implied the diversity and modularity of the network, with some certain planning schools take the dominoes. The research discovered that the scholars belong to major clusters are more active than those who are not in general.

Finally, in order to find out the philosophy behind the typical typologies of cluster, we discussed about Mike Batty s and Richard Chiverrell-John Boyle-Andy Plate s cluster, the results for this shows no big difference, as the basic structure of completed triangle would contribute to the stability and the openness on topics could gain the development.

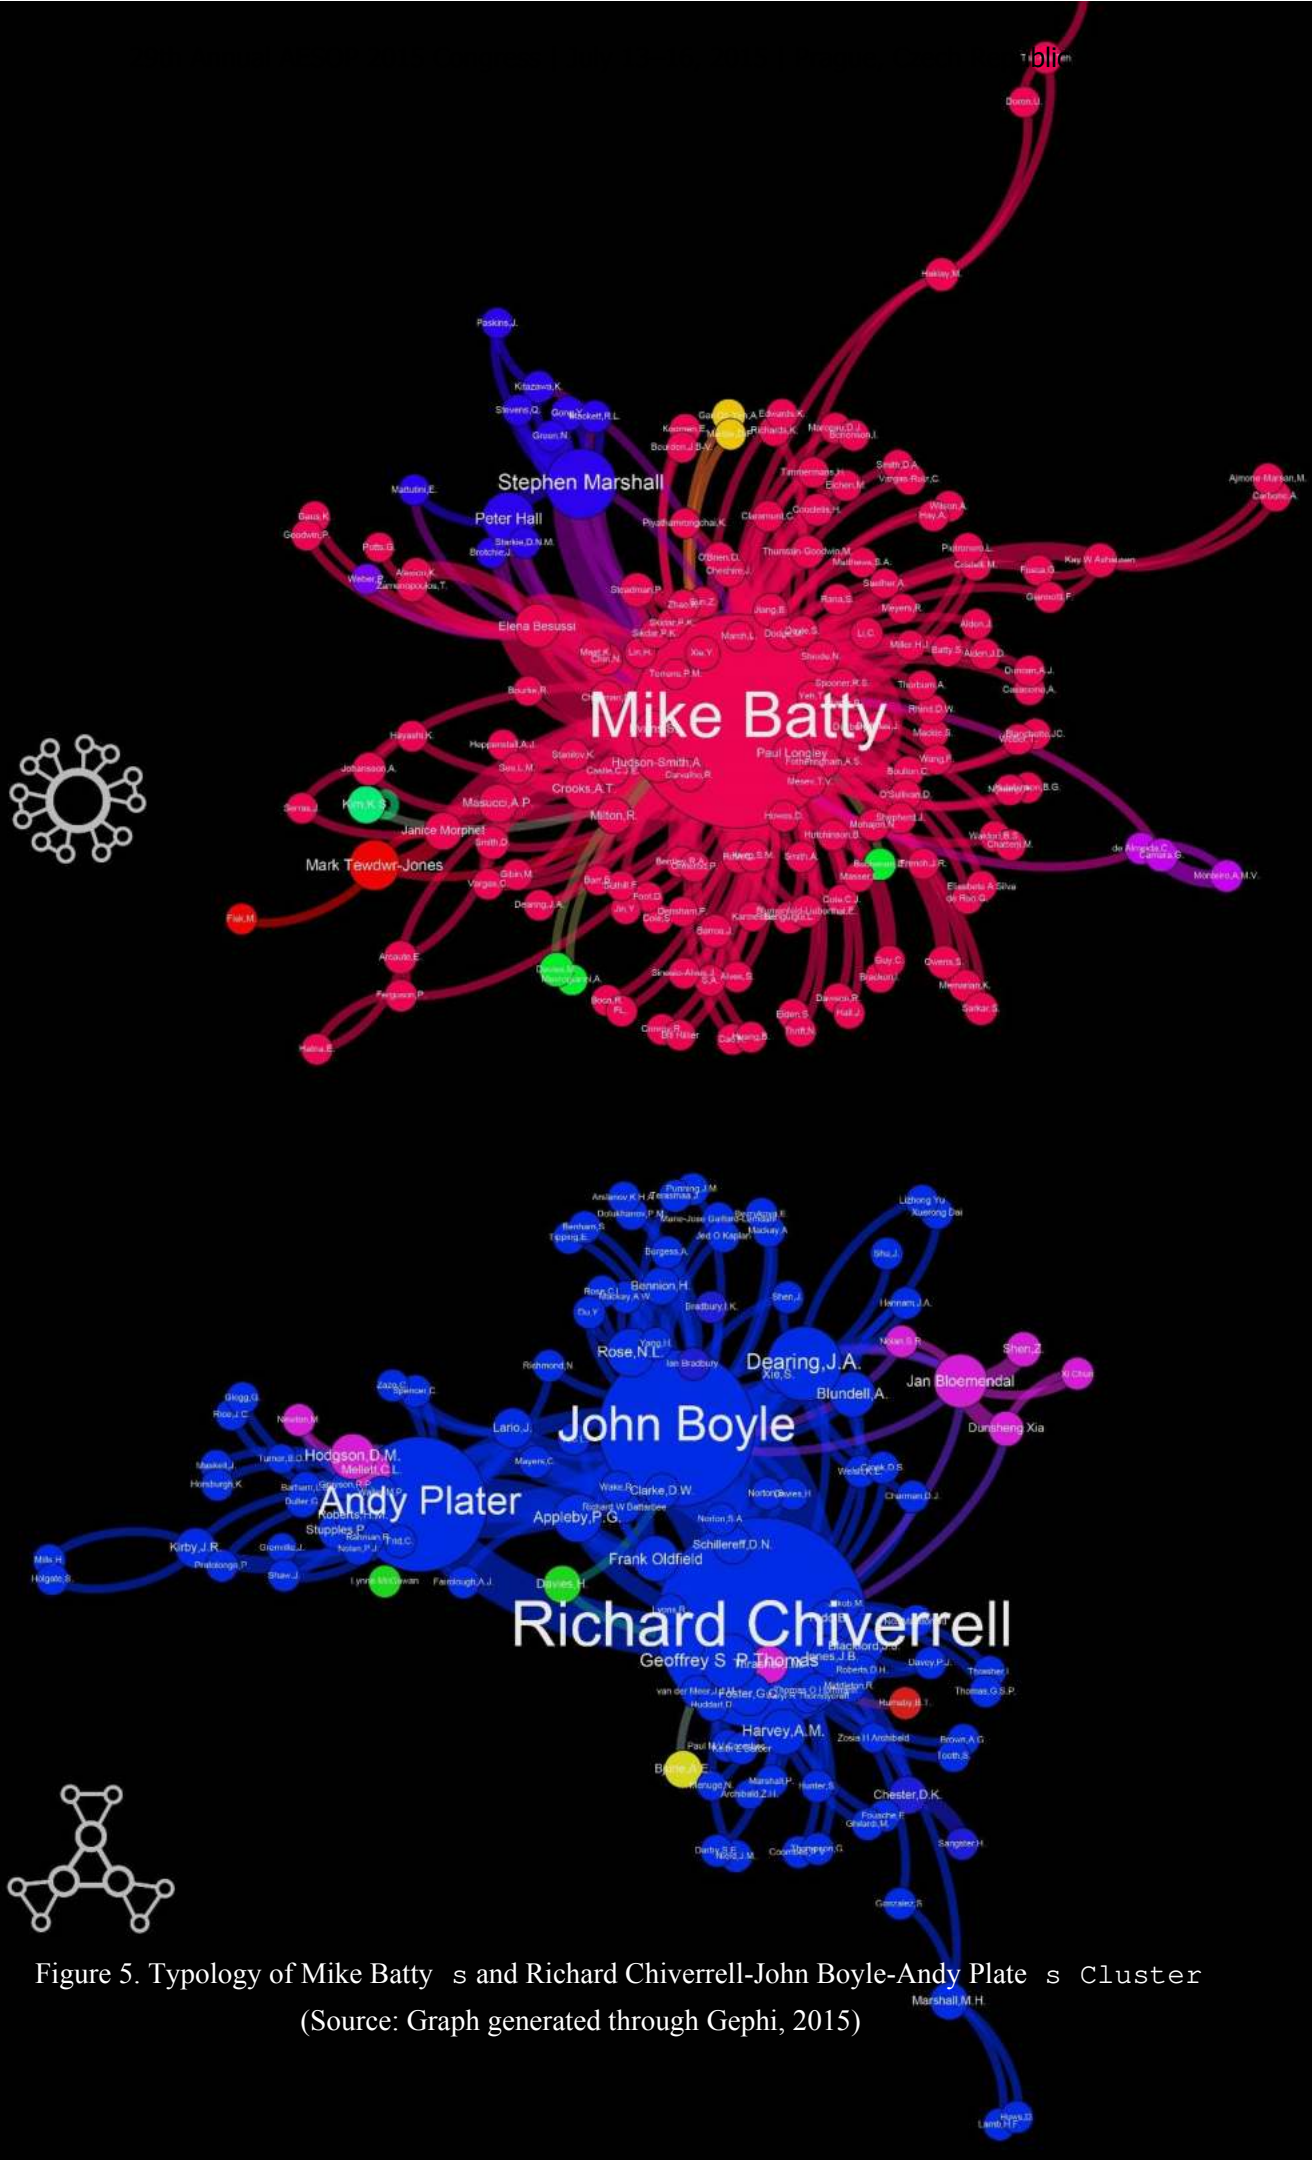

Figure 5. Typology of Mike Batty s and Richard Chiverrell-John Boyle-Andy Plate s Cluster
(Source: Graph generated through Gephi, 2015)

## 5 Anchor Cities of Planning Knowledge Network

To ensure the knowledge network has more ways to get sensed, the linkage of the network and cities should be unveiled. Anchor cities, as the term to represent such kind of planning knowledge relevant cities are the key element to be discussed in this phase.

In terms of the parameters, the data of academic outputs with location information is key. Somehow, it is possible to rank and group the planning knowledge based cities according to such data. By achieving this, the knowledge network and the cities which produce, exchange and store the knowledge would be obvious share the academic connection. So as to the closeness through the linkage of scholars. In that way, the cities could be grouped according to the closeness exchanging and storing planning knowledge .

### *5.1 Principle for Anchor Cities and the Network Connection*

The simple principle of anchor cities could be described as the relationship between cities through scholars and their academic outposts. Figure 6. Principles for Anchor Cities and the Network Connection shows how the knowledge network anchors the cities. As two main types of nodes (cities, scholars), and links (publications with location information) formed the structure, the differences between scholars and cities could also be clarified from this model.

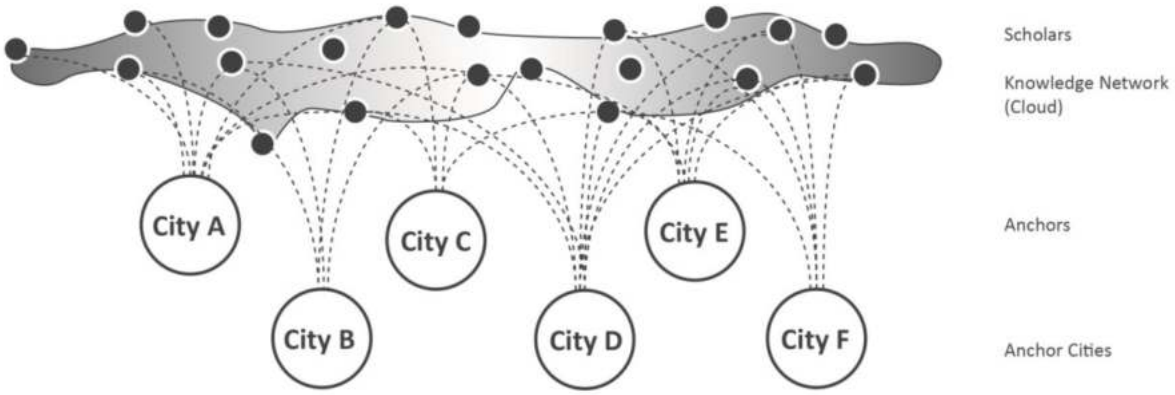

Figure 6. Principles for Anchor Cities and the Network Connection

The data resources for this phase is generate from the same database in the previous phase when analysing the knowledge network, but not all. Somehow, the publications with location information are selected. In that way, most of the conference papers, books, book chapters, reports contribute to the major part of the data source. It is according to those publications, that the anchor cities could be visualized.

As for scholars, one may build the connection between cities through only one publication, or none, or more. As for the cities, the more connection one get, especially from the scholars who have more places to be connected, it is more likely to have close relationship with other cities. In a word, the degree of connection between cities and scholars, and the closeness between each city are concerned in this phase.

### *5.2 Overview of Anchor Cities*

According to such principle, we use Gephi to visualise the anchor cities of the UK s planning knowledge network. The total number of city in such network is 303, with scholars as the links between cities. This implies that the huge knowledge network find its ancho recorded locations information. Among those anchor cities, the power of anchor (degre connections) differs. In Figure 7. Anchor Cities of UK s Planning Knowledge Network visualizing work shows the distribution and clustering of anchor cities.

We filter the less relevant cities, as showed in Table 2. Major Anchor Cities of UK s Planning Knowledge Network, there is major anchor cities. From this table, It is obvious to know that London not only have the largest number of planning scholars counted as the main entities in the network, but also the number of planning schools, scholars.

Another important finding is even the absolute value of the number of scholars is high, the cooperative degree is even higher, which means there are more related scholars that beyond these 104 scholars in London s case. Meanwhile, it could be possible that London attracts not only the local scholars but also scholars from the state. This hypothesis has been proved in the next step.

Table 2. Major Anchor Cities of UK s Planning Knowledge Network

| Rank | Anchor City | Degree of Cooperative | Key Planning Schools | Number of Targeted Planning Scholars |
|---|---|---|---|---|
| 1 | London | 468 | University College London<br>London School of Economics and Political Science<br>University of Westminster | 104 |
| 2 | Oxford | 88 | Oxford Brooks University | 31 |
| 3 | Cardiff | 75 | Cardiff University | 56 |
| 4 | Liverpool | 73 | University of Liverpool | 65 |
| 5 | Edinburgh | 69 | Heriot-Watt University | 21 |
| 6 | Bristol | 69 | University of West of England | 42 |
| 7 | Manchester | 59 | University of Manchester | 16 |
| 8 | Glasgow | 51 | University of Glasgow | 33 |

(Source: Dataset of UK Urban Planning Schools, 2015)

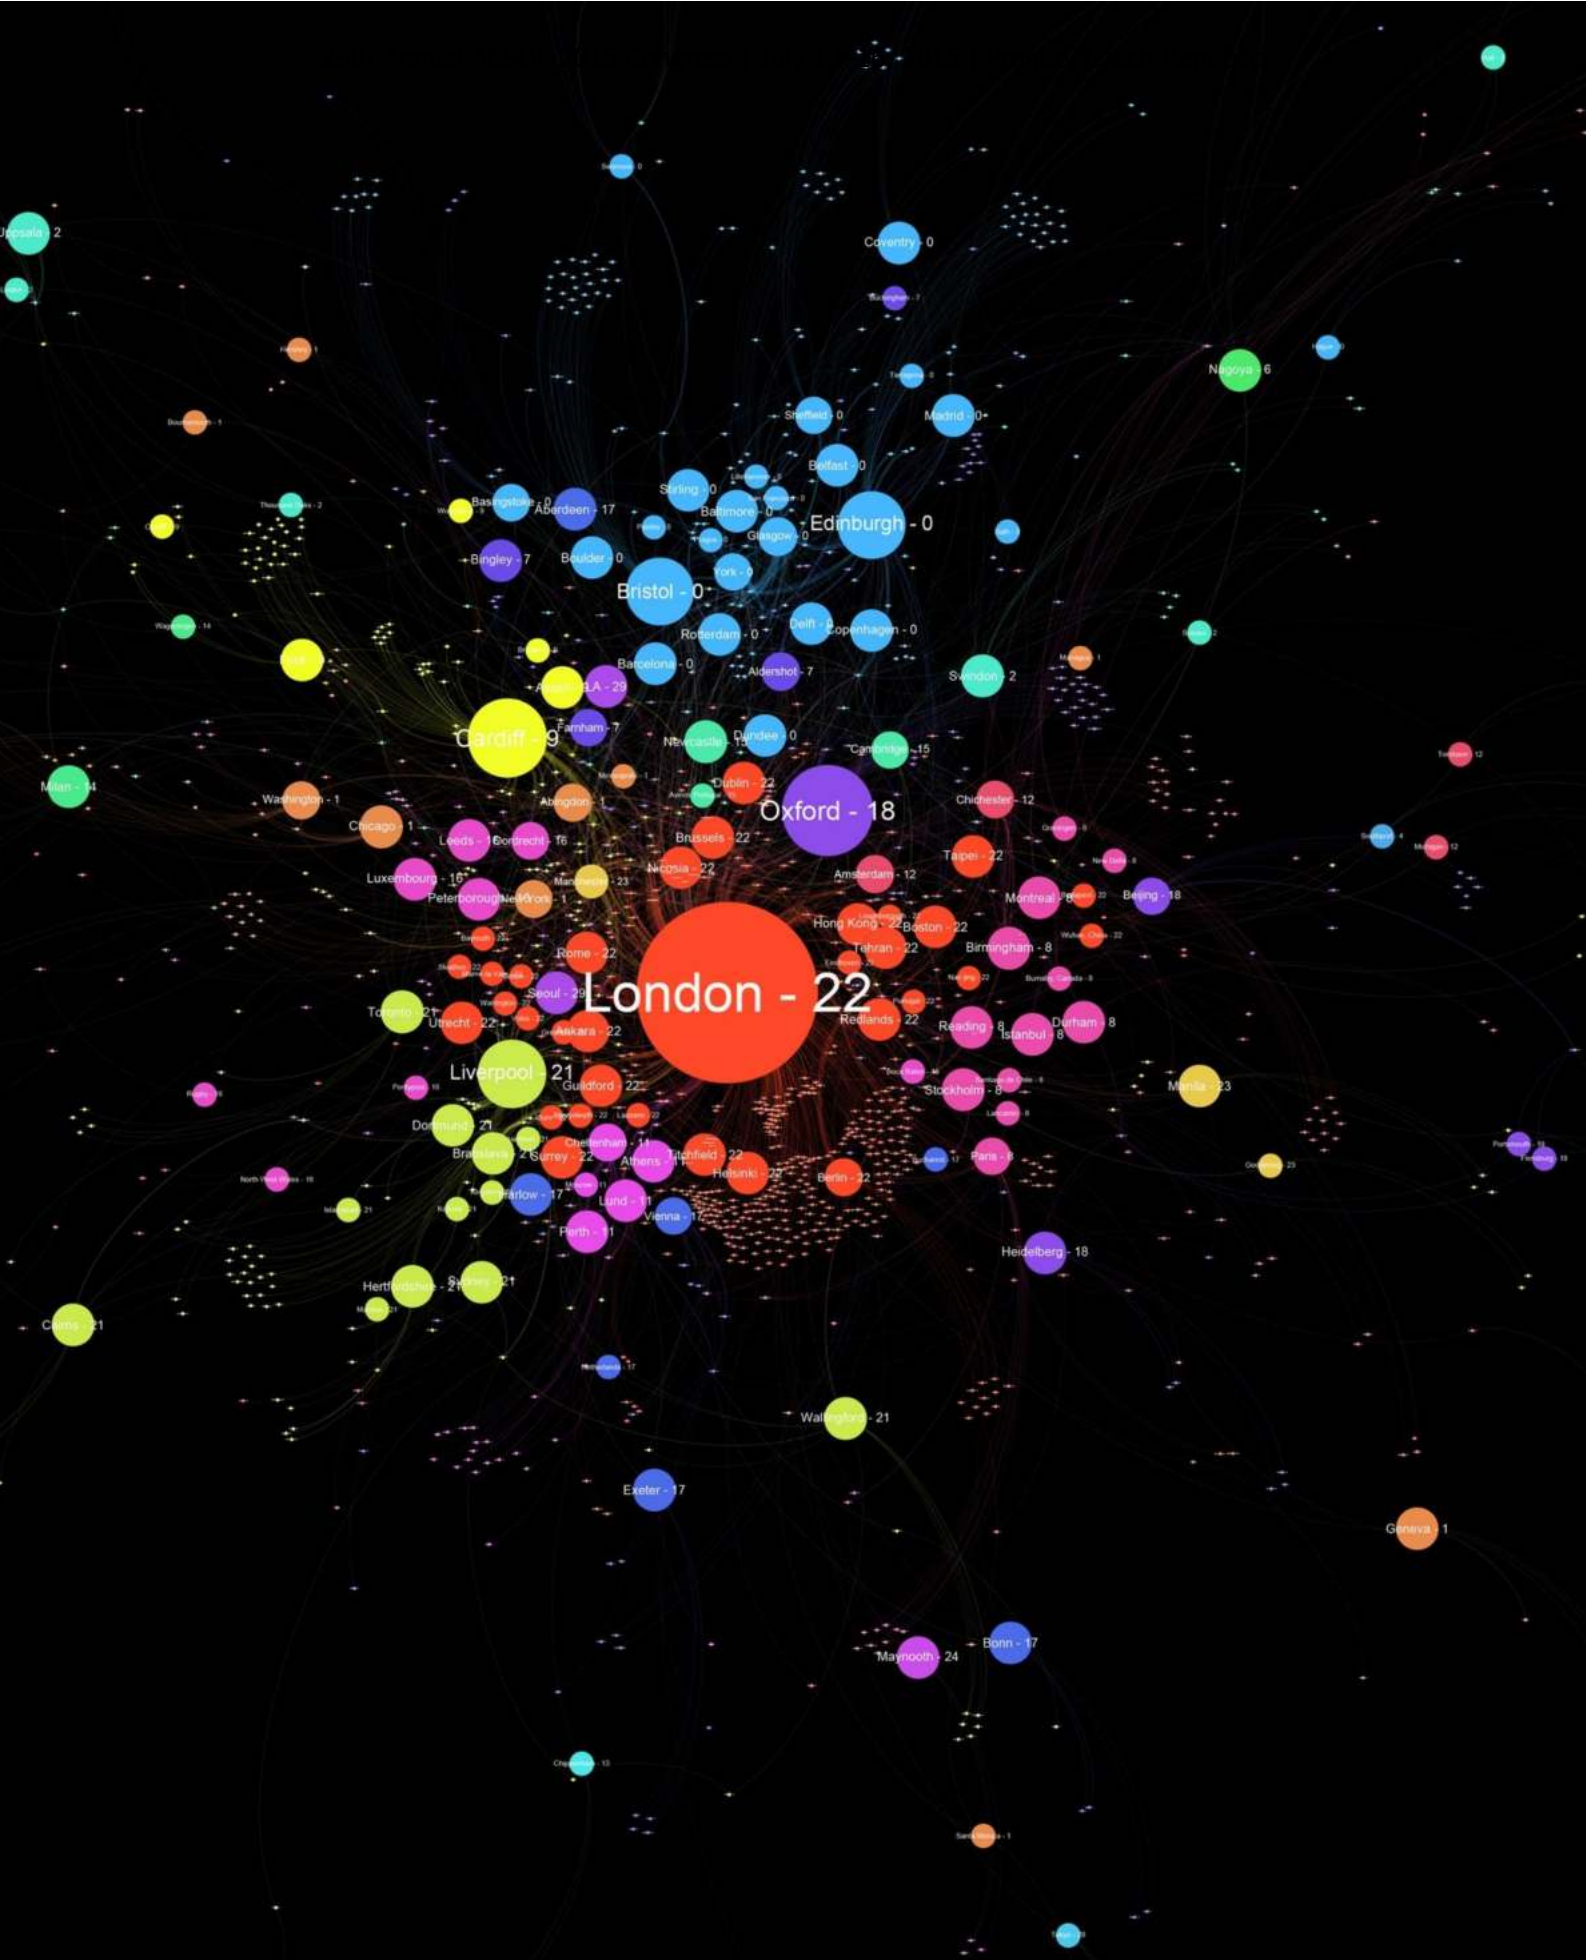

Figure 7. Anchor Cities of UK s Planning Knowledge Network

(Source: Graph generated through Gephi, 2015)

### *5.3 Clustered Anchor Cities*

According to the principle, one city build the connection with another city through common scholars who contribute the academic outputs in both cities. Hence, it is easy to understand that the more common scholars in a group of cities share, the more chance they would form a cluster together. In other words, the scholars along with their academic outputs, makes it possible for cities to be close.

In Table 3. Major Anchor Cities Clusters of UK s Planning Knowledge Network, the ma cities clusters are showed, as the top 8 clusters occupied 78.92% in total proportion of degrees, involving 70.62% of all cities.

Table 3. Major Anchor Cities Clusters of UK s Planning Knowledge Network

| Rank | Proportion of Degrees | Anchor Cities Clusters | Number of City | Members | Gephi Code |
|---|---|---|---|---|---|
| 1 | 24.04% | London Captial Group | 74 | London, Dublin, Utrecht, Brussels, Nicosia, Boston, Redlands, Berlin, Helsinki, Titchfield, Surrey, Ankara, Rome, Tehran, Hong Kong, Taipei | 22 |
| 2 | 9.62% | Edinburgh-Bristol-Glasgow Group | 30 | Edinburgh, Bristol, Glasgow, Coventry, Baltimore, Sheffield, Belfast, York, Copenhagen, Rotterdam, Delft, Madrid | 0 |
| 3 | 8.33% | Liverpool Group | 26 | Liverpool, Dortmund, Toronto, Wallingford, Sydney, Hertfordshire, Kingston | 21 |
| 4 | 6.09% | Leeds group | 19 | Leeds, Luxembourg, Peterborough, Dordrecht | 16 |
| 5 | 5.77% | Birmingham-Reading Group | 18 | Birmingham, Reading, Stockholm, Durham, Montreal, Paris, Istanbul | 8 |
| 5 | 5.77% | United State Group | 18 | Chicago, New York, Washington, Abingdon, Minneapolis | 1 |
| 7 | 4.81% | Cardiff Group | 15 | Cardiff, Assen, Frick, Woodstock | 9 |
| 8 | 4.49% | Amsterdam Group | 14 | Amsterdam, Chichester | 12 |
| Sum | 78.92% | - | 214 | | - |
| Rest | 31.08% | - | 89 | - | - |
| Total | 100% | - | 303 | | - |

(Source: Dataset of UK Urban Planning Schools, 2015)

### *5.4 Summary of Anchor Cities*

As the scholars keep creating planning knowledge in different cities, the records of such academic outputs with location information makes it possible for this research to take advantage of. Anchor cities, play the role of knowledge produce, exchange and store place, are essential to be studied in

order to make the network sensible. As been showed in the visualized work, anchor cities, through the connection by scholars, displayed differently both in degrees of academic cooperation, but also in clustering. In total, five reasons that caused the cities to form clusters, to share common scholars and to play the role of anchor in similar areas in the knowledge network.

First, geographic correlation is important. Inside most of the clusters, key cities in a region share the same cluster. Together, they formed a strong network anchor region, with the local research programs completed by intercity scholars.

Secondly, academic events brought certain types of scholars together, which, on the other hand, build the relationship to their base cities. Usually, both cities always shared certain type of planning issues.

Thirdly, London as a special case, implies not only a strong cooperative relevant with cities in the region, but also shows a relatively high involvement among the capital cities globally. For the reason of its high value of academic mobility and accessibility for planning scholars around the globe, this makes sense. On the other hand, international academic events also make London capital group the most significant and trans-continents one.

Fourthly, the importance of the scholar shall be stressed, as the United State Group shows. The certain group of scholars who are active in both United State and UK, contribute to the strong correlation between certain UK cities and United State cities.

Last but not the least, as the planning knowledge network is an open system, it is impossible to have no connection with other planning knowledge networks, like United State, etc. Once the UK cities been connected to United State cities, it is inevitable to build links with the clusters in United State. Hence, according to the clustering algorithm, a group of cities with high inter correlation but less connections exteriors is tend to be catalogued in an individual cluster, Then Abingdon, rather than London, shares the cluster of Chicago, New York, Washington, and Minneapolis.

## 6 Conclusions

### *6.1 Summary of Anchor Cities*

The major goal of this research is to gain understanding of the sensible planning knowledge network of UK. Open source data and the models, methods, tools used in the research lead us to the planning knowledge network finally. It is essential to make the network sensible by visualizing the knowledge cooperation among scholars, and also the attempt to find the anchor cities that allows the knowledge network to have physical meanings on a number of cities. By doing so, the planning knowledge network is somehow sensible.

During the process of research, some important findings are discovered. The closeness of scholars inside the network was transformed into clusters, like Mike Batty s Cluster, and Richard Boyle-Andy Plate s cluster, etc. Scholars belong to major clusters are more active in academic cooperation than those who are not, in general. Within the clusters, the typology are different, but share the same ideology that the completed triangle and openness on cooperation could contribute to the development of clusters.

Such closeness also reflect on the physical space, the anchor cities. Like showed in the case of London capital group, Edinburgh-Bristol-Glasgow Group, etc., anchor cities also have the tendency to get clustered. The reason of the anchor cities clustering is complicated. Some due to the geographical correlations, academic events, scholars individual academic activities, even the exterior network interfere the process and results of clustering anchor cities, as the United State Group case implies.

### *6.2 Inadequate and Extension*

However, some problems are still exist in the process and findings of the research. For example, to obtain the data from open sources, it is risky to regard the publications online covers all academic outputs. The same problem also remains in the incomplete UK planning schools taken into consideration, as only

six been studied, and more deep analysis should be added to the measuring part. For the anchor cities study, the results are just proper for UK, instead of even larger territories.

This research still remains a great possibility to be extended in further research. For not only more complete in coverage of knowledge network in UK, but also in depth of data visualization and analysing methods. It is believed that this research just unveiled the corner of a mine , with more applicable and instructive findings are to be discovered and discussed. The devotion on UK s case help us a lot to have meaningful adjustment and thoughts on the whole research program that has a larger horizon of the entire Europe.

## Acknowledgement

To complete this research, we should give thanks to prof. Alessandro Balducci (Politechnico di Milano), who offered us the many access to European planning schools information. guidance of his not only benefits this research, but also the whole research program. Prof. Izabela Mironowicz (AESOP) patiently and selflessly offered the information. Moreover, we also would like to thank those groups that operate such open source platforms, which allow us to have free access to data mining, visualizing and analysing tools.

# EU S SMART CITIES POLICIES: FROM STRATEGY TO IMPLEMENTATION

Fang Yao
College of Architecture and Urban Planning, Tongji University, Shanghai, China, fangyao0818@gmail.com

*Abstract: In the current international situation, the European Union is facing the important issue of restructuring development. The proposal of smart city policies will be one of t measures to break through the bottleneck of economic, social and environmental development in the next decade or even longer. The concept of smart city in EU has long been proposed and gradually developed in recent years, and EU has preliminary built the complete smart cities development objectives and roadmaps. The paper shows that EU has formed the smart cities policies system from strategy to implementation. The system mainly consists of four-levels of top-down structure: respectively the strategy, research, platform and project level, to meet the requirements of different stages of smart city developments, involving a number of significant EU's development policies and research projects. The paper also found that EU needs to strengthen the cooperation between government, industries and the citizens, to develop information and communication technologies, and to accelerate smart cities and smart technologies marketization, therefore to finally meet the strategic objectives of the EU's future plan and to achieve the realization of smart cities.*

Keywords: EU, smart cities, urban development strategy

## 1. Introduction

Since the issue of Smart City being raised, it has become a research development-related issues. According to statistics, more than half of the global population lives in cities, the Earth has entered the "urban era", while the European region as one of the earliest urban areas, more than 80 percent of citizens living in the city. Every year the cities product economic cost and energy consumption that accounted for the majority of social resources. Under the aftermath of the global economic crisis, the climate and environmental issues are still very severe, European cities get into the bottleneck of development and need urgent profound restructuring and innovation to achieve a new round of development growth (Barresi and Pultrone, 2013). As the planet becomes more urban, cities need to become smarter.

Smart City is just able to combine both the EU strategies and the measures together to promote the development of European cities. The concept Smart City includes innovative, low-carbon, sustainable development and other criteria, which are the EU s strategic focus over the nex (Tregoning et al., 2002; Moraci and Fazia, 2013). Plus the use of smart technologies such as information and communication technology (ICT) is also important to achieve increasing smart growth (Santinha and Anselmo de Castro, 2010). The EU as one of the world's most important economies, having both diverse and unified city model, is able to fully integrate their resources to promote the smart cities policies, thus studying about EU-led smart cities policies has important

meanings and values.

## 2. The history of Smart City and Smart Cities Policies

### 2.1 Definition of Smart City in EU context

Under the EU context, the most reliable source of a definition of smart city is usually considered the research paper by a group of researchers led by the Centre of Regional Science at Vienna University of Technology (Giffinger et al., 2007) entitled Smart cities: ranking of European This classification of the six characteristics of urban smartness is present in most literature about the smart city, which are Smart Economy, Smart People, Smart Governance, Smart Mobility, Smart Environment and Smart Living. There are 31 factors and 74 indicators under the six characteristics. The research about medium-sized smart cities later became the learning templates for many European smart cities studying and the six characteristics also became an important source of smart city standard definition.

In a report entitled "Mapping smart cities in the EU" made by the EU in 2014 (Manville et al., 2014), they made a deeper and more comprehensive definition about Smart City based o also compared and classified the European smart cities. The research report thi is a multi-stakeholder partnership, making use of advanced technology (especially ICT technology) to solve public issues, those solutions developing and perfection through smart city initiatives or projects, as well as various actions and networks. The report also retains and reinforces the six characteristics as the criteria of definition to form the structure of smart city (Figure 1).

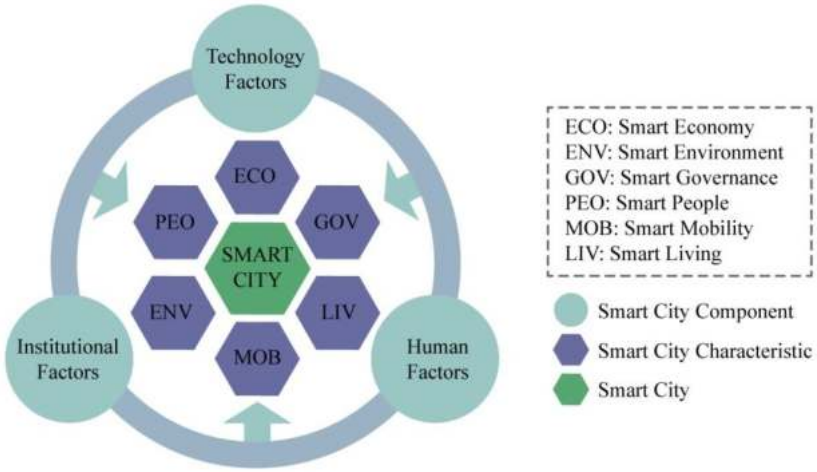

Figure 1. The components and characteristics of smart cities (Manville et al., 2014)

*2.2 History of Smart Cities policies development*

Since long ago the EU started thinking about using new ways to manage urban growth. From the 1990s, there is the emergence of sustainable development policy concept. In July 2005, the European

Union formally implemented "i2010" Action Plan, which stresses the importance of acceleration the introduction of eGovernment in Europe (Deakin, 2009) as well as the communication technology, new network, new service and media[1]. In 2006 the EU launched the European Network of Living[2], which uses new tools and methods, advanced information and communication technology to solve social problems. In 2011 the European Commission introduced the "Europe 2020", proposing three priorities of smart, sustainable and inclusive growth and determined the digital agenda as one of the seven flagship initiatives(EU, 2013). The following "Digital Agenda for Europe" explicitly listed smart city as one of the key projects. The latest progress is that in July 2012, the European Commission launched the "The European Innovation Partnership on Smart Cities and Communities (EIP-SCC)" to promote smart technologies development, and from 2013, the budget increased from 81 million to 365 million.

### 2.3 Motivation about EU s Smart Cities policies

1) EU s economic crisis and its accompanying hazards make EU need new stimulation of deve
The European debt crisis began in 2008 has several manifestations (McCann and Ortega-Argilés, 2013). Unemployment has constantly increased in several EU countries, with a particular burden on younger generations, and this dilemma has not yet been completely removed (Caragliu et al., 2011; Caragliu, 2013), EU countries hope through the economic stimulus package to save the domestic economy and enhance international competitiveness. For the regions whose majority of the population living in urban areas, they need a new way to manage the complexity of city life. Smart City concept combines many important issues of economic, social, environmental which are important for urban transformation.

2) EU s backward in the field of information technology urges its smart technology to d
Compared to other industrialized countries such as United States and Japan, EU is relatively backward in the field of information technology. According to statistics, Google, Amazon and other successful Internet providers that origins outside Europe; at the list of Fortune 500 companies, only one of nine ICT operation company is European company; among the highest 54 visited sites in the world, only four from Europe (EU, 2010). Today the information industry is flourishing, the importance of information security is growing, EU has fully conscious the importance of information technology industry.

3) Smart City concept will help cities save energy and create greater economic benefits
Smart City as Europe-wide demonstration projects, are able to improve energy efficiency by large-scale deployment of low-carbon technologies. Europe as a highly urbanized area, more than half of the pollution generated by the city, 70 percent of the energy consumed in the city, so the cities are the key to the EU low-carbon economy. The openness and connectivity of the European Single Market have allowed its cities to become hubs for the creative economy, technological and societal innovation,

[1] http://europa.eu/legislation_summaries/information_society/strategies/l24226j_en.htm
[2] http://www.openlivinglabs.eu/

welfare enhancement and sustainable development (Roche et al., 2012; Manville et al., 2014).

4) Smart City reflects the people s vision for clean, livable, sustainable urban
Smart City concept is prevalent in Europe also because it fulfills people s image of clean and livable urban environment, reliable advanced technology development, and stable and harmony social-economic environment (Vanolo, 2013).

## 3. Important structure and components about EU Smart Cities policies

Due to EU s special political joint system, making the European Union could integrate researc resources, provide fundings, and form a unified strategic and implementation system, therefore makes the EU Smart Cities different from other countries and regions. At the same time, it is possible to take into account the different characteristics of member states, to conduct different implementations with both integrity and flexibility.

Basically, the EU smart cities policy system can be divided into the following four levels: the **Strategy** level, EU s important strategies and major decisions for the future, Smart City aspects; the **Research** level, under the guidance of Strategy level, usually charged by the EU major research institutions and departments, can also provide adequate financial support for research; the **Platform** level, is a convergence between research results and practical application, it aims to provide cooperation opportunity for various stakeholders such as the city government ,the research department and the enterprises, to share information and experiences, and to find suitable solutions; the **Project** level is directly involved in the implementation of the smart cities, including the pilot smart city, smart technology solutions, regulations and activities etc.

### *3.1 The Strategy level*

One of the most important strategies that has great impact on Smart City is the European Union s ten-year growth and jobs strategy that was launched in 2010. The Europe 2020 Strategy is intended to act as an umbrella organizing framework under which all EU policies will operate over the coming decade (Caragliu, 2013). Overall, the strategy wants the EU to become a smart, sustainable and inclusive economy. These three mutually reinforcing priorities should help the EU and the Member States deliver high levels of employment, productivity and social cohesion[3]. Concretely, the Union has set five ambitious objectives on employment, innovation, education, social inclusion and climate/energy to be reached by 2020[4]. Each Member State has adopted its own national targets in each of these areas. The strategy is also supported by seven flags which the EU and national authorities reinforce their efforts in areas supporting the Europe 2020 priorities such as innovation, the digital economy, employment, industrial policy and resource

[3] http://ec.europa.eu/europe2020/index_en.htm
[4] http://ec.europa.eu/europe2020/europe-2020-in-a-nutshell/priorities/index_en.htm

efficiency[5]. The relationship between three targets and seven flagship initiatives are as follows (Table 1), the contents of Smart City belongs to the Smart Growth, the initiatives and measures of Smart City considered to be a beneficial tool to achieve Europe 2020 objectives.

Table 1. Europe 2020 priorities and flagship initiatives

| Smart Growth | Sustainable Growth | Inclusive Growth |
|---|---|---|
| Digital agenda for Europe<br>Innovation Union<br>Youth on the move | Resource efficient Europe<br>An industrial policy for the globalisation era | An agenda for new skills and jobs<br>European platform against poverty |

Digital Agenda for Europe (DAE) is a branch strategy of Europe 2020, it aims economy and help Europe's citizens and businesses to get the most out of digital technologies. Launched in May 2010, the DAE contains 101 actions, grouped around seven priority areas, including create a new and stable broadband regulatory environment, launch grand coalition on digital skills and jobs, launch new electronics industrial strategy etc. Over the next decade, by increasing investment in ICT, improving eSkills levels in the labour force and reforming the framework conditions for the internet economy would increase the European GDP by 5%, or 1500 per person. In the end of 2020, up to 900.000 digital jobs will be provided, while 1.2 million jobs could be created through infrastructure construction, this would rise to 3.8 million new jobs throughout the economy in the long term[6].

In terms of Smart Cities, digital technologies translate into better public services for citizens, better use of resources and less impact on the environment. Smart City makes the traditional networks and services more efficient with the use of digital and telecommunication technologies, for the benefit of its inhabitants and businesses.

*3.2 The Research level*

The complete name of FP7 is 7th Framework Programme for Research and Technological Development, which is the European Union s main instrument for funding researcl 2007 until 2013, the programme has a total budget of over 50 billion. It re increase compared with the previous Framework Programme (FP6 only about 63% of FP7), reflects the high priority of research in Europe[7]. The Seventh Framework Programme (FP7) bundles all research-related EU initiatives together under a common roof playing a crucial role in reaching the goals of growth, competitiveness and employment[8], such as a new Competitiveness and Innovation

[5] http://ec.europa.eu/europe2020/europe-2020-in-a-nutshell/index_en.htm

Framework Programme (CIP), Structural and Cohesion Funds, the European Research Area (ERA). The objectives of FP7 have been divided into four categories: Cooperation, Ideas, People and Capacities (Table 2). For each type of objective, there is a specific programme corresponding to the main areas of EU research policy.

Horizon 2020 is the biggest EU Research and Innovation programme ever with nea funding during 2014 to 2020 (not included the private investment). It promises to bring more breakthroughs, discoveries and great ideas from the lab to the market[9]. Horizon 2020 emphasizes on excellent science, industrial leadership and tackling societal challenges, the goal is to ensure Europe produces world-class science, removes barriers to innovation and makes it easier for the public and private sectors to work together (Table 3).

In Horizon 2020, the ICT Research & Innovation is a spotlight. The ICT sector represents 4.8% of the European economy. It generates 25% of total business expenditure in Research and Development (R&D), and investments in ICT account for 50% of all European productivity growth. EU investments in ICTs are due to increase by about 25% under Horizon 2020 compared to FP7[10]. Horizon 2020 will support the whole chain from basic research to innovation that can deliver new business breakthroughs. It underpin innovation and competitiveness across private and public sectors and enable scientific progress in all disciplines, that is the reason that ICT-related topics can be found in all priorities, from Excellence Science to Industrial Leadership , to Societal Challenges , re secure, clean and efficient energy, smart, green and integrated transport and climate action etc.

*3.3 The Platform level*

The Smart Cities and Communities Initiative (SCC) was launched in 2011. It has close relationship with FP7 and Horizon 2020. In the coming year 2012, the European Innovation Partnership on Smart Cities and Communities (EIP-SCC), the Partnership is under the framework of Digital Agenda as well as directly funding by Horizon 2020. In the year 2012, only 81 million has be SCC initiative, covering only two sectors: transport and energy. Demonstration projects financed under the scheme can be in either one of the two sectors, rather than the two combined. Starting from

[10] http://ec.europa.eu/programmes/horizon2020/en/area/ict-research-innovation

2013, the budget has been increased from 81 Million to 365 Million, coveri
of two: energy, transport and ICT. In addition, each and every demonstration project financed under the scheme must combine all the three sectors[11].

With this Smart Cities Partnership, the EU will combine cities, industries and citizens, through a more sustainable way to improve city life, to establish a strategic partnership between European cities and industries and to contribute to the EU s 20/20/20 climate action goals. Current the potential of smart technology innovations, such as high-tech risks, the uncertainty of the return on investment and regulatory difficulties. The Partnership aims to overcome bottlenecks impeding the changeover to smart cities, to co-fund demonstration projects and to help coordinate existing city initiatives and projects, by pooling its resources together[12].

The European Innovation Partnership on Smart Cities and Communities (EIP-SCC) consists of High Level Group, Sherpa Group and Smart Cities Stakeholder Platform (Figure 2). The representatives of Higher Level Group are coming from industry, research and cities, together with Sherpa Group, they are responsible for the Strategic Implementation Plan (SIP), which helps promote Smart Cities into practice. It also helps how the European Commission can support these measures during the next Research Framework Programme (Horizon 2020).

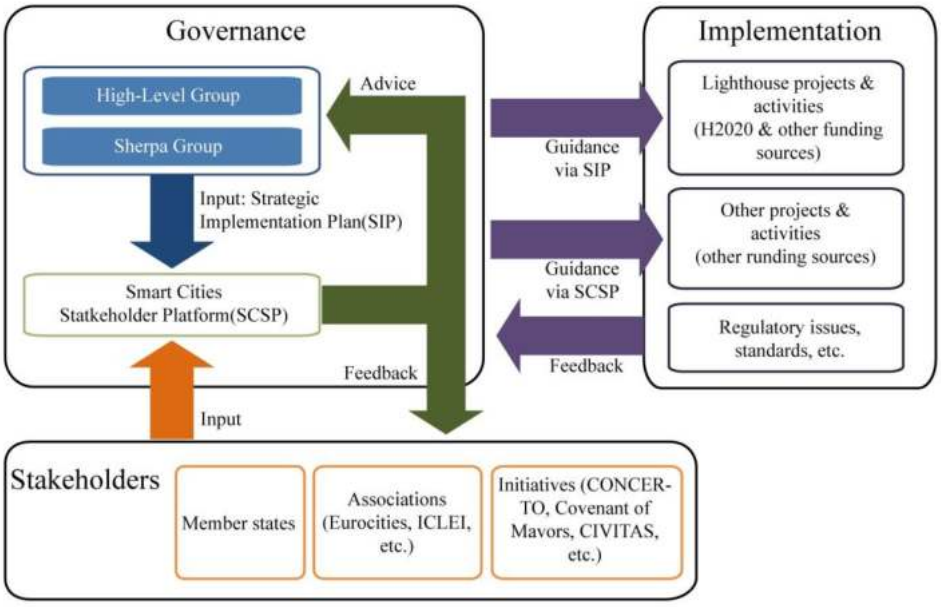

Figure 2. European Innovation Partnership on Smart Cities and Communities operation mode (Resource:http://ec.europa.eu/eip/smartcities/about-partnership/how-does-it-work/index_en.htm)

The Smart Cities Stakeholder Platform was initiated by the European Commission with the dual aim of identifying and spreading relevant information on technology solutions and providing information

[11] http://europa.eu/rapid/press-release_IP-12-760_en.htm
[12] http://ec.europa.eu/eip/smartcities/about-partnership/what-is-it/index_en.htm

for policy support to the High Level Group and the European Commission. The Working and Coordination Groups are at the heart of the Smart Cities Stakeholder Platform. There are three thematic expert (technical) Working Groups, each dedicated to one technology area, and three horizontal groups, for developing strategic visions for the future based on the work undertaken in the Platform[13]. The Smart City Stakeholder Platform provides a unique opportunity for individuals and organizations across Europe to take part in establishment Europe s Smart City Ro and analyzes all information stakeholders input, you can upload all the data and add any news about your city and the projects or you can look for specifically tailored projects for your city. The Platform also helps High Level Group feedback on Strategic Implementation Plan, the Group and the Stakeholder Platforms work together to encourage and support more extensive cooperation of smart cities.

*3.4 The Project level*

The Project level consists of all sizes and forms of projects and becomes a Smart City project library, which covers the urban pilot projects, smart city organizations, the use of smart technology and other aspects.

For instance, the Strategies Towards Energy Performance and Urban Planning(STEP-UP) aims to bring together excellence on energy planning from four European cities together with their industrial and research partners, running from 2012 to 2015. The Planning will assist cities enhance their sustainable energy action plans and integrate energy planning into their sustainable city planning. The programme is working together with twelve organizations, local government, research and commercial partners in the European cities of Ghent, Glasgow, Gothenburg and Riga. The programme is also part of the EU FP7. The main targets of STEP-UP include to create a coherent and easy-to-use model for energy planning that helps to achieve Europe's 2020 energy targets; to deliver wider policy objectives such as improving security of energy supplies, achieving urban regeneration and economic growth; and to make these cities better places to live, work and do business[14].

ICT for Energy Efficient Neighbourhoods (IREEN) is funded under the FP7 as a Coordination and Support Action. The project commenced from 2011 to 2013 with total budget of 1, aim is to extend the notion of energy positive buildings. Energy positive are build those that have the capacity to generate more energy than they use, this can be achieved in three ways: spending less energy than they have produced over a time; facilitating eco-responsible behaviours; consuming low energy over their life cycle. The project engaged with[15] a wide range of stakeholders including those from technology, energy, construction, local authorities, building managers and owners.

The whole structure system of EU s smart cities policies and their relationships are listed below (Figure 3):

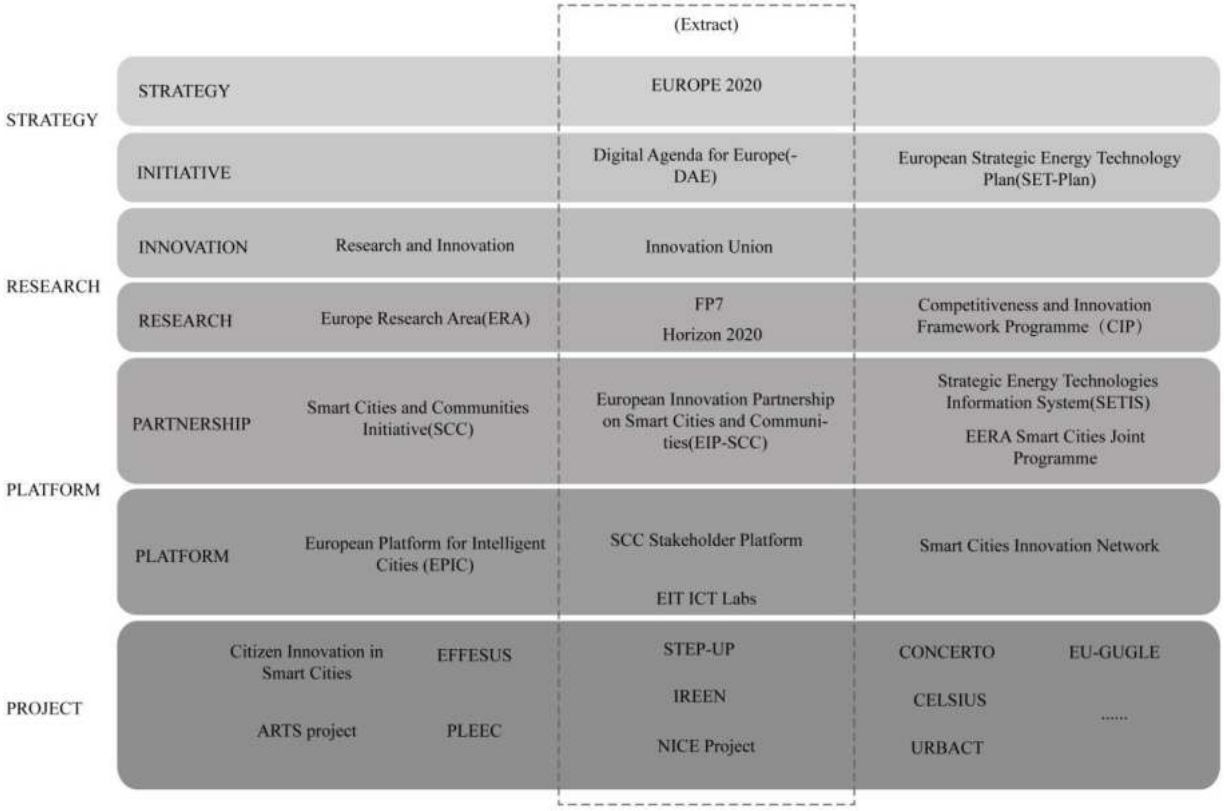

Figure 3. The structure of EU smart cities policies system

## 4. Evaluation of EU s implementation of Smart Cities

### *4.1 Achievement of EU Smart Cities*

According to a latest EU research report (Manville, etc., 2014), seriously speaking nearly all the Smart Cities in Europe are in the primary stage of development and they still has a long way to go for the strategy of Europe 2020. In the key research cities, more than two-thirds of the smart city projects are still in the planning or pilot testing phase. The smart city projects mainly clustered into five characteristic types: neighbourhood units, testbed micro infrastructures, intelligent traffic systems, resource management systems and participation platforms.

The study also found that most of the smart city projects are towards the goals of Europe 2020, proving that the problem facing European cities are widely recognized. Smart City initiatives can be considered as a useful tool for cities to achieve their Europe 2020 targets. In most of smart cities initiatives, the environmental issues and green solutions appear to be the principal concern; nearly 50% of sampled initiatives address environmental problems through improved energy efficiency in buildings or smarter city transportation options. In addition, over one-third have initiatives that support

the attainment of poverty reduction targets while one-fifth of cities have initiatives that address employment. However, only few initiatives encourage private sector R&D investment. Some cities have project portfolios that aim to contribute to the attainment of multiple Europe 2020 targets.

The analysis found that by far the "smartest" five European cities are Helsinki, Hamburg, Amsterdam, Barcelona and Manchester. Although the implementation focus of the five smart cities are different, but the results of comprehensive evaluation shows the advantages.

*4.2 Funding of EU Smart Cities*

Since the great majority of Smart City initiatives in Europe had been financed by research funding, rather than on a commercial basis, thus it is necessary to understand the constitute system and operations of EU research funds. The European Union possesses five key funding opportunities to support research and innovation: the Research Framework Programme, the Competitiveness and Innovation Framework Programme, the Structural Funds and the Cohesion Fund within the Cohesion policy; the European Agricultural Fund for Rural Development and the European Fisheries Fund within the Rural development policy and the Common Fisheries Policy[16].

Usually smart city-related issues are funded by Research Framework Programme, Competitiveness and Innovation Framework Programme, the Structural Funds and the Cohesion Fund. Among them the Research Framework Programme is the most important source of funding and able to lead the smart cities research and become the core of innovation, system integration and standards establishment. The other two programmes are also important funding sources, they are not only involved in the Framework but also provide supports for other studies. In addition the Structural Funds and the Cohesion Fund support qualifying smart city projects, such as URBACT projects.

Furthermore, the EU act as an important guarantee for Smart Cities research and implementation, plus each projects could get funding from local government and private sectors, together they constitute the funding system of smart cities. Study also shows that projects using multi-channel sources of financial support are much easier to be successful.

*4.3 Evaluation about EU Smart Cities*

The EU has built a unique smart cities policies system, which already made some achievements, but also accompanied by a corresponding problem.

1) From the perspective of structure, the smart cities policies system constitu
from strategy to implement, however the complexity of the system may cause some difficulties while performing.

[16] http://cordis.europa.eu/eu-funding-guide/home_en.html

The EU smart cities policy system consists of four levels: the Strategy, the Research, the Platform and the Project, each level has own responsibilities and higher levels direct or cooperate with lower levels, the projects often reflect the strategy of Europe 2020 and the Innovation Partnership of Smart Cities, thus forming a complete industrial-chain system, which helps the final impleme Cities. But it is undeniable that the huge EU policy making system, as well as the research funding, are too complex and inextricable to manage, will cause some problems of coordination.

2) EU has a clear objective to develop and implement smart cities, which helps strengthen the confidence of the industries and governments to implement smart cities, but the "bottom-up" smart city participation is still weak.

From long ago EU considered that the smart city transformation can help them achieve their goals in environmental, social and economic aspects. The Europe 2020 strategy and other initiatives also stressed this point. For the government, these policies contribute to smart cities pilot development in order to achieve the future needs of the cities as soon as possible. For the enterprises, clear goals can directly enhance the confidence of research development, they are more willing to invest and promote the development of new technologies and intelligence technologies. At the same time, it cannot be ignored that the meaning of the smart cities includes Smart People and Smart Living, therefore the role of citizens should not be forgotten. We must focus on bottom-up participation in smart cities planning to build more livable and harmonious smart cities.

3) The system has built a multi-stakeholders platform for the governments, industries and the public, but most of smart city projects are still dominated by the city government, enterprises participate in the marketization of smart city technologies need to be strengthened.

The stakeholders of the EU smart cities policy system includes the European Commission, the European (and the world) industry enterprises, the Mayors and relevant EU organizations, and the citizens. Today the stakeholders platform is open, any stakeholders can participate and seek for better solutions. The technology platform is also established and the experts are integrated to guide the key technologies. The benefits of smart cities sometimes are not obvious and cannot entirely returns to investors, but it should be taken into account, which explains why most of the smart city projects are government-led. But it is undeniable that a market-driven business model is critical, the transformation of science and technology of smart city is important, and in this respect the EU still needs efforts.

## 5. Conclusions

Considering its international situation, the EU makes Smart City to be one of the most important issues to promote the EU's economic, social, environmental development for the next decade or even longer. The EU also develops a complete policies system from the strategy to the research and to the implement, in order to promote smart technology innovation leading by the information and communication technology industry; to define the goals of environment, energy, transport,

employment and other aspects; to build a platform for cooperation with governments, businesses and the citizens. Current European smart cities construction is in full swing and has achieved some success, especially in some big Smart Cities, the Smart concept has started to show some advantages. However in the future, the EU Smart Cities still need to strengthen bottom-up participatory mechanisms and marketization to be able to protect the long-term implementation of the EU smart city plans and to promote smart city vision finally realized.

# UNIVERSITY-LED SMART CITY RESEARCH COOPERATION IN EUROPE

Fang Yao

College of Architecture and Urban Planning, Tongji University, Shanghai, China, fangyao0818@gmail.com

*Abstract: With the development of Information and Communications Technology (ICT), the smart city has increasingly become one of the urban planning research focuses in recent years. Universities and other higher education institutions have become the major research organizations for smart cities. This paper investigated higher education institutions in 15 European countries and a total of 122 university-led smart city research organizations or alliances. Classifying and analyzing the research cooperation patterns of these research organizations or alliances, the paper summarizes four types of cooperation patterns, which are research project, research group, research institution and research platform respectively. Then the paper introduces Fuzzy Consistent Matrix to evaluate the performances of four types of cooperation patterns with five factors, including internal factors and external factors. The results show that the platform pattern is the most preferred pattern of smart city research cooperation, followed by research institution, research group and research project. The research platform can maximize the integration and collaboration of research resources and people, thus it should be applied to future smart city research.*

Keywords: smart cities, research cooperation, European universities

## 1. Introduction

In the past few decades, European cities and policy makers have been engaged in initiatives aimed at improving cities environment, infrastructures and services to provide better economic, social and living conditions for the citizens and to enhance the competitiveness and attractiveness of the cities (Neirotti et al., 2014; de Jong et al., 2015). The concept of smart cities brings more effective means in responding to these requirements, especially with the widely use of Information and Communications Technologies. In European context, smart city strategies have been greatly valued. For example, European Union s strategy of Europe 2020 has clearly wanted the EU to become a smart, sustainable and inclusive economy ((Caragliu, Del Bo and Nijkamp, 2011; Lazaroiu and Roscia, 2012; Caragliu, 2013). Smart cities are sustainable, ecological, intelligent and harmonious (de Jong et al., 2015), thus the concept and the best practice of smart cities could effectively assist with the implementation of EU s strategies.

Meanwhile, the level of scientific research cooperation has been growing worldwide, with no exception in Europe, therefore the level of international research cooperation, intra-EU cooperation and inter-organizational collaboration have been increasing rapidly in Europe (Hoekman, Frenken and Tijssen, 2010). The EU has been committed to promote collaborations across universities, enterprises

and governments to transfer knowledge and technologies, and to establish connections among researchers and scholars in different cooperation countries (Cummings and Kiesler, 2007). For instance, European Framework Programmes are the most significant research instruments and funding in Europe, which constitute a pool of research-related initiatives of EU (Hoekman, Frenken and Tijssen, 2010). Most of smart city-related research are based on collaboration research, and many of them are supported by European research programmes and fund.

This paper aims at studying smart city-related research cooperation which is led by European universities in 15 countries. Summarizing different patterns of cooperation, analyzing and comparing which kind or kinds of patterns are preferred by smart city research.

## 2. Data collection and methodology

*2.1 Definition and classification of smart cities*

Before collecting the data of university-led smart city research cooperation in Europe, the notion of smart cities should be defined. Despite the extensive discussion, there is no general consensus on the definition and classification of smart cities at global scale (Angelidou, 2014; (Jucevi ius, Pata ien and Pata ius, 2014); Neirotti et al., 2014; Ben Letaifa, 2015). Even the improper use of smart cities in superficial ways may mislead the meaning of smart cities. The main reason is that the needs of smart cities are highly depend on the contextual condition of different countries and cities, such as natural resources, technology development, government etc. So there is no one-size-fits-all exists for smart cities (Ben Letaifa, 2015, pp.1415).

However, there is a wide agreement that smart cities are characterized by the widely use of Information and Communications Technologies (ICT) in different domains of urban system (e.g. traffic control system, security cameras, power grid, waters, etc.), in which ICT system plays the central role (Neirotti et al., 2014). ICT help cities make better use of urban and natural resources, enhance the efficiency of urban systems, and prevent the cities from hazards and disasters. In other words, the technology-based approaches and solutions endow cities with digital nervous systems plus the abilities to sense and react.

On the other hand, although ICT-based solutions are considered as one of the most special features of smart cities, a growing number of scholars have realized that smart cities contain not only technological capital but also human and organizational capital. Social, economic, political and cultural context shape the ways of cities to become smarter and information technologies are complementary tools, depending on the cities backgrounds and needs. In that way, smart cities initiatives can be fostered by education, innovation industry, social welfare system and city liveability.

Based on the understanding above, smart cities contents could be divided into two categories, one is tangible, including smart infrastructure, transportation, energy and nature resources etc., the other is intangible, including social capital, innovation economy, public administration, intellectual capital etc. (Neirotti et al., 2014). Similarly, the classification could also be expressed as hard domains and soft domains of smart cities initiatives.

Some other scholars think that ICT-based smart cities solutions emphasize top-down monitoring of city systems. The other aspect of smart cities is bottom-up approaches in which the public could get access to the data and make their own decisions, and the authorities are fair and transparent enough when making decisions (Ben Letaifa, 2015).

*2.2 Data collection*

ICT-based solutions are not the only way to evaluate smart cities has become widespread awareness, this paper explains the notion of smart cities from both research and practice aspects.

In the research aspect of smart cities, the paper retrieved and extracted the data from published scientific articles of the Web of Science . The Web of Science is a bibliographic by Thomson Reuters, which is considered as one of the most comprehensive and reliable research database worldwide (Hoekman, Frenken and Tijssen, 2010). The paper retrieved smart city as th theme of literature and the search period was limited between 2000 and present. The retrieval date is 13th March, 2015 and total of 1253 eligible articles are selected.

Statistics showed that since 2011, the number of publications regarding smart cities has considerably increased (Figure 1), thus selecting publications from 2000 could represent the research of smart cities. And the results covered 15 European countries the paper studies, as well as United States, China, etc. (Figure 2).

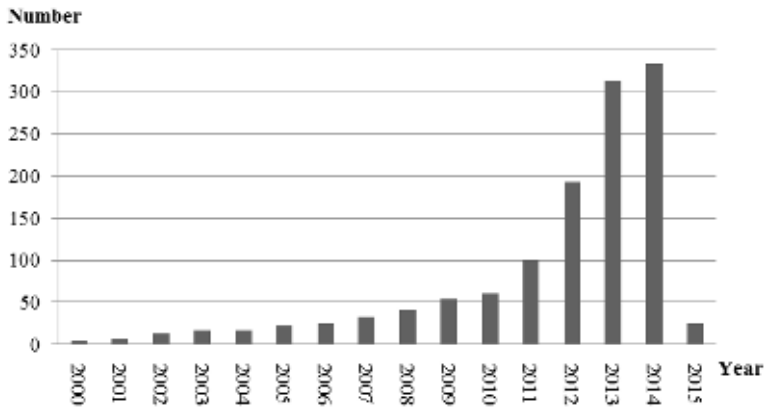

Figure 1. The number of smart cities publications in Web of Science (2000-2015)

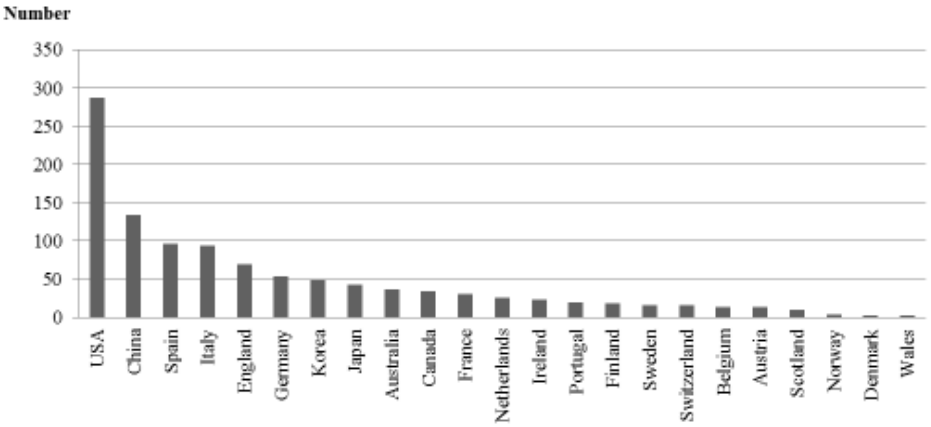

Figure 2. The number of smart cities publications by countries/regions

Analyzing the retrieval results, ten categories of smart cities research topics are classified according to the Web of Science categories and listed by the number of publications (Table 1). The 12 categories include Computer Science/ICT, Engineering, Environment/Ecology/Energy, Urban Planning, Science, Traffic Engineering, Geology, Administration/Management/Political Science, Economics, Biology/Medicine/Health, Sociology/Culture/Education and Architecture.

Table 1. Classification of smart cities research categories

| Categories | Web of Science categories | Publications |
|---|---|---|
| Computer Science /ICT | Computer science information systems, Computer science artificial intelligence, Computer science interdisciplinary applications, Telecommunications etc. (10 items) | 905 |
| Engineering | Engineering electrical electronic, Automation control systems, Engineering civil, Engineering mechanical, Engineering manufacturing etc. (11 items) | 540 |
| Environment/ Ecology/Energy | Environmental studies, Energy fuels, Environmental sciences, Ecology, Water resources etc. (7 items) | 310 |
| Urban Planning | Urban studies, Planning development (2 items) | 201 |
| Science | Physics applied, Thermodynamics, Mathematics applied, Mechanics, Physics multidisciplinary etc. (15 items) | 146 |
| Traffic Engineering | Transportation science technology, Transportation (2 items) | 104 |
| Geology | Geography, Remote sensing, Geography physical etc. (5 items) | 92 |
| Administration/ Management/ Political Science | Management, Operations research management science, Political science, Public administration, International relations, Law (6 items) | 65 |
| Economics | Economics, Business, Business finance (3 items) | 48 |

| | | |
|---|---|---|
| Biology/Medicine / Health | Public environmental occupational health, Infectious diseases, Plant sciences, Social sciences biomedical etc. (11 items) | 48 |
| Sociology/Culture/ Education | Sociology, Education educational research, Social work, Art, Criminology penology, Cultural studies etc. (10 items) | 46 |
| Architecture | Construction building technology, Architecture (2 items) | 33 |
| Sum | | 25381 |

As for the practice aspect of smart cities, the paper selected 15 smart cities evaluation index system around the world to classify smart cities practice, including European medium-sized smart cities rankings (Giffinger et al. 2007), Smart City Evaluation System by The World Economic Forum, and by International Data Corporation etc. Calculating the frequency of sub-index of those evaluation systems, the results contain 10 categories of smart cities practice in Table 2.

Table 2. Classification of smart cities practice categories

| Categories | Contents | Frequency |
|---|---|---|
| Computer/ICT/Internet | Ubiquitous network, Internet popularity, Information and communication facilities, Computer, Radio etc. | 90% |
| Society/People | ICT social foundation, Social justice, Social security, Social inclusion, Smart people etc. | 82% |
| Culture/Education | Knowledge-based labor, Education, E-learning, Culture and Entertainment, Cultural heritage protection etc. | 30% |
| Government/Management /Public Services | E-government, Smart urban management, Public platform database, Democracy, Government transparency etc. | 65% |
| Environment/Ecology/ Energy | Ecological conservation, Renewable energy, Urban waste management, Food and agriculture etc. | 78% |
| Traffic | Transportation information, Smart logistics, Automatic toll road, Urban convenience etc. | 60% |
| Infrastructure | Municipal facilities, Smart grid etc. | 40% |
| Planning/Buildings | Smart planning, Compact land use, Green building etc. | 45% |
| Economic/Business | Smart industry, Economic information service, Enterprise innovation etc. | 35% |
| Medicine/Health care | Medical information system, Home health services etc. | 20% |

Combine the analysis of smart cities research and practice above (Table 1 and 2), the paper determined 8 domains of smart cities: Information and Technology, Environment and Energy, Society and People, Government and Management, Transportation and Infrastructure, Economy and Innovation, Medicine and Health, Planning and Architecture (Table 3). This classification is consistent with the literature review about smart cities (can be divided into hard and soft domains).

Table 3. Final classification of smart cities domains

| Categories | Contents |
|---|---|
| Information and Technology | ICT, Computer science and technology, Remote sensing, Geographic information technology, Internet of things etc. |
| Environment and Energy, | Environmental monitoring, Ecological protection, Renewable energy, Energy efficiency, Water management, Atmospheric research etc. |
| Society and People | Social justice, Social inclusion, Social security, Education level, Recreational activities, Heritage protection, Public space management etc. |
| Government and Management | E-government, Public platform, Government transparency, Smart city management etc. |
| Transportation and Infrastructure | Traffic information, Smart traffic management, Green transportation, Smart municipal facilities, Smart grid etc. |
| Economy and Innovation | Information economy development, High-tech Industry, Enterprise information innovation etc. |
| Medicine and Health | Public health, Medical information system, Food and agriculture etc. |
| Planning and Architecture | Smart planning method, Smart buildings, Green buildings, Building services etc. |

According to the classification of smart cities domains, the paper screened 122 smart city research cooperation institutions or organizations which were led by universities in 15 major Europe countries. They are listed by countries in Table 4.

Table 4. Screening results of university-led smart city research cooperation

| Regions | Countries | Numbers |
|---|---|---|
| Northern Europe (4) | Finland | 6 |
| | Sweden | 9 |
| | Norway | 5 |
| | Demark | 6 |
| Central Europe (3) | Germany | 20 |
| | Austria | 6 |
| | Switzerland | 4 |
| Western Europe (5) | UK | 21 |
| | Ireland | 5 |
| | Netherlands | 7 |
| | Belgium | 2 |
| | France | 13 |

| | | |
|---|---|---|
| Southern Europe (3) | Italy | 7 |
| | Spain | 7 |
| | Portugal | 4 |
| Total | | 122 |

Those collaborative institutions are mainly located in western and central Europe, around the North Sea, English Channel and Cantabrian Sea. They are distributed more in countries like UK, Germany and Netherlands etc.(Figure 3).

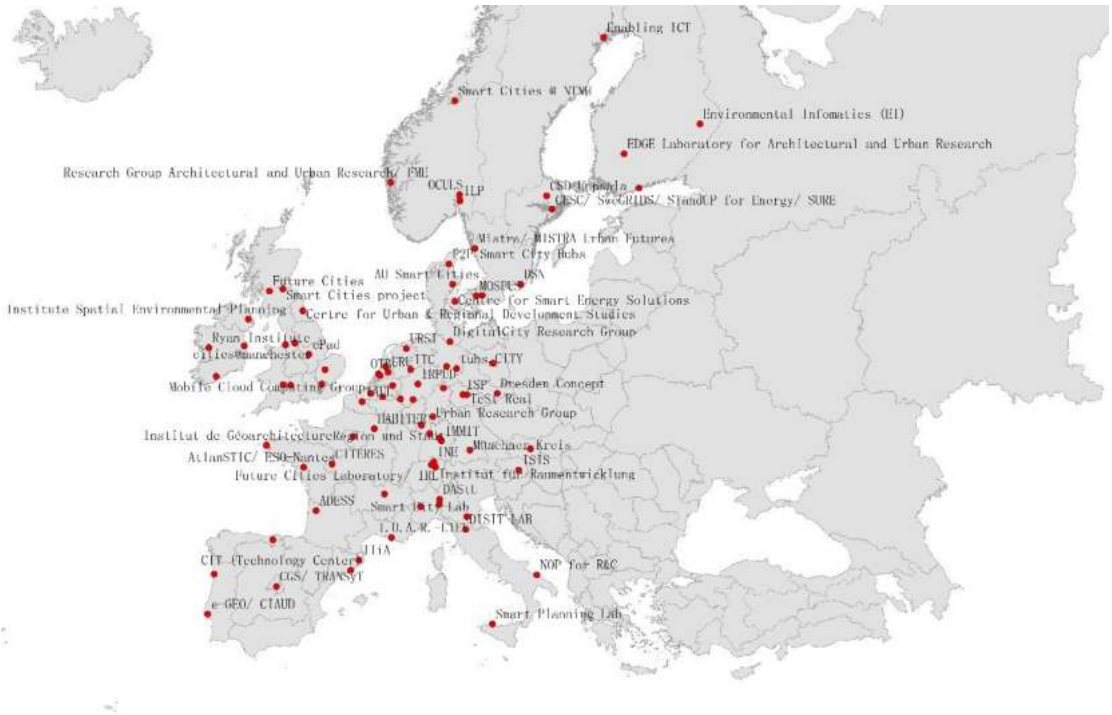

Figure 3. The distribution of university-led smart city research cooperation

*2.3 Methodology*

This paper attempts to analyze and compare different patterns of smart city research cooperation led by universities, involving in several qualitative factors which are difficult to quantify. Therefore, the paper introduces Fuzzy Consistent Matrix for cooperation pattern performance assessment. The method and procedures are as follows:

Suppose there are N decision-making alternatives, then $a_i$ (i=1, 2, , n) constitutes preferred alternatives set. And suppose there are M evaluation factors, then $e_k$ (k=1, 2, , m) constitutes factors set. The corresponding weight of each factor is $w_k$ (k=1, 2, , m), and

$$\sum_{k=1}^{m} w_k = 1 \tag{1}$$

Step I: Constitute preferred relationship matrixes. According to the supposes, there are N decision-making alternatives under M evaluation factors, therefore M single-factor fuzzy preferred relationship matrixes are established, named $B_k$,

$$B_k = (b_{ij}^k)_{n\times n} \quad (k=1, 2, \ldots, m) \tag{2}$$

where $b_{ij}^k$ represents when evaluation factor is $e_k$, the priority relationship between $a_i$ and $a_j$, and values are as follows:

$$b_{ij}^k = \begin{cases} 0 & \text{when evaluation factor is } e_k,\ a_j \text{ is superior to } a_i \\ 0.5 & \text{when evaluation factor is } e_k,\ a_i \text{ equals } a_j \\ 1 & \text{when evaluation factor is } e_k,\ a_i \text{ is superior to } a_j \end{cases}$$

Step II: Transform matrixes $B_k$ (2) into fuzzy consistent matrixes $R_k$,

$$R_k = (r_{ij}^k)_{n\times n} \quad (k=1, 2, \ldots, m)$$

$$\text{where } r_{ij}^k = \frac{r_i^k - r_j^k}{2n} + 0.5, \ (r_i^k = \sum_{l=1}^{n} b_{il}^k, r_j^k = \sum_{l=1}^{n} b_{jl}^k) \tag{4}$$

Because $l = 1, 2, \ldots, n,$ are

$$r_{il}^k - r_{jl}^k = 0.5 + \frac{r_i^k - r_l^k}{2n} - 0.5 - (\frac{r_j^k - r_l^k}{2n} - 0.5) = 0.5$$

$$\frac{r_i^k - r_j^k}{2n} + 0.5 = r_{ij}^k \tag{5}$$

Through (5) to verify $R_k$ is fuzzy consistent matrix.

Step III: Calculate univariate priority. $s_i^k$ represents the priority of decision-making alternative $a_i$ (i=1, 2, …, n) under the evaluation factor $e_k$ (k=1, 2, …, m),

$$s_i^k = \frac{\overline{s_i}}{\sum_{l=1}^{n} \overline{s_l}} \tag{6}$$

$$\text{where } \overline{s_i} = \sqrt[n]{\prod_{l=1}^{n} r_{il}^k} \tag{7}$$

Step IV: Calculate multivariate priority. $S_i$ (i=1, 2, …, n) represents the comprehensive priority of

decision-making alternative $a_i$ (i=1, 2, , n),

$$S_i \quad \sum_{k=1}^{m} w_k s_i^k \quad (i=1, 2, , n) \tag{8}$$

Finally, the most preferred alternative among N alternatives under M evaluation factors is selected.

## 3. Results

*3.1 Patterns of University-led smart city research cooperation*

By analyzing 122 university-led research cooperation engaging smart cities research, the paper summarizes four types of cooperation patterns, named research project, research group, research institute, and research platform respectively (Table 5, Figure 4).

Table 5. Patterns of University-led smart city research cooperation by countries

| Countries | Research Project | Research Group | Research Institute | Research Platform | Total |
|---|---|---|---|---|---|
| Germany | 0 | 4 | 13 | 3 | 20 |
| Austria | 0 | 1 | 4 | 1 | 6 |
| Switzerland | 0 | 0 | 3 | 1 | 4 |
| Finland | 1 | 2 | 2 | 1 | 6 |
| Sweden | 0 | 2 | 5 | 2 | 9 |
| Norway | 0 | 2 | 3 | 0 | 5 |
| Denmark | 1 | 1 | 3 | 1 | 6 |
| UK | 1 | 4 | 14 | 2 | 21 |
| Ireland | 0 | 1 | 3 | 1 | 5 |
| Netherlands | 0 | 0 | 6 | 1 | 7 |
| Belgium | 0 | 0 | 1 | 1 | 2 |
| France | 0 | 1 | 11 | 1 | 13 |
| Italy | 1 | 2 | 4 | 0 | 7 |
| Spain | 0 | 1 | 5 | 1 | 7 |
| Portugal | 0 | 0 | 4 | 0 | 4 |
| Sum | 4 | 21 | 81 | 16 | 122 |

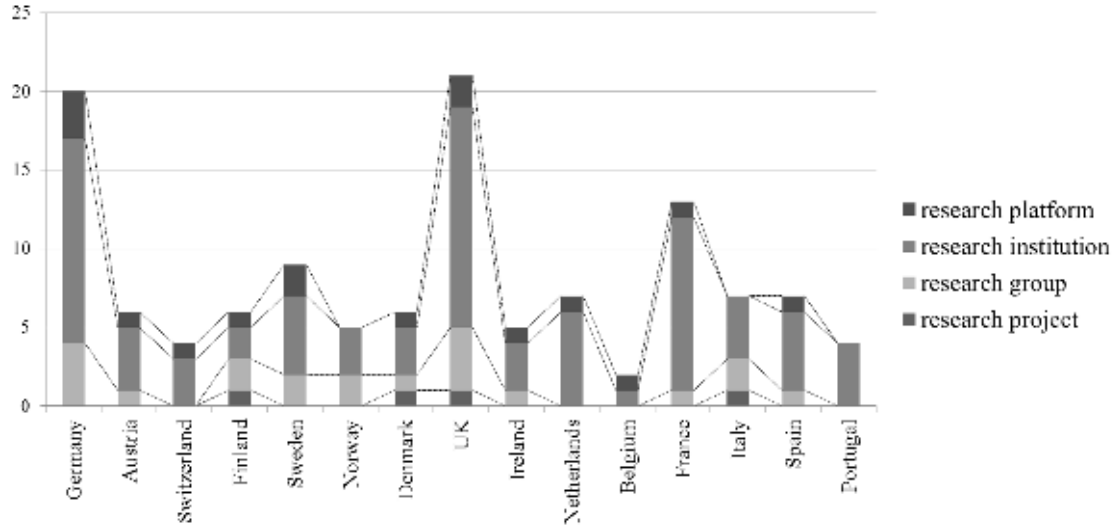

Figure 4. Patterns of University-led smart city research cooperation by countries

1) Research project

Research project pattern is research collaboration that based on one single research project related to smart cities, which is the most basic and simple cooperation pattern. Many of those cooperation projects are initiated by European Union research programmes. Some of them are sponsored by national research institutions, enterprises or local governments. Such kind of cooperation last for relatively short time, generally for the period of 3 to 5 years with loose organization structure. Smart cities research requires multidisciplinary and cross-regional researchers, those people and research resources join together to form temporary research collaboration.

2) Research group

Research group pattern is collaboration based on common research contents. Compare with research project pattern, this pattern forms a relatively long-term and stable research alliance. Those research groups are not joined because of one single research project, but joined to conduct a series research projects related to smart cities which are led by universities. The team size of research groups are small, there are rarely more than 50 people in the research group. And the organizational structure is simple, consisting of a team leader or co-leader, several professors and research staffs to form a close cooperation relationships.

3) Research institution

Research institutions are the most common type of collaborative research pattern, accounting for more than 65% of European universities-led smart city research cooperation. It is the most stable form of

cooperation. As the name implies, research institutions refer to the research entities that are long-term exist and conduct multiple smart cities research. These institutes could be est single school or department, by multiple schools and departments in the university as an interdisciplinary research organization, by one or more universities and by the government or EU. They could also be funded by enterprises to conduct joint research and technology transfer regarding smart cities. All these research institutions highly rely on universities taking charge of research and training programme, but they are individual institution.

The organizational structure of research institutions is much more complex than the former two research patterns. They have a clear division of responsibilities including teaching, researching and managing, especially for institutions having the task of teaching and training. Many institutions are origin from research groups or even research projects, after years of development they grow up as research institution, which is a more advanced research cooperation pattern.

4) Research platform

Research platform pattern is a more complex and sophisticated form of cooperation because they set a relatively virtual cooperation platform compare with institutions. On the platform, partners from universities, governments and business work together. This pattern of cooperation is relatively new and not as common as research institutions. Research platform pattern has the highest potential to organize and form a wide national and international cooperation.

The core of the platform is managed by one university or multiple universities who are taking charge of arranging scientific research projects, conferences and seminars. Another important work for those people is recruiting different researchers from other institutions, universities, companies etc. based on research needs. Therefore, after each time of research cooperation, the collaborative network will be expanded. Research platforms integrate more potential research resources include the talent, technologies and facilities in order to form a greater cooperation network. This kind of cooperation also attracts universities and governments attention financial supports.

However, this pattern of research cooperation also has disadvantages. The platforms are not entities, whose researchers and research places are unstable for the most of research platforms, which increases the difficulty of cooperation. There are less research results made by the platforms than stable research institutes, and many of research results are conferences articles and working papers. They need more practical research results like technologies, planning methods, books etc. But it is undeniable that research platform is an innovative pattern of research cooperation, especially with the rapid development of ICT. The platform partners can cooperate by teleconference and the internet, there is no need to do research face to face in a fixed place, thus the research platform will better adapt to

these changes. In summary, the similarities and differences of four types of research cooperation patterns are listed below (Table 6).

Table 6. Comparison of university-led smart city research cooperation patterns

| Items | Research Project | Research Group | Research Institute | Research Platform |
|---|---|---|---|---|
| Research projects | Single | Multiple | Multiple | Multiple |
| Team size | Various | Majority small size | Majority middle, large size | Various |
| Cooperation partners | Multiple | Multiple | Single or Multiple | Multiple |
| Cooperation methods | Interdisciplinary | Interdisciplinary | Interdisciplinary | Interdisciplinary |
| Organization | Simple | Simple | Complex | Complex |
| Stability | Short-time, unstable | Short-time or long-time | Long-time, most stable | Various, unstable |

*3.2 Preferred cooperation selection*

Suppose there are 4 cooperation alternatives, respectively research projects ($a_1$), research groups ($a_2$), research institutions ($a_3$) and research platforms ($a_4$). And suppose there are 5 aspects of evaluation factors, considering both internal factors and external environmental factors, respectively smart cities research fitness ($e_1$), operational or management difficulty ($e_2$), research mainstream adaptation ($e_3$), economic benefits potential ($e_4$) and European policies compliance (e5). See Table 7.

Table 7. Evaluation factors of university-led smart city research cooperation

| Categories | Factors | Name |
|---|---|---|
| Internal factors | Smart cities research fitness | $e_1$ |
| | Operational or management difficulty | $e_2$ |
| External factors | Research mainstream adaptation | $e_3$ |
| | Economic benefits potential | $e_4$ |
| | European policies compliance | $e_5$ |

1) Smart cities research fitness means whether the research cooperation pattern are suitable for conducting smart cities research because smart cities research need interdisciplinary researchers and inter-regional or international collaborations. The more partnerships in the research, the more ideas and intellectual benefits generate during the cooperation. From this point of view, research institution and platform patterns are superior to research project and group patterns because they have larger cooperation network.

2) Operational or management difficulty means whether the research cooperation demands more inputs of personnel, facilities, funds and time. Although the institution and platform pattern will attract more partnership, multi-institution and inter-regional cooperation tend to have less frequent and effective collaboration but more often diverging interests, free-riding and conflicts (Adams et al., 2005; Cummings and Kiesler, 2007). That is, they will experience more difficulties and complexities during the cooperation research processes.

3) Research mainstream adaptation means whether the research cooperation is common and effective cooperation pattern that is required by urban planning research and innovation development. The extensive research cooperation provides more shared resources and expertise, which are required by smart cities research in the field of urban planning.

4) Economic benefits potential means whether the research cooperation will contribute to generating more economic benefits and attract research funding and contracts. Despite the fact that research institution and platform patterns have more potential partnerships, multilateral cooperation foster more coordination cost because of geographical distance and institutional differences (Cummings and Kiesler, 2007; Hoekman, Frenken and Tijssen, 2010). Further study shows that research organizations and project teams within one institution is more effective in integrating research resources and expertise and more likely to be successful.

5) European policies compliance means whether the research cooperation is encouraged in European context (e.g. the research projects under the research framework of European Union), and whether the cooperation supported by national or local governments. Since more significant public funding are used to foster inter-regional and transnational research collaborations in Europe, perhaps research platform is more preferred by the policies.

Adopting Fuzzy Consistent Matrix to select the most preferred cooperation pattern for university-led smart city research. First, constitute preferred relationship matrixes as below:

$$B_1 \begin{matrix} 0.5 & 0.5 & 0 & 0 \\ 0.5 & 0.5 & 0.5 & 0 \\ 1 & 0.5 & 0.5 & 0 \\ 1 & 1 & 1 & 0.5 \end{matrix} \quad B_2 \begin{matrix} 0.5 & 0.5 & 1 & 1 \\ 0.5 & 0.5 & 0.5 & 1 \\ 0 & 0.5 & 0.5 & 0.5 \\ 0 & 0 & 0.5 & 0.5 \end{matrix} \quad B_3 \begin{matrix} 0.5 & 0.5 & 0.5 & 0 \\ 0.5 & 0.5 & 0 & 1 \\ 0.5 & 1 & 0.5 & 0.5 \\ 1 & 0 & 0.5 & 0.5 \end{matrix}$$

$$B_4 \begin{matrix} 0.5 & 0 & 0 & 0.5 \\ 1 & 0.5 & 0 & 0.5 \\ 1 & 1 & 0.5 & 1 \\ 0.5 & 0.5 & 0 & 0.5 \end{matrix} \quad B_5 \begin{matrix} 0.5 & 0.5 & 0.5 & 0 \\ 0.5 & 0.5 & 0 & 0 \\ 0.5 & 1 & 0.5 & 0.5 \\ 1 & 1 & 0.5 & 0.5 \end{matrix}$$

Second, transform 5 matrixes $B_k$ (k=1, 2, 3, 4, 5) into fuzzy consistent matrixes $R_k$ (k=1, 2, 3, 4, 5):

$$R_1 = \begin{matrix} 0.5 & 0.4375 & 0.375 & 0.1875 \\ 0.5625 & 0.5 & 0.4375 & 0.25 \\ 0.625 & 0.5625 & 0.5 & 0.3125 \\ 0.8125 & 0.75 & 0.6875 & 0.5 \end{matrix} \quad R_2 = \begin{matrix} 0.5 & 0.5625 & 0.6875 & 0.75 \\ 0.4375 & 0.5 & 0.625 & 0.6875 \\ 0.3125 & 0.375 & 0.5 & 0.5625 \\ 0.25 & 0.3125 & 0.4375 & 0.5 \end{matrix}$$

$$R_3 = \begin{matrix} 0.5 & 0.4375 & 0.375 & 0.4375 \\ 0.5625 & 0.5 & 0.4375 & 0.5 \\ 0.625 & 0.5625 & 0.5 & 0.5625 \\ 0.5625 & 0.5 & 0.4375 & 0.5 \end{matrix} \quad R_4 = \begin{matrix} 0.5 & 0.375 & 0.1875 & 0.4375 \\ 0.625 & 0.5 & 0.3125 & 0.5625 \\ 0.8125 & 0.6875 & 0.5 & 0.75 \\ 0.5625 & 0.4375 & 0.25 & 0.5 \end{matrix}$$

$$R_5 = \begin{matrix} 0.5 & 0.5625 & 0.375 & 0.3125 \\ 0.4375 & 0.5 & 0.3125 & 0.25 \\ 0.625 & 0.6875 & 0.5 & 0.4375 \\ 0.6875 & 0.75 & 0.5625 & 0.5 \end{matrix}$$

Third, calculate univariate priority according to the formula (6,7):

$s_1^1$=0.1823, $s_1^2$=0.3151, $s_1^3$=0.2185, $s_1^4$=0.1823, $s_1^5$=0.2176;

$s_2^1$=0.2168, $s_2^2$=0.2827, $s_2^3$=0.2500, $s_2^4$=0.2506, $s_2^5$=0.1846;

$s_3^1$=0.2506, $s_3^2$=0.2176, $s_3^3$=0.2814, $s_3^4$=0.3502, $s_3^5$=0.2827;

$s_4^1$=0.3502, $s_4^2$=0.1846, $s_4^3$=0.2500, $s_4^4$=0.2168, $s_4^5$=0.3151;

Finally, calculate multivariate priority $S_i$ (i=1, 2, 3, 4) according to the factors weights belo
8):

Table 8. Weights of evaluation factors

| $W_1$ | $W_2$ | $W_3$ | $W_4$ | $W_5$ |
|---|---|---|---|---|
| 0.27 | 0.18 | 0.13 | 0.17 | 0.25 |

The comprehensive priority of cooperation patterns are $S_1$=0.2197 $S_2$=0.2307 $S_3$=0.2736 $S_4$=0.2759, and $S_1<S_2<S_3<S_4$. The results indicate that considering these five factors or criteria, research group pattern is superior to research project pattern, and the research institution and platform patterns are superior to the former two. But the difference between institution and platform pattern is extremely small. It should be noted that the four types of cooperation patterns have no absolute priority, but have preferred solutions under different conditions.

## 4. Conclusion

European university-led smart city research has a range of cooperation patterns which are innovative and have deep insights of smart city research. A growing number of urban research institutions join in the research of smart cities, and more smart city research platforms will be set up in the future.

For large-scale smart city research institutions, which have better research projects and networks, the pattern of research platform will help them move one step further. By multi-disciplinary partnership s participation and interaction, the research platform expands the collaborative network of institutions and organizations. As for smaller smart city research groups, whose strength is the flexible and weakness is lack of enough research projects and funds. The platform pattern will help them attract more partnerships and to be better involved in collaborative research. And the platform pattern would not spend too much organization and management cost, only a small group of people could take charge of the daily works.

However, despite the high potential to become the most promising research cooperation pattern, the research platform also has its own flaws. For example, the organizational structure is looser compare with research institutions, which makes it difficult to function efficiently and have substantial research results. In order to deal with the situation, the platforms need to set up management teams for taking charge of publishing working paper, contacting with their research members regularly, publicizing the collaborative research results through internet and other advanced technologies. Research platforms should cooperate with institutions who already have good research foundation and extensive research cooperation network, and making full use of those advantages. Moreover, the universities and local governments should encourage this kind of research pattern and involve in the research network, thus help promote further development of smart city research.

# Study on Public Participation of Urban Planning in the Age of Big Data

Hexia ZHANG, Xiaoming KUANG, Lu WANG, Jun CHEN

Shanghai Tongji Urban Planning & Design Institute, Shanghai, China, heskia717@hotmail.com

*Abstract: Along with the development and popularity of the information technology, the concept of big data has gradually come to public attention. A variety of new data types and new data sources have greatly expanded the data view of urban planning. On the one hand, it has formed a new method of public participation in urban planning, on the other hand, it has also provided a new analysis tool for the research of urban planning. This study, taking big data, urban planning and public participation as the starting point, tried to seek the best combination and establish a potential bridge among them. In this way, planners can not only apply the new technology into urban planning, but also deeply understand the urban planning during the technology development. As a result, a visual, dynamic and interactive smart city platform will be built to improve the ability of information exchange and the level of public participation. As a reaction, public participation, with the mining of diverse knowledge and the participation of multiple thinking, can also ref*ine planners understanding of urban planning, *is favorable to their policy behavior. Therefore, in the stage of practical application, with the new technology such as big data, planners can transport and release information, citizens can sharing experiences and present opinions, decision-makers can absorb suggestions as references for urban planning.*

Keywords: public participation, urban planning, big data

## 1 Introduction

Along with the development and popularity of the information technology, the concept of big data has gradually come to public attention. A variety of new data types and new data sources have not only greatly expanded the data view of urban planning, but also quickly promoted the innovation of thinking mode, value guidance and technical method in urban planning. Through the transition of urban planning, which is form simple observations, fragmented statistics and rough sets to complex simulation, dynamic evolution and subtle individual, big data will provide infinite possibility for urban informationization construction and management.

Since the Urban and Rural Planning Law firstly established the mechanism of public participation in urban planning on January 1, 2008, public participation has become the impetus for the further development of urban planning. The core value of public participation is to encourage people to actively participate in urban planning and explore various knowledge sources with the aid of technology. Through the participation and integration of multidimensional thinking, designers and decision-makers can refine the understanding of city and improve the precision of policy.

So we can say that big data and public participation are the two significant trends of urban planning transformation. However, in practice, we find that the basic data needed for urban planning are collected, processed and used by different functional departments separately, thus information isolated island will be formed and cannot support the rational analysis and scientific research. Moreover, obstructed channels and the imperfect mechanisms of public participation also restrict the public demands expression for urban planning, construction and management.

Therefore, this study tried to seek the best combination and establish a potential bridge among big data, urban planning and public participation, aiming at providing technical support and decision basis for scientific and rational urban planning.

## 2 Connotation of big data

Big data is a huge set of concepts, referring to the vast, diversified and rapidly increasing information property, which has the stronger power of decision-making, insight and optimization due to the new processing mode. Michael Batty, a British scholar, has pointed out: Big data i fit into an Excel spreadsheet. (Batty, 2012) He revealed the double connotation of big data. Firstly, the data sample size of big data is large enough. Secondly, big data is not a new concept, but a sample quantity expansion of traditional small sample data analysis. That means the analysis space can be fully covered only based on the sample data, and then the analysis result will be displayed intuitively.

Volume , velocity, variety and value, as the 4V advantages of big data, provi platform between users (Philip Chen and Zhang, 2014). However, These advantages also result in several problems, such as available data explosion and public demand diversification. The generation of SoLoMo precisely makes it possible to obtain extensive data and promote public participation. Social, Local and Mobile are the most representative technological concept of SoLoMo, which brings Social Networks Service, Location Based Service and Mobile Terminal together. It is this immediate information interaction and transmission that meets the needs of public participation in urban planning to a great extent.

### 2.1 Social Networking Service (SNS)

Social means an online community created by individuals having the same interests based on social networking service (SNS). This kind of service always bases on internet and provides various interactive platforms for user connection and communication. It gives data specific social attribute, and makes the process of data propagation predictable and traceable. At the same time, This kind of platform generally extends and spreads by the realistic social relations, so it is able to provide indirect description of the individual information source to a certain extent. The vast amount of users with specific social attribute are the objective foundation of directive data collection and broad public participation.

Sina Weibo, as a SNS platform for information sharing, spreading and obtaining based on user

relationship, can accomplish text update, information publish and instant share. The basic characteristic of Sina Weibo is to encourage the target audiences to pass message to others, forming a new dissemination mode that the exposure and influence grow at a geometric rate. Relying on the social networking tools represented by Sina Weibo, on the one hand, planners can spread urban planning knowledge more effectively, on the other hand, public can express their appeals and maintain their rights with the help of network platform.

## 2.2 Location Based Service (LBS)

Local, as the core of SoLoMo, is the mapping of the individual users of network virtual world in the real physical space. Through the location based service (LBS), it can record the geographical location and give data spatial attribute. The main functions include localization (individual position orientation), guidance (path navigation), query (query somebody or something), recognition (recognize human or object), event trigger (send a message to the individual in a particular situation). Data generated in these function processes precisely can provide objectively true individual behavior records for urban planners.

LBS focus on obtaining the spatial position and behavior of individuals. However, spatial resources allocation, as the most central question of urban planning, involves a large number of the spatial, social and economic information which is always difficulty to obtain. GIS technology can provide the perfect database organization, lively visual interface and 3D real feelings. What s more, WebGIS, the internet platform and getting rid of GIS tool software, enable public to easily obtain the comprehensive information by web browser and even directly present their opinion on planning scheme. That is called the PPGIS, which is internationally popular in recent years. It can provide spatially-related information service for LBS with the support of GIS.

## 2.3 Mobile Terminal

Mobile terminal is a terminal that with which individual can produce and receive data. It mainly includes smart phones, tablet computers and various application programs based on them. Related technologies involve global position system (GPS), gyroscope, acceleration transducer, augmented reality (AR), two-dimensional code or other things networking technology such as NFC. Mobile terminal, with perfect multi-media capability and a large number of interactive technology integrated in small devices which are easy to carry and hold, has already become the substantial platform that recording specific individual behavior, raising public planning awareness and expressing public subjective willingness. Along with the growing popularity of different kinds of mobile terminals, they are gradually taking the place of desktop PCs and becoming the main medium of SNS and LBS.

For different events or locations, developers can develop specific mobile terminal applications to popularize urban planning knowledge and encourage public participation. However, the technical threshold of native APP development is relatively higher. Therefore, in the public participation, developers can make an easy secondary development relying on the social platforms, so that users can

interact information with PPGIS server and query content in the social platform interface. Through uploading photos and comments with location information, which can be viewed and analyzed by planners and public, the traditional working mode of urban planning will be changed. So, we can expect that using mobile terminals and application programs to encourage public participation in PPGIS will quickly gain in popularity as an easier and better way.

## 3 Public participation mechanism in urban planning

SoLoMo, as an integrative concept generated in the age of big data, corresponds to the public thinking mode in today's society and integrates into life in all aspects. SoLoMo application can effectively protect the informed right of public, widely collect and analysis data produced by public, promptly provide various expression ways for public. Thus, it can improve the public participation mechanism in urban planning and guide the design effort to proceed in an orderly way.

### 3.1 Extend the ways for public understanding

SoLoMo, with its unique attributes, fills in the blanks of information dissemination and presentation media of traditional urban planning at different aspects and levels, and gradually becomes an important way for public to understand urban planning. With the portability of mobile terminals and the transmissibility of social networks, SoLoMo provides a professional and dynamic display platform of urban planning for public.

Take the application of AR technology in dynamic presentation as an example. AR technology, applies the virtual information to the real world and overlays virtual objects, scenes and system prompts generated by computer onto the real scenario, thus achieves the aim of reality augmentation. Relaying on LBS, the individual geographical location can be positioned accurately. Thereout, applying AR technology to mobile terminals can provide specific scene information and real tour experience. In the meantime, using the angular sensor technology can accurately analysis the individual orientation and angle, which contributes to provides the appropriate visual angel pointedly. What s more, SNS also provides convenient transmission ways and wide user base for this platform, which enables AR technology to apply to the scheme demonstration phase of urban planning through SoLoMo. This dynamic and vivid demonstration, low requirements on professional knowledge and rich in interesting, is very applicable to public-facing planning scheme notification.

### 3.2 gather the data generated by the public

In the context of big data, urban planning pays great attention to public participation, and emphasizes to introduce public city image into planning and design. City image, drawing from the traditional ways such as questionnaire survey, still has deficiencies in sampling quantity, manifestation mode and so on. However, SoLoMo can not only enlarging the sample size, but also embody the abstract conception in the geographic space accurately. As for the data produced by public, it has the advantages of immediacy,

dynamism, universality and convenience. Therefore, it can promote the dynamic recording of city image in urban planning and the interaction between them, making it possible for the city image to guide the planning and design.

Take the area boundary definition by Flickr as an example. Flickr, composed of mobile terminals, application programs and websites, is a platform that provides storage and sharing service for digital photos. Based on the support of social network and GPS, The core characteristics of Flickr include enlarging and reorganizing the data uploaded by users, giving images attributes such as longitude and latitude described by users. Livia Hollenstein and Ross S. Purves reanalyzed the boundary of the city center of London with Flickr data. Through filtering the labels of the images uploaded by users, they collected the image data with labels of Northlondon, Innercity, Eastlondon and Camden, Mayfair, Soho, thus they analyzed the spatial data distribution and obtained the density gradient variation.

### 3.3 Enrich the public feedback means

SoLoMo can spread messages efficiently and rapidly between mobile terminals with the support of social network. Its feedback mechanism follows the laws that from point to surface and from bottom to top. In the field of urban planning, it is always from practitioners including planners and designers to public, then to more practitioners, finally to decision-makers. With the guidance of practitioners, on the one hand, public interest is widely attracted, leaving the specific incidents as society hot spots, on the other hand, a large section of public opinion will draw the attention of more practitioners. Therefore, the discussion environment, integrating social public and professional planners, is mutual complementation and mutual benefit.

Take the reconstruction project for Enning Road as an example. Enning Road is the most complete and the longest arcade-house street in the city of Guangzhou. From the year of 2007, Liwan District Government began the large-scale old city reconstruction for this road. In the process of multilateral game, the scheme has been changed multiple times and the reconstruction has come to a deadlock. The academic concern group of Enning road reconstruction was founded in March 2010. Its members include undergraduates and volunteers, and their majors involve urban planning, architecture, sociology, economic, geography, journalism, etc. Through the further study and accurate evaluation of the situation of Enning road reconstruction project, The group, as a third party different from governments and residents, provides professional advices for the old city planning and development. It devotes itself to improving the government consulting process, rationalizing the resident compensation plan and building the discuss platform for all relevant stakeholders. At present, this group are gradually integrated into the residents of Enning road. They jointly drive the implementation of the organic renovation way, whose core ideas are government leading, public participation, gradual treatment and incremental improvement (Zhou Kai, Yan Yan and Song Bin, 2012).

## 4 Realization of public participation in the urban planning of big data era

In the age of big data, a platform is needed to realize the public participation of urban planning. This platform, is not a graphics design platform such as CAD, but a broader platform which provides public participation and use based on GIS technology (Batty, 2013).

### 4.1 Involuntary participation: public participation of urban planning

Public participation in traditional urban planning is voluntary. That means participators provide information for urban planning consciously. However, participators involved in this public participation form are restricted, and the information provided by participators is mainly limited by their spirit of dedication and degree of participation.

Urban planning in the age of big data places more emphasis on involuntary public participation. Nowadays, urban residents are in numerous digital networks, such as mobile communication, bank, GPS, etc. Public will inconsciently leave their daily digital paths, while they are getting benefit from the web service. These digital paths can fully reflect the real life of urban residents. The data, as the product of urban residents daily digital paths, will be more helpful in promoting urban op if it is once associated with data from other sources. Thus, it can guide the environment-adapted and futurity-oriented planning decisions.

### 4.2 Induced using: construction of public participation platform

Based on the principle of involuntary public participation, induced using has already become the basic principle for constructing public participation platform in the age of big data. Induced using, including benefit-induced using and interest-induced using, can construct the public participation platform of urban planning with the help of corresponding forms such as services, games and forums.

Take the icity program in England as an example. With the help of infrastructure constructions such as wireless networks and sensors, it have already established a service platform, which includes climate information release and public facility use, etc. Through inducing residents and encouraging the third parties such as developers, small and medium enterprises, neighborhood associations to use the data produced during the use phase of icity, decision-makers can discovery the public interest, improve the service strategies and increase the service content. As another example, the students from HafenCity University Hamburg designed a game named B3 (Murgante, Gervasi, Iglesias, et al., 2011), when they were designing the market update in the district of Billstedt. This game makes residents to design the infrastructure constructions in their heart such as squares, seats, trees and children playgrounds, and induces the data reflecting the habit and willingness of residents to generate. In addition, Brain McGrath, an American scholar, established the virtual space platform and the on-line forum system about urban evolution in the urban design of Roman with the spatial data of archaeology and the temporal data of systematology. Through inspiring the passion of public participation, urban design will become the city image advocated by most residents rather than the city simulation created by few experts.

### 4.3 Data visualization: construction of urban planning platform

Traditional urban planning, only relying on the point-line-surface cartography mode, can t fully expression the complex information which implies non-space data. The design platform of traditional urban planning can boil down to the mapping platform of design achievements, while that of the urban planning in big data era is not only the expression platform of design achievements, but also the exchange platform which provides data analysis with abundant visual representation.

Data visualization technology developed in recent years will efficiently solve the problem of urban planning platform construction in the age of big data. Data visualization can realize the data analysis and communication with the application of tables, diagrams, pictures and other intuitive data visualization mode. Accordingly, it can inspire the public participation. The theory comes from the perception study of brain science. When all sense organs of human are perceiving things, 70% information is obtain by eyes. What s more, eye is the sensory organ whose perce (Long and Dhillon, 2014). On the one hand, the visualization function of human eyes can analyze a mass of abstract data, and the new data analysis technique can amplify and expand the human eye vision. On the other hand, the creative nature of human is benefit from the mutual action of the logical thinking and imagery thinking, therefore, massive amounts of spatial data and non-space data can inspire the imagery thinking and creativity of human only through the data visualization technology (Post, Nielson and Bonneau, 2003).

Data visualization technology will encourage designers, managers and public to understand and participate in the whole process of urban planning. Moreover, in the circulatory design flows, public can constantly feedback information and designers can accordingly modified result. Therefore, it is necessary to construct the data analysis platform and the design communication platform in the urban planning platform of big data era. The data analysis platform synthetically integrating the machine learning algorithm, can capture the corresponding social-networking data. With the correlative thinking of big data and knowledge discovery, the visual interface whose data updated automatically and timely will be established to induce more public to focus on and participate in data feedback. The design communication platform, based on the visual interface of data analysis platform, builds the visual interface for design scheme and the feedback environment for plan implementation and public participation. It can provide instant feedback on the dynamic data of public participation and plan implementation and timely correct the design scheme.

## 5 Conclusion

Big data can provide the ideal public participation platform for urban planning and realize the long-distance communication. With the help of the platform such as e-government and SNS, which play an important role in information disclosure and positive interaction, a new paradigm of public participation in urban planning will be created to change the traditional urban management pattern and the urban planning process.

The appearance of big data realizes the real-time dynamic interaction and communication of government, planners and public in the process of planning investigation, scheme development, planning evaluation, plan implementation, etc. It is conducive to promoting the scientification and humanization of planning process and advancing the democratization process of urban planning. Moreover, with the big data analysis of urban planning, construction and management expressed by public through e-government and SNS, government and planners can promptly adjust the urban spatial layout, optimize the public service facilities allocation and innovate the urban management pattern.

However, big data only provides the tools and methods. To realize the real public participation and scientific planning still need the unremitting efforts of planners. With the open attitude and scientific spirit, planners can really exert the advantage of big data to provide a key support for urban planning under the background of new urbanization.

# TRACK 17

# Ethics and Justice in Planning

## Track description

Co-chairs: **Simin Davoudi**, **Willem Buunk**

In recent years, there has been a growing interest in research into normative and moral aspects of planning in both planning practice and theory. This includes concerns over justice and fairness as well as a number of other values such as aesthetics, safety, health and wellbeing. This track is open to papers that provide a deeper understanding of the wide range of ethical and moral dilemmas with which planning practice and theory are confronted.

The pursuit of justice is seen as central to the justification of political authority and political obligation. In this sense justice often has a legal connotation and is about how people are treated. Another meaning of justice is how society s benefits and burdens are distribu distribution is decided upon. In the past few decades planning theory has been largely preoccupied with just processes and appears to have paid less attention to just outcomes. We suggest that such dichotomous position is not helpful and instead planning theory and practice should embrace the concept of just planning defined broadly in terms of distributi ognition, capability and responsibility, without subsuming any one of these into another. Despite the acknowledged significance of such inclusive understanding of justice, the bulk of justice studies continue to focus on distribution. We welcome papers that aim to fill the gap.

In addition to issues of justice and fairness, planning involves a number of other social, economic, cultural and environmental values. The process through which these are defined, debated and prioritised is a contested one and riddled with complex power-knowledge relations. Planners in their daily practices and thoughts are immersed in a wide variety of moral concerns and values, some of which become overt while others remain implicit. Clearly articulating these normative issues is in itself a major challenge, but one that planners ought to aspire to.

In this track we welcome papers that critically engage with a) theoretical debate on ethics, justice and other moral concepts and normative value, b) provide practical examp good/bad approaches to spatial development and (un)ethical practices in p light methodological challenges of assessing claims of justice, ethics or other moral concerns. We welcome papers that address any of the above questions theoretically or empirically and challenge the taken for granted assumptions about just planning , good planne outcomes of planning. We look forward to receiving your papers and having stimulating discussions in Prague.

# ASSESSING LAND TAKE IMPLICATIONS FOR ENVIRONMENTAL JUSTICE: A CASE STUDY USING THE ECOSYSTEM SERVICES APPROACH

Francesca Assennato [1-2], Luca Congedo[2], Giacomina Di Salvo [3] and Andrea Strollo[1]
[1]*Sapienza University of Rome, francesca.assennato@uniroma1.it*
[2]*Italian environmental protection and research institute ISPRA,* [3]*Architect PhD in Town and Regional Planning, Italy.*

Key words: Ecosystem services, land take, environmental justice

Abstract
*Land take is consuming a non-renewable resource and an essential one to human wellbeing?, with relevant social impacts and different implications as far as several sectors of the economy are concerned (EC, 2012). Assuming that (a) right livelihood is based on ecological balance and social justice (Shiva, 2008) land take may be considered as an unjust practice, in terms of fair share, equal opportunities, recognition and participation of present and future generations. Within the frame of the Land System Science (Verburg et al., 2013; Turner et al., 2013), the relationships between land take and environmental justice is analysed through the lens of the ecosystem services (ES) approach (MEA, 2005). ES evaluation is a challenge to be undertaken by planners (De Groot et al. 2010) because it enables the assessment of the benefits that the natural environment provides to human well-being and can help to assess environmental justice claims.* A case study has been carried out for one of F *15 wards, the X Municipality, where large amount of green land was built up in recent years and more is expected in the future causing relevant impacts such as increasing flood risk, overloading of existing drainage and sewage systems, loss of agricultural land, natural area fragmentation. A GIS-based semi quantitative assessment of relevant ES has been conducted, and a number of experts (including scientists and local administrators) have been consulted to gather their views on values and responsibilities connected to land use change occurred in the area. The case study draws out lessons for an analytical framework that operationalizes the ecosystem services approach to assess environmental justice land take implications.*

## 1. Introduction

How to assess and manage social inequality resulting from land-use changes, in particular those produced ad consequence of land take and unequal access to ecosystem services? This is the question we are trying to answer in this paper, using ecosystem services (ES) approach (MEA, 2005) as a lens to analyse the relationships between land take and environmen evaluation is a challenge to be undertaken by planners (De Groot et al. 2010) because it enables the assessment of benefits that the natural environment provides to human well-being and can also help to assess environmental justice claims .
The X (10th) District case study was selected both because of the relevant land take acted in the area in recent years and for the expected further changes in next future. impacts such as increasing flood risk, overloading of existing drainage and sewage systems, loss of agricultural land and natural area fragmentation are increasing In the area together with land take.
The way land use changed and loss of natural soil took place in the area brought to unequal access to ES, influencing environmental conditions and causing justice concerns. The expected further transformation, planned in 2008, made the X District an interesting opportunity to analyse potential land take and ES impacts on environmental justice.

## 2. Background and conceptual framework

Concepts of Environmental Justice, land take, and Ecosystem Services are integrated in the proposed methodology, with the assumption that the effects of land take on ecosystem services profoundly influences environmental justice in the study area.

*2.1. Environmental justice*

Recognizing that a right livelihood is based on ecological balance and social justice (Shiva, 2008), there is a concern about distribution of scarce resources between present and future generations and between social classes, but also about people s capabilities to access these resources with framework of participation and democracy (Sen, 2009). In this framework, land take must be considered as an unjust practice, which relates to efficient and fair use of present resources, to the equal opportunities between present and future owners, and to a just consideration of local issues and participation of communities.

The environmental justice (EJ) is a multifaceted concept, emerged first in US in the early 1980s from environmental activism struggling against polluting facilities, and then addressing social factors like income, race and other socioeconomic variables and disparity in hazard levels and environmental quality. The EJ debate has been further developed by the political and the academic spheres, leading to a four dimension concept of Environmental inequality (OECD, 2006; UK Environment Agency, 2007; Pye et al.,2008) that are: exposure and access inequalities (distribution of environmental quality/goods); policy inequalities (effect of environmental policies); impact inequalities (different environmental impact of individuals and social groups with regard to their incomes and/or lifestyles); policy-making inequalities (access to environmental policy-making).

Integrating environmental and social initiatives at the local level, with the objective of achieving more sustainable environmental and social policies, is possible with a common objective (Pye, 2008). In these terms analysing the potential of ES scheme to address social dimension of ecosystem benefits could lead to a new synergy making environmental policies more equal.

Following the growing interest in studies addressing urban ecosystem services distribution by race, ethnicity, socioeconomic class, and other demographic characteristics and studies on social-ecological resilience and adaptive governance of ecosystem services connecting fields like ecology, planning, and law, there is a promising research area addressing the distributional impacts of providing ecosystem services and the challenges posed by pursuing environmental equity, in order to guide decision makers to equitable urban ecosystem services provision (Salzman et al. 2014). The main research questions emerging from these studies are: how to incorporate environmental equity and justice concerns into planning for ecosystem services? Should certain ecosystem services (e.g. parks and green space) be prioritized over others? How to deal with the impact of pre-existing levels of environmental inequality in a community and which inequality to address first? Which stakeholders must be involved in policy making?

In this context, several studies considering equitable environmental benefit provision, such as ecosystem services, are becoming more common and highlight some interesting research area (Ernstson, 2013).

Considering that the main issue is related to assuring environmental equity and justice in accessing ecosystem services, this paper tries to integrate land take, ecosystem services and inequality in a methodological approach that includes the quantification of land take, the assessment of land take impacts on ecosystem services, and the assessment on inequality in the case study, analysing main factors in decisional process through a network analysis, as proposed by Actor-Network Theory (Latour, 2005).

*2.2. Land System Science and land take*

As highlighted by the Guidelines on best practice to limit, mitigate or compen the European Commission (European Commission, 2012), soil provides a great variety of ecosystem services with direct and indirect use value for humans.

In the last few years, the increase of land take in Europe has been mainly driven by demand for industrial, commercial infrastructures, and transportation, without a direct correlation to demographic growth (Indovina, 2009). Consequently, the attention towards the land take issue has increased in the last decade, particularly at European level with the Thematic Strategy for Soil Protection (European Commission, 2006; European Commission, 2011).

In this conditions of increasing land take, the unjust social and economic effects shall be addressed by national policies particularly those dealing directly with spatial planning and land management to achieve a more efficient, sustainable and durable use of natural resources. The European Union developed a specific environmental monitoring product (i.e. Degree of Imperviousness) in the frame of the Copernicus initiative, which aims to foster the assessment of land take and urban fragmentation at regional and local level (European Commission, 2014). Moreover, the role of ecosystem services related to soil is crucial in the mitigation and adaptation to extreme events such as floods or droughts (European Commission, 2014). In fact, land cover change caused by human activities has indirect effects on climate processes (i.e. non-climatic driver) because of the role of soil in carbon fluxes and greenhouse gas emissions (IPCC, 2001).

Considering the complexity and interrelation of land cover change and environmental phenomena, this study endorses the framework of Land System Science (Verburg et al., 2013), which is a set of disciplines that aims to understand the relationship between urban development and impacts on ecosystem services. In particular, the Land System Science considers land cover change as cause and effect of climate change, which allows to analyse the interrelation between ecosystem services and adaptation in order to improve policies and planning processes (Verburg et al., 2013). In order to assess ecosystem services, land cover monitoring of urban and peri-urban areas through remote sensing can be both affordable and efficient in order to support planning processes (Maes et al., 2012; Brook and Davila, 2000), allowing the assessment of land cover change and the impacts thereof on ecosystem services (Chen, 2013). This study used a built-up map developed by ISPRA using remote sensing images and semi-automatic classification techniques.

### *2.3. Ecosystem services approach and methods*

The role of soil in the ecosystem is fundamental because of the provided services in terms of food production, biodiversity, and sustainability (Lal, 2005). The comprehension of how the land use trend can affect the ecosystem services is an innovative tool in the planner s hands benefits that people obtain from ecosystem (MEA, 2005) can be used by the pu as an incentive to reduce the soil consumption and the urban sprawl. It should be noticed that an exclusively monetary evaluation of ecosystem services has the main risk of underestimating the natural resource values, and generate a trade based on compensation, with evident unequal effects on poor people and countries. The purpose of evaluation should be to associate a value to the soil as a resource with a unit of measure easily comprehensible by everyone in order to motivate the public opinion to avoid its uncontrolled urbanization.

In this study, we analyse two individual ecosystem service as a demonstration of the evaluation method proposed: carbon storage and habitat quality. The economic value has not been defined. It must be pointed out that crop production is the only ecosystem service with financial data available. In evaluation of the first ecosystem service, habitat quality, the average agricultural values have been linked to the land use classes to get a picture of the crop production extent in the area. Average agricultural values do not represent cost of production but the expropriation price of the land. Another ecosystem service evaluated is carbon sequestration. Ecosystems regulate the atmospheric concentrations through the carbon flows, playing a role in regulating the Earth climate. Soil ecosystems have a great carbon absorption capacity. Capturing carbon, not binding the oxygen in the atmosphere, lead to a prevention in the greenhouse gas formation such as carbon dioxide.

## 3. Methodology

The research focuses on land take, as one of the major drivers in reducing, unequally, the ecosystem services. Once established the linkage between ecosystem services and environmental justice, the case study analyses the land take amount, the effects on the ecosystem services and the inequalities in this situation. The target is to provide useful tools for the planner, the end user of the study.

X District was chosen because of the relevant land take in past years and for the remarkable social differences at local and urban level.

The proposed methodology used to relate Ecosystem Services of Land with Environmental Justice, implies a comparison of outcomes from a public consultation at the local level and two different environmental evaluation about land take and ecosystem services in the area. The focus is to highlight impacts of land take on environmental quality and equal distribution of ecosystem services.

*3.1. Land take*

To assess land take impact on environmental quality, land cover monitoring is crucial for environmental sustainability. There are several ways to monitor land cover, the use of which depending on the specific objectives and scale of the study (Verburg et al., 2013).

A key factor as far as the environmental monitoring is concerned is spatial resolution.

European Environmental Agency (EEA), in collaboration with other European and National Institutions, developed several High Resolution Layers (HRLs) in the Copernicus framework, referred to the year 2012. The main objective of HRLs is European countries land cover monitoring with a highly detailed level (20m resolution) regarding major environmental issues (i.e. soil imperviousness and natural cover such as forest, grassland, wetland, and surface water).

In Italy, ISPRA developed a monitoring network to assess land take evolution over time at national and regional level; this method has a high accuracy level , nevertheless it doesn t allow urban areas spatial analyses or cartographic representation. In this study we used a Very High Resolution Layer (VHRL) that identifies built-up areas with a spatial resolution of 5m (year 2012), this allows an accurate estimation at local level, developed by ISPRA in 2015(ISPRA, 2015).

The classification process is based on semi-automatic identification of built-up areas from satellite images (i.e. RapidEye) and the integration of local ancillary data such as OpenStreetMap enhancing the classification results and correcting omission and commission errors.

Further, a classification of 2000 has been produced by photointerpretation [1] using the 2012 classification applied to 2000 high resolution images .

It is worth mentioning that the VHRL and HRL of impervious surface have some classification differences in terms of definition: the Copernicus HRL excludes from the impervious area: railway lines, dump sites, mines, which, on the contrary, are included in the ISPRA VHRL.

*3.2. Ecosystem services assessment SE*

Land take affects the ecosystem services, decreasing the offered benefits and increasing natural environments degradation . To quantify the selected ecosystem services carbon storage and habitat quality it has been used the InVEST (Integrated Valuation of Ecosystem Services and Trade-offs) evaluation software, a tools set developed by Stanford University within the Natural Capital Project. InVEST, together with a GIS software, allows to establish where the ecosystem services are provided and to quantify the variations caused by different soil uses in two different periods.

As far as Rome District X is concerned , the case study area, maps and data come mainly from the regional level ones, sometimes even national. The proposed models ideal application would require on site samplings or even more accurate studies of the selected area.

InVEST model Carbon Storage and Sequestration provides a map that links lar codifications with the sum of the carbon values of the main four natural pools: above / underground biomass, soil and dead organic matter. Working on the X Municipality, the reference values of the forest categories land use have been obtained starting from the biomass volumes charts published by the Italian Forest Inventory ( Inventario Nazionale delle Foreste e dei Serbatoi For Carbonio - INFC). Once established the connections between INFC and land use categories, the pools data have been calculated through coefficients derived from scientific literature (IPCC, 2006).

As far as others land use classes are concerned (urban and agricultural) the soil s data have been obtained by matching, at national level, the land use / cover map and the SIAS map ( Sviluppo

[1] Thanks go to Eng. Monica Palermini for photointerpretation and correction of the 2000 and 2012 study area VHRL .

Indicatori Ambientali sul suolo ). Aboveground biomass, belowground biomass and dead organic matter values have been extracted from literature researches.
Some values (continuous urban fabric, port areas, dumpsites and building sites) were forced to zero.
The reference is Lazio Region land use map of (2003).
The second InVEST model applied to the area of interest, Habitat Quality , has While some consider biodiversity to be an ecosystem service, this model treat attribute of natural systems, with its own intrinsic value (NCP, 2014).
The test on the X Municipality has been developed with the aid of Nature s Cha 2009).
The threats analyzed, based on values extracted from bibliography (Terrado et al., 2015), are: urban zones and road net (coming from the Urban Atlas layer) and agricultural zones (from the Land Use Map of Lazio Region).

*3.3. Values and responsibilities*

Environmental Justice dimensions selected for the case study analysis (Beretta,2012) are:

1. Exposure and access inequalities: unequal distribution of environmental quality and natural resources availability, connected to a higher vulnerability;
2. Policy inequalities: unequal impacts of environmental policy and regulations, fiscal regulation and economic incentives;
3. Impact inequalities: unequal environmental impact from individuals and groups with different behaviour, life style, education level and different impacts of settlement models on land take and ecosystem services;
4. Policy-making inequalities: unequal access to policy making, in terms of existing and effective participation processes, , different perceptions of topic relevance an/or under representation of certain interests or groups.

These dimensions, as explained in the 2.1, are related with values and issues emerging from the case study in District X, here analysed. Relationships between land take and environmental justice in the case study are investigated trough the critical reading and network analysis of the participatory process involving citizens, public administration and other actors, through the lens of Ecosystem services.
The participatory process object of this analysis has been framed within two initiatives promoted by the City of Rome Municipality planning department, involving the Ostia X Distr March 2015):

1. the local level urban planning conferences: a cycle of public meetings that brought to a Values Charter a shared document summarizing perceived local values, pl objectives. This initiative consisted in six local conferences coordinated by the Municipality planning department and participated by an average of thirty neighbourhood committees representatives , private citizens and some cultural and environmental associations.
2. the 100Resilient Cities program, participated by Rome administration and promoted by Rockefeller Foundation. It focused on proactive and integrated strategies to face sustainability challenges, and it is aimed to allow cities to survive, adapt, and react to chronic stresses and acute shocks (environmental, social, economic). The workshops, coordinated by Rome Resilience office , involved a more complex stakeholders netwo institutional, scientific and economic level. A specific water cycle management workshop focusing even on hydraulic risk assessment (February 2015) provided information about perception of land take effects in Ostia and its inner-land.

Many authors, investigating in the last few decades how policy works and which are main factors in decisional success or failure, focused on network analysis. Actor-Network Theory, developed initially in sociology in the 1980s to study scientific practices (Latour, 2005), includes things and objects together with humans values and relations, in actor-networks able to achieve power enrolling more humans, artefacts and social arenas in their articulation. Assuming that a policy success depends

strictly on the ability to correctly understand the decisional situation and consequently strategies preventing and overcoming obstacles (Dente, 2014). Adopting conceptual frameworks to understand how public and private interests are represented and how policy decisions are taken in the decision-making process analysis is very useful. The main questions to be answered are:

- who are the actors of the process, and which is their type, including managers and scientists, the nature of their goals, which resources and abilities they have, and the decisional arena they belong to;
- how actors participate in constructing values around different and sometimes opposite resources, including ecosystem services (i.e. their role in the interaction);
- which are the connections in the network and their type of interaction: comparison, bargaining and problem solving (Richardson, 1982).

The discussion on decision making about natural resources can be divided into two views : the finding the right trade-off , on a rational and science-based solutions basis , a position we represented by PES, and the value perspective , helping to un-pack the inherent political and relational process that such problems entail. We assume that a value perspective together with a strong ecosystem services bio-physical evaluation is to be preferred, to achieve a more effective natural resources and services protection. In the given condition actor-network analysis used in our case study helps understanding structural conditions (that give shape to the network) with direct influence on decision about land take, giving analytical tools to understand why certain values (and certain ecosystem services) would be prioritized over others (Enstrom, 2013).

## 4. Case study findings

### *4.1.* Rome s X District area and the environment

The X District territory lies off the GRA[2] in Rome south-western area : its borders are the sea, the river Tiber and Castel Porziano natural reserve . It is one of Rome largest and most populous areas, spreading on 150 sq. Km and with 220 thousands inhabitants, by 2012 rates. Despite that, the population density is rather low (522 per sq. Km) if compared to an average urbanized surface. The district faced a very quick urban growth, over the last 40 years. What happened led to several consequences, which affect:

- land take
- Ecosystem services (on both offer and demand)

These are the reasons why this territory is a relevant case study for this paper. The Ostia District urban development was based on extensive housing (mostly unauthorized or un-planned) [3] . This characteristic can be regarded in terms of both values and criticism with values lying in a high rate of green areas and permeable soil, as in private gardens, and criticism focused on the extensive housing itself, which means a wider land consumption than in intensive housing.

The sudden and massive urbanization brought systematic soil sealing in an area with a fragile balance on both hydraulic and hydro geological aspects. Furthermore, the building expansion itself did not mean an adequate infrastructure development, which led to a disruptive perception, that backed up criticisms perceived by the population. Free un-urbanized ground is mainly included into the Castel Porziano Natural Reserve area and along the river Tiber. Both areas represent founding values for environmental and ecological reasons.

The urban growth process in this area is grounded on historic reasons linked to the progressive development of Rome towards the sea[4]. Before that, by the end of XIX Century, a vast land

[2] Gran Raccordo Anulare , the highway surrounding the city of Rome

[3] not planned neighbourhoods cover up to 64% of the urbanised area.

[4] In the 1916 the town plan for a core residential and tourist area of Ostia has been published as a part of the Fascist program for a monumental expansion of the capital towards the sea, having the EUR district as head. This planned expansion was supported by a big infrastructure system including two main roads (Via del Mare

reclamation for agricultural use was planned and realized around Ostia. It was only by the beginning of the second half of last Century that this area faced a huge, systematic expansion, partially planned by urban plan in 1962.
In those years, most part of residential development took the typical forms of urban sprawl. This problem affected particularly the inner portion of the territory, while on the coast itself the urban development tended to be intensive and mostly planned.
The development and growth of neighbourhoods that started as unauthorized ones and later redeveloped after being regularized[5], had a huge and risky impact in land use terms: it represents half of the entire urbanized area in Ostia hinterland.
Actually, with population facing flooding hazard, that risk is considerably higher. The fact itself that the vast majority of those suburbs was built on wet-lands, with no adequate infrastructures put peoples lives at risk.
The new urban plan for Rome released in 2008, reaffirmed the greatest part of the previous program, and added some new ones, focusing on its full implementation. Similar transformation has certainly affected other Districts, but some factors are more relevant in the Ostia area because of :

- The effects of land take on hydraulic and hydro-geologic hazard
- Presence of significant environmental values and ecological potential in the surrounding area
- The present perception/awareness of land take as loss of environmental values and of an increased flood risk

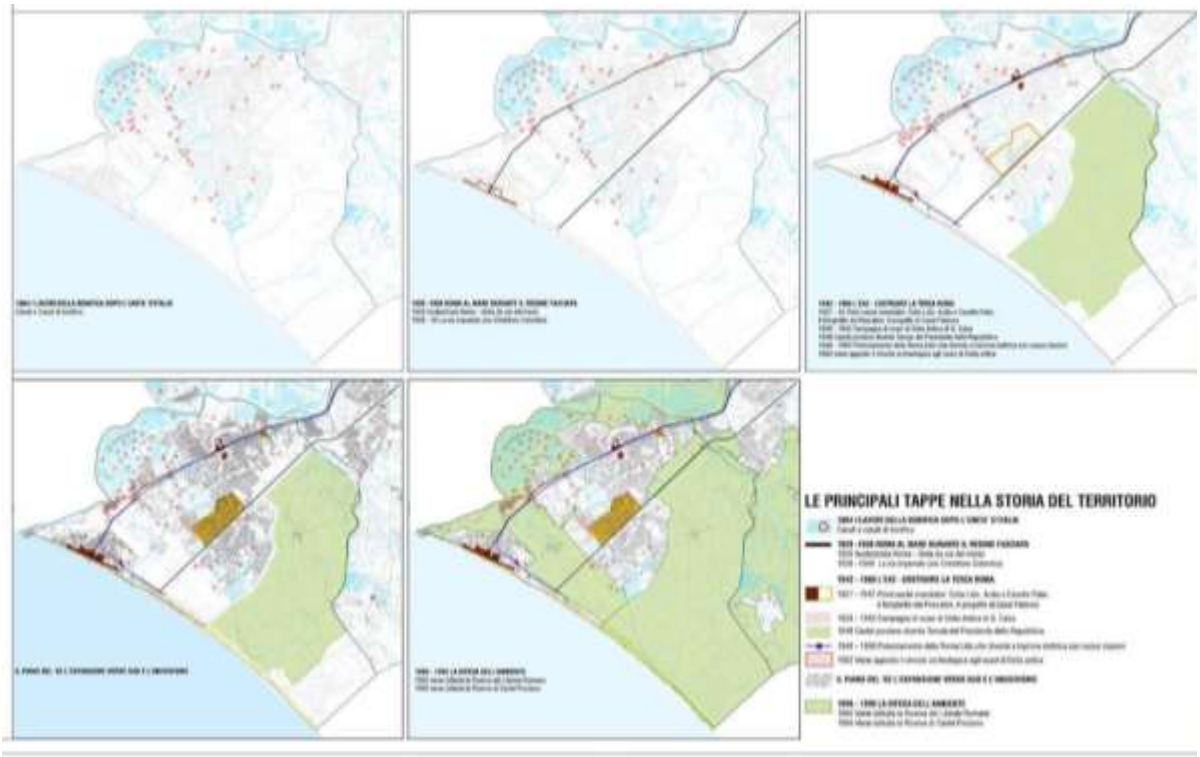

Figure.1 Trasformation process of District X

Making actual reference to the resilience concept, which goes along with ecosystem services, environmental values are recognized as structural ones for the territory. Coast, beaches with dunes, the

and Cristoforo Colombo) and the railway Roma- Lido . Nevertheless until the World War II Urbanised area was represented only by few isolated suburbs of public housing (INA Casa).
[5] A variation to the Regulatory Plan in 1978, followed by executives plans for the spontaneous areas, the so-called O-zones .

river Tiber itself along with the canalization system made for reclamation, archaeological sites and areas of private green inside neighbourhoods, are globally recognized as environmental resources, which made resilience easier and allowed to offer eco system services both in the local and extended area. The above figure (Fig.1) represent the transformation process through the years from late XIX Century up to date, and the potential further transformation in the previsions of the 2008 urban plan of Rome.

*4.2. Land take and ecosystem services in the study area.*

As shown also by ISPRA monitoring network, impervious surfaces in Rome remarkably increased in the last few years. The built-up area has grown from 7.1% of the 60s to 26% in 2008 (Munafò e Tombolini, 2014). The built-up surface of the Disctrict X, the case study area, has been estimated for 2012 using the Copernicus HRL, resulting in 3.410 ha, that is 22.6% of built-up in the study area.

In addition, this study used the ISPRA VHRL for 2012 producing the 2000 classification for the District X. Figure 2 illustrates the imperviousness classifications of 2000 and 2012 in the study area.

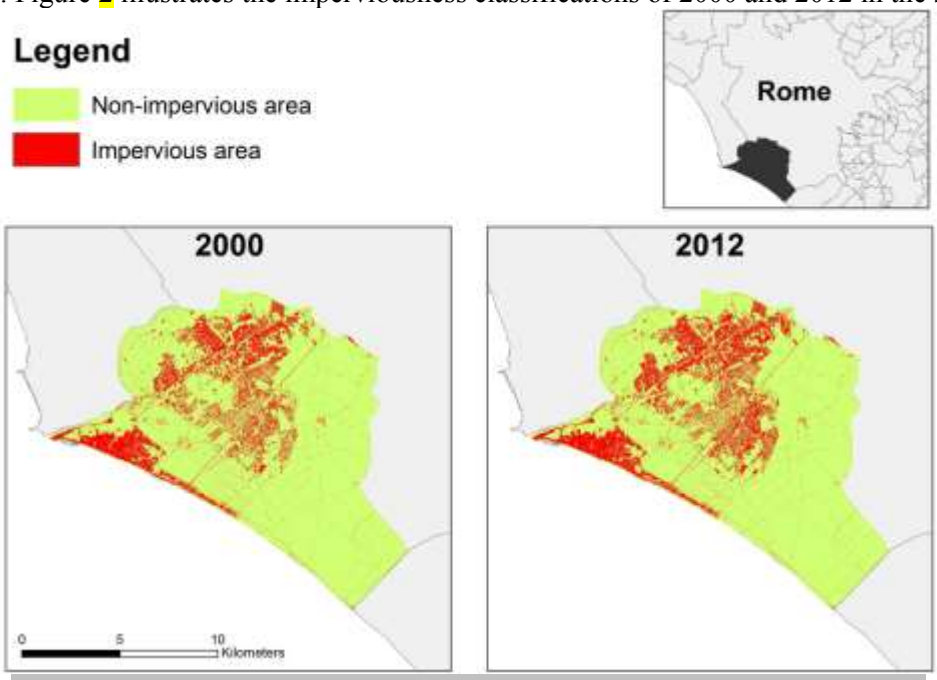

Figure 2. Imperviousness classification of X municipality for 2000 and 2012 -

The built-up surface of the Municipality for the 2012 using the ISPRA VHRL is 2.620 ha that is 17.3% of built-up in the study area. It is noticeable that spatial resolution of used data influences the estimation of impervious surface causing a difference in the two estimates of about 5%. In addition, the classification of 2000 showed that impervious surface was about 2.300 ha (15.2% of the study area). These results demonstrate an increase of impervious surface of about 300 ha in a dozen years which can be related to the urban development (both formal and informal) described in the previous paragraphs. It is remarkable that the use of the VHRL allowed for accurate estimates and facilitated the production of the 2000 classification. Therefore, this type of study could be used by local administrations to create and update a database of impervious surfaces with little effort.

In terms of ecosystem services, the presence of a forest area consisting of 6.000 hectares makes District X the most relevant carbon storage for the entire Rome area. Taking account of the agricultural zones, mainly situated in the NE and the input (minimum) coming from the medium/low built-up urban fabric, a total estimate is around 1.500.000 tons of carbon stored in the area distributed as showed in the Figure 3.

Soil consumption causes the emission of noticeable quantities of carbon from this large storage into the atmosphere, so increasing the formation of dioxide and consequent negative effects on the climate.

In Figure 3, it is shown how urbanized areas with less carbon-intensive soils than forest areas - provide a lower level of habitat quality and, at the same time, generate environmental degradation along its boundaries. As shown in lower part of Figure 4, the area includes the Castel Fusano Pine Forest and the Castelporziano Reserve, both rich of vegetation and carefully protected from the human influence. The habitat quality is at a very good level (left map), only presenting some degradation along its boundaries, affected by the considered threats (right map). As shown in the ma negative effect is maximum when a small natural area is surrounded by a built-up zone.
By matching the land use classes and the average agricultural values coming from the public chart for Lazio Region - rural area No 15 Lido di Roma (source:Agenzia delle Entrate), - a to around 220 MM has been estimated for the whole territory of District X.

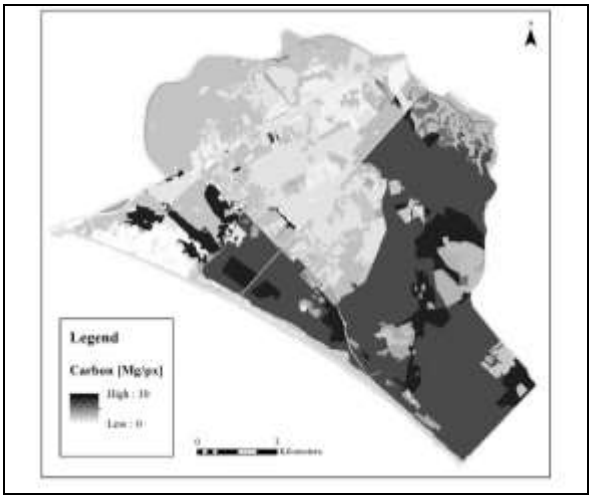

Figure 3. Carbon distribution map in the ecosystems of District X. Values in Mg/pixel (20x20 m each).

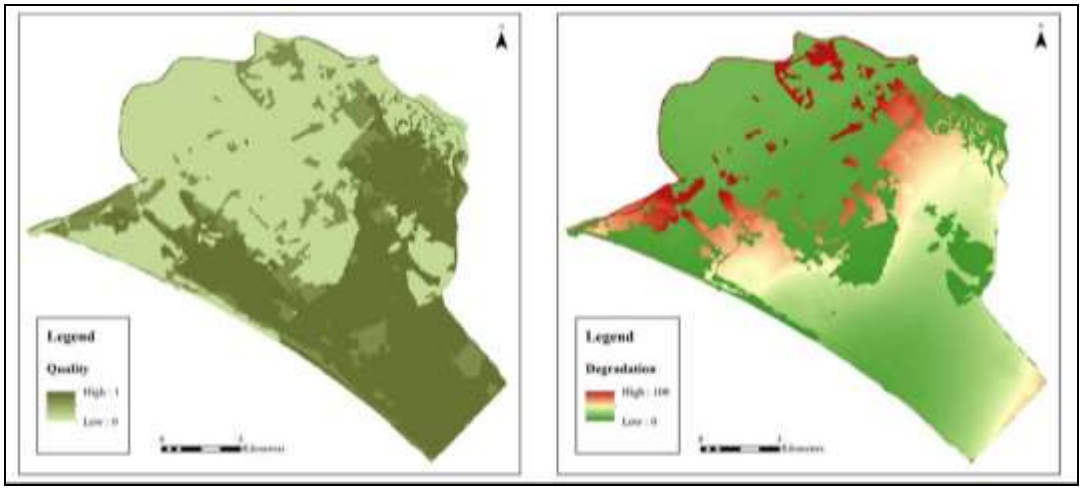

Figure 4. Habitat quality and habitat degradation maps in the District X of Rome.

*4.3. Views on values and responsibilities.*

In the public meetings of urban planning conferences in the District X, for the definition of a Value Charter, population interests were manly represented by neighbourhood committees, private citizens and some cultural and environmental association. The main outcome was a quest for a stop to further urbanization, and for re generation and renovation of existing structures. It is largely recognized that urbanization in Rome in the last twenty years was too much and unqualified. As a result, Rome is

actually facing lack of public services and infrastructure along with proliferation of commercial and residential buildings. In this context, the Value Charter construction process was focused on four criticalities, all relevant for land take prevention:

- flooding risk and security of buildings, especially in informal neighbourhoods grown on wet lands;
- lack of mobility infrastructure (the existing highways and railways were planned in the late 50 );
- despite a grate extent of green spaces the informal settlements are not providing the necessary services to community in terms of quality of life;
- the lack of valorisations of the rich environmental, historical and archaeological heritage on the territory , represents an economic and cultural loss for community.

Land take and ecosystem services are deeply interconnected with those criticalities. Despite the role of ecosystem services had not been explained in the participation processes, the natural resources availability, including land, and the sustainability of their use was perceived like one of the principal issues that affects also life quality of inhabitants,,. The strategic role of unsealed soils in terms of environmental quality and resilience to natural risks emerged as a priority in the value charter. After years of continuous and unlimited urbanization in the area, the discussion is finally on alternative development scenarios focused on renovation and re generation.

Figure 5 Extract of value charter of District X- Objectives for the urban planning development, resulting from the participation initiatives

It must be pointed out that the stakeholder participation was not full. Stakeholders that have a very strong position in influencing land use decision, as economic actors and land owners, real estate companies, land and environmental protection public agencies, and public services managers did not participate. For that the Value Charter must be better intended as a citizen
analysis of the workshop on water cycle in District X, within the participatory process of 100 Resilient cities program in Rome and the four urban planning local conferences, was an useful tool to identify

actors to involve and values/needs and opportunities to be considered (table 2), with the aim to improve the functioning of ES and to limit land take in the area, preventing more injustice.

Table 2 the water cycle participatory process in District X -Values/needs and opportunities

| **Values/needs** | **Opportunity** |
|---|---|
| The need for a vision for the district ; | Participatory initiatives (i.e. Contract for a water district area) |
| Pilot projects to help coordination and problem solving; | Rehabilitation of the Tevere river |
| Best practices sharing and integration of action under different policy sectors; | Research and case studies from university |
| Providing awareness and supporting transition; | New regulation on building sector for Rome area |
| Promoting new and present business sectors, including archaeology; | Awareness of citizens about natural resources values; |
| Training for enterprises and citizens | Coherence of plans from different level or sector |
| Promote networking | Overcome illegal behaviour |
| Overcome fragmentation in territorial management | Overcome disapplication of regulations and incoherent licencing for new buildings |
| Fiscal incentives for reuse, regeneration and renovation | Transition to smartness for old approach enterprises |
| Communication between actors; | Overcome Lack of planning |
| Simplified (and clear) regulation framework overcoming fragmentation of competences and responsibility; | Overcome Lack of communication, education, training about environmental matters |
| Usability and maintaining of public resources and spaces; | Overcome Lack of effective knowledge by decision makers |
| More participatory democracy in decision making; | and lack of coordination about environmental condition |

The actor network scheme, focusing on land take and ecosystem services issues in X District is shown in the Figure 6, dividing actors by type (by colour of rectangle): orange for technical and operative institutions (general interests- bourocrats), blue for elective institutions (politicians bureaucrats), red for special interests actors, green for university and research bodies (experts). In the scheme we show different arenas (by colour of circle) highlighting how actors are connected to ecosystem services management.

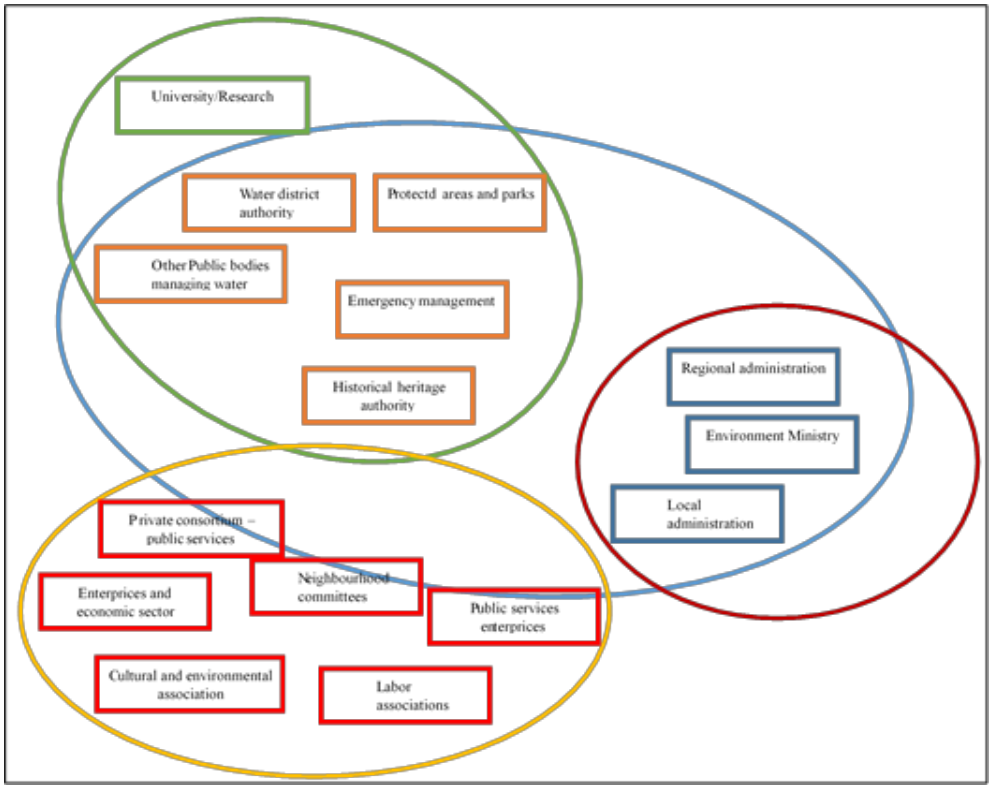

Figure 6 Distict X Actor network on land take and ecosystem services

The green circle, including research and operative institutions is involved in ES management and discussion, and offer technical competence. The dark red circle include institutional competences involved at different level depending on the regional and local policy (in the case study, institution at district and municipal level are involved, without specific regional policy). The yellow circle include social actors, with a scarce level of connection with ecosystem services at the moment. it must be pointed up that only few of these actors have direct competence on ES and that the main (perceived) problems are economic and cultural obstacles. Finally the blue circle identify those actors to involve in awareness program in the next future.

*4.1. First findings from the case study*

A qualitative classification (high, medium, low) of relevance of connections between ES of land and environmental justice issues is provided (Table 2), with the aim to identify more sustainable land use planning directions. The classification is based on case study results on land take, ES and citizen s values. Some of the implication for ES management, urban planning limitation are discussed.

| | | Dimensions of environmental justice | | | |
|---|---|---|---|---|---|
| Ecosystem Services | | Exposure and access | Policy | Impact | Policy-making |
| Provisioning services | Food production | | | | |
| | Non-food biomass | | | | |
| | Reservoir of minerals | | | | |
| | Fresh water supply | | | | |
| Regulating services | Water storage | | | | |
| | Run-off and flood control | | | | |
| | Pollution attenuation | | | | |
| | Global Climate | | | | |
| | Local climate | | | | |
| | Biodiversity | | | | |
| | Invasive species | | | | |
| | Air purification | | | | |
| | Noise control | | | | |
| Cultural services | Recreation /Tourism | | | | |
| | Archives of human history | | | | |
| | Landscape | | | | |
| | Education | | | | |

Table 2. relevance of connections between ES of land and environmental justice issues

A first reading of the table shows that unequal distribution of environmental quality and natural resources, and the resulting different level of vulnerability, has a strong connection with provisioning and regulating services. An increase of ecosystem services, like food production, bio-mass and fresh water supply or runoff and flood control, help in increasing resilience at local level. Provisioning services, like the availability of food produced in agricultural areas and the access to the drinkable water, directly contribute to guarantee an essential level of social justice.

Regulation services improve the response capacity of urban settlements to mitigate effects of natural hazards linked to climate change (flood, drought). Those services have an important role in reducing environmental inequalities and have significant relationship not only with exposure and access inequalities but also the other dimensions of environmental justice (policy, impact and policy making inequalities). It must be pointed out that services as global climate, having impacts at the global level, are not directly producing inequalities. Indirect unequal effects comes from

stresses on economic systems and capacity to cope transitions produced by global change.This is the reason why we evaluate a low connection with unjust exposure or access.
As highlighted by the participatory activities, both workshops of Resilient cities program and the urban planning local conferences, cultural services have an important role for local communities and impacts on environmental justice, particularly in policy-making and participatory process.
The environmental and cultural values from Values Charter discussed above are a representation of social meaning of the ES, here connected to different justice dimensions. Cultural services (tourism, heritage, education, landscape) valorisation is directly connected to the awareness of inhabitants about environmental resources and its economical, touristic and cultural potential. Thus, working on ES awareness in local communities is also a way to promote a sustainable economic development.
This table highlights how different environmental policies influence the ecosystem services management and perception. Notwithstanding a broad regulation on environmental management at the European level, Italy still suffer from difficulties and delays in adoption of EU Directives, for example water Directive 2000/60. In this case the lack of regulation and the ineffective policy results in a unequal effects on water storage ecosystem service. Another example for Italy is the lack of effective regulation on land take, dangerous for ecosystem services produced by soil. The table offer the base for a first discussion to define tools and methodologies, with the final aim of guiding the discussion and policies on ES management, urban planning and land take limitation in a more equal way.

## 5. Conclusions

This research, focused on land take as one of the major driver in impoverishment of ecosystem services, tried to highlight the resulting social inequalities, in particular those produced as consequences of unequal access to ecosystem services.
As a result, it can be affirmed that there is a problem of social inequality produced by land take. There is a certain level of awareness by citizens, certainly of land take and of loss of environmental quality, less of ecosystem services values.
Environmental assessment of land take and ecosystem services and promotion of awareness must work together for the common aim of helping land planning in reducing unequal effects of land take. It must be pointed out that the choice of the two ecosystem services analysed in the case study, even partial, is specific for that area. Studies on local condition should be based on a specific selection of the proper ecosystem services to evaluate.
High resolution data used in this study of land take are a useful tool for local administration for making decision. Their free accessibility make them also a tool for population in assessing the decisions on land use and therefore foster environmental justice.

# PLANNING AS HUMAN DEVELOPMENT: RESOURCES, CAPABILITIES AND RESPONSIBILITIES

Claudia Basta

Wageningen University and Research Centre, Environmental Sciences Department, Land Use Planning Chair Group, Wageningen, the Netherlands, Claudia.basta@wur.nl

Keywords: Resourcism , Capability Approach, Responsibilities

**Abstract**

*In recent years the debate on justice focused on the matter of (in)equality and on the challenge of advancing social justice (also) through the practice of urban planning (e.g. Fainstein 2010, Soja 2010). With this paper I wish to contribute to this debate by focusing on two central points, namely, (1) the interpretation of social justice, in planning, as a form of spatial equality , and (2) the matter of defining the equality of what consistent with the mandate and scope of public planning.*

*Drawing on Amartya Sen s* The Idea of Justice *(2009) the paper retraces the origins of the debate on equality and summarizes the perspectives of two relevant philosophical lines of inquiry, namely, the resourcist and the capabilities inquiries. The former perspective approaches equality in terms of the resources at disposal of individuals and strives for defining the social minimum which should be equally allocated to all; approaches equality in terms of the possibilities of realizing the pric individual has in the concrete realm of her living environment. Whilst the former inquiry concentrates on the equality devised by essential goods and universal liberties, the latter concentrates on the pathway to equality achievable by acting on the s individuals with different often, limited - capabilities.*

*By recalling these two perspectives on equality the paper intends to promote a discussion regarding how the two respective evaluative frameworks do and could further inform the scope of public planning interventions*.

## 1. Introduction

In writing this paper I have made some choices about which I wish to inform the reader at the outset. The first is the narrative style which I have opted for, which consists of inviting the reader to reason on her personal experiences while I will elaborate on personal experiences of mine; the second is to limit literature to the essential literature needed to convey my position. My underlying intent is to limit the philosophical premises of my position to their essential tenets and introducing them in the succinct and essential form conveyable through simple personal examples. The empathic reasoning which I try to stimulate in the reader may be fertile of further debates at the yearly AESOP congress in which this paper will be presented.

First of all, I want to introduce the main theme of the paper with a question. Why do we think that human beings are all *equal*? To do so, we need a conception of *equality*, and some ideas regarding how to measure it. In some way, our conception of equality has to do with the observation that we belong to the same species; then, with the further observation that we all have the same basic vital *needs* (eating, drinking, resting). The following observation is that among these needs there are some which need to be secured through certain *means*; that is, food, water, shelter. Then, it takes little to realize that these needs are not comprehensive of other needs, which are relational and emotional: the need to be cared for (on which we depend for much of our life), the need to care for others (something we tend towards for all our life), the need to respond to the stimuli implicit in these relations (experiencing anger, compassion, love, humour). Then, it comes the spiritual which is not necessarily attached to the religious sphere: Marx s conception of human significance, for example, relates to our constant dialogue with ourselves and with nature (Marx, 1844); however, it is easy to observe how despite the (Western) post-modernist claim of the death of god as privileged reference of our spiritual dimension, such significance is found by many in the constant dialogue with *her* God.

None of these elements explains equality though they do participate in its definition; but they are not what we mean when we say we are all equal on earth . What we mean with that is that *each human life has equal worth*. And this is an intuition a *moral* intuition, to be more precise, to which the idea that all human beings are *entitled* to the same set of fundamental means and rights by virtue of birth follows. Now, the immeasurable part of our intuition of equality is our common worth; life insurance companies may well attach a figure to it, however we all know that worth and economic value are not the same. The measurable part consists of those means and rights; how much freedom we need, what type of freedom we need, what rights do we need to secure all of these measurables are the detectors of our condition of equality from one another.

And here is where it starts the problem. Philosophical inquiries rooting in the most diverse ideological backgrounds share this fundamental intuition of the equality of worth of human life, but have been debating for centuries on (i) how to define the liberties and means each and all are entitled to across different cultures and situated conditions, (ii) the indicators through which appreciating the concrete equality of people in relation to these liberties and means, and (iii) what role the state has in securing them and whether this role is desirable at all; if so, within which margins and limitations?

These three points cover centuries of political philosophy and economic inquiry which will be unduly difficult to cover in the limited space of this paper. Therefore, I will only touch upon some of the moments of the relevant debates conducive to formulate my position in relation to equality, justice and urban planning. I will start with clarifying how the notion of equality philosophical accounts of the term, namely, Rawls s *Theory of Justice* (1971) and Se *Justice* (2009). Based on the writings of these philosophers I will outline the broader inquiries gravitating around their ideas, namely, the resourcist and capabilities inquiries. In the following section I will discuss the evaluative frameworks engendered by the respective notions of equality and I will discuss their relevance to the contemporary challenges of urban planning in relation to themes such as the growing cultural diversity of European citizens, the increasing distance not only physical, but also perceptive and experiential - between the poor and the wealthy areas of our cities and between the corresponding life conditions of their inhabitants.

I will conclude by proposing to re-centre the mandate of urban planning on a renewed humanism and to put at the centre of the evaluative practice of urban planning the human fundamental capabilities (Basta 2015; Nussbaum 2003; Sen 2009). My proposal is to endorse a planning approach orientated towards creating fertile relational conditions between urban resources whose fair provision shall

remain the guiding principle of state intervention and the transformative capacity of citizens in relation to their capabilities whose consideration and enhancement should be the evaluative focus of the practice of planning day to day.

**2. What is equality, and why it matters to urban planning?**

Few concepts attracted comparable scholarly interest as the concept of *equality*. The concept entails a descriptive component the intrinsic equality between you and me and a prescriptive component the extrinsic equality that you and me consider just to share with others. The first component relates to the equality of worth of our lives; the second to the equality of the human rights that need to be secured to affirm and protect that worth. From Marx and Engels s conceptio significance of human life which in their *Political and Philosophical Manuscript* they identify in man s necessity to cultivate a continue dialogue with nature and with the self, die (Marx, 1844) to the liberal thinkers who reflected on the role of the state as provider of the basic means and opportunities enabling to pursue that significance (Rawls 1951, 1971; Sen 1979, 1989, 2009) innumerable pages debating the most diverse aspects and implications of these ideas have been written.

Such enormous scholarly interest in the notion of equality has reached its momentum since equality started to be recognized as the *pre*-condition of justice[i]. This occurred also albeit not exclusively - thanks to the systematic economic analysis of Marx and Engels, which positioned equality as a primarily material rather than spiritual condition; however, what equality is and how to measure it remains an open question ever since. For Marx, as well-known equality related to the material condition of sharing the ownership of the means of production enabling the transformation of matter into goods without the parallel production of capital surplus (the capital, that is, the means of production, being commonly owned together with the transformed matter). For Marx the Marxists, and the so-called Neomarxists we are equal insofar you do not own the means upon which my capacity to transform matter depends, and do not own the outcomes of that transformative capacity. For utilitarian thinkers like Stuart and Mills an implicit idea of equality related to the equal worth of each and all citizens in counting for the social pursuit of happiness; this is what we all experience when, as children, we have to decide what game playing and we opt for the game that satisfies the majority. The cumulative happiness of our group of buddies is the maximum happiness achievable; the *distribution* of that happiness though implies that the majority of us enjoys whilst a minority doesn t. So, we all counted equally for determining the happiest choice but in our final condition of happiness we are, in fact, not equal.

It is with the contractarian tradition inaugurated by Hobbes, Locke and Rousseau that the discourse on equality started to be centred on the liberties and resources each citizens shall have but it is only with Rawls, in the second half of the past century, that the distributive outcomes of those resources started to be the fulcrum of inquiry on equality. To go back to my example, Rawls was among the first to reflect with philosophical rigour on the fact that as children we could all equally contribute to determine the cumulative happiness of our group of buddies but that somehow, for some reasons, some of us were unhappy in the end.

I will linger on this latter point which, in my opinion, is the underlying point of the contemporary discourse on equality. The assumption of thinkers like Rawls is that, by intuition, you and me would agree to be entitled, by virtue of birth, to a certain set of liberties and means without which we would be deprived of our mutual opportunities of self-realization. Self-realization in the Raw

conception does not relate to satisfaction or happiness , as the classic u
articulate it, but to be what one wants to be . Rawls conclude through the mechan
ignorance, which I have shortly summarized in a previous writing (Basta 2014) that you, me and all others, under condition of ignorance, would agree on assigning to all of us a set of liberties whose definition is pretty close to that of human rights and means whose identification is pretty close to that to which human rights conduce: basic education, shelter, medical treatment, and so on. This set of liberties and means would be the basis of our social contract and the aim of our coexistence would be that of expanding them from the perspective of the most disadvantaged. This means forcing a little the example of our group of buddies that our normative goal would be to ensure that each of us depart from the equal decisional condition; not determining the game that we will play in the end based on the criterion of cumulative satisfaction.

In reality, the accent on self-realization as what one wants to be which I mentioned above in exquisitely Rawlsian but rather conduces to his fellow Sen, who departing from the ideas of Rawls formulated the famous question Equality of What? (Sen, 1979). Sen challenged this idea of eq as the equal distribution of liberties and means and of social justice as the expansion of those who relate to the individuals departing from a disadvantaged condition; this, according to him, reduces equality to what people have disregarding what people *can concretely do and be* with what they have. Going back to our group of buddies, we may well agree that all of us must depart from the same decisional condition; none of us has to prevail on the other, each of us has the right to propose the game she desires, all of us have to possess the means through which the entire set of games proposed can be played. Does this make us *equal*? According to Sen, it depends on whether our fundamental capabilities are *equally enabled*.

I will give an example. When I was a child, I developed cross-dominance, that is the tendency to use the right or left hand (and eye and leg and hear) depending on the task and not depending on the dominant side of the body that, for 95% of the global population, is either right or left. Thus, I would write on the notebook with the left hand and throw the ball with the right on; I would write on the board with the right hand and hold the racket with the left one. At school, to help myself adjusting to circumstances I had to use some tricks; one typical trick was to incline the notebook towards the right side, when writing, so to compensate for the asymmetric use of my body. This would lead me to take some weird positions on my little school desk. The teacher would recall me all the times claiming that to learn to write well I had to do like others keeping the notebook straight and that if I would, I would overcome that confusion with my hands. In her good faith, she was making a statement of equality: I had to behave equally so to achieve equal results. What she couldn t see is that to achieve the same functioning of others writing orderly and straight I had to be provided other means the freedom to incline my notebook and possibly a wider school desk because *the means everybody had, could not have the same effect on me.*

This is the best summary I could give of Sen s theory of capabilities. It is starting from this observation that equality is not about what means one has, *but about what these means do to her,* that Sen proposed an idea of justice based on the idea of our fundamental capabilities. I will give another example. If you and I are assigned the same means for example, the same education but I have a cognitive impairment, I will not achieve the same functioning that you will achieve. Assuming that I could achieve that functioning by being provided another type of education for example, a teacher experienced in my impairment *then* the means that I shall be provided shall be adapted to my specific capability. Our equality, in other words, is not measured through the allocation of the same mean but through the level of functioning that we can achieve based on our respective capabilities.

This idea of Sen may attract criticism in fact, society, in its organized form known as the state, cannot tailor the means to assign to each specific capability without incurring in the contradiction of treating individuals differently. This was the concern of my teacher, in fact. It is my claim, however, that mature democracies have increasingly orientated their distributional effort in the direction of enhancing capabilities rather than allocating equal goods. Not only: they have also converted capabilities into *objects* of rights. I will give another example. Nowadays, nobody would question the right of a person with impaired mobility to commute on public means as any other non-impaired individual. The history of removal of what in my country of origin are called a long, painful and slow history of social struggle and campaign though. To convert the capability of circulating into a *right*, and to convert such right into design solutions transforming the city in both its public and private spaces, much political activism and social campaign had to be organized. Many more examples could be given from the establishment of social assistance services for elderly, to the educational support given to children with impaired learning abilities, to the mandatory allocation of work posts to people with disabilities the message being that society (or at least European society) has made quantum leaps forward in allocating public resources by bearing in mind the diverse level of capabilities of its citizens and by orientating the ultimate scope of public policy towards enabling equal functionings rather than towards the distribution of equal means.

This brings me to discuss the role of the state in relation to these means. I do so in the following section.

**3. Resources and capabilities: ideas for political synergies**

The debate on the role of the state here intended as the organized and regulated form of social coexistence in relation to resources and capabilities inspired, in my opinion, the most important political philosophy writings of the past two decades. Philosopher Martha Nussbaum is particularly inspirational for the rigour of her inquiry and for her tendency to ponder her ideas always by considering the cross-cultural interpretations they may be subject to. This immunizes her reflection on capabilities from the ideological tone that always in my opinion permeates the writings of prominent theorists in planning theory for example, Harvey, 2008 who have reflected on the city, as a micro-dimension of the state, in relation to (political, albeit they claim human) rights.

To avoid confusing the reader, I will proceed with some order. What is the role of the state towards the resources citizens shall have access to in order to pursue their self-realization? This question calls for a theory of *right* the rights you and me have and for a theory of *duty* the duties you and me and all others have towards each other. Lefebvre s writings constitute the main point-of- theory, for the former issue (e.g. Purcell 2002; Harvey 2008). Little has been written in relation to the latter issue, albeit one could conclude that prominent paradigms like participatory and collaborative planning imply a conception of duty for instance, the duty to provide opportunities of participation to citizens and of formulating goals and constructing decisions together with them and also that citizens participation implies some notion of obligations for example, of bei considering others interests next to the own interests, and so on.

Coming to the main question, one way to reflect on what resources the state shall secure and provide to all is to reason on the notion of *social minimum,* that is, the *bundle of resources that a person needs in order to lead a minimally decent life in their society* (White, 2004). I could engage with the debate on what this bundle consists of however, more fruitful is to construct a reply through observation. What do you, reader, have (had) access to through your life that related to some sort of

social minimum? I can help by replying to this question from the perspective of my experience: a public pre-schooling and schooling system, which enabled my parents to keep working while I was looked after by someone else who was teaching me important things; a public healthcare service, which enabled me to recover from injuries and illnesses; public means for commuting to and from schools and sport facilities, most of which were accessible through the payment of small fees, since they relied on public funds; a public university, that I could attend paying minimal yearly fees due to my scholarly merits, promptly assessed and rewarded by the academic administrative system; plenty of public space and green areas, easily accessible from my parents house and re

The following question is, what among these resources (I realize, privileges) constitute the social minimum one shall be provided in the society in which she lives (in my case, Northern Italy, specifically Venice). In a real setting, at this point of the conversation a fierce debate would probably erupt. Ultraliberals may well reply, none: their theory of right is positioned at the right extreme of *negative* rights, whose fundamental principle is that the state shall *not intervene* in any aspect of one s life. Communists may well reply, all of them and more: their theory of right is positioned at the left extreme of *positive* rights, whose fundamental principle is that the state shall provide all means one needs to live a decent life (and thus prevent their allocation through market mechanisms). Centrists may reply, some of them, for example schooling and education but not sport facilities, whose management should be left to private initiative: their theory of right is a combination of positive and negative rights, whose principle of reference is that the state shall secure the provision of non-exclusive (thus, public) goods, leaving to the market to provide exclusive (thus, private) goods.

To continue reasoning concretely rather than theoretically, let s now observe European democracies position themselves on the spectrum of negative and pos imagine this spectrum as a line at whose left we position positive rights and at whose right we position negative rights. The transition from one to another extreme of the line is continuous not divided into discrete intervals. Where does, for example, my country of residence stands on the line? I would say central however, with a tendency (for many, disappointingly) to move gradually towards the right side of the spectrum. My country of origin is in some respect more on the left side for example in relation to healthcare and for others more on the right side for example in relation to social security. We could replicate this simple exercise for all European countries and then extending it to other countries in the world. Remaining in Europe, however, would lead us to position the majority of countries somewhere centrally; in fact, our constitutions are written based on the recognition of certain positive rights for example, the right to access education and negative ones for example, the right of not been prevented from exerting some fundamental liberties.

This does not reply to my original question; but it helps to introduce my reasoning on what further duties we could associate to the state in relation to the capabilities of its citizens. If we accept as you and me most likely do this idea of the state as provider of some sort of goods and means to which all of us are entitled, *then* the following question is whether the state has a duty also to ensure that you and me can derive the same functionings from them. In part, I have already replied to this question, and I did so again through observation: we already live in states securing effective relational conditions between (social and urban) resources and our capabilities in relation to big and small difference, insignificant and significant impairments. The public university in which I work, for example, has ensured that my desk and my screen are positioned compatibly with my height and with my slight visual impairment; while you read this paper, you might be in a similar *enhanced* condition.

And so with this, I introduced the concept of *enhancement* which is a concept central to my discourse on the political synergies to be activated between resources, capabilities, and cities. I develop it in the following section.

### 3.1 Enhancing capabilities: planning as human development

In this paper I have opted for writing in a narrative style and for avoiding the level of abstraction with which I have treated the theory of capabilities in other contributions (Basta 2014, 2015). I did so for encouraging the reader a peer academic, but ideally anybody else to reflect on her situated, daily, unique life conditions so to grasp the main message which I am trying to convey in an emphatic rather than analytical way: planning is an exercise of *enhancement* of *human development*.

The line of reasoning which I followed to arrive to this proposal by no means a conclusion is that the type of equality we value is the pre-condition of the justice we want; my assumption is that urban planning aims at advancing such justice, therefore, through observation, I proposed that maturely democratic states are called to allocate basic resources to all *and* creating relational conditions between such resources and our capabilities in such a way to enhance our equal functionings. Two theoretical questions remain: the first is that which urban resources shall be equally accessible (thus, being part of the social minimum), and the second is whether these are alway specific capabilities. This latter question is particularly important for urban planning.

To respond to these questions, I refer to Nussbaum s Central Human Capabilitie sake of completeness I report integrally as it appeared in 2003 (Nussbaum, 2003):

> 1. Life. Being able to live to the end of a human life of normal le before one's life is so reduced as to be not worth living.
> 2. Bodily Health. Being able to have good health, including reproductive nourished; to have adequate shelter.
> 3. Bodily Integrity. Being able to move freely from place to place; t assault, including sexual assault and domestic violence; having opportunitie and for choice in matters of reproduction.
> 4. Senses, Imagination, and Thought. Being able to use the senses, to imag and to do these things in a "truly human" way, a way informed and c education, including, but by no means limited to, literacy and basic ma training. Being able to use imagination and thought in connection with ex works and events of one's own choice, religious, literary, musical, and one's mind in ways protected by guarantees of freedom of expression with and artistic speech, and freedom of religious exercise. Being able to ha and to avoid pain.
> 5. Emotions. Being able to have attachments to things and people outside who love and care for us, to grieve at their absence; in general, to longing, gratitude, and justified anger. Not having one's emotional develo

and anxiety. (Supporting this capability means supporting forms of human a
shown to be crucial in their development.)
6. Practical Reason. Being able to form a conception of the good and to
about the planning of one's life. (This entails protection for the liber
observance.)
7. Affiliation. A) Being able to live with and toward others, to recogni
human beings, to engage in various forms of social interaction; to be ab
of another. (Protecting this capability means protecting institutions that c
forms of affiliation, and also protecting the freedom of assembly and po
the social bases of self respect and non humiliation; being able to be
whose worth is equal to that of others. This entails provisions of non
race, sex, sexual orientation, ethnicity, caste, religion, national origin.
8. Other Species. Being able to live with concern for and in relation
world of nature.
9. Play. Being able to laugh, to play, to enjoy recreational activities.
10. Control over one's Environment. A) Political. Being able to particip
choices that govern one's life; having the right of political participatio
and association. B) Material. Being able to hold property (both land
having property rights on an equal basis with others; having the right
equal basis with others; having the freedom from unwarranted search and
able to work as a human being, exercising practical reason and ente
relationships of mutual recognition with other workers.

In a forthcoming article, I indulge on the source of inspiration that Marx s
dignity constituted for Nussbaum s attentive definition of the fundamental huma
move directly to the extraction of the capabilities which, in my opinion, could be related to the urban realm of human life more explicitly than others. These are, evidently, the capabilities related to the exertion of control on the environment, which for Nussbaum are material and here, pace Marx, it compares private property and immaterial the most important one being the capability of participating in the decisions which affect one s living environment.

Compared to the language of rights as used to promote the right to the city -a
if I had the space to discuss it at length here, I would explain my grounded scepticism the language of capabilities used by Nussbaum to articulate human functionings differs because it is (i) affirmative: capabilities are inherently positive their spectrum could be visualized as a compact circle with at its centre the notion of human dignity, and (ii) substantial: capabilities are *objects* of rights not rights *per se*; that is, they can be evaluated as ways in which people can function, not as entitlements that people have. I will clarify this latter point with an example. If I sit on a wheelchair, I am entitled to circulate on your same bus this, in fact, is meant to be equipped to allow me to travel as comfortably and safely. However, if one wants to investigate whether I can indeed circulate as comfortably and safely as you do, the question I would be posed is not whether I have that right but whether yesterday, the day before and the day before it I could take that bus or not. This example serves to

clarify what I mean when I say that capabilities are affirmative and substantial (I can or I can t do something) in contrast with the formal nature of rights (I have or I don t have that right).

Now, when thinking of what one can or cannot do in cities, some of the functionings related to Nussbaum s capabilities most of us would regard as fundamentals are, together with other functionings that I will elaborate on in more details in a forthcoming article,

1. The capability of living in a safe place commensurate and adequate to one
2. The capability of living healthily and receiving affordable medical treatment in the city,
3. The capability of travelling from one part of the other of the city safely and inexpensively,
4. The capability of meetings others, joining and creating groups, cultivating interests and sports,
5. The capability of accessing nature, of being surrounded by green and animals,
6. The capability of working and of constructing the own path of development freely,
7. The capability of learning, acquiring new competencies and forming new ideas, of relying on a pre-schooling and a schooling system which secures these functionings to children.

My idea is to use these functionings as reference for devising evaluative instruments capable of investigating what people can concretely do and be (Nussbaum, 2003; but also Robeyns, their living environment and for generating the actual knowledge on the city from which urban planning could tap its inspirational guidance. Nussbaum, however, offered me an opportunity to reflect not only on the front of inspiration but also on the front of the responsibility which the exertion of the right to participate in decision-making (one of the few rights she explicitly associates to capabilities) constitute for (we) citizens. I reflect on this, briefly, in the following section, which precedes my conclusions and ideas for further research.

**3.2 Capabilities as responsibility**

On why capabilities entail an individual responsibility I discussed in a previous contribution (Basta 2015). I would like to return on that point and to connect it with the line of reasoning which I followed in this short paper.

Having a right does not mean exerting it. Two conditions are necessary: (i) the concrete opportunity of exertion, and (ii) the will of exerting it. Positive rights of the kind parti can be discussed from both perspectives. Here, I will focus only on the second one.

Some months ago the municipality of The Hague invited all residents of my district to participate in a meeting in which the project of renewal of the system of collection of domestic waste would have been presented. This project included some changes of the routes of the cycling paths so to make space for the new underground containers. These changes demanded to eradicate some magnificent oaks whose blooming in the spring, I can tell, was an event we were all looking for every year. My partner attended that meeting, which I could not attend instead. When he reported the discussion he told me that our neighbours expressed firm opposition against the removal of the oaks something we could expect, considering and that the representatives of the municipality responded that their removal was inevitable; the roots of the oaks had caused several cracks on the paths, and it would have been unduly costly to first remove them, and then replanting them. The story continues with some rumours regarding a petition launched to save the oaks to which we two did not participate, simply for the fact that we were not informed about it. Another petition was launched to prevent one of the cycling paths facing our street to be re-routed. I thought this latter petition was unmotivated, as evidently the re-routing of the path was based on safety concerns related to its proximity to a traffic light at which cars, in the morning, used to line up in numbers. I didn t sign this latter pet

the former one. So the oaks were cut and the cycling path re-rerouted, with much discontent from the side of our neighbours.

Of this story I wish to highlight two things. The first, is the petition for saving the oaks which I could not sign; the second is the petition for not re-routing the cycling path which I haven t signed. I former case, was I prevented from exerting a right? Obviously not; simply, I concrete opportunity of exerting it. In the latter case, was the right of my neighbours of not seeing the path re-routed violated? Certainly not, as the reasons of the municipality for re-rerouting it were very well-considered. In this latter case, I had the opportunity of signing the petition, and *not* signing it consisted of the equal exertion of my right.

What bothers me still is the petition which I couldn t sign though. When I think for not having attended that meeting. There, I could have probably been informed of that initiative, and I would have most likely signed the petition; through it, I could have exerted my right to make a point regarding our much valued oaks. Not having attended that meeting means, for me, not having been *responsible* towards *my right* to try to save them.

This is what I mean when I say that capabilities call us to act responsibly: to take full ownership of our opportunities to participate in decision-making without expecting that others will knock at our doors and will create all the conditions for us to do so. Active citizenry, and here I conclude, means *responsible* citizenry: it entails some sort of obligations moral rather than legal; but not for this less important to exploit all the opportunities we have to participate in the transformation of the city that the language of rights (in Harvey s use of it) reduces to something we must *h* that there is something that we must *do* in return.

**4. Conclusions**

I have a few hundreds of words left to conclude my journey throughout personal experiences, the theories which may help framing them and orientating them towards a higher level of abstraction, and what I wish to propose as a way to regard urban planning - and ultimately to make urban planning happening in a certain way. If I had more words I would linger on why the language of rights, totally prominent in planning theory, is important to convey one s political position in relation to these issues but not conducive to engender viable evaluative instruments for detecting how people, concretely, live in their cities and how much they can and do contribute to its transformations.

The language of capabilities is a more robust point-of-reference for formulating these evaluative instruments, and many of the example which I gave support this proposal of mine. Urban planning has to re-conquer space for growing its evaluative practice, abandoning or at least limiting its tendency to occupy terrain for implanting a judgmental narrative on how cities are produced.

This space could be reconquered through a new humanism, capable of re-centring the discourse on planning on human development what people can concretely do and be and of steering its evaluative practice towards the formation of knowledge regarding how a more capable and responsible citizenry can be encouraged.

Philosophers have always given an hand to all others along this difficult journey. Let s not confine them in their world of ideas and neither in the most remote and unattractive rooms of our congresses.

[i] I feel the duty to signal that several monotheistic religions have been founded upon this recognition in the order of thousands and not hundreds of years and that philosophers of the stature of Kant and Hegel thanks to whom we could read Marx at some point - were impregnated, if not of the respective ontology, most certainly of the respective transcendentalism. The secularization of the European philosophical inquiry across and beyond the era of Enlightenment is, in historical terms, the new born baby of human thought. The idea that religious beliefs do no longer play an ontological and epistemological role in today s Western society shall be therefore re-considered. When orientating our intellectual reflection from a position of *self-reflection* (we philosophers talking about and among ourselves) to a position of *observation* as philosophers like Sen and Nussbaum invite us to do the world would appear closer to what it is: a world where people construct their identity, perceptions, explanations, judgments and ultimately idea of self-realization upon the foundations of their religious belief. Whilst the reader may wonder why this should be of importance for European urban planners, I invite the reader to reflect on how much space is allocated to cultivate such credos in our cities; the role and significance that that space has had historically and has for many still; and how much disputed and contended that space can still be. A practice of planning insensitive to the symbolic and concrete importance of this space is a practice we should neither desire nor encourage. It is a practice of which we should, rather, discuss beyond the notion of diversity and the discourse on rights and frame within a broader humanistic discourse on the concrete space that what many regard as the source of their human significance reclaims in our cities. I will not do so here; my proposal ends with this note.

# WHO IS ENTITLED FOR THE RECOGNITION OF PUBLIC RIGHT IN THE URBAN DOMAIN? A PERSPECTIVE FROM THE SOUTHERN ITALIAN CONTEXT

Giulia Bonafede

University of Palermo, giulia.bonafede@unipa.it

Keywords: Relational public spaces, services, responsibility

## Abstract

Who has the right of access to public space of the city and what are the limits depending on the circumstances: the shift between the public and private spher institutional system, laws and planning tools. If many scholars focus on rel public/political spaces, the sphere of public facilities is a central issue. In by an ancient national law, aimed at ensuring minimum collective rights, the standards as mandatory quantity of areas to locate within the municipal plans regions of Northern Italy have satisfied and raised this standard, the southern situation of severe shortage. This lacking of equipment, during the long period affects mainly the disadvantaged groups of the population. Although the urban intercept the multiplicity of services required by the plurality of social group public/private partnership does not ensure the creation of truly inclusive spa quality. Even new national bill on urban regeneration appears unfair. Subjugate interests, it raises questions of planning responsibility with respect to popul most easily excluded, not possessing negotiable values such as property rights New issues are arising from legislation proposal involving the equality between distribution. These approaches lead to rethink on public responsibility and ab depending on the geographical context, and economic-political and bureaucrat reference, on the basis of Arendt s thought.

## 1. Introduction

Scholars have highlighted many facets of public space often in compare with (private, social and political) from really different perspectives. Among explorations, the relational nature is surely one constant feature of the publi has been highlighted, for instance and not exhaustively as an informal contact simultaneous encounter of social needs, which are motivated by individualizatio (Lefebvre, 1968), as speech and action among equals in political pluralism (Ar reciprocal recognition of differences, which are moved by power relationships am (Young, 2000) and eventually as collaborative and communicative interactions Hillier, 2003).

This relational nature is certainly connected to the collective mode of using pu in the double meanings of spatial and political dimension. The rights corr dimensions, which should be sustained by the free participation to the city. Ac (1968), such rights to the city consist in a form of conflicting appropriation, in terms of property right and is based on the recognition that the social nee They interact in urban space with rhythms and different time of the daily life survival and security reasons, but also because inhabitants are moved by desire of welfare that the recreational and ludic dimension of creativity and festivity

development.

Since judgment and responsibility are framed by institutional, economic, and pol
case study from a southern Italian context, where unbalancing in provision of
exacerbated, will show to what extent these collective rights to the city ar
planning practice, which of them are ascribable to previous government and whic
current political government.

## 2. From relational values to responsibility for public space

### 2.1 Power relationships and implications in planning

Lefebvre s idea that the city is a continuous and complex oeuvre, worked by th
citizens, leads to consider urban space as a social product of a collective acti
value and perceived significations that should not be converted in tradable g
exchange value. The same participation to oeuvre is recognized as a right an
terms, as a right of responsible self-government of urban space.

Although the relational values and use of public space are socially produced, it
they are gained without explicit or latent struggles among different social groups
power relationships, which are not habitually symmetrical (Young, 1990), neithe
nor in the public arena of planning process.

Who has the right to the public space and what are the boundaries to have acce
rights, as several authors pointed out (Mitchell, 1995; Harvey, 2013), vary beca
situations, the shift between public and private sphere, the political-instit
economic system, the norms and the plans. The public space in itself cannot
considered as neutral and fixed over time, this idea should be demystified, beca
result of impermanent conflicting interests and power relationships.

For instance, when the private space of house increases for wealthy people, i
usually out from this sphere (like places for encounter, gyms and fitness, garde
for disadvantaged people in terms of areas dedicated to common activities, the
services takes a compensation function (Ricci, 1999). Also, when the rules esta
time to use specific public spaces, like parks and gardens for instance, it mea
will be included while some other will be explicitly excluded (Mitchell, 1995).

The spatial plan, in particular, as a political representation of the conceiv
1968) can reshape power relationship among social groups, by affecting the reso
and the rights to the city, when it do not become just a cultural mediator for
economic interests. It is well known from Gramsci analysis that the hegemon
necessarily imposed from the top of an ideology, can be instituted also throug
civic society, through consensus. This latter interpreted as common sense
traditional values and interests, contributes to the continuation of a cert
whether it is not permeated by original cultural processes, also imported by cul
is not rooted therefore on the development of ethical principles (Chambers, 1990

Such a process of consensus building despite being deeply decentralized is not
manipulation of neoliberal hegemonic social groups. Strategies of expropriatio
some concepts on equality principles in urban regeneration and participative p
typically displayed from southern areas of the world (Holston, 2008; Miraftab, 2
Lo Piccolo, 2010).

They are habitually based on economic domination and on the ability to produce c
persuasive discourse, by influencing for personal advantage the public are
participative planning practices, which rely on citizens inclusion perceptio
utilized for strengthening the pre-constituted economic interests. The commo
though interpreted as a result of conflicting interactions among social grou

automatic sum of private interests), is realistically driven by hegemonic cultu
crisis of ethical principles, without a real perception of political responsibil

2.2 Arendt thought on political responsibility and faculty of judgment

With this regard to ethical principles during period of crisis, Arendt (2003)
between individual and collective responsibility as well as the judgment facult
dynamic process of the thought, an apparently less political activity since
soundless dialogue with themselves and staying in company with themselves.

While the responsibility in face of the law is always individual, the collect
intrinsically political, both when an entire community or a government takes th
past actions, even of only one of its members, and when a community is deemed
what has been made in its name (Arendt, 2003, p. 129). This latter case is the most inte
Arendt because concerns any kind of political community (beside revolutionary
totalitarian regimes) that takes the responsibility of its past and of its prede
benefits of their merits as well as being aware of the disadvantages caused by t

However, the political community is not guilty for the misdeeds of its predec
ethical level nor at juridical level, as well as political community cannot ascr
of its predecessors. Supporting, unlike obeying to, the speeches and the action
is understood as an equal among equals, for initiating new political processes
redeem the past with unpredictable results anyway.

The political responsibility does not however exclude the individual responsibil
faculty of judgment whether political actions, laws and orders are not aligned w
principles. In this case the not-participation (that can be a choice in demo
develop in active resistance. The faculty of judgement, which is founded on self
not, or not only, discern the lesser evil, which in particular circumstances is
distinguish good from evil, justice from unfairness.

The Arendt reflections are framed in a period of political balances reconstructi
totalitarian regimes, caused by a severe crisis of common ethic, resulting
fundamental ethical laws with the complicity of a wide section of well-educated
system of thoughtless bureaucrats. That period for its example of limit case,
circumstances of crises in which the thought faculty missing and therefore the
an own judgment causes negative consequences in the arena of public domain.

This ability to form an own judgment is independent from intellectual capacit
cultural background, rather rests on the habit to think, to doubt and to wonder
order to make flourish the conscience, which is interpreted in the double meani
to examine opinions revising their validity. Unlike prejudice, the faculty of judgm
particular cases, which cannot subsume to general rules (Arendt, 2003, p.163
thinking, people cling to the rules of already prescribed behaviour and get used
rules content as to not take a decision (Arendt, 2003, p.154).

Nonetheless, Arendt wonders to what extent the faculty of thought, exercised i
into political sphere, hoping for an answer by political philosophy, considers
maieutic, as one of the most political activities during periods of crisis of
purifying and invisible activity of the wind of thought frees the judgment fa

product (Arendt, 2003, p.163). The thought does not create values or discovers c
good because rather disperses the consolidated rules of behaviour; however its e
relevance leaps in the foreground during emergency periods and finishes of be
political field (Arendt, 2003, pp.162-163).

As highlighted by other authors (Davoudi and Brook, 2012) responsibility and ab
are strictly linked to political participation (or not participation) in publi
decisions, to establish norms, laws and plans. In a period of economic crisis a
well as of political representation, I wonder who is entitled for the acknowl
rights in urban space. Who holds this responsibility? I try to answer by explor
of southern context, framed by Italian debate on new bill on urban planning pri
proposed erasing of norms on public space of services.

2.3 Law principles on the right to the public services equipment in Italy

In Italy the public space of services is ruled by a national law enacted at the
last century (n. 767/1967) and in particular by a related ministerial decree (MD
the decree on urban standards . Unlike other European nations, these law and de
allocation through municipal urban plans of a minimum of areas per person dedi
services, the so-called urban standards.

According to the decree, in particular, the municipal urban plans distribute
neighbourhood the minimum need of areas per person of four main groups of public
urban standards): public schools; public parks for game, sport and leisure; pub
areas for other collective facilities like those for culture, health, security,
While at general level of urban scale, municipal urban plans allocate minimum th
areas per person dedicated to public urban parks, hospitals and high school
standards). Additional typology of local and general facilities can be obviou
standard without any predetermined quantity of areas.

These minimum needs, expressed in square metres per capita, were appraised on
several researches, professional handbooks and planning practice, mainly foc
technique, in a period of great expansion of the cities. The cultural debate on
decode social needs through the sizes of areas for services came also from ot
architectonic projects of specific buildings and facilities like schools, playgr
ground etc. (Falco, 1987).

Consequently to widespread demands raised by civic society and by radical planne
social needs and democratizing planning, the left-wing political parties have fo
that time to improve and modify the entire body of laws that had ruled urban pla
war world. The reformer law and related decree were indeed obtained through soci
political mobilizations for claiming collective right to the city, in orde
urbanization and unequal decisions in planning practice, mostly influenced by
southern regions also by criminal groups, like mafia, with the complicity of so
Nevertheless, the decree on urban standards has interrupted fertile researches
of the public space for services and currently it fails to intercept the multip
claimed by the plurality of social groups inhabiting the city.

Waiting for an updated national law on the principles for urban planning, many
officials and planners, however have interpreted over the time these urban st

flexible approach, by including private facilities within urban plans. This pro
privatization has involved both northern and southern regions, although minimu
public space has been previously ensured in the northern regions (also because
laws), while a severe shortage has been usually recorded in the south.

As some scholars have pointed out from the point of view of the distributive
private sector can be more efficient than the public sector, nothing hinders
with full tariff for wealthy people provided that ensure free services for low-
therefore means to maintain minimum standard of public space for services in the
(Falco, 1987; Ricci, 1999). Consequent to the development of neoliberal economy
sector shrinkage, even the private provision (sometime even inconsistent with m
not definitely sufficient to balance the great lack of urban services, which ge
the southern regions.

Mostly in great cities like Palermo, the public/private partnerships (the
programs) focus their attention on the multiplier effect of the real estate i
improve the urban quality of neighbourhoods at high risk of social exclusion, us
of these kinds of interventions. Unlike the partial success recorded in northe
areas these programs substantially favour the creation of private facilities, wh
to medium-high income population groups, leaving practically unchanged the pu
services and the deprived social context (Bonafede and Lo Piccolo, 2007).

Despite the effort of the third sector (voluntary services and associations) te
disadvantaged groups of population continue to be affected by the public equip
remaining in urban condition of overall hardship mostly in marginal neighbourho
regions. In addition, during periods of economic crisis, the segment of popul
needs of the public services like health, school, culture and sport, increases r

In this situation, the right to minimum equipment per person of public servic
discredited by neoliberal positions instrumentally, when not utilized as persu
business. Actually, the decree on urban standard does not appear adequate for
different demands expressed by the flows of socio-cultural groups, which are m
body of the city, like the migrants for instance. However, the current debate o
the Principles on matter of public spatial policies and urban regeneration
rarely focalized on the enhancement of public services equipment in urban domain

The new national bill does not regard the development of policy for recognizing
redistributions of the rights to the city, the quality of services and their s
environmental protection and of the number of population compared to morpho
typological aspects within the urban fabric (rather than the old zoning). The bi
to ensure indifference of owners positions principle with respect to the plan

Such indifference principle implies the rights for owners to build on the en
city through the free exchange and transfer of such building rights from one
depending on negotiation with municipal officers on distribution of the services
indexes, probably equalized, which are established for urban and rural zones wit

As some scholars highlight from this perspective, the development of financial
building rights will explicitly imply the growth of private buildings unlin
demographic dynamic and soil consumption concerns. Despite volatilization of fin

fact the capital has always the need to invest in tangible goods as the urban
2013). While, it seems that municipal technicians and planners need to become s
in order to acquire areas for services for free, by exchanging with private owne
in other areas or by increasing the building index in built-up areas.

Though, this indifference principle does not ensure that public action can be fr
influence of the individual owners and of the great financial capital. On the
giving to the private owners more contractual power with respect to the public
expressly requests only the owners as included subjects in processes of pla
regeneration.

While the bill considers the building rights freely tradable as a precondition
treatment of the property, the previous national decree on the urban standards
the minimum equipment of public services per person is simply eliminated by the
Decisions on the issue are devolved to the regional levels of legislation, whe
allowed to establish criteria for planning public equipment. However, the region
a weak role in the absence of national principles to which the regions should
Moreover, regional laws cannot refer to national norms abolished, unless local
new laws more restrictively.

In this background, the only recognized form of equality is incorporated
commodification. When the inhabitants do not possess negotiable values, like p
steady incomes, how do they access the rights to the city? Does the minimum equ
services per person continue to be a form of equity? Who is not involved by e
among owners, has the right to participate at the democratic processes of pl
relational values of public space yet significant?

These questions are linked to concepts of political responsibility and faculty o
period of economic crisis and ethical values, which in their turn are reflect
planning practice. To start answering the above questions, a particular case of
within Italian south regions. It clarifies how much the political responsibility
governments is really hard to bear for the political community in terms of publ
and urban low quality. The analyses illustrated in the following subsection are
to appraise how much these law rights on public space endowment have been overwhe
initiatives and principles are implemented by current government, taking respons
in the terms clarified by Arendt.

2.4 Public space of services in the Italian southern context: the case of Palerm

In the last year, the new municipal government of Palermo (in charge since 2
update the urban plan, since urban constraints had expired. In addition to oth
infrastructures, these constraints regard the public areas dedicated to ser
Therefore, the debate on the new urban plan was the occasion to revise the goal
of uncertainty regarding national and regional laws on urban planning and a
minimum
equipment of public services per capita.

The municipal directives for the plan, a sort of technical/political guidelines
of technical department of urban planning, illustrates existing public serv
prevision, by describing typologies and areas occupied or still to be emp
neighbourhood except for historical centre because is ruled by a different pl

indications, these data on areas are not linked to the number of inhabitants, ju
public services
are not distinguished from the private ones. While the population is known, da
between public and private services are not therefore available.

By using data provided by municipal offices, the analysis is therefore addresse
existent and in prevision amount of services per person within the entire m
aggregating 23 neighbourhoods; 2) the distribution of existent services per
typology and for each of the 23 neighbourhoods; 3) the existent and in previsio
urban level per person; 4) the consequent soil consumption, measured as percent
areas designed to services on the entire area of Palermo (except historical cent
urban level. The first three analyses use instead the index of square metr
($m^2$/inhabitant).

The typology of services and the quantity per capita are compared with the
standards of 1968 as described in the subsection above. The data of popul
neighbourhood is provided by municipal office for the year 2010. The total popu
655,380 inhabitants, while the total area of Palermo (except historical ce
157,433,036 square metres.

Table 1. Local Services Palermo 2010

| Typology | Urban Standard ($m^2$/inhabitant) | Existent ($m^2$/inhabitant) | Prevision ($m^2$/inhabitant) |
|---|---|---|---|
| School | 4.5 | 1.9 | 3.3 |
| Common Interest | 2.0 | 1.4 | 2.7 |
| Park | 9.0 | 2.3 | 6.0 |
| Parking | 2.5 | 0.7 | 2.4 |
| Total | 18.0 | 6.2 | 14.4 |

Table 2. Local Services Soil consumption Palermo 2010

| Typology | Theoretic by Standards (%) | Existent (%) | Prevision (%) |
|---|---|---|---|
| School | 1.9 | 0.8 | 1.4 |
| Common Interest | 0.8 | 0.6 | 1.1 |
| Park | 3.7 | 1.0 | 2.5 |
| Parking | 1.0 | 0.3 | 1.0 |
| Total | 7.5 | 2.6 | 6.0 |

The analysis on the entire area of Palermo (except historical centre) illustra
public service equipment is equal to about a third of the minimum established by
shortage is mostly recorded for parks (equipped for game and sport) and for
(primary, secondary, kindergartens and nursery).

Furthermore, the supplementary areas in prevision for the public equipment do
situation (Table 1). Also by adding these new areas foreseen by the directive
amount of services does not reach the minimum established by law, mostly regard
public parks.

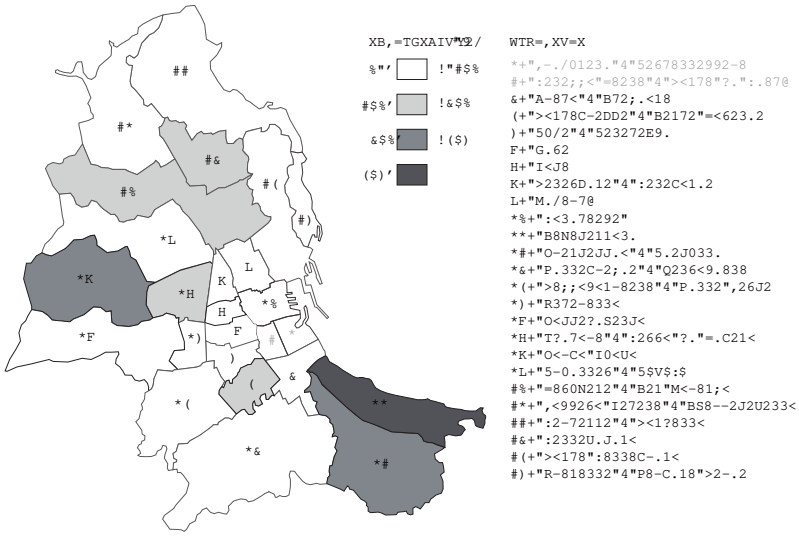

Figure 1. Schools per neighbourhood (m²/inhabitant)

In particular, the distribution of services per-neighbourhood shows that in t
cases, the areas for schools are minus or equal to two squared metres per inh
Only four neighbourhoods, Montegrappa-Santa Rosalia (n.4), Uditore-Passo di R
Resuttana - San Lorenzo (n.20) and Pallavicino (n.23), have an endowment of educ
between two and three square metres per capita. Two neighbourhoods, Brancaccio
and Borgo Nuovo (n.18), exceed three square metres per person and only one, Set
has equipment above standard, probably resulting from a high concentration
schools which should be more correctly included in urban facilities level.

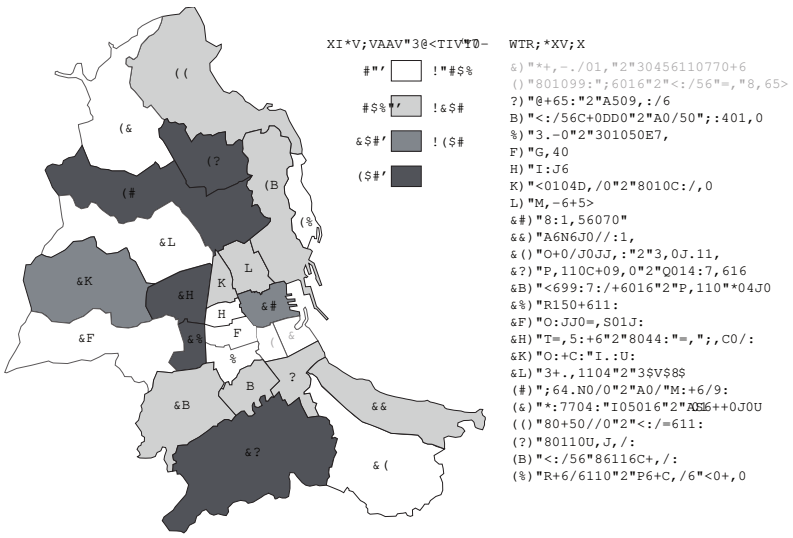

Figure 2. Common interests facilities per neighbourhood (m²/inhabitant) Palermo (m

With regard to facilities of common interest (Figure 2), five neighbourhoods
exceed the standard (two square metres per person) and the central Politeama nei
is near to mandatory minimum, while eight neighbourhoods reach no more than one
per inhabitant and eight others have values less than or equal to 0.5. In addi

analyses could probably show a large incidence of the religious facilities co
services for collective activities.

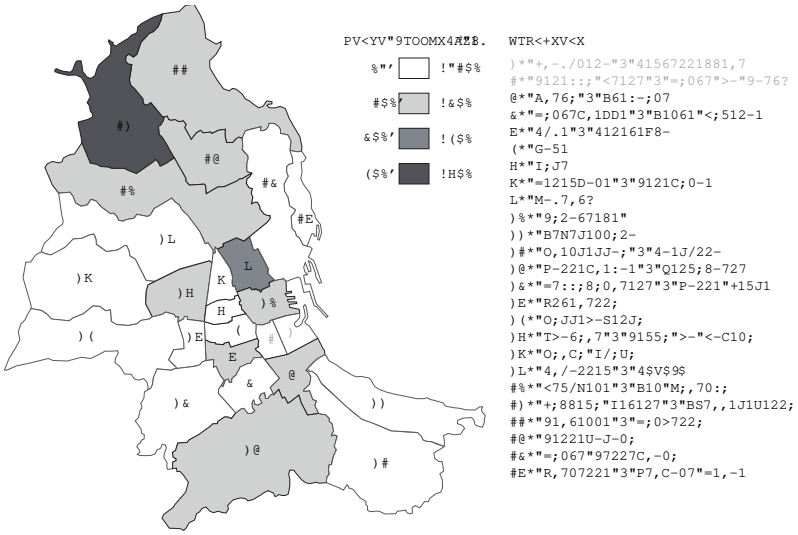

Figure 3. Public parks per neighbourhood (m$^2$/inhabitant)

The public parks for games and sport (Figure 3) only in Tommaso Natale–Sferra
reaches values between six to seven square metres per person, while in the
neighbourhood (n.9) the values are between four to six square metres per perso
neighbourhoods the values are between two to four square metres per person, whi
the thirteen neighbourhoods the equipment of public parks is not over two sq
person.

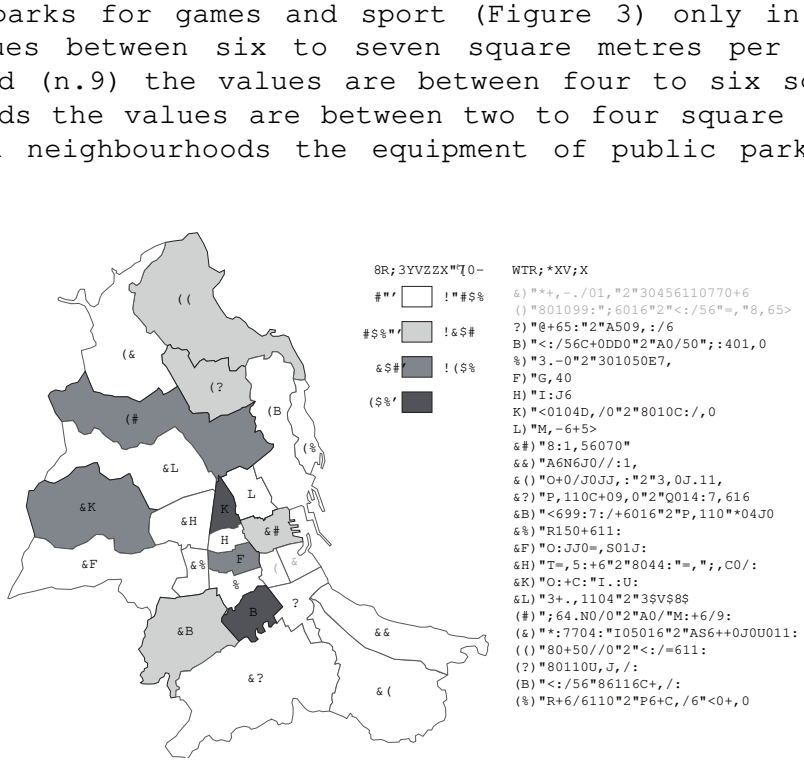

Figure 4. Parking areas per neighbourhood (m$^2$/inhabitant)

With regard to parking areas (Figure 4), the highest values are recorded in Zisa
(n.18) and Resuttana–San Lorenzo (n.20) that exceed the standard in Montegrapp
Santa Rosalia (n.4) and Malaspina–Palagonia (n.8) because of computation of gre

should more correctly be included in services at urban scale. For four neighbou
n.22, n.23), the equipment of parking areas is between 0.5 and 1.0 square meter
all other neighbourhoods the recorded values do not exceed the 0.5 square meters

Table 3. General Services Palermo 2010

| Typology | Urban Standard ($m^2$/inhabitant) | Existent ($m^2$/inhabitant) | Prevision ($m^2$/inhabitant) |
|---|---|---|---|
| High School | 1.5 | 0.5 | 1.3 |
| Hospital | 1.0 | 1.7 | 1.8 |
| Urban Park | 15.0 | 3.7 | 3.7 |
| Total | 17.5 | 5.9 | 6.8 |

Regarding the public equipment at the general levels as urban parks, hospitals
(which should overall respect the minimum quantity of 17.5 square meters per cap
is not better. As can be seen (Table 3), also in this case the recorded total va
the mandatory quantity. Only hospitals have values over the required standard pe

Table 4. General Services Soil consumption Palermo 2010

| Typology | Theoretic by Standards (%) | Existent (%) | Prevision (%) |
|---|---|---|---|
| High School | 0.6 | 0.2 | 0.5 |
| Hospital | 0.4 | 0.7 | 0.8 |
| Urban Park | 6.2 | 1.5 | 1.5 |
| Total | 7.3 | 2.5 | 2.8 |

In this background, the incidence of soil consumption of public equipment on t
Palermo is really modest both considering local services at neighbourhood scal
general facilities at urban level (Table 4).

2.5 Results

Based on data of directives for urban plan, the analyses highlight a great d
equipment, which is not balanced by foreseen provisions, neither in quantitative
general levels, nor in distributive equity and qualitative terms. The municipa
promote the attention on efficiency in managing public/private services, althou
the references to the spatial and environmental qualities of these latter.

An interesting spatial analysis, which is based on a social hardship index, is
section of the municipal directives as an unconnected aspect from public serv
Linkages between these two aspects are needed. Nothing is therefore said on
demands of multicultural city, on the inclusion of disadvantaged social groups
environmental issue (like energy saving, alternative energy using, soil perm
conservation and security of buildings and on sustainable mobility) as some
criteria (or parameters) to consider for an equitable public provision of servic

The issue is particularly problematic since in Palermo the endowment of fac
computed not only by including the private services, but also by referring to
inhabitants. In other words, if the volumes of buildings for housing become the

100 mc per capita) to appraise corresponding number of population (as original
decree on urban standards), the quantity per capita of the endowment of servi
further, showing instead a great wastage rate in terms of empty housings.

Furthermore, the municipal directives for the urban plan do not mention many
buildings and green areas, which are derelict in the city, in order to be re
services functions. A transparent appraising of convenience for their renovati
increase and enhance public space of services should be taken in consideration b
to privates. With this purpose, exhaustive maps of public properties and their c
needed as well as descriptions on the use of urban space.

In a frame of severe contraction of public local finance, according to munici
acquiring of the new areas designated for public facilities relies explicitl
measures among owners and consequently on the building rights freely transferab
distributed on all over urban zones. Implicitly inspired to the abovementio
principle, these measures imply the same ethical questions regarding exclus
inhabitants from the democratic process of planning.

Moreover, the public services reduction in favour of private ones has been o
period of crisis and deregulation because of the contraction of local public fi
Italian northern areas where though regional laws had already increased the mini
public services compared with the quantity established by decree on urban standa

Some private services provided that are subjected to particular conventions witl
certainly contribute to improve the urban endowment, although the public prop
warranties over the time, principally if the latter is recognized as a commo
treated as a particular form of private property of local government. Such dist
in the public institutions and latent conflicts which practices of the public
which are insurgent from the city, have the merit to make manifest.

## 3 Conclusions

In a frame of neoliberal practices development, the value of relational use of
related rights of citizenship are considered negligible compared to the value of
commodification. Although neoliberal tendencies are more developing in contemporary
Italy social and political concerns about the public space decline in former t
minimum measures for territorial allocations of public services. These minimum
aimed at ensuring, at least on the theoretical level, rights of citizenship, re
social needs and according to distributive equity principle.

In following periods in Italy, the deregulation practices in planning have tri
principles of equity and social justice with flexibility and efficiency from a
avoiding answering plurals social demands and, mostly in Italian southern co
redistributing citizenship rights for deprived population groups. Neoliberal p
aimed at promoting privatization of public spaces removing their public relation
only resulted in exclusion of weaker social groups from citizenship rights, b
confusion among political ends, technical tools and ethical principles.

It is not, in fact, political aim of every government (central and local)
endowment of public space for services (distributive justice) expanding access t

which at certain strict conditions could be justified by means of compensatory
owners. Conversely, some urban plans as representations of political space a
privates real estate values and the construction volumes consistently with t
rights of building inherent any privately owned land and freely tradable in the

According to a recent Italian bill, the principle of equality to have access to
be replaced by indifference principle among all owners regarding public dec
planning as well as, in a technical level, the building index could be indiffe
urban zones in the city. In other words, these urban zones are equally indiffere
do not have intrinsic features as well as private sphere and public sphere are
mere properties. Consequently, according to bill, only owners could be enablec
public spaces of services under their entitlement of properties to participate
plan and to negotiate their freely tradable building rights.

In a background of political representation crises and of public local financ
negative impact mostly on southern contexts, is the public actor (as local go
institution) aware to represent inhabitants both owner and without property? In
who is entitled for acting in the name of the public property contextually rep
who are not owners, according to the national bill, the first ones will be r
participation to planning process, while the second will have only the individu
respect law. This mode of equality is a paradox in front of the law on urban pla
arena, because it introduces a great discrimination among citizenship rights,
owner and who is not an owner; between social groups, which are entitled for rec
space and excluded ones.

As highlighted by Arendt, whether social sphere is governed by difference and
principle, regulated by uses and customs, while private sphere is governed by e
ruled by daily necessity, the public space, which is eminently political and re
instead governed by equality principle and is regulated by law. Juridical acts,
avoid preferences in social relations, are not however entitled of establishinc
discrimination or exclusion in democratic regimes (Arendt, 2003).

Even though I agree with many scholars that pointed out the unrealistic dimensio
ideal public space, constantly defined and equally accessible, but rather the
struggles over time, reflections on principles that inspire laws on urban pla
ethical concern. In this frame of flipping of ethical principles, discriminatio
not only private interests of owners will certainly compromise distribution o
services, but also the deprived inhabitants will be excluded from public spa
Distributive equity and equality/indifference among owners are definitely confli

From a southern Italian perspective, national influence of such indifference pr
laws has more serious consequences, since public endowment of services per pe
prejudiced by a severe shortage, especially in disadvantaged areas. Who takes th
deprived people? Compared with insurgent claims in other geographical context
1998, 2003; Holston, 1998, 2008; Harvey, 2013), in southern Italian regions ar
Palermo disadvantaged social groups mostly occupy public property in order to
while relational values of public services and their social use are usually
income social groups, who implement fragmented forms of self-management.

Although occupation of abandoned public spaces in order to recover their socia
resistance against privatization and a rebellion against economic domination o
additional questions on the distributive equity regarding low-income social gro
Are these latter groups allowed to be included in these rebel social spaces? A
goods really able to ensure inclusivism or are they in themselves new forms of p
social discrimination?

Scholars argue that this contradictory condition arises from neoliberalism a
inclusion (manipulated) and redistribution (denied); squatter movements by en
fissure are useful in order to destabilize the neoliberal hegemonic order (Mir
consider this contradiction a way to develop claims of urban rights in urban r
neoliberal economy (Harvey, 2013). Urban planning therefore is able to undertake
a bureaucratic process deemed functional to neoliberal principles or radical, in
movements, in order to contrast unequal principles and rights.

As Fraser highlights  justice today requires both redistribution and recognitio
sufficient  (Fraser, 1998, p.5) where participation links together these prin
revisions for new development of relational values of public space are requ
participative practices, which besides routine useful to depoliticizes communit
enhance democracy, including deprived social groups in deciding rights to p
services. This entails the reject of whatever indifference principle among urban

Although urban standards, as minimum public space per person, appear an insuffi
distributive equity, appropriately integrated with social hardship index, urban
parameters should be still a purpose to reach in Italian southern context i
disadvantaged inhabitants to have rights to the city; reducing or delegitimizin
authorization to enact undemocratic urban planning processes. Whether loca
automatically aligns with national economic principles, as the indifference pri
focalize its judgment faculty on local context, substantially avoids of inte
standards on public services as a democratic finish line that should be improv
extend rights rather than reduce them. When local government through urban plan
space for services implicitly reinforces neoliberalism of its predecessor wit
responsibility for the present and future actions.

The thought of Arendt leads me to consider responsibility as a prerequisite f
political initiatives. The faculty of judgement therefore helps to distinguish
previous ethical principles and its political inheritance. From a southern Itali
a local government, as well as the community, is politically responsible when
predecessor s actions and ethical principles, and independently from national di
judge the need to change political direction.

Palermo urban plan at municipal level. Analyses on the municipal directives have
thanks to the work I developed within this frame in order to highlight critical
services provision.

# THE POST-DISASTER AS AN OPPORTUNITY TO RECONSTRUCT A MORE JUST CITY

Giulia Bortolotto
Departement in urban Planning, Design and Architecture Technology (PDTA); Ph.D student, , Sapienza, Università di Roma, Roma, Italy, giulia.bortolotto@uniroma1.it

Keywords : disaster, reconstruction, justice

**abstract**

*This paper would like to investigate the response strategies to a disaster from two different cities.*
*In this context, the disaster looks like as an opportunity for the city to be able to decide the direction for their reconstruction.*
*The reflections relate the strategies undertaken by two cities: New Orleans and Beirut hit by a disaster, respectively by Hurricane Katrina and a civil-war.*
*As the disasters give rise to complex situations (new socio-spatial configurations, conflicts, inequalities) and have greater effect on the most vulnerable populations, it is believed that the issues related to justice in post-disaster may be interesting topics of discussion.*
*For this purpose, firstly , the paper would like to promote reflections on the concept of disaster. Generally disasters are classified according to their root cause. This paper would like to draw on definitions of disaster from the social sciences in order to develop reflections with reference to the disaster impact (effects) rather than the phenomenology (causes) .*
*After that, an exploration of the direct and indirect effects of disasters will drive the reading of the case studies. In the end, the analysis of the response strategies of the two cities will investigate the effects previously identified whether or not they were considered and the implications it had on the city.*

## 1.Introduction

This paper would like to proposes the first part of a doctoral thesis, still ongoing, that wants to investigate the operation of the planning in the context of the post-disaster situation. The thesis intends to inquire the possibility for planning to catch the disaster as an opportunity to operate with the a propose of urban justice. Many academics argues that planners should strive for "just city" as a main goal or main objective of the planning acts (Fainstein, 2000, 2005, Krumholz and Forester, 1990; Harvey, 2003). The thesis intends to investigate how these debates may be declined in a post-disaster situation. The importance of justice in the city is highlighted by Susan Fainstein that describes the justice as one of the main elements of a good city but also one of the most transgressed elements (Fainstein, 2009). According to the Susan Fainstein's ideal of "just city" the city is identified as the place " public investment and regulation would produce equitable outcomes rather than support those already well off " (Fainstein, 2009,p.3); More over pena families or those who have less, excluding them from rights that are enjoyed by others who are wealthy individuals it is unjust. Democracy, diversity and equality are the three main qualities that made up the Fainstain's "Just city". Equality is foundamental even for Uitemark's just city. In according to him, a "just city" are requires to be both " accessible to each and every person irrespective of their purchasing power", and to be a city where " residents have control over their living environment, that is, they engage with the polity of which they form part". (Uitermark 2009,p.359). This investigation of the the implications of disasters and their considerations in planning in terms of justic, would like to propose the first part of the PhD research. This first part starts from the definition of disaster deduced from the social sciences, identifies the effects of disasters and ends finding the majors key to put the focus on the justice in the city in post-disaster situation.

Regarding this, it has been chose to start with scouting the international literature including different discipline and proceeding with the classification of the disasters effects. Finally, this major effects are investigated in two specific context: the city of Beirut and the city of New Orleans.

The choice of this two context is linked to the easy availability of information on the disaster effects and the planning activity in the post-disaster phase. More over this two disasters, are considered interesting because are at the same time originated from different causes and the time elapsed since the disaster is sufficient to investigate tree different phases: the pre-disaster, the moment of impact, and the post-disaster.

The proposition of the direction that the planning has undertaken in response to the disaster and how it has considered whether its effect will advance the considerations on how the latter seizes the disaster as "windows of opportunity". At the end all these considerations want to be useful to explore and persecute the concept of "windows of opportunity".

**2. Disaster as "windows of opportunity"for...**

Disasters can be seen: in one hand as an "windows of opportunity" for the city to improve itself (Cuny 1983, Burby et all 2000, Vale and Campanella 2005,) in the other hand they can unleash the latent situations which, if not considered, hinder the city in the recovery. Infact in some case, they may perpetuate the economic and social inequalities pre-event. As like disaster of deliberative human origin (M.C Treu, 2010), for someone this disaster may represent the opportunity to increase the prosperity, the power and influence, whereas in an extreme point of view , they can become an influential power tool ( N.Klein , 2009).

These results underline and highlight the lack of clearness of what can be defined as "better" and "more just", which implies the lack of a conceptual framework to guide recovery efforts (Regnier 2008).

**What is a "Disaster"?**

When an external event impacts violently into an urban system, it causes a shock and a interruption of the normal course of his function. If you imagine two similar events, like two earthquakes, with the same intensity, duration, magnitude, but dislocated in two different place, one in a desert uninhabited and one in a city, it is simple to understand that the two outcame are very different. Therefore an event can be defined "disaster" only when it strikes people socially organized in a space(Marcuse 2013; Donovan 2013; Ligi 2009).

In the sociology of disasters, academics define the disasters as "collective events that require extraordinary efforts to protect and defend a social resource whose existence was seriously threatened." Ligi 2009).

In according to Daniel P. Alchrich and Michelle A.Mayer, the disaster is "an event that interrupts the normal activities and causes severe damage to the society. Disaster can be defined as events that can both kill people and destroy homes, infrastructure, economies and the human bonds in a society, in other words everything needed for a society to operate properly "(Alcrich, Meyer, 2013). Therefore, disasters are social phenomena (Cutter, 2010).

**3. Disaster effects**

The consequences of disasters on society are often similar: extensive loss of life, economic block, destruction of the natural environment and of buildings, obstacle of development and endangered local institutions and livelihoods . However, the damage directly caused by the effect of the agent itself (direct damage ) are not sufficient to explain the consequences of disasters (Tierney, 2001). Quarantelli argues that "even if indirect effects (secondary impacts) are massive, the recovery process sometimes ignores or minimizes this indirect effects of disasters" (Quarantelli, 1999). in agreement with this approach, we intend to provide a classification of the effects of disasters which takes into account the direct and indirect effects.

**Physical impacts**

The physical impacts of the disasters have several effects. In one hand affects people regarding their personal health, mortality and violence (Charveriat, 2000) ; in the other hand affects the damage of the built environment as damage of material goods and infrastructure (Tierney 2001).

The physical destruction has even other indirect effects on the society , like:
- the destruction of home and key building (such as public facilities, cultural and historic buildings) has a double indirect effects. First on the reorganization of urban space due the forced moving of people, the second on the loss of "identity" of individuals who see destroyed their landmarks.
- the destruction of infrastructure (such as roads, bridge and dams). For example, the importance of the destruction of transport infrastructure, is evident since the phase of response to a disaster because trasnportation is a major conponent in any emergency preparedness and evacuation plan. Unequal access to transportion alternatives in a disaster increases the vulnerability of the poor, elderly, and disabled people. In addition, their destruction cause indirectly the difficulty for individuals to access to homes and jobs.
- The destruction of businesses and workplaces causes indirect damage to the economy and productivity (Lindell and Prater 2003).

**Social impact**

In addition to the physical impact, the disaster generate effects on society. The entity of these effects are strongly correlated on the social context, this is specified in the concept of social vulnerability. In according to Winsner, social vulnerability is defined as "the characteristics of a person or a group that affect their capacity to anticipate, cope with, resist and recover from the impacts of a natural disaster" (Wisner, 2004) . This concept is also been expanded in post-conflict situations by Aurbee . In according to Aurbee, social vulnerability is defined as 'the characteristics of a person or group in terms of their capacity to anticipate, cope with, resist and recover from the impact of any form of natural or artificial hazard '. Cutter describes social vulnerability as including "the susceptibility of social groups or society at large to potential losses ( structural and nonstructural) from hazard events and disaster"(Cutter,2006).

This vulnerability (or susceptibility) to the impacts of disasters of a group of individuals, according to Susan Cutter, "is not only a function of demographic characteristics of the population (age, gender) but of more complex constructions" (Cutter,2006).

For this reason, the social vulnerability is influenced by the :

1-socioeonomic status (income, poverty, employment and education variables).

2-minority status (social and economic marginalization of racial and ethnic groups).

Smith and Petley argue that inequality in society are highlighted more after a disasters. As stated by Haas recovery is not an equal process: infact it accentuates the disparity between those who can rebuild in a faster way and better position. Those who have greater access to resources before the disaster continue to have greater access even in to post-disaster situation (Haas, 1977).

The importance of recognizing explicitly the role of the vulnerability during the recovery process is highlighted by Wisner et al. (2004), which defines the recovery based on the reduction of vulnerability. He argues that to reach a real recovery, the people (individuals, families and communities) in the post-disaster must have reduced their vulnerability and increase their resilience. A community is defined as resilient if it swiftly recovers after a disaster ( Cimellaro 2010).

A further element that affects the social vulnerability is the social capital. Many studies have focused on social capital in the post disaster shown the ability of disasters to modify existing levels of social capital (Putman 1993 Catiglione, Van Deth and Walleb, 2008 and so on). In according to Putnam social capital is

defined as, features of social organizations, such as networks, norms, and trus
cooperation for mutual benefit (Putnam,1993: p. 35). Studies have been demostrated that disas
reduce the social. Social capital may deteriorate following a disaster because of dislocation of network members, loss of network ties through injury or death, or overwhelmed network resource capacity (Kaniasty and Norris 1993).

**4 disaster in Beirut and New Orleans**

**Beirut pre-disaster context**

Beirut in 1970 was a city with a million inhabitants. Originally, the inhabitants were Sunni Muslim and Greek Orthodox Christians, with a small percentage of the Jesuits. Beirut also has become home to many immigrants and refugees, including Armenians and Greeks, that added to the diversity of the city and enhanced its commercial base. The social tolerance between ethnic groups and the many sects of the city (including Shiites, Sunnis, greek-orthodox, greek-Catholic, Maronite Catholics, Druze and Jews) was guaranteed by common economic interests.

The downtown was the Lebanonís Melting Pot; place where people from all walks of life mingled. Khalaf argues that "the relation and the intercultural mixing in the city center, was strong. Many merchants of various communities were partners in private business and in the old souks and bazaars, artisans and merchants have worked side by side. Christians and Muslims have continued to meet in an official capacity, and served on the same committees, tribunals" (Fawaz, 1983). In addition, the historic core contained important buildings such as the Parliament and a number of ministries, the Municipality, the Central Post Office, banks and public squares.

**The disaster effect in Beirut**

The destruction that followed the civil war broke out in 1975 caused massive displacement of population.. During the war, Beirut was divided along ideological and religious lines. The famous "green line", starting from Martyrsí Square in the historic center, divided the city in two part est and west. The central district was completely abandoned because it was the main combat zone. In particular, commercial activities and businesses destroyed where relocated in the suburbs, in the specific in coastal areas north of the city. The population that had animated the old town before the war moved to the suburbs and Ras Beirut, while the buildings destroyed were occupied by people displaced by the war and forced to take up residence in abandoned buildings.

**Beirut post-disaster and reconstruction. Solidere 's Master Plan in the City Center**

After the war, the city started the reconstruction phase channeling his forces over the city center as part more destroyed. Because the government had no effectively and efficiently structure neither enough funds for reconstruction, the physical reconstruction and development of the central areaentrusted in 1991 was assigned to a private company known as Solidere (Lebanese society for the development and Reconstruction of Beirut Central District). The vision of the Solidere's Master Plan in the City Center was to create a lively center of activity mixed: commercali activities, offices, administrative buildings, public spaces, recreational areas and cultural in addition to residential areas.

The goal was to restore Beirut as a regional and international center business: the new city center was to become a coveted tourist destination and prime residential area. Beirut had to have the most beautiful center city of the Middle East.

In the preliminary phases, the objectives of the master plan were established to the citizens. On this occasion, the citizens did not agree on replacement of most of the urban fabric with new forms because the latter was

completely unrelated to those pre-existing. In short, the plan presented ideas were not shared by the inhabitants (Gavin, 1996).

However, the aim of recreating a sense of place that is a sense of "community feeling of identity" was expressed in its slogan "anciet city for the future.". The goal of this slogan was very clear in the strategy of mixed uses. this strategy had a double goal: promoting the housing market and creating an urban fun life in continuity with the atmosphere that existed in Beirut's downtown before the war. Look to the future, however, was seen as the development of grand scale of the project, using mostly high-rise buildings and modern construction technologies to represent wealth and regeneration.

**Outgoing**

the conflict caused extensive damage to the urban fabric. As regards the downtown, almost all of its buildings and infrastructure had been destroyed. the population was forced to abandon their homes and leave the downtown, as well as for security reasons. These movement have caused the destruction of the existing social network. The aim of the Solidare's plan was to recovery of the economic aspect. In this direction, the plan held was concerned by type of building and their economic use . The fragmentation of property, as a result of the conflict, allowed Solidare to expropriate all the eligible parties. Moreover, the target population was made up of Lebanese expatriates or wealthy Arabs and not the old citizens and merchants. The reconstruction was not sent to the effects generated by conflict: the pre-disaster population, the urban functions of the city, the activity, the increase in urban poverty.

The fragmentation of property, as a result of the conflict, allowed Solidare to expropriate all the eligible parties. Moreover, the target population was made up of Lebanese expatriates or wealthy Arabs and not the old citizens and merchants. The reconstruction was not sent to the effects generated by conflict: the pre-disaster population, the urban functions of the city, the activity, the increase in urban poverty.

**New Orleans Before Hurrican Katrina**

The population of New Orleans before Hurricane Katerina was estimated at 484.672 inhabitants (2002). New Orleans was characterised by high poverty rates and low-wage jobs (Gault et al., 2005) was infact one of the poorest cities of the USA, with a poverty rate Opinions more than twice the national average (Center for Progressive Reform, 2005). The main core city, the Orleans Parish, and the region with about the 23% of the residents of New Orleans, the Jefferson Parish, lived in poverty. In Particular, the 48% of Orleans and 32% of the residents of Jefferson was low income. Eighty four percent of New Orleans residents living in poverty were African-American. The Ninth ward fully reflect these characteristics, infact before the hurricane the Lower Ninth had a population of about 14.008 inhabitants, 98% made up of African-Americans and 34% of the population lived in poverty. However, in their marginalization, the African-American population was organized in social circles creating a socio-political tradition, self-help, mutual aid, and resistance to structures of oppression. This enabled the population to realize institutions, social networks and events that was expressed in a neighborhood full of small businesses, barber and beauty shops, corner stores, eateries, gasoline stations, day care centers, as well as public schools and many churches.

**The disaster effect in New Orleans**

The disaster effect in New Orleans On August 29, 2005, Hurricane Katerina has caused destruction and flooding in 75 percent of the city. Immediately after the disaster, 200,000 individuals were dislaced (FEMA2005). The New Orleans African American residents were much more likely than displaced white residents to end up living far from the region. Many African American displacees ended up in cities suh as Houston and Atlanta. For these people, the forced movement to another state destabilized generation-old networks of kindfolk and close - knit comunities. Infact , longstanding social aid and pleasure clubs, organized to support leisure and community needs, have dispersed, as have church congregations and parishes. In addition, the displaced have been labeled as "refugees" (Rhodes, 2010) this alludes that is not as if they had lost only their home, but also their right to have a home.

**Post- disaster and reconstruction. People's plan of Ninth Ward district**

After Katrina, New Orleans Mayor *Ray* Nagin asked the ULI to prepare a strategic plan for the reconstruction of New Orleans that would guide the work of his committee recently established. ULI sent 40 of its members representing the public, private and non-profit organization for the city, under the leadership of Marilyn Taylor of Skidmore, Owings and Merrill , an architectural firm in New panel was published after a careful review of the planning reports of the past, the analysis of past data and present the United States Census, the visual inspection of the city, 300 local interviews and the organization of a local town hall meeting . Amongst other things, the ULI s report suggested a strategic operati redevelopment : the short-term rehabilitation of the areas that were less damaged and the destination of a park and wetlands for areas badly damaged. Many of these areas fall in the district Nith ward. However, the report of the mayor recommended the creation of planning teams to production of recovery plan for areas badly damaged. For this occasion, ANCON contacted the Department of City and Regional Planning for technical support, planning and design for all those who sought to rebuild New Orleans. The team format started a qualitative and quantitative analysis (Reardom, 2006). The quantitative analysis showed that a relevant part of the Ninth Ward was recoverable (as opposed to the analysis given in the report).The qualitative analysis, based on participatory processes, showed that residents of the area were willing to move to reconstruction of their neighborhood. This effort is underlined in the People's plan, presented just a month after. The People's plan is a strategic plan of action aimed at identifying a recovery model for the area. The vision of this plan is to "Create a Opinions more vibrant, sustainable and equitable 9th Ward That offers former and current residents, business owners, and institutional leaders to higher quality of life and attracts new residents and investors eager to participate on in an unprecedented revitalization of one of America's most historically, culturally, and socially significant urban communities ". The aim of the equity, highlighted by the plan, is clear both the result to be reached and plan process itself. Infact, the team was working both to ensure that all inhabitants to be able to return in their neighborhood and also that all inhabitants to be able to be part in the process. For example, in addition to the activities of survey and collection of information on the economy, population, employment etc, people and civic organizations were interviewed to collect their ideas about the redevelopment strategies. These analyzes have identified a series of answers to the issues that concerned the city both before the disaster (as endemic crime, the lack of jobs etc .) and after the disaster (lack of funds to rehabilitate houses, close of business etc.).

**Outgoing**

The impact of Hurricane Katina involved the devastation of 80% of the city. The Lower Ninth Ward recorded the largest number of damages. The majority of the population was forced to abandon their homes and leave the downtown, as well as for security reasons. The destruction of homes, economic structures and roads caused a lot of indirect damage to society as a weakening of social networks and, in turn, the increase in their social vulnerability. The Nagil's plan appears to take no account of this aspect. The right to return to their homes was not equally guaranteed to all citizens: while citizens of the less damaged houses was given the chance to rebuild, to the citizens of the houses damaged this possibility was not offered. the goal of the

People's Plan was to address this issue in order to allow the same right to citizens of the most damaged . It is possible to observe through analysis of the case of Ninth Ward that through the active involvement of the population, the solutions are directed not only to the physical reconstruction (the plan gives different directions), but also are directed to social reconstruction. the solutions, in the process and in the outcome, have been directed to the reduction of social vulnerability because they aspire to :

-Enable all citizens access to the assets. objective of the plan is not only to allow all citizens the right to return to their homes, but also to be able to improve their living conditions through the attention paid to the improvement of urban spaces and work spaces.

- Ensuring that all citizens the access to "power". the planning process had a strong inclusive nature. That has been reflected in the People's Plan. In this way citizens had access to power to target and contribute to the rebuilding process of their living environment.

**5.Conclusions**

As Ozerdem Argues, if disasters and their impacts are the result of unresolved development challenges, then disasters can Shops provide new opportunities for development. 'This requires a development approach That is both sensitive to opportunity and able to reserved respond by designing reconstruction Programmers to built such opportunities' (Ozerdem, 2003). In this way, the opportunities can be seen in a perspective of social justice. in according to Harvey, the right to the "just city" "is not morely a right of access to what the property speculators and state planners define, but an (common) active right to make the city more in accord with our hearts desire, and to re-make ourselves thereby in a different image" (Harvey, following Mar 2013: p.42).In the case of Solidere the disaster has been caught as a "windows of opportunity " to rebuild a beautiful city center for a great city. The beautiful city center is in reality as an exclusively island isolated by the city. In this direction, it did not take account the impact generated by the war. The plan helped to perpetuate the economic and social inequalities by moving these issues in the other part of the city.

In the case of Lower Ninth ward neighborhood the People's Plan grasps these opportunities. Infact, it has double objective of making a city accessible to all and creating a city where residents are committed to have control over their living environment. The consideration is this was been possible because the plan aimed at the reduction of social vulnerability increasing the quality of social network. Social vulnerability and social network of a community destroyed are some of the key processes affecting the level of impact of disaster and as such should be considered as main components in the efforts of the reconstruction.

Keywords: sustainable transport, social justice, limits to growth, Belgium

## Abstract

*In the field of mobility and environment, recently a number of promising developments can be observed. Despite the sustainability optimism emerging from such observations, the Club of Rome question whether there are any limits to growth is increasingly relevant. Perhaps even more important, policies with respect to mobility, accessibility and environmental impact seem not to contribute automatically to social justice. Through adding a limits-to-growth stance and a social justice perspective to what is called the orthodox sustainable mobility vision, we argue that all possible controversies on environmental impacts eventually boil down to an ethical debate. Such* debates are not the exclusive domain of experts, hence we state that there are sustainable mobility . Experts can nevertheless play a particular role in discus *mobility. In order to make our ideas tangible and to demonstrate the consequences, we apply this to a number of policy decisions in Belgium that carry the "sustainable mobility" label. Starting from our Belgian case study, in the conclusions we adopt again a global perspective, in which we stress the importance of looking for synergies between those environmental and social justice measures that allow for accounting the ethical dimension of sustainable mobility debates.*

## 1. Introduction

*In the field of mobility and the environment, a number of promising developments can be observed*

In Belgium, as an example, quite some indicators suggest that sustainability objectives are slowly but surely achieved within the field of transport. With an average annual growth of 2.41% between 2000 and 2011, inland navigation in the Flemish region could make a nice report (Meersman et al., 2013:27). In 2011, sulphur emissions from inland shipping, rail and road transport have practically disappeared, but twenty, or even only ten years ago, the situation was entirely different (ibid.: 90) . When looking at Belgium s federal home-to-work travel survey, we see that both public transport and bicycles have gained market share between 2005 and 2011 (Verhetsel et al., 2014:37). Also, national road traffic statistics show that the number of kilometres driven per car registered in Belgium is decreasing, while the number of train passengers increased by as much as 50% between 2001 and 2010 (Statistics Belgium, 2014). Still in Belgium, we see the $CO_2$ emissions of newly sold cars falling from 160 g/km in 2002 to 130 g/km in 2012 (MIRA, 2013).

And these are just some figures. Sustainable mobility has become a common notion in many policy plans at almost all levels of government, in which emphasis or even general meaning may vary considerably (Bulkeley and Betsill, 2005). At the European level, for example, the term is used to indicate a decoupling between the growth rate of transport and its associated adverse effects (Tight et al., 2004). At national or regional level, under the same heading, new technology is subsidized and efficiency increasing measures are funded. And at the local level, the notion of sustainable mobility is often used to justify investments in pedestrian areas, parking policy, and the construction of bicycle tracks. This goes along with the drawing up of Sustainable Urban Mobility Plans (SUMP). But except in policy circles, sustainable mobility is also live among the public and businesses. In many cities, cycling has actually become fashionable, railway station precincts are refurbished, and the car is no longer the sacred cow it was in the 1960s. Some authors have even identified a paradigm shift, in which the smartphone has become an attribute more importantly to a contemporary lifestyle than the car (Davis et al., 2012). Finally, we can refer to concepts such as Transit Oriented Development, Smart Growth and compact city policies which have increased in popularity. This collection of ideas can be labelled the sustainable mobility paradigm (Banister, 2008) or the ort transport vision (Baeten, 2000).

The spread and acceptance by many scholars and practitioners of the sustainable transport paradigm is a complex process, which is not only about knowledge diffusion, but also about opposition, struggle and the promotion of alternatives to traditional views. A number of papers in transport studies have portrayed sustainable mobility as an alternative to predict and provide transp discussing these two visions on transport policy, Enoch (2012) speaks in terms of camps and tribes Traditional transport planning is the domain of conventional transport engineers and economists, while sustainable mobility is rooted in urban planning and related disciplines. In a similar fashion as with sustainable mobility, Transportation Demand Management (TDM) or mobility management is seen as an alternative to strategies that provide additional capacity to meet travel demand (Giuliano, 1992; Meyer, 1999; Vanoutrive et al., 2010). TDM on the other hand, attempts to manage demand by promoting public transport, the bicycle, telework and flexible work schedules. One of the most cited articles adopting the alternative point of view is The sustainable mobility p 2008 by David Banister. This paper is largely structured around four transition lines that are, according to the author, essential to sustainable mobility: travel mode choice, urban and regional planning, technology, and travel substitution.

In the present paper, the aim is to challenge the orthodox sustainable transport vision, of which Banister s seminal paper is exemplary, by confronting it with two potentially tr being firstly the urge for growth, and secondly the issue of social justice. By doing this, we highlight the ethical dimension of sustainable mobility, and sustainability in general, and we argue that this dimension should be made more explicit in current debates. In the next two sections we will elaborate

on the meaning of each of both issues in relation to the notion of sustainable mobility. Earlier discussions can be found in Baeten (2000), Essebo and Baeten (2012) and Farrington (2007). Here, the focus is on Belgium and thus not on the global level (in contrast to e.g. Holden, et al. 2013, 2014), furthermore, we discuss some recent contributions such as the socio-technical transition approach (Geels, 2012) and the book How Much is Enough (Skidelsky and Skidelsky, 2012).

After a discussion of the environmental dimension in the next section, we illustrate the paradoxical, often ironic and sometimes even cynical situations to which measures in the field of sustainable mobility can lead, when viewing these from an ethical perspective. Again, we turn to a number of examples from Belgium, which may be considered fairly representative in terms of mainstream sustainable mobility policies, considering the central location of the country, and its engagement in relation to the European Union.

## 2. A limits-to-growth perspective

*Despite the sustainability optimism emerging from recent observations, the Club of Rome question whether there are any limits to growth is increasingly relevant*

By 1970, environmental reports sounded far less optimistic than the positive introduction of this paper. The oft-quoted report of the Club of Rome (Meadows et al., 1972) argued that the growth of the world population and its consumption would slowly but surely bump against the carrying capacity limits of the earth. And even though in the seventies global warming was not yet on the political agenda, the impending exhaustion of natural resources made the problem outlined very palpable, especially after the outbreak of the first oil crisis in 1973.

Ever since, within many economic sectors, ecological thinking has become the formal reason to adopt a perspective of energy efficiency more often or more quickly. The concept of carbon intensity, which measures the ratio between $CO_2$ emissions and economic output, is a logical product of this way of thinking. Indeed, today, many economic sectors can rightfully be proud of their improved carbon intensity level. In the developed world, examples include the energy sector, but also heating emissions from new houses are declining.

But do we observe such results in the transport sector too? From time to time car manufacturers show off with new, high efficiency concept cars . But in reality, the fuel consumpti the world is hardly, if at all, going down (Chiara and Canova, 2013). Recently, the market for large cars has only steadily increased, and in smaller cars, part of the potential energy savings are offset by the presence of a range of new gadgets. Furthermore, replacing a thirsty car with a more efficient one does not mean that the old car is removed from the market: used vehicles remain a prized import product in many Third World countries, even the less fuel efficient ones.

Broadly speaking, we can say that mobility has been growing quasi continuously in the course of time. In 1960, the number of motor vehicles registered in the world was estimated at 127 million, while in 2010 more than 1 billion vehicles occurred in the tables (Davis et al., 2011). It is interesting to note that the average increase in the number of cars in this era (slightly more than five per cent per year) was even higher than the world s GDP growth (a little less than five per cent per to indicate that the increase in the number of cars in the world proceeds in interaction with economic development in general. But does this also apply to the amount of kilometres travelled?

Until recently both scholars and policy makers assumed a steady increase in distances travelled. Although global figures on this are not readily available, many developed countries do keep related statistics. For the United States, for example, we see that the mileage increased from 1,600 billion in 1983 (when the effect of the then crisis started to wane) to more than 3,000 billion in November 2007, just before the international fuel prices showed an unprecedented peak (Davis and Baxandall, 2013). Since then, the statistics show some decline, and the 2007 mileage level was not reached again.

Today we see this phenomenon, which was meanwhile baptized peak car (Goodwin, up in many other countries too. In Belgium, our example, we see not so much a decline in the growth of the overall distance travelled, but rather a stabilisation of the number of kilometres per inhabitant since 2007, and a decrease when counting per registered vehicle (Statistics Belgium, 2014). In other words, the Belgians just continue to buy additional cars, but are driving these less than they would have done before.

The discovery of the mentioned kink in the growth curve may have provoked some almost euphoric reactions among activists and even researchers: finally, the limits to growth had become visible in the behaviour of the motorist! It is therefore no coincidence that the term "peak car" was clearly inspired by peak oil . The latter refers to the expected production peak of petroleum, wh bell shaped curve fitting in nicely with the discourse of The limits to growth 2008). Meanwhile, however, it has been demonstrated that the relationship between peak car and peak oil is not unambiguous: there is not a clear correlation between the distances travelled, and the oil price on the commodity market. Perhaps, apart from the fuel market, a number of other developments are at stake as well. Newman and Kenworthy (2011) point out, for example, that decline of private motor traffic is mainly recorded in a number of larger Western cities. In some of these cities, including Vienna, Zurich, Brussels and Stockholm, current policies are not by chance targeted on discouraging additional car traffic. Narrowing roads (for example, by sacrificing a lane to the benefit of a bicycle path or a reserved tram track), the introduction of road pricing or a restrictive parking scheme affect the motorized traffic volumes in the city. However, this does not necessarily mean a reduction of the number of trips: the cities mentioned are known for their traffic growth being shifted towards public transport and cycling.

Perhaps, we have arrived at an important nuance of the peak car discourse. Although today continuous growth of surface traffic should no longer be taken for granted in any context, we cannot just transfer the principle to other forms of mobility. Just as mobility within emerging countries, international trade, and therefore also intercontinental freight transport, keeps growing unabatedly. And the same goes for air travel. In these subsectors, the limits to growth are nowhere near in sight, and this applies too for associated greenhouse gas emissions or consumption of fossil fuels.

Although in the developed world the growth of car traffic may start to collide with spatial and environmental constraints, the human desire for ever more interaction with the world seems to translate into a choice for ever faster means of transport, of which the exploding air travel market is the ultimate outcome.

The foregoing considerations suggest that growth in mobility is inherent to present-day society, in which the increase of travel speed can be seen as the equivalent of the increasing efficiency that is typical of a growing economy. The parallel with the issue of economic growth, and its possible limits, can hardly be denied. Although in his study Prosperity Without Growth (2009) his utmost to show that the statement reflected by the title of his book is a real option, he only succeeds partially in this. Since increased efficiency is inherent in our system, less and less work is needed to maintain the same standard of living. If we want to stay at work all together, this means that either we need to produce more (with the same amount of labour), either we should work fewer hours in total (Skidelsky and Skidelsky, 2012). But even more free time leads to more consumption, and the desire for more and better of anything seems to be latent in all of us. And even though for many Westerners the degree of saturation at which more consumption no longer equates with more happiness has been reached yet, in most of the world this is still far from being true (Inglehart and Klingemann, 2000).

In our Belgian case too, in the recent past we can distinguish some policy measures which, according to official communication, contribute to greater sustainability, while focusing in practice on additional growth and more consumption of fossil fuels.

In 2004, a new access plan to the national airport in Brussels was decided on. Although at the time, the airport had already a rail connection with the capital, a second and a third rail branch were planned to connect Antwerp (in the north) and Leuven (in the east) as well. These investments were supposed to contribute to the expansion of the airport, offering an alternative to using the congested motorways near the airport. According to regional economic theories, such measures increase the accessibility of the airport, making it thus more attractive for both travellers and airline companies. Since aircraft may be considered among the least efficient forms of transport when it comes to emissions and fuel consumption, we can assume that such investments in airport accessibility will lead to an increase in emissions over time. However, the federal government clearly thought otherwise. In late 2008, the new rail access projects where included in the federal climate accounts, in which it was simply assumed that any new rail passenger is a former car driver (National Climate Commission, 2008, p. 58). So there would be fewer cars on the road, and part of the climate goals would be achieved. Despite the highly questionable nature of such an assumption, the effect of the measure was never monitored. In contrast, in 2013 a plan was launched to add a new motorway access to the airport anyway, in the direction of Leuven.

In the city of Ghent we see a similar paradox in the redevelopment of the central station area. In the context of the Spatial Structure Plan for Flanders, an overarching vision for the sustainable spatial development of the Flemish region, efforts have increasingly been geared towards upgrading the precincts of mainly the larger railway stations (RSV, 1997[2004]). By creating density and functional diversity in areas that are well served by public transport, local modal split adjustments towards public transport where hoped for. Near the Ghent railway station, which is one of the three largest Belgian stations in terms of passenger numbers (45 000 passengers a day, planned to increase to 60 000 (NMBS, 2014)), a large-scale programme was developed including apartments, offices, all kinds of amenities, and a large car park. The construction of the 2800 vehicle large car park fitted explicitly in a programme to encourage train use by long-distance commuters (Coppens, 2010). Employees living in Ghent s suburbs, which were used to go to work by car, would henceforth be ab at the station, then take the train to their office in Brussels or elsewhere. This would lead to quite some savings in terms of $CO_2$ emissions. However, the local environmental movement was skeptical of the plan, and a couple of years after the opening of the car park, it organized a user survey. The survey results showed that only a very small minority (four out of one hundred surveyed parkers) had indeed switched to the train for their long haul (as could have been expected on the basis of studies reported in the Park and Ride literature (Zijlstra et al., forthcoming)). However, the majority of the users of the car park consisted of commuters who previously arrived by a local train, or by bus or tram before taking the express train in the station. Therefore, the construction of the car park had led to more car use, instead of less. In addition, the parking had contributed to a local concentration of particulate matter production in the surrounding residential area (GMF, 2012).

In 1997, the regional city of Hasselt introduced a subsidy in order to make access to the city bus network free of charge for all passengers, a situation which would last for the next seventeen years. After the introduction of the measure, as expected, the number of bus passengers increased to an important extent. However, a survey found that of all additional bus passengers, only 16% would have taken the car in case the bus would not have been for free. Six out of ten additional bus passengers would simply have stayed at home in that case, and another two out of ten would otherwise have been walking or cycling (Van Goeverden et al., 2006). In the university city of Leuven, between 2001 and 2013, free buses where offered to the student population. Again, an important shift from the bicycle to the bus was noticed. In Leuven too, the subsidy caused an increase in demand and a need for more buses, making it unlikely to meet the original sustainability targets.

Better than any theory, these examples demonstrate that perhaps the growth of mobility is much more intertwined with the present structure of society than experts and activists would like to admit. If that is true, then it seems that only a real shortage of, for example, energy, or physical or environmental space, can obstruct the expansion of the transport system. And it may also mean that any attempt to reduce the environmental impact of an individual trip may be insignificant for the world in its entirety.

However, as we shall argue in the next section, such debates risk to neglect the dimension of social justice.

## 3. A few considerations on social justice and transport

*Policies with respect to mobility, accessibility and environmental impact seem not to contribute automatically to social justice*

The development of a transport system which is overall less environmentally harmful does not automatically guarantee a fair distribution of access to transport and to full participation in society. While this argument may not apply to all facets of the sustainable mobility paradigm, it is indeed likely that positive interventions in planning may only affect those who are in the position to have their voices heard, while technological solutions seem to be first and foremost reserved for those who can afford it. Through careless implementation of sustainability-aimed transport policies, we risk limiting access of mainly vulnerable groups in society. Moreover, it is presumably not the aim to *design and develop a low carbon post-car system that does* [ ] become like George Orwell s 1984 (Dennis and Urry, 2009, p.11). This concern was already expressed by Baeten at the turn of the 21st century, who wrote that *the orthodox sustainable transport vision actually leads to the further empowerment of technocratic and elitist groups in society while simultaneously contributing to the further disempowerment of those marginalized social groups who were already bearing the burden of the environmental problems resulting from a troubled transport system* (2000, p.69).

The environmental justice literature focuses on the maldistribution of the environmental burden of, among other things, transport activities. Although the size and even the sign of effects varies across cities and regions, there is some evidence that low-income and minority communities are exposed to higher levels of noise and air pollution (Schweitzer and Valenzuela, 2004). This is one side of the (distributive) justice coin. The other side concerns the morally proper distribution of transport benefits (Martens, 2006, 2012).

The orthodox sustainable transport vision generally favours public transport in general, and rail in particular. However, attempts to attract new customers by investing in suburban commuter rail projects might result in the neglect of poor transit dependents in city centres. In such occasions, public transit is promoted as a solution for congestion and air pollution problems, and thus not as a social service (Garrett and Taylor, 1999). In this context, Reeves (2005) writes that sustainability thinking has changed little in the paternalistic approach of transport planners. In the past, reasoning often departed from facilitating travel with the family car, which used to be driven by the man in the household. Today, the focus has been shifting to the development of large-scale rail infrastructure, which usually focuses on improving access to job concentrations in the larger conurbations, and connecting these with each other by means of fast trains. While such projects are usually viewed as sustainable, they are still mainly serving members of the hyper-mobile society, usually highly educated and often male. The needs of socially vulnerable groups, which are rather located in the sphere of buses, transport on demand, and dense networks of facilities close to home, are much less evident in this discourse.

The outlined dynamics usually apply in the context of an urban area. But also at the regional scale, the orthodox approach to sustainability is not always compatible with social justice. It is known that in the United States residents of poorer states travel, or need to travel, greater distances by car compared to residents of wealthier states (Baxandall, 2013).

But in Europe too, examples may be found: in Belgium, an average inhabitant of the Walloon region has a longer drive to work than his Flemish compatriot (Verhetsel et al., 2007), who on average has a higher income. This means that in some less prosperous regions, people are required to spend a disproportionate share of their salary on transport, at least if they want to be assured of a certain level of income and accessibility. In such cases, environmentally-inspired tax schemes (such as carbon

taxation or some forms of road pricing) aimed at discouraging long distance travel may be detrimental to the poorer regions and their inhabitants (for an overview of studies on equity and road pricing, see Levinson (2010)).

Again in Belgium, a long tradition of commuter subsidies determines travel patterns in questionable ways. Already in the nineteenth century, cheap rail subscriptions were offered to workers, supporting a suburban commuter system and purposely limiting urbanization (Dujardin et al., 2012; De Decker, 2011). Over the last decades, the subsidy was extended to car commuters, in the form of a company car tax deduction. While this measure is very selective, because it only includes that class of staff that can claim a company car, this tax deduction is generally seen as a compensation for the high taxation of labour (Vanoutrive et al., 2010; Zijlstra et al., 2014). Since the scope of this favourable tax regime is mainly on the higher income groups in the private sector, an equivalent measure was introduced for public sector employees and those who choose not to go to work by car. For this purpose, in 2004 the third party payment system was introduced, which meant that almost all staff in the public sector and part of the private sector were allowed to take the train and the bus to work entirely free of charge (Belgisch Staatsblad, 2004). The social-democratic coalition partner in particular communicated this measure as being in favour of sustainable mobility. A large number of employees would change towards public transport instead of going by car, for which they would have to pay themselves. Official communication did not mention that the measure was largely covering those who were already using public transport, for example because they work in the centre of Brussels or another large city. Besides, in 1999, a bicycle allowance was made tax exempt and had already been introduced to many employees commuting by bike (Belgisch Staatsblad, 1999). Because cycling was considered the most sustainable form of travel to work, and thus the cost of bicycle maintenance and specific clothing would no longer have to be borne by the employee. With this combination of measures, finally almost the entire continuum of travel to work seemed to be covered, which compelled the OECD in 2013 to severely criticize the Belgian commuter policy because it was apparently subsidizing every mode of transport mode: car, train, bus, tram and bicycle (OECD, 2013).

OECD s criticism regarding the lack of distinction between travel modes was cer
what was conveniently overlooked is the fact that most of the subsidies might essentially end up with higher income groups. Private employers offer their company vehicles usually only to executive and representative staff members, in contrast to labour class workers and assisting or cleaning staff. In the public sector, jobs with above average salaries are typically located in large urban areas, such as Brussels, where the train is the most efficient means of transport. Less well-paid jobs in the public sector, e.g. in education, health care, maintenance or support services, are often found in places where public transport is hardly a real alternative to the car, e.g. due to low service frequencies. So, public sector employees in decentralized locations are often obliged to cover their own (car) commute expenses. With regard to bicycle subsidies, it is less clear which groups are reached, although, depending on the context, cycling is not necessarily associated with lower incomes (Vandenbulcke et al., 2011). In short, commuting subsidies, whether targeted to sustainable mobility or not, mainly reach the middle class, and therefore contribute negligibly to wealth redistribution. However, finding quantitative evidence for this statement is difficult, since in Belgium such redistribution effect of transport subsidies are not purposely monitored. For the UK, the Sustainable Development Commission (2011, p.7) concluded that  The richest 10 per cent of the population effecti
four times as much public spending on transport as the poorest 10 per cent.

Another example is situated in the domain of subsidizing electric vehicles. On January 1, 2010, tax
deduction of company cars in Belgium was linked to emissions. This means that CO2
accounting, very economical cars on diesel or gasoline may be deducted from taxable revenues at a rate of 100%, while electric car expenses may be deducted at a rate as high as 120%, which should be regarded as an important subsidy. Since the tax deduction system is proportional, this also meant that expensive electric cars would receive a larger subsidy compared to more democratic, small electric cars. In the first months after the introduction of the new tax regime, eight out of the fifteen electric cars that were sold in Belgium where Tesla Roadster, which then cost around 84,000 euros (Mobimix, 2010). These sports cars were sold to company managers which were looking for an ecological

showcase for their business. The Tesla Roadster was characterized by a zero local emission rate, an incredible acceleration potential, space for one passenger at max, and the quasi absence of a trunk. Although the assortment of electric cars sold in the following years would better correspond with the image of the zero-emission car as an efficient, useful and responsible vehicle, the Tesla sports car may have become an icon of the discrepancy between a techno-optimistic sustainability discourse and the pursuit of social justice.

In other words, the sustainable transport discourse may be used to support policies that are potentially socially inequitable. But then the question remains, what is just, fair or equitable? Numerous principles have been proposed by transport scholars to distribute benefits and burdens among members of society (Hay, 1995; Langmyhr, 1997). The dominant principle is that of demand, which is a key element of standard transport models. A simple example of a demand-based strategy is the building of a new railroad where, according to model estimates, there is a large enough customer base. The number of people that is willing or able to pay is a crucial element of cost-benefit analyses for such and similar projects, together with travel time savings and the related value of time. It is now common to use the equity value of travel time in order to avoid evaluations that favo incomes (van Wee, 2011). However, even when the average income is used, the approach works to the advantage of the more mobile higher income groups, in particular since current travel patterns are used to estimate future demand (Martens and Hurvitz, 2011; Martens, 2006).

Martens (2006) argues in favour of a need-based approach as an alternative to demand-based models. Accessibility gains are seen as the prime benefit, while a less well-off individual facing a gain in accessibility is valued higher than the same increase in accessibility faced by someone who was already better off. Defining needs empirically is, however, not without challenges. It is difficult to distinguish between needs and wants, since defining needs might turn into a paternalistic exercise, while these are heavily dependent on personal and contextual characteristics. Nevertheless, a novel paradigm with needs, access(ibility) and social inclusion as key concepts, that accessibility narrative , has gained some popularity (Cass et al., 2005; Martens, 2012; Preste Raje, 2007; Farrington, 2007; Farrington and Farrington, 2005).

Social inclusion refers to the ability to participate in normal activities of society. Accessibility is a crucial concept since exclusion is a constraints-based process, i.e. exclusion is a lack of access to opportunities (Cass et al., 2005; Preston and Raje, 2007; Clifton and Lucas, 2004). The concept of accessibility is preferred over mobility since in a situation where potential destinations are located in the neighbourhood, less mobility is needed to reach a standardized set of destinations (Levine and Garb, 2002). This illustrates that accessibility is a derived need, i.e. transport is needed to reach destinations.

According to Martens (2012), transport should be distributed independent from the way in which other goods are allocated, notwithstanding the derived nature of transport and accessibility. He claims that:

> a strong case can be made for the recognition of transport as a separate *sphere. Transport has developed from a taken-for-granted and hardly disputed good, to a* highly desirable good, an indispensable resource shaping one s life path, availability is subject of public debate.

Given the increased spatial reach of daily lives, people need a certain level of mobility and accessibility to be socially included. Accordingly, authors refer to mobility r accessibility rights (Farrington, 2007) and basic levels of accessibility (Preston an Although a significant part of the sustainable mobility literature does not explicitly refer to accessibility rights, social justice is often implicitly present. Calls for mixed land use, proximity and compact cities are not only motivated by decarbonisation dreams, but also by the new narrative of accessibility. Studies on the adverse effects of sustainable transport policies illustrate that the aspiration of social justice cannot be replaced by objectives like compactness, transit-oriented development and bicycle friendliness (see, for example, the discussion of social equity and

investments in transit cited earlier (Garrett and Taylor, 1999)). As a consequence, ethics and social justice deserve a central place in the sustainable mobility paradigm.

Besides demand and need other distributive principles are mentioned in the literature such as merit, expectations ((legal) certainty), procedural fairness, formal equality, and outcome equality (Langmyhr, 1997; Hay, 1995). In practice, a mix of these and other often overlapping principles will be applied. Indeed, theoretical purity is impossible, but ignoring the ethical dimension of transport policy and research might relegate social justice to the background.

## 4. From the limits to growth to ethics

*All possible controversies on environmental impacts eventually boil down to an ethical debate*

The aim of the present paper is to challenge the orthodox sustainable transport vision from two perspectives that may draw too little attention in current debates. First, we discussed this paradigm by confronting it with the troublesome issue of the limits to growth. Then, we challenged the sustainable mobility paradigm by confronting it with the literature on social justice and transport and studies on social exclusion and transport. Apparently, the discussion seems to confirm the idea that all debates on sustainability eventually boil down to ethical discussions.

While the report of the Club of Rome has achieved an iconic status in the environmentalist movement and has played a significant role in the development of the sustainability discourse, economic growth is generally not questioned by sustainable mobility scholars and practitioners. From the same observation, Essebo and Baeten (2012) problematize sustainable mobility, and sustainable development in general, since such visions unconvincingly attempt to integrate the opposing goals of growth and biophysical limits. Also Tim Jackson s work (2009) points out the co the current economic system, in which growth is necessary to maintain employment levels, and the physical limits of the earth in terms of raw materials, energy and environmental space.

The sustainable mobility literature acknowledges biophysical limits which are made concrete by making reference to peak oil, climate change and greenhouse gas emissions. A typical paper starts as follows:

> Environmental problems such as climate change pr*esent formidable challenges for trans* *which is one of the few sectors where $CO_2$* emissions continue to rise. (Geels, 2012, p.4
>
> Car travel is related to climate change, dependence on fossil fuels, and *(Buehler, 2011, p.644)*
>
> The carbon dioxide (CO2) level *that causes global warming has been increasing rapidly since 1990 and many countries are trying to reduce these $CO_2$* emissions. (Ding et al., 2014, *p.109).*

These three randomly selected examples illustrate that biophysical limits are commonly expressed in scientific terms. It is about tons and atmospheric levels of $CO_2$, estimated oil consumption and percentages of carbon reduction and some other IPCC terminology.

Although we do not call into question the added value of research on climate change or estimations of effects of greenhouse gas emissions, we want to point to the moral and ethical dimension of anti-growth (or pro-growth) claims. As father and son Skidelsky (2012, p.131) argue: *the environmentalist case for growth reduction cannot be explained as a pragmatic response to known facts. It betrays a passion, a will to believe, to which the facts are incidental.* Interestingly, they illustrate this wi example in the field of transport: *if current fears about global warming turn out to be baseless, climate radicals will not abandon their opposition to long-distance flying and four-by-fours; rather,*

*they will find new arguments to justify their austerities.* (p.132). Although this quote does not do justice to the variety of visions hold by environmentalists, the point is clear: it is very likely that carbon emissions will have a significant effect on climate, but the apocalyptic visions that regularly accompany such scientific findings, are part of a storytelling process (in the sense of Hajer, 1995). Although this does not mean that efforts to limit greenhouse gas emissions and air pollutants serve no goal, it mainly suggests that we should take the ethical nature of environmentalist debates into account in any case.

The Skidelskys prefer an environmentalism based on ethical values, called good-life environmentalism, over one that hides behind climate models. Their openly paternalistic approach condemns greed, insatiability and other vices in themselves, and thus not for their climate impact. They put forward seven basic goods which are essential for the good life: heal personality, harmony with nature, friendship and leisure. We will not go into detail on the exact meaning of these goods, but we highlight that this is a positive stance towards life. Note that also for Jackson (2009) the aspiration is to provide capabilities for flourishing. This is particularly the case when we realize that in the past, the move towards a more egalitarian society has mostly been a matter of redistribution of surplus wealth. In a society without growth, welfare redistribution can only happen if the well-off would surrender a portion of their wealth. Although inequality is not necessarily linked to growth (Aghion et al., 1999), it is clear that the reproduction of power relations ensures that wealth redistribution in a stagnant or declining economy is hardly happening beyond mere philanthropy. The argument of the Skidelskys can straightforwardly be applied to the case of sustainability, as can be illustrated by Neuman s discussion of sustainable urbanism (Neuman, 2005). To hi too vague a term, and the search for an exact definition is doomed to failure. *the way things ought to be and how we ought to live.* (p.17), it is *a category of the good.* (p.17). An if the ethical nature of sustainability is not taken into account, dogmatism is likely to prevail. Ethical questions do not have an answer, they require a dialogue. For Neuman (p.17), *Sustainability is a debate about how to live.* , and according to us, we can simply replace sustainability by mobility or sustainable urbanism.

Seeing sustainable mobility as a debate or as an ethical question might have some implications for scholars in the field. It implies that everyone has something to say about sustainable mobility. Given that *there are no experts in morality* (Skidelsky and Skidelsky, 2012, p.145), the role o is not to prescribe what to do, but to substantiate the debate, to point to adverse effects, to indicate what is possible and to reduce illusion, especially when illusion leads to exclusion. This view on the role of research is not new (see e.g. Sayer, 1992; Feyerabend, 2011), but we would like to stress this point again. The statement that *there are no experts in sustainable mobility* must be understo way. It does, however, not imply that all moral opinions are of equal worth, or that scientific findings are nothing more than opinions. And even though scientific findings may lead to disenchantment, they can also nourish the debate and bring it to higher standards.

## 5. How to achieve Utopia?

*It is yet unclear how the highly popular sustainability transition approach incorporates questions of growth and social justice*

The previous section indicates that sustainability and sustainable mobility relate to the good life. This is a positive approach which stresses what sustainable mobility is or ought to be. This stands in contrast to approaches where the focus is on the negative, i.e. sustainable transport is about mobility with *less* $CO_2$ and *less* congestion. Among others, Goldman and Gorham (2006) make such a distinction between emphasising *what sustainable transport should not do* and *what the ideal system should do* (p. 264). They also distinguish between end-state visions and efforts that see sustainability as a pathway. Good-life mobility can be seen as a pathway or a good life or a permanent dialogue on mobility, but it can also be seen as some kind of desired end-state, a world where the good life is the norm. In order to be able to continue our story, we

provisionally define the good life as a situation characterised by a permanent dialogue on ethical questions. In line with Sen (2009), we do not put too much emphasis on highly idealist descriptions of utopias that show little correspondence to the world today. What is of importance here is that it brings us to the following essential question: how to achieve a situation which is considered more just and sustainable?

Besides a description of some essential features of the sustainable mobility paradigm, the iconic paper by Banister (2008) provides an overview of the necessary conditions for change. He a public acceptability and confidence are the keys to turn sustainable mobility into practice. Essential elements to promote the public acceptability of sustainability include information, communication and involvement, policy packaging and coordination across sectors, the adoption of more controversial policies in stages, and a reflexive attitude in order to remain flexible. In ess pragmatic and down-to-earth guide for the promotion of sustainable mobility.

Banister s pragmatic approach is one way to deal with the pathway to a more desi discussion to a meta-level is another. Most likely, the fastest growing family of perspectives on change is the so-called transition approach (Rotmans et al., 2001; Geels, 2012; Schwanen et al., 2011). In order to promote his socio-technical approach to transitions, Geels (2012, p.471) critici alternative approaches such as environmental economics, political science and industrial ecology since these focus *on a limited set of dimensions of (un)sustainability. The socio-technical approach to transitions instead highlights co-evolution and multi-dimensional interactions between industry, technology, markets, policy, culture and civil society.* (p. 472). Although this multi-dimensional approach looks promising, the transition literature largely neglects social justice and limits to growth related issues. Geels (2012) (awkwardly) refers to political scientists as being too on decision making processes, but the fact that he cites Newell (2008) to position this approach in the literature indicates that he actually means political ecologists and cognate scholars. The reduction of political science or political ecology to studies on political debates about emission targets and the bureaucratic implementation thereof in Geels (2012), ignores relevant issues discussed in that literature (e.g. Braun, 2006; Castree, 2000). Social justice and uneven development are core concepts in this stream of research, themes which only occupy a marginal position in transition studies. Note that Geels (2014) cautiously discusses political economy issues in a recent paper, including the role of firms and industries, economic growth, neo-liberal thinking and the role of the state in establishing the conditions for capital circulation. However, he did not without a long introduction on carbon-dioxide levels and tipping points, and without making clear how insights from political ecology have changed the transition approach.

Also in two well-cited other papers in the transition literature that deal with power (Avelino and Rotmans, 2011) and the geographical unevenness of transition processes respectively (Coenen et al., 2012) at least one difficult question raised in work on political ecology is not treated to some extent. And that question is whether the growth in energy consumption and transport is an essential feature of present-day society. Avelino and Rotmans (2011) give an overview of the conceptualisation of power in different literatures in an attempt to give the concept a place in the interdisciplinary transition framework. However, this has not yet resulted in the integration of uneven development in the transition approach. The second paper, by Coenen et al. (2012), cites virtually all famous, especially radical, geographers (Amin, Baeten, Brenner, Coe, Cooke, Cox, Harvey, Massey, Peck, Theodore, Sayer, Swyngedouw, ; admittedly, several of them without a formal background in g However, difficult issues are circumvented and the idea that the elimination of spatial barriers is an essential element of world capitalism (often referred to as the annihilation o `time-space compression (Brenner, 1999)), is not discussed.

Outside the transition literature, Schwanen et al. (2011) argue that the socio-technical approach to transitions offers an interesting perspective. However, they add practice theories as a promising research framework, an argument based on the critique of Shove and Walker (2007, 2010) on the transition approach. This focus on everyday practices illustrates that behavioural change is constrained, and shows the complexity of practices like daily showering or driving. Doing so, practice

theory stresses the importance of the demand-side which is less well developed in the socio-technical transition literature. The practice approach also illustrates that individuals are not the (self-)entrepreneurial, rational, utility-maximising, well-informed agents imagined in the neoliberal discourse.

The adoption of the transition label by policy making in Belgium illustrates that the introduction of this concept, like sustainability, does not automatically lead to major changes. In the Flemish region, Flanders in Action (Vlaanderen in Actie, ViA) is a project set up by the regional government to achieve an innovative, sustainable and warm society by 2020. Major challenges consequences of the economic crisis, the energy question, mobility problems, ageing and poverty. Transition is proclaimed to be the method used, since small adaptations to the as the transport system) are not considered sufficient. The goal is to develop new systems, meant to replace the existing unsustainable ones through many small improvements. This process is seen as a partnership between all sorts of societal stakeholders and is subject to permanent evaluation (Flemish Government, 2014). However, critical observers note that such transition initiatives are exemplary of green washing, post-political policy making and the persistence of power imbalances, despite the sometimes radical discourse (Debruyne and De Bisschop, 2013).

We can conclude that the predominant focus on climate change and decarbonisation in transition studies reflects a negative interpretation of sustainability, which stands in contrast to the good-life environmentalism of the Skidelskys, and, strikingly, the Transition Movement which emphasises community building (Hopkins, 2011). But as the study on scientific research about clima mitigation in transport by Schwanen et al. (2011) illustrates, a negative perspective on sustainab leaves some fundamental questions unanswered. At the very end of their paper, Schwanen et al. (2011, p. 1004) actually raise the questions *What is the kind of world that we would like to live in and fir desirable and how should mobility be configured in that world?* and *Is mobility in principle a right to which people are entitled?* . In a way, this can be interpreted as what we have called limits to growth to ethics . They carried out a review of studies on climate change mitigation in transport and they ended up with some ethical questions.

It will bring us too far to criticise transition studies from a political ecology perspective, but the point that we want to make here is that a key paper by a leading scholar who wants to introduce the topic into transport studies (Geels, 2012) tends to reduce it to low-carbon transitions , thereby i questions of social justice and the nature of society. However, some other authors on which our discussion above was based, at least recognise the problem. Again, we refer to Schwanen et al. (2011, p. 1004) who raise following question: *Will neo-liberal ways of decarbonising transport not exacerbate inequalities in travel patterns along lines of gender, race/ethnicity, class, residential location and their intersections?* . Although the work of the Skidelskys is more on ethics than on political ecology, they state: *Natural limits to growth, even if they do exist, will come into play far to late to meet the requirements of the good life.* (Skidelsky and Skidelsky, 2012, p. 143). In other words, the Skidelskys share with political ecologists concerns related to social justice.

## 6. Conclusion

But where do the above considerations lead us? The apparent incompatibility of the potentially systemic urge for growth and the expected climate induced problems are reminiscent of the tragedy of the commons, as described by Hardin (1968). According to the same author, a collapse of the system could only be avoided through judicious management of individual appropriation, thus through regulation. In the context of this article, regulation reminds us of what we have called the orthodox concept of sustainable mobility. For indeed, an environmentally friendly modal shift, substitution of trips that are less necessary, increasing the energy efficiency of vehicles, and the pursuit of compact urban development are all part of a vision in which government intervention is essential. When it appears that a number of possible interventions needed to reduce the environmental burden are not

effective, while on the other hand these can lead to more inequality, the whole concept of sustainable mobility could be collapsing like a house of cards.

Our main point is that mobility is worth a debate, where we recognize that the nature of such a debate is ethical. Consequently, everyone must be given a voice, hence our statement that there are no experts in sustainable mobility. But we also indicated that experts should be a role in the debate. Because in debates on sustainable mobility, often everything is lumped together, we try to introduce some structure. A first element is the distinction between relative and absolute figures. While climate change is about absolute levels (tons) of atmospheric components, the success of strategies is regularly measured in relative figures (e.g. percentage car commuters). This mixing of absolute and relative measures confuses the debate. Second, we suggest to distinguish more clearly between scales.

Debates on mitigating climate change are associated with the global scale. Key themes are aviation and international freight, and discussions about limiting such forms of transport are necessary. Perhaps it is effective to charge aviation and international freight transport with an appropriate carbon tax. In terms of $CO_2$ emissions, the potential gains by such measures are impressive, while the effects on social justice may be relatively limited. Because at the global level, it are not the weakest groups in society who are dependent on regular air travel and consumer goods produced overseas. A broad discussion on the wider social impact is needed, as it requires rethinking consumption and production patterns and an analysis of the impact on poor migrant populations is also recommended. Nevertheless, let it be clear that anyone who talks about climate change and transport without talking about aviation misses an important dimension. Since in such a debate with a global scope, it would be much less far-reaching to neglect the bicycle.

Conversely, it might be a good idea to continuously favour the use of public transport and the bicycle in cities. Even though the expected impact on greenhouse gas emissions is only little, such policies will contribute to the quality of life of those living in urban areas, especially with respect to the socially weakest. This does not mean that all vulnerable groups will benefit from a car discouraging policy, but by offering public transport and bicycle paths as a public service, all segments of the population would face additional travel opportunities. Road safety too can benefit from such measures, while compact urban planning may improve accessibility by limiting distance between origins and destinations of journeys. Several existing ideas about sustainable mobility dovetail with these considerations, even though the contribution to social justice is often not explicitly mentioned. In this case, the suburbanisation of poverty is a possible side-effect that calls for a debate.

By stressing context sensitive use of figures, and the importance of scale, we want to show that the sustainable mobility debate would benefit from a distinction between e.g. daily urban travel, and intercontinental transport. Thinking in levels of scale does not imply, however, that global dynamics necessarily happen above our heads (Herod, 2011). Apart from awareness about the necessary distinction between various levels, also the connection between these is of prime importance. The popularity of sustainable city logistics may not result in the neglect of what origin of goods, regularly hundreds or thousands of kilometres away, and the city edge. Even more, in order to label a logistics flow as being sustainable, the production process a should be taken into consideration. In the case of food and putting it frankly, sustainable logistics is either organic fair trade, either *artisan food production* [ ] *that would help maintain links wi soil.* (Skidelsky and Skidelsky 2012, p.143). So, whether it is in aviation, cycli the real challenge is to find solutions that combine benefits in terms of climate impact, pollution and resource depletion, with more social justice, and this at all levels.

Keywords: justice, decision-making, public interest

## 1. Introduction

Planners are a special kind of professional. They are not just knowledgeable ex
plans for urban or regional development, commissioned by municipalities, priva
anyone else who pays them. Planners do their work in a strive for a better wor
hold a firm set of beliefs about what this better world should look like and
contribute to this better world. The cities they build and the developments t
cause. But planners are also normal people. Like any other professional, expert
them may think differently on what precisely is a better world. In other wor
different views of what is the just cause for planning.

The ethical concerns underlying planning efforts and spatial policies are often
of justice or other moral frames. In practice, many planning efforts relate to
and their contribution the public interest. This paper focuses on this broad pr
public interest and aims to give insight in the variety of views people have o
when it comes to the physical domain of urban and regional development. Base
research with a value-oriented approach, in which the variety of normative vie
spatial planning is defined, six perspectives on the public interest in the
presented. Each of these perspectives reflects a distinct combination of underly

This overview of six perspectives on the public interest in the physical domai
better plans. Plans that present a substantial normative choice on spatial dev
can be tested in social debate and decided upon in the political arena. The six
public interest will be characterised with a view to contemporary spatial deve
will be positioned in view of social, economical and political preferences
interventions. This helps to draw up plans and decide upon the appropriate role
dealing with spatial development issues, either in collaborative processes with
communities, or with a clear-cut division in responsibilities between gov
organisations and private parties.

## 2. The normative background of planning approaches

Spatial planning is traditionally driven by strong normative beliefs in creati
working conditions for the poor. Planning for urban development needed to pro
housing and amenities, as well as for industry and offices to provide enough pe
work. Urban and regional planning served the public interest with this social ar
in which there was a self-evident role for government intervention in the physi
justice has been a dominant underlying value of these traditional planning
growing post-war prosperity, even more prosaic social aims for planning could
governments, in order to create pleasant spaces for leisure and beautiful landsc

Decades later, this social and economic agenda gave way to more focused ec
regional development and real-estate driven inner city projects, as well as
environmental an ecological concerns. With this change in normative background
evident role for government has changed. A variety of planning approaches has
over time. In the more entrepreneurial public-private partnership approaches, pl
role of government in negotiation with private investors. Environmental concer
explicit role for government with environmental legislation, in which planning
strict and regulatory role for government and identifying the specific physica
safeguarding. In contemporary processes of transformation of existing urban are
define the division of responsibilities between community initiatives, pri
government.

In this variety of trajectories for planning policies and planning practice, the
role of government in dealing with spatial development issues. There are also
definition of the public interest that is being pursued. It s not always the
economic agenda, with social justice as its guiding principle for redistribu
defines the public interest. The public interest may also be facilitating econor
possible to create added real estate value or preserving basis environmental qu
to come.

Recent developments show an even bigger variety in government involvement
development issues. An active civic society in cities often takes matters in t
when it comes to the transformation of disused space or derelict buildings. I
claim a say over redevelopment areas in their vicinity. Local entrepreneurs dev
cases, often in the creative industry. Newly founded cooperatives of neig
sustainable energy and dedicated residential complexes are developed for people
in a sustainable lifestyle. With these approaches come different conceptionalis
interest at stake, and what role and responsibility governments needs to take fo

In the contemporary pluralistic western society, people have different notions c
Some are particularly keen to foster small-scale creative business opportunitie
others focus on climate neutral housing. Many people seem to want to see the v
their own community, whether traditional or culturally diverse. For planners t
translate this variety of views on the good society into plans that help make
urban development. The question therefore is, what is the just cause for planni
whom should this good society be created?

To find an answer on this fundamental and philosophical question, this paper
practical concept of the public interest. Using the outcomes of value orie
recognises the variety of normative views on the role of spatial planning (B
Weide 2014), six perspectives on the public interest in the physical domain are
of these perspectives reflects a variety of underlying values. It shows that v
care are not the only values that are represented in the normative beliefs o
values like safety, diversity or autonomy. The six perspectives on the publi
characterised in terms of spatial development issues and will be positioned
economical and political preferences for government interventions.

In order to gain an understanding of the variety of perspectives in society abo
in the physical domain and the extent to which the government has to assure
interest, firstly the notion of interest needs defining. In general, inte
advantage or benefit for one or more individuals, a wish that is fulfilled or a
justice. An interest derives from a certain action or structure that is offere
collective (Stone, 1997; Barendrecht and Beukering-Rosmuller, 2000). Most of the
fields of planning, law and economics distinguishes between three types of in

interests, societal interests (public interests in which the government has a m
interests (in which the government has a prominent role).

Individual interest refers to the own interest pursued by the individual, whic
interests of the individual s private sphere such as relatives and close frie
focused on the short term (Barendrecht and Beukering-Rosmuller, 2000). Bounde
private context, the individuals interest is characterized by the affective
relatives and close friends and by a bond of unconditional loyalty. When an ir
level of the private sphere, it shifts to a groups perspective. Group formatio
indeed bring benefits, sometimes to the level at which none of the members of
excluded, in which case there is some form of common interest or even a collecti

Common interest can be distinguished from shared (combined individual) interes
specific choices. When the common interest no longer relates to a specific
significant larger part of society or to the society as a whole, this interest
social interest or public interest. The next paragraph further investigates the
of public interest, with a specific focus on the various societal perspective
government in the physical domain.

## 3. The public interest in the physical domain

In most literature, a clear distinction is made between social interest and publ
to the Netherlands Scientific Council for Government Policy (WRR, 2000), social
interests that are considered important for the society as a whole, such as educ
an inclusive health insurance system. Individual interests and social interest
almost each individual needs (and profits from) such basic facilities. The pul
distinguished from social interest, in the sense that it concerns an interest f
primarily responsible. Only government can define and legitimise a public inter
(Moore, 1995; WRR, 2000: 57). However, in most societies public interests are
exclusively as a government responsibility. The public interest is often s
responsibility of government, societal institutions, businesses and communities.

Public interests can therefore be seen as social interests, for which goverr
responsibility (Baarsma & Theeuwes, 2009: 27). The traditional characterisation
in which the government either has a major or a minor role, therefore doe
historically strong involvement and responsibility of societal institutions and
in the physical domain. Public interest as a shared responsibility, based on mu
be distinguished as a third type of public interest.

### 3.1 Public interest as a government responsibility

A classic perspective on public interest in the physical domain is that in wh
appropriates the final responsibility of providing the interest, based on
otherwise this interest would not (properly) be provided to all (WRR, 2000: 57)
and coastal defenses are common examples, based on concerns of health and safet
complex of social interests which in the long term best serve the well-being and
collective, perceived as the public , including those of future generations (v
2000; Smit, 2010). According to Bozeman (2011: 12): ( ) the public interes
dependent, but not different for various groups or individuals . It exceeds the
level, as well as their temporal constraints. Public interests can match the
conflict as well, since the individual tends to focus on its own rights and inte
while the public interest focusses on (the distribution of) rights and intere
According to Moore (1995), within a democratic society the government, as
representative of its citizens, is the sole actor which is legitimated to defi

process of political decision-making. This emphasizes the formal legitimacy of
public interest. The government takes full responsibility for this type of publ
be seen as an active government assurance and structural engagement, on which pe
may establish their long-term expectations (WRR, 2000).

Economic arguments focus on collective goods that are neither excludable nor ri
prevention and military defence, which must be provided to every individual in s
al., 2003; Korsten, 2014). The government guarantees and provides these goods,
risk of free-rider behavior or due to (positive or negative) externalities th

decision-making is a normative act, in which a variety of points of view consideration and a choice is made on the preferred development, the design and urban territory (Buunk 2010; Buunk en van der Weide 2012). Decision-making development issues with a view to the public interest is based on value rationa perspectives on the public interest that play a role in plans and projects in therefore needs to be based on the variety of values people relate to in society

4.1 Interests and values

For a proper understanding of the public interest, it is important to make a cle interests (that were explored in the previous paragraph) and values. The publi representation of a public value. It is the larger picture people often like to of their views. The public interest, to which politicians, bureaucrats, and lo as justification for a particular policy they may advocate, is close to public being about the value itself, interest is one of the reasons or reference points things. People may be said to value something because it is in their interest The public interest is seen here as an overarching concept that serves to legi have on others and on society, based on personal interest people have, thei interests and, more importantly, their preferences for a good society.

In order to create an overview of the perspectives people take on the public in to look at the combination of the interests in and concerns people have for the well as their preferences and the underlying values they represent. A value expression of a deep-rooted belief, motive, incentive, desire, or ideal for (Buunk and van der Weide 2014: 217). Values have a meaning in social interacti become tangible in emotions and in the argumentation behind points of view and people make. Some people will argue for an extensive role and responsibility f preserving the quality of the physical domain as a collective good, thereby exp protection and safety. In previous research, the variety of values that play a identified (Buunk and van der Weide 2012, 2014). The values that play a role in development issues are often abstract, but become much more concrete when they in perspectives people have on a practical concept like the public interest.

Following this value oriented-approach, six perspectives on the public interest that each reflect a typical combination of three or four underlying values a development issues. For these perspectives to represent the variety of views on in the physical domain, the dominant value represents one of six moral fou foundations are groups or families of values defined by moral psychologist Jona & Graham 2007; Haidt & Kesebir; 2010, Haidt 2012). These moral foundations are intuitions people have that guide their behavior in social contact with others a behavior of others and on society. These moral foundations help to distinguis values and emphasize the orientation of desires people for a good society. Here to recognise six distinct perspectives on the public interest in the physical perspectives has a characteristic line of argumentation on what are the issues the preferred way of dealing with these issue, including a the role for govern argumentation, underlying values are expressed and the moral foundation to whi relate dominantly can be recognised.

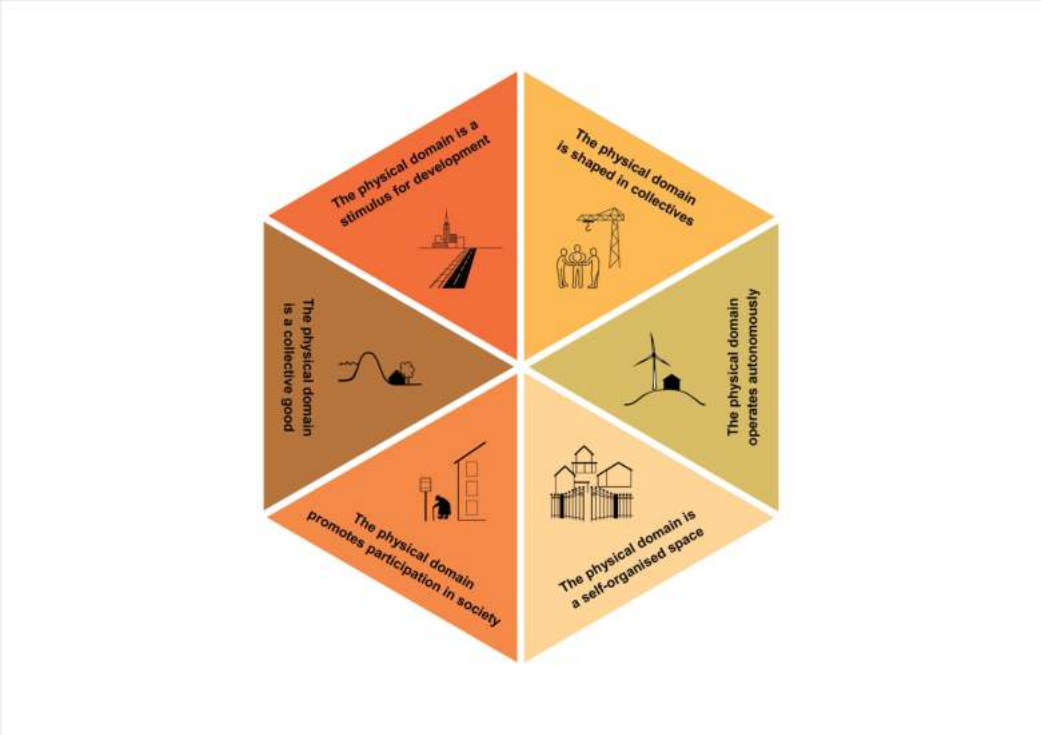

Figure 1 Six perspectives on the public interest in the physical domai

In the best-known perspective on the physical domain as common good, the argume public interest is an expression of the value of hierarchy. In particular i Netherlands, where the main urban area is under permanent threat of inundation has an undisputed responsibility for all aspects of the watermanagement. This that, when necessary, surpasses any other interests. In other traditional perspe public interest, the physical domain serves to stimulate development economicall promotes the participation of all in society. These two perspectives voice value underpins many redistributive mechanisms in economy and development opportu solidarity, which can be recognised in a spatial development that meets the n groups in society. In the other three perspectives on, the physical domain is communities or individuals that in a variety of ways and with a variety of mo action for a public interest. The characteristic line of argumentation that i these perspectives reflects the variety of collaborative approaches in dea development issues.

## 4.2 Traditional perspectives on public interest

Three perspectives on the public interest in the physical domain can be qualifie they reflect strong beliefs in the possibilities for planning and other governm planning efforts are not restricted to the physical domain; they also concern social structures and economic performance of cities and regions. The argume exemplary for these perspectives, reflect a robust trust in the ability of gove social and economic ambitions. The institutional arrangements of spatial pl countries are grounded in these notions of the public interest.

The first and most well-known traditional perspective on public interest sees t as a collective good provides a safe and healthy environment for people to li goods that are indispensible for everyone, but neither individual citizens communities can provide for these goods on their own. Watermanagement and mili are amongst these self-evident government tasks in the physical domain. Once

arrangements, zoning and installations for these goods are defined, installed an

# FROM BORGATE TO METRO-BOROUGHS. THE CHANGING CLAIMS FOR JUST PLANNING IN ROME

Marco Cremaschi[1], Carlotta Fioretti[2]

[1] SciencesPo Paris, Cycle d Urbanisme, marco.cremaschi@sciencespo.fr
[2] Roma Tre University, Department of Architecture, cfioretti@uniroma3.it

Keywords: spatial justice; urban change; metropolitan expansion.

The paper seeks a reflection upon the consequences of urban development on the practice of just planning. City change involves a complex reworking of the urban fabric, expanding boundaries, substituting people, and transforming places. Thus, the paper discusses the issue of justice in modern urban policies of Rome adopting a historical and geographical retrospective view. The overall purpose of the paper is in fact to offer a conceptual frame that may lead to a comparison.
The first paragraph set the case for such a discussion, identifying the characters of a spatial model that articulates issues of justice and planning in different zones of the city. Just policies are a varied set of heterogeneous initiatives; consistently changing over time, inextricably woven to the political role of a collective agent.
The second paragraph contrasts the struggle of an historic urban *borgata*, with the apparent quietness of a late metro-borough in the widespread city (Cremaschi, 2011), discussion of some contentious claims for urban justice. However, these are situated cases, and not immediately comparable.
Their juxtaposition helps in fact to highlight, in the next paragraph, how the changing spatial scale alters their claims for justice in planning. Our main thesis is thus that a historical perspective is needed in order to discuss the issue of justice in modern urban policies; besides, the changing spatial scale and the current rescaling process, is profoundly altering the claims for justice in planning, putting citizens and planners in front of new challenges.
In conclusion, the paper points out that a sort of centrifugal drive has in fact designed new geographies of spatial injustice. Today, fast growing municipalities deal with social conflicts, environmental concerns and cultural diversity in a piecemeal way, lacking both a general framework for interrogating urban change, and a collective actor to question its effects.

## 1. Spatial justice in the urban evolution of modern Rome

The history of urban planning in post-war Rome is a fascinating example (accurately investigated by Italian urban historians[1], though less known internationally) of a contentious policy field.
The argument postulates that justice in planning is better understood if one imagines that a sort of zoning process has historically articulated urban political issues. Roughly, a conceptual zoning results from the combination of positioning in space and time; and of representing either directly through *collective action,* or indirectly through *narratives*. This quick articulation leads to analyse four areas, the city s core and three concentric belts of neighbourhoods.
This simple model provides a sharp spatial interpretation of the social geography of the city that makes sense of major urban trends. While the city core, and the peripheral rim are fully urbanized, densely built, and heavily populated, the external zones are far wider, sparsely built, and interspersed by large natural or agricultural areas.
These zoning articulates in fact several distinctive phenomena (for instance, the growth of population: Cremaschi 2010), and corresponds to different phases of the city s growth. doubled in size between the 30s and 50s, and almost again before the 80s. Land and housing markets have steadily overheated, creating enormous profits and corruptions. Beside, urban

[1] For notorious examples see: Insolera, 1962; Parlato 1970; Benevolo 1977, 1992.

planning in Italy has been dealt with mostly locally, often by the local elites, rarely by progressive government. The growth of the population of Rome has stopped since the mid-70s, and change occurs primarily through the displacement of middle classes and (later) of immigrants from the core area of the city to the surrounding municipalities.
Namely, a profound articulation of the 20th century models influenced the production of these city zones: the metropolitan model used in fact to define core and periphery, while the incumbent post-metropolitan evolution is at the origin of the scattered and external communities.
More precisely, the urbanization process has come to define different spatial settings. These spatial settings differ by form, construction process, actors involved, and constraints posed to collective action, social and cultural profile:

a) The city ancient core and its dense popular neighbourhoods (late 19th, early 20th century). The core area changed the most, as scholarly research recorded, adding to the ancient Rome new vernacular neighbourhoods, residential areas of the new elites, government office districts including university and ministries, museums and ceremonial buildings, and eventually turning everything in the mass-tourism scene. Today, the predominant affluent population raises post-material claims for the quality of life, and an appreciation for public space. Often, these claims combine with a more radical defence of the commons, not unusually encountering the struggle of minority groups for recognition and justice;
b) The working class peripheral ring (20th century, mainly post WW2) has come to surround the city centre. During the first half of the XX century, the city has been invested by a massive immigration wave. The lack of appropriate planning strategies and housing policies led historically to massive speculation (Insolera, 1993), during and after the Fascist regime; and eventually, to the establishment of the largest informal housing sector in Europe. *Borgate* are thus the crucial offspring of the urban development of Rome in the first half of the 20th century, resulting in a divided city with a strong social, functional and physical gap (Ferrarotti, 1970). The socially homogenous post WWII working class neighbourhoods have been the cradle of all urban political conflicts, though receiving less attention from researchers, and are today ageing rapidly and on the verge of gentrification. These are the area of the traditional redistributive claims, a sort of an early right-to-city movement, which strongly affected the political life of the Capital (and in a way of the country).
c) The post-industrial, loose collection of outer estates across the main circular ring road (GRA). These area hosts a mix of extreme conditions, the poorest neighbourhoods, interspersed by Social Housing Estates and by spot settlements of refugees and Roma. In fact, during the last quarter of the 20th century, first public agencies, then private promoters, built up a scattered collection of outer estates. No doubts that these areas does not support an organized mobilization, even less so for social justice. It rather corresponds to the political space of individual mobilization, sometimes invested by right wing political entrepreneurs.
d) Finally, the last ring hosted suburban communities that have been invested by metropolitan flows, and converted into the new metropolitan neighbourhoods. These settlements have been renamed metro-boroughs. In fact, the fast growth of metropolitan area has often changed the destiny of neighbouring townships, which become attractive for a highly mobile population. These areas mix local folks, new young families and international migrants, who tend to commute on a broader geographical scale though they may set a claim on local welfare services. However, these fast growing municipalities deal with social conflicts, environmental concerns and cultural diversity in a piecemeal way.

The contemporary story of Rome, as sketched trough the simple zoning scheme, asserts precisely that a claim for spatial justice has been formulated in the 60s, and has become integral part of the political manifesto of the Communist Party and other left-wing political groups, that later arrived to govern the city in a progressive coalition.

This claim was supported by the image of the divided city and brought to a local political manifesto stressing the centrality of urban issues, thus profoundly different from the traditional position of Socialist and Communist parties. The political priorities of the main left party, the Italian Communist Party, were reoriented towards urban issues, and a concern for the quality of life.

In particular, urban informality was included in the political agenda, influencing backwards politics and policies. Eventually, both leftists and Christian-social activists coalesced in a civil rights movement that forced an agenda for urban rehabilitation. Urban claims (housing, schools and transport), rather than labour, reframed the political agenda.

In fact, post-war political action concentrated upon the Borgate. A consolidated feature of the city, they indicate precarious, sometimes informal and illicit settlements (self-)built to respond to the growing urbanization and to the displacement of people due to the vast program of city renewal brought about, in particular, by the fascist regimes. Known for the typical strong solidarity of close communities, they have been the cradle of early urban protest movements, having in turn influenced the trajectory of left parties[2] (Berlinguer, Della Seta, 1960; Foa and Natoli, 2014). Since then, Rome has offered in fact a unique collection of a political reflexive practice of urban struggle, well before Lefebvre s writings, and late fame: earl of the 50s; more divisive and contentious issues in the late 70s; late squatt current through fragile insurgent movements fostering a more balanced approach to both the metropolis and the environment.

In addition, the main narratives changed over time. The main narrative seeking to capture the process of city change has been based upon the image of the two cities, the first corresponding to a bourgeoisie, which was central in both spatial and political terms, and was able to influence in particular the flow of public resources; the second, to a populace relegated to the physical and political margins. The divide between the city centre and the peripheral districts was the grand narrative of the 1970s, a spatial metaphor that has ever since oriented the leftist understanding and policies of the city.

Over the past forty years, since the first leftist government of 1975, Rome has changed radically. Today the city is no longer poor and magnificent as Pasolini wanted. The capi the agglomerative core of the region, since urban development has structured a vast urban field almost coincidental with the region. In the meantime, the post-war economic boom had brought about a new sense of wellbeing and optimism. Eventually, the expectations of people went well beyond the administration s capacity, and it was unable to fulfil even the origi

Under represented social needs, often reframed on wider or smaller scales (transport and urbanity, for instance), both improper and unusual for political action. Sudden confrontations often explode, contrasting old class solidarity and xenophobic mobilization. Even more importantly, the political space has been restructured along these patterns of metropolitan organization. Since then, the history of the Roman periphery has been the history of a divorce between the declining commitment to collective policies and growing claims for individual wellbeing.

Of this tumultuous process of growth, two distinctive social and spatial formations have emerged, post-war *borgate,* and late *metro-boroughs*.

Table 1 The zoning of justice claims and policies

[2] Being a government city, and lacking an industrial working class, Rome (sometimes describes as a colonial c

## 2. Comparing a borgata with a metro-borough

To shed light on the consequences in terms of spatial justice of the described phenomenon of urban change two case studies are discussed, belonging to two different historical and spatial zones. The first one is Pigneto, a neighbourhood of the eastern periphery of the city on the borderline between dynamics of degradation and trajectories of trendification considered as a *borgata*. The second is Riano, a small municipality in Rome metropolitan area, which has almost doubled its population in the last ten years, mainly because of an influx of people moving off Rome city core, in other words a *metro-borough*.

### *2.1 The working-class borgata*

Pigneto[3] is a neighbourhood of nearly 50.000 inhabitants located in the oriental periphery of Rome, in the Municipio[4] V. It was a working class neighbourhood, spontaneously developed at the beginning of the twentieth century around local industries.
The majority of inhabitants were workers, railwaymen, artisans, many of whom were immigrants from southern Italy attracted by the labour opportunities during fascism and after the war. The characteristics of this area, dense in relational bonds, inspired many of the cinematographers

[3] The area s boundaries are ambiguous, because they include simultaneously a large territ variety of neighbourhoods and sub-zones within it. Boundaries change according to the perspective, whether it be administrative, historical or that of inhabitants perception. Depending on which these different definitions is deployed, Pigneto either includes or does not include the neighbouring areas of Prenestino and Torpignattara. For the purpose of this research it is considered the triangular area, squeezed by two major roads (both of Roman origins) the Prenestina and the Casilina, and crossed by Via del Pigneto which connects Piazza Caballini to Via dell Acqua Bullicante

[4] Rome Council is divided in fifteen administrative districts called Municipi which have management and financial autonomy.

representative of Italian neo-realism. The neighbourhood was the setting for Pasolini s w particularly *Accattone* (1961) and his novel *Ragazzi di Vita* (1972), both of which describe the extreme poverty of these zones.

The area well represents the dualism of the urban evolution of Rome, because it was born outside the town plan, in a fragmented way to a point that it has been defined as an (Severino, 2005). The first nucleus where formed by self-built housing organized in *spontaneous borgate*. In the 1930s appeared other neighbourhoods realized by Rome s governorshi back to that period are both the Borgata Gordiani, a settlement of very rudimental single storey houses (almost shacks) meant to host temporarily low-income inhabitants evicted from the city centre, and the *villini* area, a sort of garden city, characterized by low density, high quality, detached-housing, built for state employees and railways workers. The zones in between these formal and informal nucleuses have been filled up for subsequent additions by high-density housing, tall apartment buildings (6-8 floors) mainly part of the speculation of the 60s an

From an economic point of view, the population was traditionally employed locally in the transport sector and in industry, but the majority of the factories closed down with deindustrialization process during the 1960s and 1970s. Historically, the neighbourhood showed considerable vitality in commercial enterprises, which made it self-sufficient. During the nineties there was a significant reduction of the local traditional shops following a wider national trend which saw corner shops hit by the competition of large retailers, and following the progressive trajectory of decay of the neighbourhood. Since 2000, this trend has been counterbalanced by the growth of ethnic businesses, and the reconversion of some commercial premises into pubs, restaurants and other nightlife venues, located in a relatively confined area in the west closer to the city centre.

Table 2. Demographic data of Pigneto and Riano. Source: Roma Statistica, 31 dicembre 2013; demo.istat 31 dicembre 2013

| | Population | Pop density (res/Kmq) | Ageing index (>65/<14) | Foreigners (%) |
|---|---|---|---|---|
| Pigneto | 47.680 | 20.289 | 202 | 18% |
| Riano | 10.155 | 399 | 93 | 16% |

Demographically, it has an ageing population, testified by an ageing population index that in 2000 was almost the double the city average. Today, the growing number of immigrants who tend to be younger counterbalances this trend. The area is one of the most multi-ethnic in Rome, with a percentage of foreign residents that has increased from 2% in 1991 to 18% today, well beyond the city average (12%). The main nationalities are Bangladeshi and Chinese.

Another influx of young population has been provided by the new creative class , young people, students and artists, who began to move into the neighbourhood in the late 1990s, attracted by the romantic heritage of Pasolini, and the cultural connotations of the neighbourhood (Annunziata, 2011).

*2.2 The metro-borough in the widespread city*

Riano is instead a small municipality located along the northern border of Rome City Council. Historically it was a village based on agriculture, with the main nucleus dating back to XII century clinging onto a tuffaceous hill.

Just after WWII it begun a modern activity of tuff quarrying, and Riano was interested by Italian immigration, hosting workers from other regions. Also thanks to that, the population growth increased especially after 1951, and the town developed spontaneously. The absence of any planning regulation and the particular orography of the tuffaceous area characterized by peaks and valleys resulted in an extremely fragmented settlement lacking of a clear fo high-income gated community was also established, made of low-density villas and facilities. The

quarries and related plants occupy a large part of Riano, while the rest is mainly agricultural land interspersed with scattered houses.
The two traditional economies, agriculture and mining, had progressively shrunk and today the major job source for Riano s inhabitants is represented by the City of Rome whic far. In the last 10 years Riano saw a significant increase in the population, passing from 6.486 residents in 2001 to 10.155 in 2014. This growth is mainly due to people who moves its residence from Rome to the Province, looking for more affordable way of life, commuting daily for work.
Among them, there has been a relevant component of foreign immigrants, attracted both by the housing affordability and also by the availability of jobs in the construction sector, which was flourishing together with the progressive expansion of the metropolis. In 2014 foreign residents in Riano were 1.596, that is to say the 15,7% of the population. Immigrants are coming from 66 different countries and the 60% is represented by a single group, the Rumanians.

## 3. Today s geographies of spatial injustice

*3.1 Halfway between disadvantage and gentrification*
In the Italian planning discourse, the word describing the essence of spatial injustice is *periferia* - peripheral neighbourhood. The term *periferia* pinpoint the distance of an area from the centre, both in physical and functional terms. Describing Pigneto as a *periferia* today is not completely appropriate, if considered that the city has grown so extensively that such distance has reduced considerably, even if in relative terms.
However, issues of spatial injustice seems to be still up-to-date. The urban evolution of the area, as described above, had cumulative consequences that led to a degree of disadvantage that is still visible. In particular, the lack of a master plan also meant a general lack of public spaces in terms of accessible green areas, playgrounds, squares, cultural and community spaces etc. and today the few public spaces are characterized by neglect and lack of maintenance, which sum up the disrepair of the poor quality built environment. The massive construction of high-rise housing in the 70s onwards meant that the area became the densest in Rome (table 2), but with a very low service provision in comparison to that.
Another common indicator of spatial injustice is that of socio-spatial segregation. Fainstein in its seminal book Just City warns about the risk of segregation, and advocates for neighbourhoods porous and internally diverse. Several authors depict segregated neighbourhoods as the spatial expression of social exclusion (Murie and Musterd, 2004). In the case of Pigneto-Torpignattara is not correct to think at the area as segregated. It is true that some strong boundaries (the railways, the aqueduct) contributes to isolate physically the area. However, rather than being characterised exclusively by social deprivation, the neighbourhood is internally mixed, with some parts badly-off and in decline and others, more well off. Also from the viewpoint of ethnic diversity, immigrants presence is extremely varied (in terms of nationality); the general incidence of foreign resident on total population is still relatively low, with the exception of some concentrations.
The piecemeal growth, combining formal and informal, public programs and speculation, housing and productive spaces, resulted in a strong differentiation in terms of housing types and tenures, commercial vitality and the social profile of the population. In the last 15 years a process of trendification of the area has started, with the opening of a considerable nu leisure venues. Even if scholars do not agree if it is completely correct to talk about gentrification (Annunziata, 2011), it is true that this process started to attract new population which enriched even more the internal diversity. At the same time, the trajectory of the neighbourhood is far to be predetermined: together with the trendification begun also a serious issue and consumption, which according to the inhabitants brought back the neighbourhood to the level of social emergency of the 80s.

*3.2 Urban growth without urbanity*

In the last 15 years, a strong process of metropolitan expansion has invested Riano. This trend reflected the wider phenomenon of re-localisation of Rome inhabitants outside Council boundaries, in the small towns of the first ring, and further out, along major transport corridors. Dissimilar to other realities, Riano had a very small vacancy ratio, less than 5% in 2001. That meant that together with the population, there was also the housing growth with an increase of 51% in a decade. These are impressive figures, if considered that only two other towns in the province have similar percentages of building production.

The houses growth did not correspond to an increase of the services and an upgrade of the infrastructures, in particular mobility ones. The town plan designed in 1999 had clearly underestimated the growth and it expanded the original urban settlement spontaneously born and consequently lacking any formal and structural elements.

The result was a built up area where houses respect fairly construction standards, but there is not a clear urban form. The neighbourhoods are nearly accessible, with under-dimensioned roads, often lacking basic elements and street furniture such as parking spaces, sidewalks and appropriate public lighting. The urban deficiency concerns also sociability and gathering spaces, such as parks and squares. For culture and leisure, Riano s inhabitants depend entirely on for example for cinemas, theatres, libraries or bookshops. In other words, it is lacking an urban infrastructure of open and collective spaces so important for daily encounters among diverse people (Amin, 2002; Iveson and Fincher 2011).

A research of the Rome Province denounces a similar situation all over the towns of the first ring, witnessing that this expansion process is not assuming the character of a metro[5] but instead that of a *periferia* (Provincia di Roma, 2010, p.6). The overall urban deficiency and the dependence from Rome suggests that Riano is at risk of suffering in the future from the classical ills of deprived peripheries: housing speculation, weakness of the urban infrastructure and social malaise.

The economic and functional dependence of Riano from Rome means firstly a high pressure over transportation. This seem to be an issue of spatial justice considering the higher dependence over public transportations of lower income groups and vulnerable categories such as specific age groups (elderly, minors) and immigrants. Public transportation become an important challenge to manage at the metropolitan level. Riano is a stop of a light railway that connects Roma with Viterbo, this line is frequently congested, and users complain about overcrowding and malfunctioning. Given this situation, it is not astonishing that public transports become places of friction, in particular when overcrowding lead to forced contact between diverse populations. Accessible and efficient public transportation is at the same time a social question and an issue of environmental sustainability considering the level of pollution produced by a town of commuters strongly reliant on private cars.

There are also other consequences of the uneven growth of Riano on the environment. The massive housing expansion permanently affected one of the most important assets of the area: the natural landscape. The town plan has been subsequently modified by zoning variances, which involved also part of the rural land, through a process of questionable legitimacy. In particular, a housing development of 117 villas organized in 16 agricultural hamlets was bui within Zone E (agricultural zone) for a total of 1.319.509 square metres (131 acres)[6].

This happened because of the strong demand for single-family houses surrounded by greenery exercised by new-inhabitants, following the dream of home ownership unreachable in the City Capital, but also attracted by a countryside life style. On the contrary, foreign immigrants tent to occupy a different housing stock in the metropolisation process: they are almost exclusively in

[5] In the sense of an area organized in a polycentric way and thereby capable of offering job opportunities, to contain commuters flows, ensuring a multidirectional mobility, to locate services in catchment areas.

[6] This complex is today the subject of an investigation of an alleged abuse.

private rent, in the more affordable houses of the old town, which was progressively abandoned for better living conditions.
Considering also the presence of a gated community, it is reasonable to wonder if the metro-boroughs can be considered the setting of new forms of spatial segregation. The percentage of immigrants in the old town is particularly relevant, more than 40%, but it is not a ghetto. Migrants are extremely mobile in these areas, the old town represents often an entry point, an intermediate house, and then they change gradually residence, looking for a home better suited to their needs. It is also important to stress how the concentration in the old town is not perceived negatively neither by immigrants themselves who describe it as a place of inclusion, functional to stabilization, nor by Italians who recognise the beneficial outcome of such phenomenon. Immigrants are enacting a spontaneous process of re-population of the old town, with positive gains in terms of revitalization of the urban space, but also in terms of management and upgrade of the built environment. Instead of segregation, it seems more appropriate to talk about a process of differentiated geographies, consequence of a phenomenon of residential insertion completely driven by the market, in which Italians are land consumers, while immigrants are existing stock re-users.
Riano and its surroundings resulted to be a convenient place to relocate not just the population, but also other issues that the city of Rome is trying to handle. An example of that is the tentative to use the exhausted quarries for the new Rome s dump. That decision was strongly opposed the local community supported by the Council. The official reasons behind the opposition where environmental, the proved risk of groundwater pollution, but there was also a strong NIMBY movement relative to the proximity of the site to the urban settlements, at the risk of devaluation of lands that could be interested by the housing expansion. The opposition was finally successful thanks to the wide mobilisation of all citizens, also migrants, and the organization of dozens of demonstrations, assemblies and sit-in. The mobilization was disruptive and Riano was reported as a model of civil strife.

## 4. Planning for justice in Rome s metropolis

### *4.1 Empowering a powerful community*

The highest pick of decline for Pigneto was in the 80s when the consequences of de-industrialisation, neglect and abandonment were more evident. In the same period, the left-wing city government begin a policy of rehabilitation of the periphery and legalizat city. Pigneto was individuated as a target area, with the aim of reversing some of the issues of injustice as individuated above.
Since the mid 90s to the 2000s, a series of initiatives of regeneration we mobilizing funding through public-private partnerships and thanks to the use of new planning tools such as PRIU (Programme of Urban Rehabilitation) and CdQ (Neighbourhood Contract)[7] (Fioretti, *forthcoming*).
The objective of such programmes was to overcome the socio-spatial polarization and enhancing the quality of the neighbourhood for the local community by making the fragmented urban fabric more permeable, refurbishing the public space and creating new services and meeting points. In other words, there was a commitment in terms of redistribution, giving those material assets the local community lacked.
Furthermore, following a wider process at the Council level the Neighbourhood Contract promoted citizens participation in the designing process, demonstrating a commitment to democracy, and acknowledging the importance of just processes besides just outcomes.
It is important to specify that the Council involved almost exclusively representatives of local networks: associations, unions, neighbourhood committees, self-organized social centres (Allegretti, 2004). Pigneto has a socio-cultural context with a strong history of activism, thanks

[7] Area-Based Initiatives acting in neighbourhoods affected by multiple deprivation.

to the presence of organized groups that over time had carried on many campaigns for raising the livelihood of the area, ascribable to the right to the city tradition. These g wing tradition since the neighbourhood was working-class, particularly active in the antifascism and a theatre of clashes during the Resistance.
Thanks to that (and to the harmony in that period of political views among the Council, the Municipio and the local political arena, all the three left wing) the participation process was relatively smooth and successful. On the other side, that constituted a strong limit for reaching a wider scope of citizens, especially most marginal groups and those people who usually tend not to participate, such as migrants[8].
The Council seemed to recognise the ongoing spontaneous market-led processes of transformation, incorporating in the regeneration private interventions as well. The idea was that of providing for a strong public infrastructure, a strategic framework, built in a consensual manner together with the inhabitants, to take up the challenge of accompanying those changes, softening the eventual negative external factors.
However, the programme, that seemed so promising in its premises, was less successful in its implementation. The public-private partnership mechanism seemed to be unbalanced, with exaggerated leanings to private interests. The most innovative public actions, especially those aimed at the realization of community facilities, the establishment of a permanent workshop for citizen participation and the inclusion of migrants, were particularly weak, when realized.
That determined a rupture in the relation between the local government and the citizens. Their involvement in the process had made citizens more demanding, and more attentive to the effective enforcement of the commitments signed in the Contract (Allegretti, 2004). Th participation in a society that was already socially and politically organized (already capable in a sense) contributed, even if not completely wittingly, to empowerment, to raise the capability of the local society.
The local forces, associations, schools, migrants communities, mobilized around Neighbourhood Committees, used it to protest and to encourage the Local Authority to fulfil the promises made, among the claims that for denied spaces , or measures against gentrifica Independently from the success of the single struggles, this form of antagonism succeed in something more general: the recognition of migrants as active agents in the upgrading of their living environment.

*4.2 Who is claiming for spatial justice?*

Inaccessibility to services, overconsumption of greenfield, forms of spatial segregation, the issues of spatial injustice in Riano seems serious but the claim for spatial justice is much less strong than in Pigneto, and the public government seem to respond to injustice in a fuzzy way.
It must be said, that there is a general acknowledgement of the implications of the drastic changes that affected the Council in the last 15 years. The new local government elected in 2011 based its election campaign precisely on the issue of change, gathering left-wing forces and a Romanian participation under a civil list called Fresh air . Nevertheless, concrete mea new challenges are hesitating.
In particular, the local government is now engaged in drafting a new plan to compensate the lack of public services, facilities and infrastructures. However, the task is difficult and the Municipality, lacking resources, proceeds in piecemeal way through regional funding, and concession fees.

[8] Immigration was recognized as a key priority in the Neighbourhood Contract, but the initiatives devoted to that were finally weak, and lacked of long term commitment (for a detailed discussion see Fioretti, *forthcoming*).

More seems to be done on the immaterial side, especially in terms of recognition, if considered that in Riano local authority there is a Romanian councillor[9]. This means that the local government is at least recognising the importance of the migrants component of the acknowledging its positive contribution (for example in terms of vitalization of the old town), and giving them voice in the decision-making arena. But again, also in this field, it does not translate in a clear strategy for promoting diversity and interculturality and the potentialities are not capitalized by urban policy (Fioretti, 2014).

Not only the local government does not have the resources and capacity for a clear commitment in terms of just planning, but also it must be said that there is neither a clear claim coming from the civil society. The local community has been invested almost passively by the process of metropolisation, half of the residents are recently arrived, and many are foreigners. The population is extremely fragmented in its composition, lacking political commitment and organization, still looking for an equilibrium as part of the metropolis, the small-town identity that seems to be lost.

The only episode that witnessed a wide and overwhelming mobilization of all citizens and local forces was that of the movement against Rome s dump. That testified an environme but it is not possible to say that the movement was inspired by a clear identification of sustainability as a key goal for the local society. Instead, it seemed to be more dictated by an individualistic worry, linked to a NIMBY phenomenon.

That example it is interesting because it shows two major limits that inhibit an impulse towards just planning in Riano: first, the lack of a collective awareness of justice values to be claimed; and second, the fact that major issues transcend the local scale.

That can be translated in a lack of two key category of spatial justice: capability and responsibility, to be considered together, being extremely intertwined in this case.

The inhabitants of Riano are individually capable. Many moved in Riano from Rome, driven by a conscious choice, the dream of the single-family home in the green. It means they does have access to opportunity, as testified by their individual (spatial) mobility.

However, they lack of a collective awareness and pursuing of the assets that contribute to the quality of life, which means also a lack of responsibility towards the territory.

## 5. Conclusion

This paper addressed the question of how the social, spatial and geographical features of urban change affect the analytic dimensions of justice, and consequently, the ideal of just planning. The answer depends on whether justice is conceptualized as a universal, normative model; or as an evolving set of practical rules that results from a collective, shared vision (which often requires a reflexive political actor).

We tried to make the argument that the shift from a dimension of justice to another is not purely analytical; on the contrary, it is the outcome of an historical process. It is positioned in time and space, and heavily influenced by the political actors and processes that have tried to address it.

This is bold statement, obviously, which deserves a better attention at a theoretical level, implying that one cannot forget the issues of power, temporality and materiality when addressing urban change.

However, some conclusive remarks sprung out from the investigation of city change at the scale of local development. In particular:

a) The two views are not mutually exclusive. The first classically lies at the core of the Enlightenment project, and it qualifies European societies as a sort of genetic code, and provides the basis of ideological arguments. However, the second illuminates a fairly large set of conditions where a local (Elster 1992) rule intervenes, eithe

[9] That was possible because Romanians are EU nationals, they do not need the permit to stay to reside in Italy and can access to local elections

individuals access to goods or, on the contrary, imposing social burdens on their actions.

b) Both views are needed when dealing with urban space, *space* being at the same time part of the power structure, and a very specific set of local arrangements. However, a general model of spatial justice is hardly tenable, being such the variety of institutions, individual preferences, and collective identities.
c) Following these suggestions, justice cannot be conceived as a single theoretical object, but rather it can be conceptualized as a multilayered normative ideal.

If justice cannot be considered a monolith, just planning is obviously a complex dispositive that progressively adapt to changing situations, positioned in time and space; according to political strategies that combine elements of redistribution and recognition; affecting the quality of the societal entitlements or limitations. For this reason, certain categories used to evaluate the just city as periphery, density, *mixité*, segregation are context dependent, and cannot be used as universal principles.

However, the two case studies suggest something more, related to the how different components mingle in a political, historical ideal of justice.

Let s remind that, in an effort of qualifying the just city, S. Fainstein had to combine as different ideal dimensions as equity, democracy and diversity. Though demanding, this opening is likely not enough: in many fields, scholarly discussion has recognized the opportunity to encompass a broader view of justice, including additional dimensions like recognition, capability and responsibility (Davoudi, 2013; see also Fincher on diversity; Cremaschi and Fioretti 2015). It has been also stressed the importance of considering both the dimension of procedural justice and questions of value (Campbell, 2006).

In particular, the two case studies has shown different combinations, with a similar result:

a) a redistributing, or creative process, depending on whether it mainly leads to the transfer of goods, or to the recognition of identities;
b) legitimating claims either to goods or values, to material and non-material assets that society exchanges;
c) unfolding in situated processes, i.e. in historical conditions, under material and political constraints
d) needing for a collective and relational conception of values beyond the individual dimension.

Finally, it has been underlined how the juxtaposition of the two cases, shows a variation in the spatial scale in which the issues of spatial justice are framed. In the pursuing of the just city , planning should be more responsive to the phenomenon of rescaling driven by urban change.

**THE SECTORAL PLAN FOR HEALTH PROMOTION: AN INNOVATIVE INSTRUMENT FOR A MORE JUST CITY**

Heike Köckler[1], Andrea Rüdiger[1] and Sabine Baumgart[1]

[1]TU Dortmund University, School of Spatial Planning, Department of Urban and Regional Planning, heike.koeckler@tu-dortmund.de

Keywords: healthy urban development, sectoral instrument, environmental justice,

*The promotion of health is a joined interest of urban planners and health professionals. Due to the existing and increasing inequity in health and the knowledge on vulnerability and environmental determinants of health, the concepts of health inequity and environmental justice enrich each other (Bolte et al., 2012). One approach to reach more health for all promoted by WHO is called "health in all policies". One policy field for health promotion is urban planning.*
*Today health professionals make only little use of urban planning as policy for health promotion. To face this shortcoming the Landeszentrum Gesundheit (LZG, NRW Centre for Health) pursues the development of an innovative instrument: the sectoral plan for health promotion (Fachplan Gesundheit). This plan is based on an integrated spatial analysis of health, social and environmental data, identifies risks and potentials, develops goals and strategies to identify specific measures. This instrument was theoretically developed, illustrated through fictitious plans (LZG, 2012) and tested in a county and a city in 2014. As common in health promotion a consequent consideration of the vulnerability of the population is a natural approach in these plans. Therefore such plans are not only useful for health promotion; they have the potential to put discussions on justice in planning on a solid ground and provide information for planning decisions.*
*The approach and first experiences from the practical test will be presented and put in a wider context of planning. Here we argue why we see the healthy urban development plan as a promising tool for a more just city.*

## 1. Introduction

The present discourse on urban healthy development stands for the revival of health promotion in urban planning that has had received little attention in the last decades of the 20th century (Corburn, 2013; Böhme *et al.*, 2012; Köckler *et al.*, 2014). One reason for this growing interest is the existing and increasing inequity in health, that leads to differences in life expectancy by class and/or neighbourhood (CSDH, 2008; Junior-Forschungsgruppe Salus, 2012).Furthermore the knowledge on both the vulnerability of people and the relevance of environmental determinants for individual health, make the promotion of health for all a joined interest of urban planners and health professionals. While health inequity that correlates with social and/or environmental factors is often seen as an inequality there is a strong interest and contribution of the disciplines of healthy urban planning and public health in the discourse on environmental justice. The concept of environmental justice stands for social justice according to environmental concerns (Bolte et al., 2012).

Several analyses in the field of environmental justice conclude that certain groups of society are more exposed to environmental stressors and have less access to environmental goods than the average of the comparable population (see for Germany e.g. Raddatz and Mennis, 2013) and have to face negative health-outcome due to this factors (Fecht *et al.*, 2015; Bolte *et al.*, 2012). These groups are often deprived groups or groups with a certain ethnicity or migration background. In the discourse on environmental justice such differences are judged as distributional injustice, because an identifiable sub-group of the overall society is not treated equally regarding environmental quality. As environmental justice is not only a concept for analysis, but a vision such results on distributional injustice often lead to claim making for change (for the concept of claim making in environmental justice research see especially Walker, 2012, chapter 1 and especially chapter 3).

The concept of environmental justice encompasses besides distributional justice procedural injustice as another relevant concern. Procedural injustice "stands for unequal opportunities in the meaningful

involvement in environmental decision-making processes as well as the initialisation of such processes." (Köckler, 2014, p. 141). Procedural justice is understood as one determinant of distributional justice as Schlosberg (2007, p. 75) points out „For the environmental justice movement, the demand for more public participation and procedural equity in the development, implementation, and oversight of environmental policy is the key to address issues of distributional equity, recognition, and capabilities."
In the field of urban healthy development it is not only the public that should and could be meaningful involved in decision making. Relevant stakeholders, like the health authority, should also be involved, as they know better than the planning department about health inequality and could play the role of an advocate for deprived or marginalised groups (on advocacy planning in the context of environmental justice see: Harwood, 2003).

The integration of health aspects in urban planning is on the one hand based on law. In Germany §1 of the Federal Building Code calls for healthy living conditions at work and at home. On the other hand it corresponds with the WHO strategy "*health in all policies*" (Ståhl *et al.*, 2006). This calls for considering health in different policies. Urban and infrastructure planning are fields of policies mentioned in corresponding statements (see e.g. WHO and Government of South Australia, 2010).

In Germany public health promotion is based on federal acts. In North Rhine- Westphalia, one of the federal states in Germany, the Public Health Service Act from 1997 provides the legal basis for public activity in health promotion (Land Nordrhein-Westfalen, 1997). The lower health authorities are located in county-free cities or counties. In §8 of the Public Health Service Act the lower health authorities, are mentioned to be included in the formulation of statements in planning and permission procedures, if health of the population is affected. Nonetheless health professionals make only little use of urban planning as a policy field for health promotion. Often public health authorities understand themselves as reactive towards diseases (like HIV) or as active in promoting a more healthy behaviour (like providing information on healthy nutrition). If they participate in urban planning they understand themselves as reactive mainly. To increase the use of urban planning for health promotion the Landeszentrum Gesundheit (LZG, NRW Centre for Health) pursues the development of an innovative instrument: the Sectoral Plan for Health Promotion (Fachplan Gesundheit) since the year 2009.

In the following the development of the sectoral plan for health promotion as a new instrument is described by introducing its aim, first prototypes, so called fictitious Plans for Health Promotion and a first pilot-test. The authors have been actively involved in the development of the fictitious plans and the evaluation of the pilot-test. The paper closes with a conclusion on whether and how this new type of plan may contribute to a more just city with regard to the concept of environmental justice.

## 2. The Sectoral Plan for Health Promotion

The sectoral plan for health promotion is intended to be integrated in the existing structure of public health. It follows two main goals: On the hand it is meant to support municipalities and counties to organise the work of local health authorities more clear and transparent. On the other hand it is a promising tool to enforce health concerns in spatial planning procedures on the local and regional level. [1]

### *2.1 The starting point in Public Health*

The new instrument of a sectoral plan for health promotion is seen a forceful further development of the existing structures in public health in North Rhine-Westphalia. The existing structure of public health, based on the Public Health Service Act, requires amongst others running a local health monitoring. This data is collected by the lower health authority and is to take social and gender specific requirements into account (§21 Public Health Service Act). This data is published regularly in

[1] for general information see https://www.lzg.nrw.de/themen/Gesundheit_planen/fachplan_gesundheit/, last access May 11th 2015

local reports and transferred to the federal state level. It includes different data on morbidity, mortality, health care and child health. One important source of data is the school entry health examination that is mandatory for each child before going to school and therefore provides a census of all children around the age of six. More and more reports use the data to analyse whether health inequities exist in their cities or to identify districts or neighbourhoods with a specific need for intervention. In Bavaria the school entry examinations have had a thematic focus on environment and health that led to findings on environmental injustice in Munich (Thiele and Bolte, 2011).

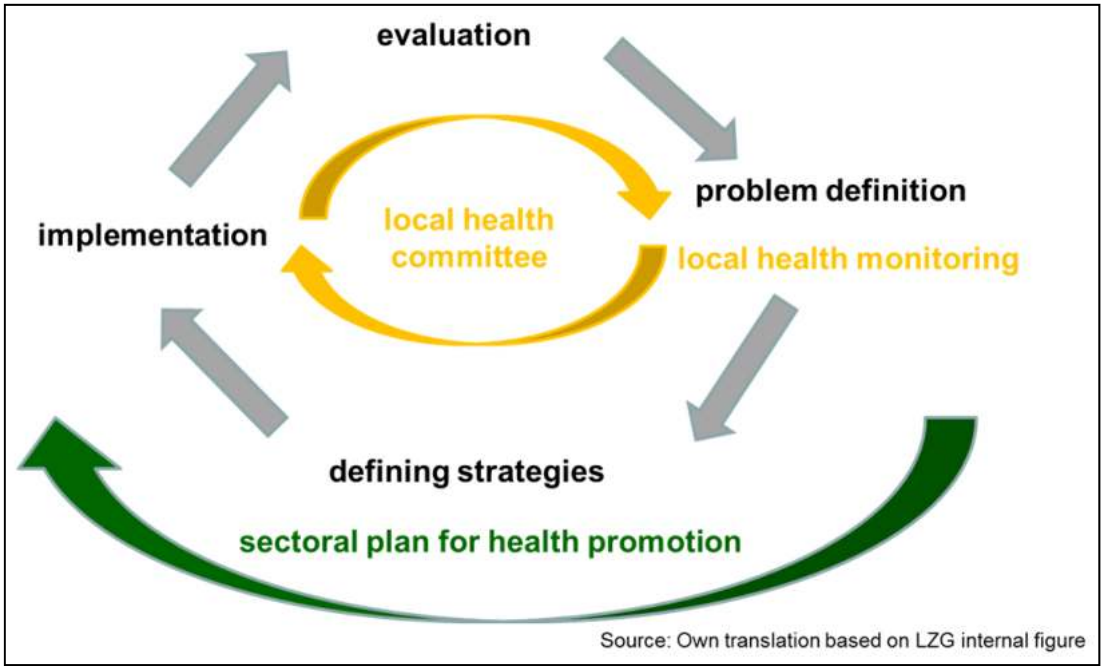

Figure 1: The sectoral plan for health promotion a contribution to the Public Health Action Cycle

Figure 1 shows the policy cycle in the version of a public health action cycle. In the cycle local health monitoring is part of the problem definition and intended to be used for defining strategies. Such strategies are amongst others developed by the Local Health Committee (Gesundheitskonferenz). In North Rhine-Westphalia, such committees are required on a legal basis. Their members are appointed by the local council and include different stakeholders from health promotion including politicians, members of local administration, provider of health services, self-regulating communities, patients organisation and others. Strategies that are developed in the Local Health Committee are implemented by its members due to their ability and responsibility. The work of the Local Health Committees differs in intensity and scope amongst each other a lot.

*2.2Protoypes of Sectoral Plans for Health Promotion*

Based on preliminary studies the department of Urban and Regional Planning of the School of Urban Planning, TU Dortmund was commissioned by the Landeszentrum Gesundheit NRW to develop prototypes of fictitious plans for health promotion. One aim was to give examples how such a plan could look like and how such a kind of plan might be integrated in planning procedures. To take different contexts into account one plan was developed for a fictitious city and another for a fictitious county. The following description refers to the plan for a city called “Healthhausen” (LZG , 2012).

In the prototypes it is suggested to develop the plan by a steering group including different stakeholder led by the mayor of a city. Another option is to develop the plan within the local health authority including contributions from other authorities and stakeholders. In general it is recommended to start with a mandate from the city council and the Local Health Committee.

Furthermore it is suggested to start the development of the plan with specific topics that are of interest in the local context. In the Healthhausen prototype the following topics have been chosen: A) healthy nutrition and physical activity for children and teenager from low income households, B) physical activity of the elderly, C) health promotion of vulnerable groups facing multiple environmental burdens.
Figure 2 shows different elements of the sectoral plan for health promotion. In the following the thematic focus C) "health promotion of vulnerable groups facing multiple environmental burdens" of the prototype for the fictitious city of Healthhausen is used as an example to explain the different elements of a sectoral plan for health promotion.

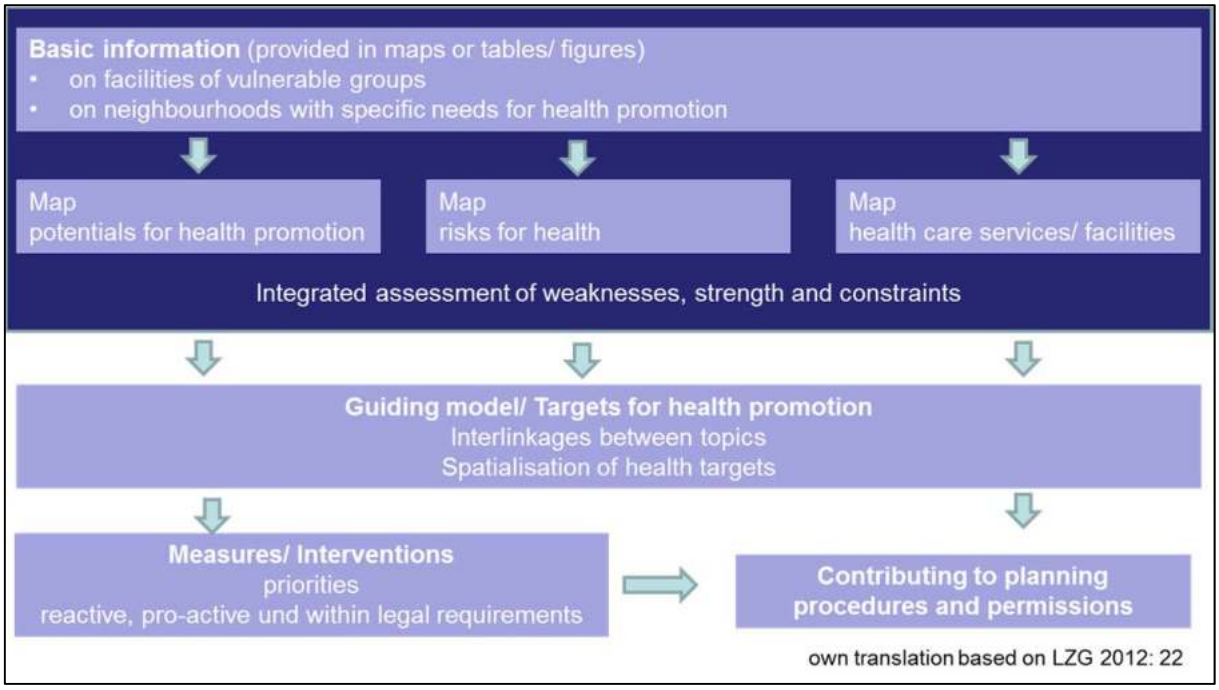

Figure 2: Elements of a sectoral plan for health promotion

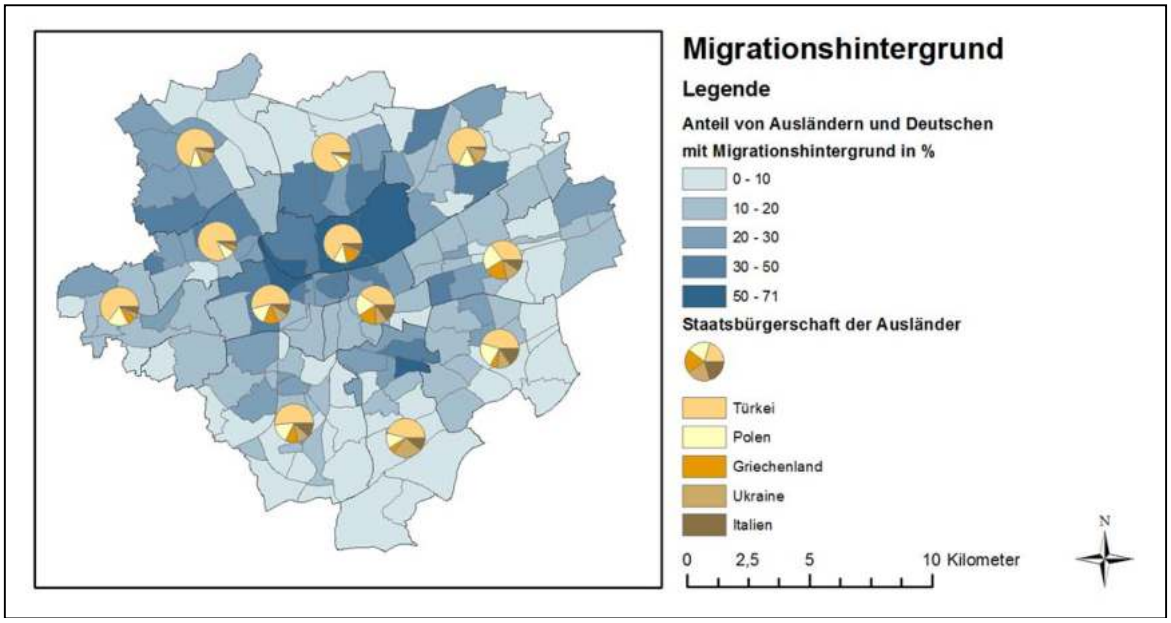
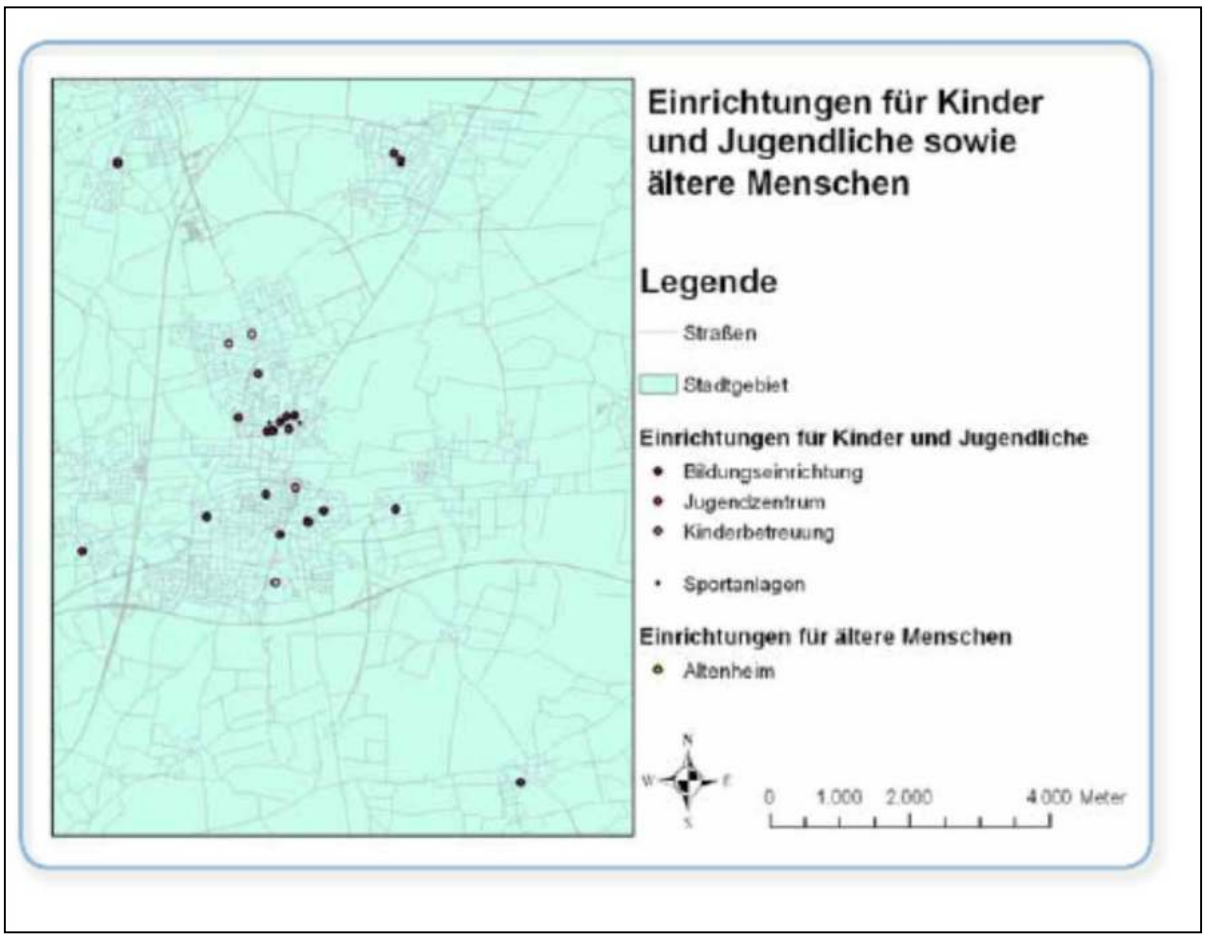
### 2.2.1 Basic Information and integrated assessment

Facing the state of research on environmental epidemiology and environmental justice, it is known that some groups of migrants and people with low income are more vulnerable towards environmental stressors than others. Therefore maps, like that in Figure 3 have been developed. Facilities of vulnerable groups are shown in Figure 4 and are available in the local health monitoring. Additionally data from the local health monitoring on health outcomes like speech disorder or overweight are mapped, too.



Source: LZG 2012: 25

Figure 3: Foreigners and Germans with migration background (share of whole population and nationality of foreigners)



Source: LZG 2012: 24

Figure 4: Facilities for children, youth, elderly and ill people in Healthhausen

The aspect of multiple burdens was dealt with by providing maps on air and noise immission based on data available in the local environment department, according to EU-Regulations (see Figure 6).

Additionally it was shown that e.g. mental maps of children on quiet areas within neighbourhoods could be integrated in sectoral plans for health promotion, too (see Figure 5).
An integrated assessment of these single burdens was not carried out, but is topic of different research activities and could be implemented based on this basic information (Linder and Sexton, 2011).
Vulnerable facilities and exposure are combined in one map. So it becomes obvious that a kindergarden is exposed to noise with more 70 Lden/dB(A). In noise immission maps such combinations of environmental stressors and vulnerable groups is not required.

Figure 7: Exposure of kindergarden with noise immissions

### 2.2.2 Targets for health promotion

In the fictitious plan for Healthhausen the targets have been formulated as a Leitbild and as action oriented targets. For the thematic focus of "health promotion for vulnerable groups facing multiple burdens" the overall Leitbild was drafted as follows: *The burden of those, who are exposed by heavily trafficked roads, is to be minimized. Simultaneously the ability of exposed population to cope with remaining environmental burdens hast to be improved.*

This Leitbild has been operationalised by the following action oriented targets:

All facilities of vulnerable groups (kindergarden, schools, homes of the elderly, hospitals), that are exposed to noise by cars are to be protected against this noise.

Next year in three Kindergardens in the northern part of Healthhausen traffic calming will be implemented

Quiet housing space is to be saved and developed. Especially in heavy trafficked roads passive noise protection is to be realized in 20% of the exposed housing space. Specific funding for deprived neighbourhoods will be provided.

The exposure at workplaces on heavily trafficked roads has to be reduced.

The Leitbild and target are exemplary, only. But they show that from a health perspective spatially explicit targets can be derived from the analysis of the maps shown in chapter 2.2.1. Furthermore specific requirements for spatial interventions, like traffic calming and development of quiet housing and working areas have been formulated. These could be used as contributions to planning procedures by local health authorities.

### 2.2.3 Measures for health promotion

Different measures for interventions have been suggested in the fictitious sectoral plan for health promotion. These have been collected in a table. Selected measures have been described in short profiles.

The table provides information on the kind of measure (organizational, related to planning or investment), costs of the measure (low, moderate, high) and feasibility (short-term, medium-term, long-term).

Table 1: Table of Measures in the fictitious sectoral plan for health promotion of Healthhausen (excerpt)

| **topic/measure** | **kind of measure** | | | **expenses** | | | **feasibility** | | |
|---|---|---|---|---|---|---|---|---|---|
| | o | p | i | l | m | h | st | mt | lt |
| **Health promotion of vulnerable groups facing multiple burdens (using the example of highly trafficked roads)** | | | | | | | | | |
| transport calming/ reduction | X | X | X | | X | | | X | |
| noise minimisation on street sections where facilities of vulnerable groups are located | X | X | | X | | | X | | |
| silent asphalt on roads with high pressure on vulnerable groups | X | X | X | | | X | | X | |
| speed limit of 30km/h at specific times of a day (depending on opening hours of facilities for vulnerabel groups) | X | X | | X | | | X | | |
| Assignments in binding land use plans on passive noise protection | X | X | | X | | | | X | |

Explanation of abbreviations used in the table:
kind of measure: o= organizational, p= related to planning, i= reltated to investment),
expenses: l= low, m=moderate, h= high)
feasibility: sm= short-term, mt= medium-term, lt= long-term

## *2.3 First experiences from a practical test in two case-studies*

From September 2013 until July 2014 the city region of Aachen and the county Unna, both located in North Rhine-Westphalia, tested the development of a sectoral plan for health promotion.. This project

was supported by the Landeszentrum Gesundheit through financing 1) a planning bureau to support the development of the plan, 2) a scientific evaluation of the process, carried out by the authors of this paper and 3) allowances for the local health authorities of Aachen and Unna. Furthermore existing, and not yet published tools, as well as the fictitious plans described in chapter 2.2 and consulting through the Landeszentrum Gesundheit for the pilot-communities were provided.
In both cases the local health authority was responsible for carrying out the project. Both, Aachen and Unna, chose a specific topic to develop elements of a sectoral plan for health promotion. While Aachen was working on social inequality in dental hygiene, Unna focussed on the exposure of children and youth to electro-magnetic fields. The main focus in this one year project was on the development of maps, targets and the identification of measures. The allowances from Landeszentrum Gesundheit were partly used to train staff members in the use of Quantum GIS. This open source GIS proved to be easy to use and sufficient for the required uses.
The evaluation report and the reports produced by Unna and Aachen will be published soon. Some lessons that can be learned and shared here are the following:

First of all, the pilot-phase proofed that the idea and methodology of a sectoral plan for health promotion is feasible in practice.

Several existing data can be used and combined to learn about social inequity in health and environmental determinants of health on the local level. In Aachen data was provided in so called Lebensräumen (life oriented areas), while in Unna data was available for statistical units, only. The life oriented approach is of higher value for health related approaches as it corresponds with the settings approach.

Staff of both health authorities worked with GIS and appreciates this as a valuable experience.

In both pilot-cases the exchange with other local departments was somewhat restricted due to the character of a pilot-project. The actors see a big potential in overcoming silo-mentality in public administration through working on a plan like this.

In the pilote phase no political mandate was formulate. Both Aachen and Unna intent to get a mandate for the further development of the plan after the pilot phase.

*2.4 Future perspectives*

In Germany different cities start to work on the local plans for health promotion independently from public financial support. For example the city of Bochum aims to develop a plan for health promotion related to an urban renewal programme for deprived neighbourhoods (Förderprogramm Sozial Stadt) in one of its districts.
At present in Baden-Württemberg, another Federal State of Germany, the Ministry of Health launched a programme including financial and organisational support to municipalities that are implementing the sectoral plans for health promotion. This project includes six municipalities, started in December 2014 and will run until February 2016. In this project the participation of citizens in the development of a local plan for health promotion is one aspect of mayor interest. [2]

## 3. Conclusion

The sectoral plan for health promotion can provide a solid basis for local health authorities to play a more pro-active role in contributing to urban planning by own, health specific, localised targets for urban development. The established health monitoring can be improved through the integration of additional spatial and environmental information and provide a more solid information basis for decision making in the whole city. Such integrated analyses provide meaningful information on vulnerable groups.

If health authorities obtain solid information that helps to identify spatial determinants of health, they can play an active role in urban planning. They can follow the invitation to submit statements in planning procedure or can even initiate planning procedures. Regarding the existing legal

[2] For further information: http://gesundheitsdialog-bw.de/gesundheitsdialog/kreisebene/fachplan-gesundheit/, last access May 11th 2015

requirements, Dieckmann (2013) has given the thought-provoking impulse that situations of multiple environmental burdens might lead to a duty for planning (Planungspflicht according to art. 1 para. 3 no. 1 BauGB). If this duty for planning exists, the municipalities would be obliged to develop a binding land-use plan. Health professionals knowing about environmental determinants of health in their city can identify such areas together with urban planners.

The sectoral plan for health promotion is a voluntary planning instrument. The municipalities in Germany have experience with different voluntary plans that can become local law through a resolution of the local parliament. Sectoral plans on retail, transport or the environment are common. To let local plans for health promotion become an established instrument in urban planning the staff of locals authorities has to be empowered to use this tool and get an understanding of being a pro-active actor on the local level.

Regarding its potential the sectoral plan for health promotion can contribute to a more just city, acting against environmental exposure of vulnerable people and decrease peoples vulnerability. The local health authority could use this tool being an advocate for those facing the consequences of environmental injustice.

*Acknowledgements: The development of the sectoral plan for health promotion is developed by the Landeszentrum Gesundheit, namely Rainer Fehr, Rudolf Welteke, Manfed Dickersbach and Odile Mekel. Martin Enderle provided meaningful contributions to basic concepts, developed a tool for the healthy plan and was consultant in the pilot-phase for the city Region of Aachen. Joachim Hartlik and Monika Machtolff were consultants in the county of Unna. In Unna and Aachen several staff members contributed to the work, in favor for all of them the project leaders Christan Scholz in Unna and Thilo Koch are to be mentioned. Natalie Riedel contributed to the development of the fictitious sectoral plans.*

**Abstract:**
Ethical Urban Planning has recently focused attention on Professional ethics. This paper presents a study of Ethical and unethical Justice in Tanzania Planning system. A qualitative methodology has been adopted to identify planners personal and organizational values and the E Justice in Tanzania Planning system and roles played by Planners. Ethical dilemmas is critically discussed and analyzed.
**This paper aimed at:**
1) Review the Tanzania Urban Planning system and Processes, review legal framework and regulations and procedures for preparation of detailed and general land use plan and compare the real practice by practitioners.
2) Identify how public and private planners prioritize areas for public interests such as open space, cemetery by identifying criteria s for prioritization
3) Study and analyses ethical and unethical justice in planning in theory and real practice.
4) Identify Challenges for ethical and justice planning in Tanzania 5) Provide possible solutions and recommendations for unethical justice in planning.
The research involved both structured and semi structured interviews for data collection. The perceptions of a wide range of key stakeholders were canvassed in a qualitative questionnaire survey. The analysis involved mainly statistical tabulations of the views and data collected, and interpretations of the statistics using SPSS. The results shows typical unethical by practitioners and legal environment has been a challenge for ethics. Political interference by decision makers to professionals is critically discussed.

Keywords: Urban Planning, ethical planning, Tanzania

## 1. Introduction

Ethical Urban Planning has recently focused attention on Professional ethics. This paper presents a study of Ethical and unethical Justice in Tanzania Planning system. A qualitative methodology has been adopted to identify planners personal and organizational values and the Et Justice in Tanzania Planning system and roles played by Planners. Ethical dilemmas is critically discussed and analyzed.

*1.1 Back Ground*

Urban and Regional Planning is a profession that puts the welfare of people on the top of environmental and sustainability agenda. The Tanzania Urban Planning sector is extremely susceptible to ethical erosion due to heterogeneous nature of the sector which makes it imperative for planning professionals to exhibit high level of professional ethics. One of the deters of meaningful development in Tanzania s Planning Sector is the menace of corruption and corrupt practices. Tanzania like many other countries in the world is faced with the problem of corruption in both the public and private sectors. . Tanzania planning system, the separation of control mechanism and acts of planning actors are mostly independent from each other. This separation and independence provokes individual actions to take place in planning control mechanisms. The land use planning process in urban areas is also not free of corruption due to lack of transparent systems, conflicts with the local government reforms and lack of innovative approaches. The

increasing unplanned settlements in urban areas show that the planning process does not respond to effective demand. Planning is promptly done in areas where kickbacks have been offered. The approval process of urban detailed plans is tedious, slow and compels the public to pay for undocumented money to officials to speed up the process.

Figure1: Location Map of Tanzania

*1.2Research Objectives and Methodology*

This paper aimed at:

1) Review the Tanzania Urban Planning system and Processes, review legal framework and regulations and procedures for preparation of detailed and general land use plan and compare the real practice by practitioners.

2) Identify how public and private planners prioritize areas for public interests such as open space, cemetery by identifying criteria s for prioritization

3) Study and analyses ethical and unethical justice in planning in theory and real practice.

4) Identify Challenges for ethical and justice planning in Tanzania 5) Provide possible solutions and recommendations for unethical justice in planning.

The method of investigation adopted in the research essentially relied on published and unpublished materials and interview to stakeholders.The research involved both structured and semi structured interviews for data collection. The perceptions of a wide range of key stakeholders were canvassed in a qualitative questionnaire survey. The analysis involved mainly statistical tabulations of the views and data collected, and interpretations of the statistics using SPSS. Also, both descriptive were used to analyze the data collected and compared respectively.

*1.3 Understanding ethics and Ethical conducts*

Ethics seems to be a concept undergoing revival and is surrounded by much controversy and speculation. There seems to be a genuine concern that the world at large is becoming less aware of the importance of ethical considerations
According to Mbatha (2005:16), ethics can be seen as a system of moral principles that is based on values relating to human conduct, with respect to the rightness or wrongness of certain actions and to the goodness and badness of the motives and ends of such actions. Ethics concerns obedience to the unenforceable moral principles that determine what is honest and fair, and the distinction between right and wrong (Lloyd & Kidder 1997:145). Ethics is a set of rules or standards governing the moral conduct of employees in an institution. Ethics deals with values relating to human conduct, with respect to rightness or wrongness of particular actions and to the goodness or badness of the motives and ends of such actions. Rightness refers to what ought to be or what is approved and wrongness to what ought not to be or what is disapproved of by society (Mafunisa 2001:335).

Ethical conduct refers to a strong desire to do the right thing, especially when behaving ethically imposes financial, social or emotional costs (Website: http://www.josephsoninstitute.org). Surveys taken by the Josephson Institute reveal that, regardless of profession, almost all people believe that they are, or should be, ethical. While most are not satisfied with the ethical quality of society as a whole, they believe that their profession is more ethical than others and that they are at least as ethical as those in their profession.

Unethical behavior may be defined as deliberate or negligent conduct constituting a deviation from or breach of the guidelines designed to inform an expected pattern of behaviour in a given situation (Maluleke, in Mafunisa 2000:53). Unethical behaviour, although it is an indication of a decline in morality, can be regarded as an indication of a negative work ethic only in so far as it relates to work performance. In other words unethical behaviour can include theft and misuse of public property and accepting outside employment during one s tenure in government with

Normative ethical theory poses the question, what ought I do? (MacIntyre, 1985; Swanton, 2003). The study of ethics, is concerned about what is right, fair, just or good; abou not just about what is the case or what is the most acceptable or expedient (F Morality refers to the actual conduct of human beings, whereas ethics (often referred to as moral philosophy) relates to the study of the moral conduct itself. As such, morality may be described as experiences of real problems, dilemmas and conflicts that need to be resolved, at times by individuals, groups or organisations. (Badaracco, 2002; Ruggiero (2004). The circumstances in which there are choices relating to moral conduct are influenced by human values (LaFollett, 2000). Values, sometimes referred to as one s principles, are those to which indi worth and become a guide or reference point for action that has moral significance (Rokeach, 1973; Singer, 1993). Values define who we are, and they influence the choices we make in life (Hood, 2003; Russell, 2001). As such, values influence human behaviour, both in private and public matters (Chatman & Cha, 2003). The personal value system of an individual develops in the context of the specific culture, society and family environment in which he or she develops.

According to Badaracco (2002) ethical dilemmas involve making choices between nonoverriding, conflicting moral requirements; for example, loyalty and honesty. SinnottArmstrong (1988) proposed that ethical dilemmas are composed of four key elements; no clear resolution is evident, the agent is required to do each of two or more actions, the agent can do each of the actions but not both and neither of the conflicting requirements is overridden. Rost (1995) noted that most people do not use ethical frameworks to judge morality. Rather, they draw on life experiences, personal values and perhaps religious convictions. This is illustrated by Beu, Buckley and Harvey (2003), who stated that while there may be basic moral norms, the dynamic business environment brings with it challenges which cannot be readily answered by moral rules. Ethical decision-making,

therefore, is not straightforward and individuals may examine and behave differently when confronted by similar ethical dilemmas.

There are a number of planning scholars whose work emphasises the moral challenges implicit in the planning profession. Wachs (1985) asserts that ethical issues are present in many areas of planning. He remarks that planners exercise their ethical judgments to make decisions that will affect private behaviour and property on behalf of the public welfare. More specific examples are included such as planners accepting gifts and the disclosure of confidential information. Hendler (1995) strongly supports the view that there is an ethical dimension to the planning profession and planning decisions do involve the exercise of human values.

Hendler s assessment draws on a number of classical ethical theories and ill relates to dimensions of the planning profession. One such theory which other scholars cite is the utilitarian theory which seeks planning decisions and outcomes which deliver the greatest benefits to the greatest number. An example in her argument involves a decision for the development of a new rapid transit line as having benefits to the commuter which must be weighed up to the harm to nearby displaced residents who are fewer in number. Howe (1990) argues that planners, whether consciously or not, make decisions from a preferred ethical theory and that a greater degree of awareness in how individual mindsets may influence decision making in planning. Nevertheless, Howe presents the two most common approaches to ethical decision making; that being utilitarian and deontological theories. The former focusing on the rightness of the consequences and the latter on the means to the decision based on principles such as justice and rights. Notably, no ethical theory in itself may be applied to face the challenges planners may face in their role. Hoekveld & Needham (2013) argue that planning involves a public agency s regulation decisi the lives of citizens and as such individual planners, while having their own values, need to be made aware of the ethical implications of their work. They make a distinction between the individual values of the planner and the ethical principles which should govern the operation of the agency. The latter, argues Hoekveld & Needham (2013), should form the framework by which planning decisions be made. Earlier research by Howell & Baum (1998) illustrates this in a case study involving the ethical challenges of community participation in planning decisions. In this example, planners espouse the value of community participation but in reality it demonstrates the ethical challenges in planning, in this case, community participation. It illustrates that planners may be committed to the principles of community participation but the process is by no means value neutral.

Birkland (1995) advocates a new ethic (an ethics-based planning approach) which takes account of planning issues which contribute to addressing questions which relate to how we, as a society, ought to live which relates to the fundamental ethical question posed by the ancient philosophers. She argues the basic decision making mechanisms for planners are based on legal, political and market systems which approach planning from a utilitarian perspective of who new ethic therefore needs to take account of planning decisions based on improving the h condition. Campbell & Marshall (1998) confirm the ethical dimension inherent in the role of planning decision-making. Most particularly, they raise the question relating to competing interests which exist in the role of planner. are planners obliged to serve the interests of employers, the organization, personal values, clients, the wider community, future generations or the profession ? (Campbell & Marshall, 1998:17). The findings arising from thei on focus groups with planners emphasised the tension experienced by planners fulfilling their obligations to corporate and political objectives against decisions which in p public interest .

The engagement of planning consultants, pressure to process planning applications and the perceived risk to the quality of the decision were also themes which emerged from the research. Studies by Howe & Kaufman (1979, 1981) used case scenarios to explore what planners thought were ethical conduct in their role. A key finding in this research distinguished perceptions of ethicality by planners. Politically orientated planners adopted more liberal interpretations to their

decisions. Technically oriented planners made decisions based more towards procedural and technical interpretations and a perceived value neutral position on planning orientations differed, both groups held similar views that the misrepresentation of information in their role was unethical. In conclusion, studies relating to planning ethics in Australia appear to be extremely limited.

A classic dilemma found in any public service profession, including planning conflict between what the agency, which presumably serves the public, defines as the public interest, and what the individual professional thinks the public interest is 1979: 250). Planners actions can never be value free, and therefore planning trace explicit and implicit considerations of ethics in planning (Ploger, 2004: 50). As Howe and Kaufman (1979) found in their empirical study based on several scenarios, ma seem to be influenced, at least to some extent, in what they think is ethical by the intended beneficiaries of their actions. The same tactic used in behalf of different groups is judged differently. They expected this effect to be much stronger for politicians, who approve much more of open value commitment, than for technicians who generally wish to be value neutral. Actually, the results are rather mixed. On the scenarios giving out recommendations, politicians are influenced more by the issue than are technicians; but when it comes to leaking information, there is no difference between the two roles. There is, however, an interesting difference on the leaking scenarios in that the beneficiary is much more important to planners who are not strongly committed to their agencies than for those who are (Howe and Kaufman, 1979: 25 vii) makes an overview evaluation for ecological ethics in his dissertation. As Joma correctly puts in the words that an ethical system must do two things: It must envision a pa and it must work out a path to the realization of that way of life that is internally consistent, yet workable in the real world. Surprisingly, recent ecological ethics have failed to realize these two components of an ethical system. From Leopold s Land Ethic to Deep Ecology, no system was born. Most of the prevailing ecological ethics suffer from being too abstract or utopian in principle . Joma s critic for ecological ethics is mostly valid for planning

## 2. Tanzania Urban Planning system

### *2.1 Tanzania Urban Planning System before Independence (1961)*

The genesis of urban planning in Tanzania owes much to the history of colonialism. In fact it is a direct legacy of it. Urban areas (towns and cities) were established in Tanzania by the colonial government in order to serve the interests of the colonial economy. Most of them were administrative centres of the colonial government. Some were import and export trade ports, like Dar es Salaam. Tanga and Mtwara. Some grew as stopping stations in the colonial transport and communication network system. (Lugala, 1989). Geographically, colonial investment and planning created imbalanced spatial development where resource rich areas received most of the infrastructural development with very little or none in the resource poor areas. During the colonial era, planning legislation was used to control and segregate the population. Residential and commercial areas were divided into European, Asian and Africa categories. Laws were put in place that dictated who could live and work where.

There was a marked difference between the areas occupied by Non-Africans and Africans. Residential areas for Whites, popularly known as *Uzunguni* (areas for Whites) were characterized by luxurious big houses of European style surrounded with golf-courses ,wide roads and open spaces. Abundant luxurious social and service system. Oyster-Bay area in Dar es Salaam City, Gangilonga in Iringa, Mlimani area in Dodoma, Lsamilo Capri Point areas in Mwanza, Forest Hill area in Morogoro, Loleza in Mbeya and Kijengi in Arusha are such places which reflect this colonial legacy. The African residential areas were characterized by shanty houses of slum type. overcrowding. poor sanitary

conditions, lacked in essential social services like water, public toilets, hospitals, community and recreational service centers, and during rainy seasons, houses kept on floating on their own sewerage.

It is in these areas where the African artisans, clerks and other Africans who worked in the colonial government dwelled. The urban planning of those days had its base on the ideology of colonialism. It was not merely a technical process which was neutral from ideology and apolitical as others would want us to believe. It is, therefore, no wonder that technocrats (urban planners) provided urban plans which reflected this legacy, and never contradicted the ideology of colonialism. Race determined where one should live and also the type of social service one should get. In any case, the Whites were the most favoured and the Africans the least favoured

*2.2* Overview of Tanzania s Urban Planning process and system after Independence

Soon after independence, that is, from 1961 - 1980, Tanzania like many other developing countries, set out ambitious social and human resources development plans including programmes generally aimed at the eradication of poverty, ignorance and diseases over two decades (URT, 2000; 1996). In 1967 Tanzania adopted the top-down policies (Arusha declaration) and in 1972 Tanzania introduced a decentralization policy. In Swahili madaraka Mikoani means giving powers to the governments; this focused on decentralizing key authorities and functions of government from the centre to the grassroots level, so as to enable the community to participate in decision making (URT, 2004; 2003; 2000).The most important intended links between local government and the residents of the given area are the Vitongoji (sub wards) in the rural areas and the urban Mtaa committees (sub ward committees), which are designed to mobilise citizen participation in local development.

In addition to the above, citizen participation in local government decision-making is encouraged by the amendments to the Local Government (District Authorities) Act 1982, which provide for Councils to organise public hearings for people to question political leaders and staff. Councils have also been empowered to establish special kinds of service boards, open to all citizens in the area and providing an opportunity to influence service provision. Participatory budget-making has also become a means to increase resident participation. It is currently enabled by the bottom-up budgeting through the ward development committees and the democratic structures above them.For urban planning, after independence in 1961, the, Tanzania Government copied and modified the British planning system. Colonial Zones were categorized as Zone I ( low density areas), Zone II (Medium Density areas), and Zone III (High Density areas). These differences were also in sizes: Zone I is characterized by large areas, compared with zone II whose areas are medium-sized, while Zone III has small areas. Zone I is planned for high- income earners, Zone II for medium-income earners and Zone III for low-income earners.

The legal basis for urban planning in Tanzania after independence (1961) was the Town and Country Planning Ordinance (Capacity 378) of 1956 as amended in 1961. This ordinance was supported by subsidiary legislation such as the Local Government (Urban Authorities) Act No. 8 of 1982, as amended in 2002, which gives power for Urban Authorities to prepare detailed planning schemes and submit these to the Minister responsible for Local Governments for approval, and the Land Act No. 4 of 1999, as amended in 2004. Sites for residential development in Tanzania are usually designated in Master Plans or Strategic Urban Development Plans (SUDP) for large and medium sized cities and Interim Land Use Plans for small towns. The urban councils (Local Authorities) are preparatory authorities responsible for preparing detailed schemes commonly referred to as layout plans, subdivisions plans or Town Planning (TP) Drawings of the area designated in the Master plans, SUDP or interim land use plans. Town Planning Drawings are prepared by the respective Local Council and approved by the Ministry of Lands Housing and Human Settlement Development. The Ministry participates in the designing and preparation of layouts only when a particular council seeks assistance. The Town and Country Planning Ordinance (Capacity 378) of 1956 was amended in 1961 after the Parliament enacted Urban Planning Act no 8 of 2007. Section 19(1b) of the Urban Planning

Act (2007) it calls for participation of all stakeholders including landowners, public and private institutions, community based organizations and non- governmental organizations in the area to be affected by the plan.

The present institutional arrangements for planning have been influenced by a civil service and local government reform programme implemented in the last ten years with the overall objective of enhancing the capacity of the local government authorities to effect service delivery. Guided by the principle of decentralisation by means of devolution of functions and finances to local levels, reforms targeted four policy areas: political, financial, administrative and changed central local relations. Implementation of the reform programme and decentralisation by devolution has involved institutional rearrangements and review and/or formulation of laws and regulations, as well as administrative procedures in 1995 and 2000 respectively (URT 1995, 2000). Both the central and local government authorities are responsible for urban and rural planning in Tanzania within the legislative framework of the Land Act Nos 4 and 5 of 1999, the Urban Planning Act and the Land use Planning Act, both of 2007. The Land Act Nos 4 and 5 provide the legal framework for land tenure and land administration in Tanzania. All the land is under public ownership, the President of the URT being the custodian on behalf of the citizens. Two types of rights to use land are recognised: government granted right of occupancy for 33 and 99 year lease periods to the holders of urban land, and deemed rights of occupancy for land occupied under the customary land tenure system. These are currently being registered and holders of land rights are issued with certificates of customary right of occupancy so that they may use the registered land as collateral for a loan. The Urban Planning Act and Land use Planning Act are the principal legislation for urban and regional planning in Tanzania. These recently adopted pieces of legislation have replaced the Town and Country Planning Ordinance Cap. 378 of 1956. The Urban Planning Act and Land use Planning Act are based on the Land Policy and Human Settlements Development Policy endorsed by the government in 1995 and 2000 respectively. Both policies are inspired by democratic principles and contemporary thought in planning which advocate involvement of stakeholders and consensus building planning processes. According to the legislation, the minister responsible for urban and regional planning is the Minister for Lands, Housing and Human Settlements Development.

The Director of Physical Planning is the chief technical advisor to the minister on matters of physical planning and the approving authority for all urban and rural plans prepared by local authorities in Tanzania mainland. The Division of Physical Planning, one of the four technical divisions of the Ministry, is currently organised into five sections: a) Physical master planning; b) Urban physical planning; c) Rural physical planning; d) Settlement regularisation; e) Physical development control. The division undertakes planning activities in collaboration with other technical divisions of the Ministry, namely the Housing Division, the Land Administration Division and the Surveys and Mapping Division. Until 1998, the division was represented in all the administrative regions by regional town planning offices. However, as part of the decentralisation and civil service reform process, the planning offices were abolished so that planning functions hitherto executed by the regional offices were assigned to local government authorities and regional secretariats which are supposed to coordinate and oversee overall regional development. Rural planning functions are also carried out in collaboration with the National Land Use Planning Commission, which serves also as advisory body to the Ministry of Lands, Housing and Human Settlements Development.

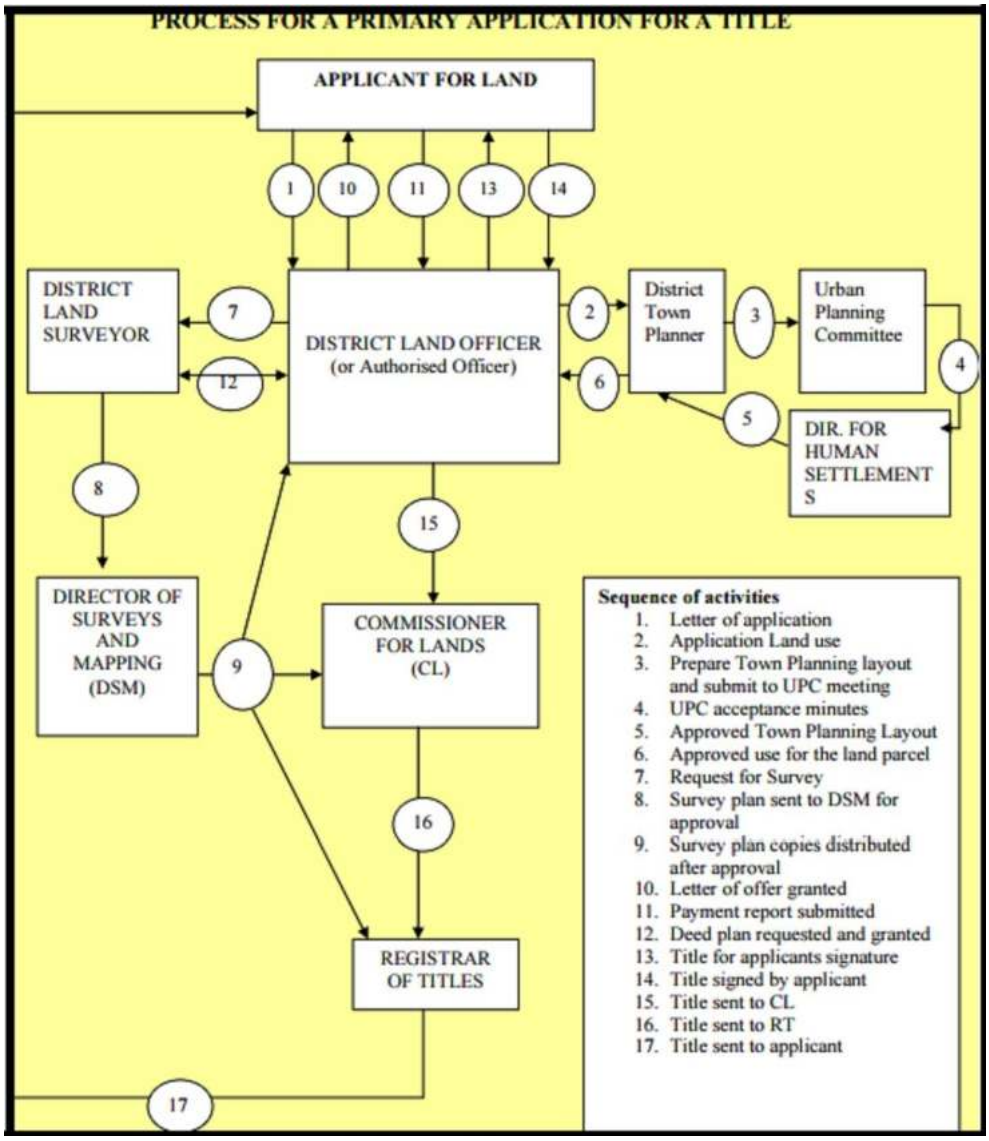

Figure 1: Process for Application for a Title.

*2.2.1 Preparation of Town Planning Drawings in Tanzania*

Town Planning Drawings are prepared by respective Local council and approved by the Ministry of Lands. The Ministry of Lands Housing and Human Settlements Development participate in the designing and preparation of layouts only when a particular council seeks assistance. The following procedures are followed by Local councils in the preparation of layouts. Detailed planning scheme (or detailed land use plan) as stated in Urban Planning Act, 2007, is th guiding scheme of urban development in Tanzania.The Following are formal procedures for Preparing the Town Planning Drawings in Tanzania.

a) Identify the area and declare it to be ripe for urban development in the government gazette.

b) Inform residents within the declared area about the intension (Public awareness).

c) Evaluate properties within the declared areas and pay compensation

d) Designing of Town planning drawings which show different land uses within the area and present them to Urban Planning Committee (UPC) of the respective Local authority for approval. The UPC consists of public elected ward representatives (Ward Councillors). Each ward Councillor must be at least one development committee; these can be finance committee,

security committee, Urban Planning Committee etc. The Urban Planning Committee approves Urban Planning Drawings.

e) Submitting the drawings to the Minister of Lands and Human Settlements Development for approval. (normally approval is done by the Director on behalf of the Minister)

f) After the approval copies are sent back to the Local authority for implementation.

*2.2.2 Preparation process of Redevelopment/urban renewal*

With assistance of Ministry of Lands, the urban councils (Local Authorities) are preparatory authorities responsible for preparing Urban regeneration Plans. The following is a summary of the procedures followed by Local councils in the preparation of urban renewal/redevelopment Plans.

*a)Establishment of redevelopment area boundary.*

This is carried out by the respective planning authority (urban council), defining the boundary and preparing a map of the area. Approval of the proposed boundaries is by the Full Council of the respective Town/Municipal or City.

*b) Submission of the approved proposal to the Director of Human Settlements*. This involves publishing of proposals in the Government gazette as an area for preparation of a Redevelopment scheme. Section 34 of the Land Acquisition Act (1967) Cap 118s empowers the Minister for Lands to declare a scheme of redevelopment. Where the Minister declares any area to be a redevelopment area, he must cause the area to be defined on a map and he must cause copies of the map to be exhibited at the offices of the local government authority within whose jurisdiction the redevelopment area or any part thereof is situated. Subject to such declaration he may advice the President where necessary to acquire land, for the areas requiring redevelopment in urban areas. In the case of redevelopment, all interests in or over land within the redevelopment area, once acquired, become extinguished.

Upon such declaration of re-development schemes, residents of the area whose buildings were of acceptable quality will be deemed to have a valid right in the area. Other residents will have to apply for rights of occupancy as developers under the new terms and conditions. In that case, the law has empowered the Minister to grant to every development owner within the redevelopment area, a right of occupancy over the land on which an acceptable building is situated. The development owner is further deemed to hold a right of occupancy over such land on such terms as the Minister may by order prescribe until the time the grant is made.

Moreover, according to section 8(3) of the Urban Planning Act (2007) Cap 355, the process for the declaration of the planning area requires (a) a favorable response at a public hearing or in the area, conducted by the planning authority; (b) a resolution by planning authority recommending the declaration of planning area; and (c) a positive recommendation by the Regional secretariat of the respective region.

*c) Preparation of base maps and collection of socio-economic data for planning purposes.*

After the declaration of the planning area, the relevant planning authorities may prepare general and detailed schemes of development. The schemes must adhere to legally established procedures.

*d) Presentation of a first draft report showing the existing situation of buildings, land uses and infrastructure to the Urban Planning Committee (UPC)* for comments and recommendation on how they would like their central area to be redeveloped..

*e) Presentation of the proposed Redevelopment plan to the Full council for approval.*

The full council consists of Ward representatives (Neighborhood). These are elected representatives by their respective neighborhoods.

*f) Presentation of the proposed Redevelopment plan to the Minister for Lands and Human Settlement Development for authorization.*

*g)Distribution of copies of the authorized plan to the respective council and other stakeholders for implementation.*

*2.3 Discussions*

Tanzania planning system, the separation of control mechanism and acts of planning actors are mostly independent from each other. This separation and independence provokes individual actions to take place in planning control mechanisms. In other words each actor begins to introduce their own way of urbanism on the basis of proposals. This cause individual interest based urban each citizen tries to implement their own way on the land. However, with respect to that condition, individual interests cause pressures on plan decisions and on local governments. The findings of this research manifest the problems caused due to the gaps in planning system, as a source of ethical problems in Tanzania. In order to eliminate this problem, the planning system should be changed in a way to give priority to public interest and to formulate comprehensive planning implementations.

Plan amendments are extensively used tool by the municipalities for directing the urban development in Tanzania. According to in-depth interviews it is observed that some of the municipalities based these amendments upon the obsolescence of the existing plan, and the others to the insufficiency and bad-quality of recently prepared plans. The implementations in Dar es salaam Municipalities are a good example for this situation.

*2.3.1 Corruption and Conflict of Interest*

Tanzania is urbanising at 4.77% annual rate of change. Unethical behaviour by politicians, technocrats and physical planners in the country threatens cohesive urban development and poses challenges to the future of Tanzania s urban spaces. The country has recently seen an explo development and settlements as citizens have lost confidence in the official town planning system. Corruption and allocation of land through political dictates has watered down the planning profession s integrity. Unethical behavior has added costs to national development and has gone a step further to hurt the poor who cannot afford the high costs associated with acts and practices of corruption, bribery, influence peddling, fraud and extortion by physical planners and their connivers.

Some physical planners are engaged in abuse of office, abuse of privileged information, favoritism, and in conflicts of interests. For example, an official in local government who prepare agendas for Full Council or Urban Planning Committee may be offered a benefit to make an applicant request for change of use or amendments Plan get favors without site verifications or Drawings verifications by the Municipal or Town Planning Authority. Corrupt planners might also advise planning committees to approve a development proposal that shouldn t have been approved if critica concealed. Likewise, a planner or a member of his family or a friend may apply for a plot advertised by the Municipality or Township, which is to be offered on a first-come, first-serve basis before anyone else, by using inside information.

Urban planners are usually hired by developers, private property owners, private planning firms and local/regional governments to assist in the large-scale planning of communal and commercial developments, as well as public facilities and transportation systems. Urban planners in the public role often assist the public and serve as technical advisors in the complex web of the community's political environment.Local public officials who work in a municipality or Town Council many times misuse or abuse their power for dishonest or unlawful gain. The improper use of influence, power, or other means for private gain is called corruption. The study revealed that local government Urban Planners works under pressure of ward councillors (madiwani). However, there exist ethical dilemmas, Foristance the interference to Urban Planner by Politicians during Initiation of Planning Process or during the Planning Process. The Politician may influence Prioritization of the zoning for public services such as Open spaces, Cemetery, schools, roads etc.

> it is common to see recommendation for allocation of cemetery to other
> *a Politian* ~interviewed Planner

Due to lack of Proper Management Plan for Compensation and lack of finance for Compensation, loops have been created for unethical officials to impose unethical behaviors during the Planning Process. The loops have been created for unethical planners to disclose the Planning Process to the Public. Unethical Planners disclose information and give favor s to those who

These favors includes, zoning their lands to safe sides , means their areas services such as roads, cemetery, open spaces etc.

There two type of Town Planning Drawings we use to Prepare, these are Plans wh *Projects and Plans which are individual initiatives, resident needing the Titles of his Plots, The first Option is more implementable, what we Normally do is zoning services such as Open spaces, Nursery school , religious sites. These are more implementable compared to those Plans initiated by Individual* Client - interviewed local Government Planner

Moreover, Local Government Urban Planners Sometimes Prepare layouts due to demand of the public clients .When a Land owner needs tittle deeds for his area, he goes to the Public O him/her the condition which require his/her land to be planned if it is not planned, or if the area has a Plan, the survey needs to follow the Town Planning Drawings. The urban Planner Prepare the layouts for the interest of the client . It is rare to see an Urban Planner zone the client open spaces. This leaves the Town or city lacking Public services such as Open spaces as well as Cemeteries. These Plans prepared in this way, lacks public support and their implementation is difficult due to the fact that they are not participatory at the same tme the government has no budget for compensation and survey the rest of the layout Plan. Local governments may be more susceptible to corruption because interactions between private individuals and officials happen at greater levels of intimacy and with more frequency at more decentralized levels.
Town Planning Drawing Process in Tanzania, especially those initiated by indivi Planners tempted, they end up doing unjustice to the community. It is automatical area cannot be zoned for Open space, thus other areas occupied by neighbours are zoned for such uses! When the time comes for a another Client of the same area needing survey of their area, they have to request for amendments of the Town Planning Drawing, these process also creates loops for corruption from the Urban Planners at Local Level up to National Level in ensuring favours for such amendments.

Unfortunately, it is not a rare occurrence that illegal construction has changed the intended land use; instead of punishing such developers and imposing measures to restore the space to the original state, the authorities would rather amend the plans and and zone the area to new land uses.
The study shows that Urban planners faces pressure from Politicians. The Politicians have high influence in Professional Practice. One of the interviewed Planner from the Regional Administrative Secretary (RAS) argued that , the pressure and Challenges is from the Local Government ( Town Council,Municipal Council). The Politicians puts pressures to them to sign the Draiwings regardless of professional mistakes.

The Planner from the District Council can tell you that these *Town Planning Drawi certain big Politician, so it is argent, needs quick approval to the Ministry of Lands, we end up signing* because of fear of job loss or being transferred ~ Town Planner from RA

Urban Planners at regional and local level claims that since enactment of the Urban Planning Act,and Urban Planner Registration Act, 2007, up to now 2015, there is no any Professional Guideline for the smooth enforcement of the Acts Number 7 and Number 8 of 2007.This puts Urban Planners in Professional Dilemma.

In addition to this, the citizen lack knowledge in Planning Process. This creates loops from unethical professionals in taking advantages. One of the interviewed residents claimed th process for preparation of the town planning drawings. What did was paying the Urban Planner some amount and Planner facilitated in preparation of the Plan. However he was not aware on the planning process. These awkward moments creates loops for unethical decisions. The study shows that 52% of those who were interviewed were satisfied with activities of the Registration Board. The rest who

were not satisfaction were asked the reasons of dissatisfaction, the main answers were doubts on accountability of the board. They claimed that the main activities so far were registering Planners, but they claimed on double standards during registration process. The interviewed unregistered Planners who are practicing claimed that they are not aware of any regulations governing registration process, no guidelines for registration process as well as criteria s for registration d Unregistered Planners claims on bureaucracy created by those who are registered, especially on signing the Drawings. The study shows that there are registered Planners who just signs the Drawings without even checking on the qualities as long as they get something from those who are not registered. This is the same as those Planners who are in Public Offices creates bureaucratic process to Private Planners when official approval is needed. This creates ethical dilemmas among Planners themselves and integrity of the professionalism.

## 2 Conclusions

Tanzania has made some attempts at formulating legislation on planning, but the laws passed have not been adequately enforced. Planning authorities and institutions have suffered neglect in Tanzania. This has occasioned a massive brain drain from the planning sector to other fields, because the sector lacks government support. Town planning has never been as fully recognized as central to delivering economic success, environmental protection and social justice as it is today. Though the government has contributed in setting up the institutional frameworks, since the actual implementations of plans is often dictated by the politicians rather than qualified urban planners. As a result, Urban Planners Practice the Profession unethical. Corruption and allocation of land through political dictates has watered down the planning profession s integrity. Unethical behavior has added costs to development and has gone a step further to hurt the poor who cannot afford the high costs associated with acts and practices of corruption, bribery, influence peddling, fraud and extortion by physical planners and their connivers.

The decentralized system is also beset with other socio-political dynamics that affect planning. Some local government politician s patronage and influence works variously to create negligence, impunity and general counterproductive behaviors. The politician is only motivated by the desire to win or retain power which is a matter of vote. There is no chance for any [planning] proposal succeeding if our political leaders think it has the potential to affect their electoral fortunes It is an open secret that the success or failure of any development management effort depends to a very large extent on how adequately the responsible agencies and department are equipped with the right number and quality of personnel and logistics to rise up to the challenge. There is also the need to ensure maximum cooperation and collaboration between all department and agencies whose work and activities impact directly on the physical development. There is lack of political will in addressing urban developmental issues. On the other hand planning registration board which could advice the ministry and the government on urban land issues are quiet. Lack of transparency and accountability in the planning practice allow for misuse and abuse of the planning system to serve the interests of the more powerful and influential groups, including those entrusted with the powers of planning. The outcomes of a non-inclusive, non-transparent and insensitive planning include: insecurity of land tenure rights and subsequently investments in land; poverty; informal land subdivision and building; unplanned spatial growth and endless conflicts in land development. These are detrimental to the residents and erode their trust and confidence in the government.

Keywords: immigrants, rural areas, landscape planning

Abstract

In the last 30 years Southern Italy has changed from being a region of emi
immigration, in main cities as well as in rural areas. Accordingly, South-East
experiencing remarkable physical, social and economic changes, with significant
agricultural landscape.
Statistics of the last 20 years show high levels of development of the agr
remarkable innovation and internationalization of production. At the same time r
show a higher concentration of – often illegal – immigrants in rural areas.
landscape planning and management ensure more sustainable local development.
The difficult immigrants conditions of life and their work in the agricultural
produce: (I) new and differentiated rural lifestyles, as social result of the
between different ethnic groups ( globalization of the countryside); (II) a "l
as spatial result of the power relations between the space of the powerful a
powerless , produced by a suspension of the rights/norms that is paradoxically
2005).
The paper focuses on the cause-effect relationship between landscape planning, a
development and exploitation of immigrants labour, highlighting th
configuration/regulation produces forms of surveillance, subjugation, exploit
(Mitchell, 2002). The paper describes (latent) conflicts and power inequali
landscape, highlighting the ethical challenges and dilemma of landscape plann
where issues of social justice, sustainable development and suspension of
intertwined.

## 1. Introduction

As highlighted by Yiftachel (1998), planning as oppression exists in a variety
a range of social relations in space. The Marxist planning theorists analysed t
planning and power in light of the exercise of political domination based on t
working class by the capitalist class (Hoch, 1984), which are mainly due
contradictions of capitalist economic power.
Alternative interpretations of power in planning beyond the Marxist analytical
undertaken more recently. Under the influence of cultural studies many scholar
impact of urban policies and regional developments on ethnic groups in order to

## 2. Theoretical and conceptual framework

### 2.1 Power relations in the domain of (planning) laws using Foucauldian approaches

Flyvbjerg (1998) has dealt with power and oppression in planning practice in
theory of power. Płłger (2008) applies the Foucaultian analyses of governmenta
arguing that planning is governmentalized through institutionalized hiera
distributing power in space and time and represents institutional ways of thinki
Intensively analysed by Hillier (2002), Michel Foucault s theories on the relat
knowledge offer a comprehensive framework through which to criticize the role
appears to be neutral and innocent from control. Although the work of Foucault is
understanding the relationships between power and knowledge, the ambiguous and i
the law is another key element in the relations between panning and power.
The exercise of power (and oppression) occur in the domain of the law , althou
manipulated and unequally applied; this is what exception means according to Ag
conceptualizes the concept of exception by connecting it with: suspension of la
constitutional principles, and misuse of norms.
Consequently this paper makes use of the integration of these approaches to cre
to understand the transformation of the landscape in the South-Eastern Sicily,
exercise of power that is produced by landscape transformation.
The paper starts by reviewing some theories of power relations starting with
Foucault and then by exploring the concept of the state of exception developed
These theoretical references provide a lens through which we can view the manip

in the South-Eastern Sicily, where landscape has been employed to serve the
control/dominate immigrant workers. As such this paper highlights a gap in plan
way in which landscape is manipulated to play the role of an exercise of power.
The Foucauldian approach (1977), is particularly helpful in understanding the
that are used by a hegemonic power as tools to control people and the space they
The Agambenian approach is helpful in understanding the way in which a he
manipulates laws to exercise power over certain social groups. Agamben (2005) a
relation between government and society: if the mandate of necessity becomes a
state can be such a superior power, if it circumvents and suspends laws and nc
that the law is obliterated in the state of exception the state still claims to
sense the power (state) becomes the law and the exception becomes a rule.
What, consequently, happens to the space, geography, and landscape when the
insists upon controlling them, or when it dominates the landscape while at the
obliterating those who are powerless? The next sections examine this issue
consequences of hegemony on landscape.

## 2.2 Power, ideology and landscape

One of the privileges of power, and an integral part of rationality, is the f
(Flyvbjerg, 1998). This general statement applies also to landscape, as a socio-
of human interventions, but of the exercise of power. The greater the power, the
this respect to define and dominate landscape, and the less need for power
landscape is really constructed.
Landscape is a material as well as cultural artefact; it is a datum , but it is
place, but it is also its imagine. When we refer to landscape, we do not only
object, but we refer to a multiple interpretation of it. Accordingly, in recent years,
literature has developed a more diverse approach to landscape. The work of Mit
book Landscape and Power, which was originally published in 1994, shifts the me
from an object to a process by which social and subjective identities are formed
Barbara Bender (1998) highlights the role of power and inequality in the (poli
landscape, and of the historical and geographical specificity of the socia
Representations of landscape become political issues mediated through the plan
tends to adopt a site specific and segregationist approach (Hillier, 1998). Acc
Purinton (2002) ideologies can play a predominant role in creating a narrative
narrative of landscape is not innocent of ideology, it can be used in the formation o
and enactment of territorial claims. It also has the ability to produce relatio
Purinton, 2002, p. 142).
Also economic power can shape landscape and many of its features, loading it wit
representations, through which new systems of authorities and beliefs are produc
relation between landscape, power and ideology makes the production of landscap
conflict a controversial issue, playing a role in the exercise of power.
Applying Agamben concepts to our planning examples, we highlight as planning s

landscape. In the light of Agamben s concepts, we analyse the technical and juri
which landscape transformations and planning emerge as an oppressive activity.
note is that also a strong economic power in the state of exception does not on
circumvent constitutional principles, but also tries to produce new laws in or
issue regulations with the purpose of exercising its control over people.
Furthermore, the work of Agamben considers the law as a paradigm of knowledge
government or a specific form of power can exercise power over people. Hen

understand the manipulation of landscape in the South-Eastern Sicily is bas
mentioned scholars work. The function of landscape as a medium of oppression
cannot be achieved without a system of laws in which the spatial knowledge s
used as an instrument of power. In the case of the South-Eastern Sicily, as it
next sections, through planning law there is an exercise of power, also when
suspended .
Thereby, landscape acquires new meanings: subjection, domination, exclusion, su
function of social control. In this sense the social control is exercised withi
the norms which are tied to spatial knowledge (planning, architecture, geograph
manipulated. According to Agamben (2005) the state of exception creates a new l
away from ordinary norms: the state of exception is the opening space in which
reveal their separation ( ) In this way, the impossible task of welding norm an
thereby constituting the normal sphere, is carried out in the form of the except
40).

## 3. The South-Eastern Sicily case

### 3.1 Local context, cultural heritage, success of the greenhouses

In the Italian national scene, South-Eastern Sicily is known as the other Sici
from the cultural and economic standpoint, comparable to Provinces in norther
within the Island , thanks to its historic autonomy (Chiaula, 2011) and a dyn
context that differs greatly from the rest of Sicily (Spataro, Gentiloni and Spa
Furthermore, South-Eastern Sicily features an exceptionally high concentration o
heritage, which on one side makes it greatly exposed to the risk of deterioratio
resources allocated to protection and preservation interventions, but, on the o
for the potential synergies that can be activated especially with respect
investments (Azzolina et al., 2012).
Nonetheless, the most manifest features of this territory are the numberless intertwi
systems of values and resources depending on one another. An intricate network
archaeological sites of the classical age, agricultural areas with farmhouses an
centres, distorting and adapting to the morphology of the territory (Nifos and L
In particular, in the hilly and mountainous zone the landscape remains almost
examples of actual rural architecture in the peasant tradition, the area being
enhanced by agro-tourism in its various forms ( Ibla sharing ).
The same thing cannot be said for the coastal landscape, in which the far-
greenhouse cultivation, continuously and uninterruptedly along the coastal stri
with an almost surreal landscape, in which the vast plastic expanse, with the reflecti
the greenhouse roofs, encroaches on the surface of the sea. This landscape
transformed because of the productive system of the greenhouses, losing the
features that have characterized it during the centuries.
Furthermore, this area is characterized by the presence of extraordinary urban
the natural morphology of the territory or the ostentatious baroque architectu
the territory contributed to the creation of a complex and polycentric settleme
and medium-sized urban areas are scattered on the edge of calcarenitic terraces
coast and creating breathtaking landscapes.
The town centres feature baroque architecture and urban style (Noto, Scicli
Ragusa, Ispica) and minor Italian Liberty style (Ispica, Canicattini Bagni).
These exceptionally beautiful urban landscapes perfectly express the baroque ic
where architecture, space and light merge and reach maximum harmony. After all

best expresses the most specific features of baroque architecture, which emerge
extensively during the 18th century (Blunt, 1968) in South-Eastern Sicily, a territory
geographical and cultural periphery (Nobile, 1990).
From the economic point of view, within the framework of nationwide policy wi
development, South-Eastern Sicily has traditionally occupied a primary role, re
process of transformation in agricultural production, supported by a combinati
entrepreneurial ability, with significant results on the international exportat
and Pitti, 2011; Giampino, Picone and Todaro, 2014).
This state of affairs has given rise to a dense mosaic of vegetable, flower
cultivation, which can be added to the renowned quality-wine production ( Cerasu
This production is centred in the Hyblean fruit and vegetable region, mainly c
fascia trasformata ( transformed strip ) (municipalities of Vittoria, Acate,
Comiso, Santa Croce Camerina) that constitutes the heart of a more wide-rangin

The success of greenhouse production, often described as the economic mira
agriculture has represented, according to Saltini (1982), one of the sprightl
phenomena to hit the entire Italian agricultural scene. This success has not bee
actual production, which has managed to profitably exploit terrain previously co
economic interest, but has triggered wide-ranging spin-offs involving sectors
agriculture, such as seed-production, commerce in pesticides and plastics (poly
of materials for packaging products, road transport etc.

## 3.2 Landscape transformation and planning suspension

The introduction of greenhouses in South-Eastern Sicily dates back to the lat
farmers decided to reconvert their fruit and vegetable production from agricult
greenhouse cultivation. This approach consented the extra production of out-o
rendering agricultural enterprise more profitable. In the wake of initial
production, especially with regard to tomatoes, soon replaced most of the tradi
activity, including that of grapes.
From this moment on, the success of greenhouse production meant that economic co
widespread and profound changes in the traditional local landscape. In order to
terrain is necessary and so, the famous macconi (sand-dunes), especially tho
(Ragusa) and Punta Secca (Santa Croce Camerina), had to be levelled out; over a
natural modulation had produced a singular landscape, with alternations of w
characterized by typical dune vegetation (Campione and Sgroi, 1994). In some cas
extended as far as the water s edge. The sand-dune landscape was reduced to co
between the greenhouses; the end-effect is one of a vast translucent surface (a
plastic sheeting), which extends in homogeneous fashion over the whole area
levelling out the terrain s natural depressions and protuberances (Campione and
As we shall see in subsequent paragraphs the new lay-out of the landscape, b
pressure of economic power on the natural morphology of the area and on who
greenhouses, represents a landscape of exception , which, re-reading the con
state of exception (understood as a suspension of the rights/norms, which is p

constitutes a possible spatial organization of this phenomenon. In this way th
becomes a landscape of exception .
In this, furthermore, the condition of exception of the Ragusan greenhouse
explicit in accordance with a dual modality: one spatial and the other social,
The former emerges through the suspension of planning-instrument contents, and
suspension of greenhouse-worker rights.
From the planning point of view, the Province of Ragusa has a greater number of
Provinces in Sicily, dealing with aspects of both territorial planning and envi
safeguard.
On the subject of greenhouses, general awareness has been noticeably heightened
impact produced on the environment and the landscape; as regards the various p
there is agreement on the indispensable delocalization of the greenhouses and s
coastal strip.
Many plans, at different institutional levels, faces this issue, with different
capacities and levels of efficacy.
Among all the planning instruments, in the area, it is specifically the Lan
Paesaggistico )[2], (2007) managed by the Superintendence for Cultural and Environmental
in the Province of Ragusa, which examines the issue of greenhouses in depth
document Progetto d ambito Macconi . The Plan sub-divides the greenhouse-belt
with different characteristics:

1. RED ZONE ON THE BEACH. The plan envisages a ban on building new greenhou
   regulation for their reorganization (reduction) in order to create a coasta
2. RESTRICTED ZONE WITHIN 150M OF THE SHORE. The plan envisages a ban on n
   greenhouses, except for those that integrate pre-existing ones or are sit
   (i.e. extensions are permitted), following the principle that only "qualit
   small-scale, poor-quality agricultural) has to be improved.
3. RESTRICTED RETRO-ZONE. The plan provides for diversification of ag
   production, with redirection towards traditional agriculture, redirect
   production towards quality levels oriented to the enhancement of orga
   production and industry certification ; the restricted zone should aim to
   the local area.

Several doubts arise about the efficacy of the planning system in this regard.
plans, with all of them tending to emphasize the need for delocalization of
salvaging of the coastal strip, why are the greenhouses still in place?
We will find our answer in the suspension (and non-application) of the actio
instruments, as provoked by the economic powers that oversee the productive sys
greenhouses. This line of thinking suggests that economic power is able to exe
political-administrative power, which actually controls and, in this case, susp
application of plans and planning decisions. In marginal contexts such as So
particular Sicily, the gap between planning contents and their implementatio
noticeable wherever there is the presence of strong economic interests, which
position to influence the political sphere.

### 3.3 Immigrant workers and the suspension of their rights

Whereas the greenhouse landscape , on the spatial front, has replaced the tr
coastal landscape, from the eminently social point of view, greenhouses have determi

[2] The Piano paesaggistico was adopted through the Decreto n. 1767 of 10th August 2010, Assesso
Culturali, Ambientali e Pubblica Istruzione.

transformation in the social landscape in this area.
With regard to the transformed strip in the Province of Ragusa, unofficial st

workers[3] employed in greenhouses; this consents a doubling of annual production of
the same time necessitates a greater number of workers.
However, apart from the profound changes wrought in the features of traditiona
this economic success an extremely complex situation sees the immigrants often l
seriously demeaning conditions.
The Ragusa area, in particular, apart from being a constant point of arrival for
from north Africa, already boasts a stable foreign presence; this is partl
immigration from the Maghreb of what are now settled ethnic groups, and partly
presence of workers (especially from Romania) on a cyclical basis, this being
Regional and inter-Regional flows, which are, in turn, linked to the various pr
2013). Most of these manual unskilled and low-cost workers in this area are un
badly paid and unprotected); compared with these conditions, the various socia
and housing aspects are at some risk (Gertel and Sippel, 2014).
With the enlargement of the European Union to include Eastern European states,
substitution of immigrant workers was noted in the Ragusa greenhouse-belt (Co
2013); there was a sudden increase in fresh flows of immigrants, especially
employment, and mostly taking the place of north Africans. These neo-EU work
countries characterized by serious socio-economic difficulties and willingly ac
(about 20 Euros for a working day of 10 hours), thus neutralizing the social
north Africans. For the whole immigrant manual workforce this was followed by a
and a worsening of living and working conditions.
Other critical conditions relate to the illegal status of immigrant greenhouse-w
them, moonlighting in the black economy and another one in the grey .
Indeed, in the Southern regions, the informal economy and irregular employment
weight. These two aspects existed well before the arrival of immigrants (De Zulu
In respect to this condition, according to certain cautious estimates by Carita
irregular workers' percentage amount to 10% (and in some periods of the year, a

active in the area are voluntary associations and healthcare structures, whic
resources available, can only respond in emergency cases (Consoli, 2009; Todaro,

## 4. South-Eastern Sicily as Landscape of Exception

In South-Eastern Sicily planning is suspended to maintain the economic power
control over the agricultural production and the immigrant workers. Consequentl
been constantly transformed resulting in a complete change in its role and mea
become saturated with elements of control (enclosures, walls, and hurdles) thus
geographical continuity, and the norms that shape it.
Generally, in spatial and social conflict conditions, a resolute power uses pl
and plans as vehicles for sustaining oppression through landscape. However, th
does not imply that the production of space goes through a clear and system
produced. On the contrary, in conflict situations, the law is very ambiguous and blur
to the political regimes sphere, according to Agamben (2005) when a regime face
circumvents constitutional principles: so an exceptional state is produced, and the legislative power
collapses, being replaced by an executive power; as result, the forms of law become the norms of
the juridical order of the state. Agamben (2005) specifies that the emptiness of
of exception which is characterized by: the transformation of legislative power
and the suspension of norms and juridical forms.
In the South-Eastern Sicily case the political regime is replaced by economic p
of exception does not mean that there is no law shaping the landscape, but that t
spectrum that can be practiced partially and ambiguously. Landscape of exception,
highlights, is produced through three inter-connected processes: firstly, the a
economic power linked to the agricultural production success; secondly, the sus
planning; and thirdly, the manipulation of landscape through the greenhouses,
control for the purpose of exercising power.
Apart from constituting the actual essence of this model, the greenhouses repre
for spatial as, well, as social manipulation and control. Under the spatial

sites), has in fact been reduced to a series of isolated strips and fragments.
heritage, the safeguarding system as laid down by law and planning instruments
and is no longer applied, consenting the greenhouses to spread everywhere, even
edge.
From the social point of view, the greenhouses constitute an enormous reservoir
non-qualified and flexible jobs to attract the international flux of immigran

consider this work advantageous when compared to the living and working con
countries of origin. This has often actually provided a solution to the princip
to conditions of illegality, lack of jobs etc. On the other side, the wide-scale
matched by adequate working conditions. Work in the greenhouses proves to be ex
in many cases, scarcely bearable (Avallone, 2011). Most of the basic individua
regards work contracts and a fair wage, and, contextually, multiple forms of vi
out.
However, the economic success of this type of agricultural production depends
work by immigrants (Osti, 2010), who are, nonetheless, unaware of this fact.
The discussion and the case study illustrate that power can produce a system o
rules which are spatially localized, allowing it to reshape landscape by elimi
zones and constructing elements of dominance and control. Under the context of
law the whole landscape is transformed from the purpose of enjoyment or agricu
into the purpose of surveillance, control and repression.
Although the greenhouses constitute an instrument for the transformation of l
manipulation, via a system of new rules imposed by economic powers, the legal v
loss of the role of safeguard of the environmental and landscape heritage fro
Thus, a question of an eminently ethical nature arises, which concerns the safe
in intensively cultivated rural areas and the repercussions, in terms of socia
(Berlan, 2008).

## 5. Conclusions

In his adoption of the Foucaltian analyses of power, Flyvbjerg (1998) stresses
and highlights the selective processing of knowledge in the planning and accrediting that is exer
power. He claims that normative rationality is the upfront planning model p
scrutiny, while the real rationality corresponds to the backstage hidden from
contrasting with the most celebrated aims of advancing democracy. On the other
Mouat (2002, p. 131) highlight how the (individual) capability of resistance relies on
cultural and financial capital i.e. knowledge (including strategic awareness),
and resources. But under which conditions can resistance be exercised? And wha
obstacles to forms of resistance?
Obstacles to any act of resistance are constituted by legal and institutional sy
of resistance by the manipulation of laws and rules, which often occurs in
producing an instrumental misinterpretation (and consequent manipulation) of rul
On the other hand, one of the main risks is the progressive normalisation of the
this might be generalised in the contemporary political and economic conjunctu
2014).
This paper offers conceptual and empirical contributions on the way in which t
manipulated. Its main task is to provide concrete examples of the ways in wh
planning by suspending and manipulating rules and laws, and its consequences no
urban areas but also for rural areas and their landscape, too. This study demon
and discussion of the planning system in South Eastern Sicily that landscape,
has been transformed into a landscape of exception. This transformation has not occurre
spontaneously or occasionally; instead it is a continuous process in which
planning is used in order to transform landscape in an instrument of oppression
way landscape loses the positive value and is transformed from a space of equit
a space of subjection and control.
This paper shows that the production of the landscape of exception is sepa
highlighting the landscape s role as a medium in exercising power over its use

characterized by the meaning of control that influences socio-economic issues
but also-life styles. Through landscape of exception citizens are prevented from fruiti
resources, like the dune system and the seaside. This means to defer the public i
"common good) for a private interest profit. At the same time, others are maintaine
a status of non-citizens, for the same economic reasons.
The manipulated normative context determines the production of a landscape of
subjection, exclusion, domination, and control exist. The common economic intere
order to legitimate landscape transformation, with a suspension of laws and pla
production of landscape is deviated from basic principles of norms.
This is a good example of the detailed insight that Foucaultian critique can cont
planning practice. Flyvbjerg (2004) makes the point that the central questi
exercised, and not merely who has power and why they have it; the focus is on p
structure. We argue that Agamben concepts add a valuable contribution to this c
mechanisms of exception which allow power to be exercised defining what counts
rule, and thereby what counts as reality (Flyvbjerg, 1998).

# Justifying planning decisions: Institutional response to planning objections in Israel

Talia Margalit[1] and Adriana Kemp[2], Tel Aviv University

**Abstract**

This paper presents our study of current planning ethics and power-knowledge relations, mapping and analyzing the ethical frames used by institutional planners to justify their decisions in eight central and peripheral Israeli cities. While objections hearings are the main procedure for public participation in Israel, the planning committees are obligated to explain all their positive and negative decisions while explicitly regarding oppositions to new schemes. Studying these answers, we find how the very notion of public interest is defined and articulated in terms of economic, legal, architectural, social and environmental reasoning. Tracing the ethical rationales leading the discourse we also learn how planners conceive their own agency in current urban citizenship. We thus map the incremental justificatory notions by mutually analyzing procedural and substantial terms of distribution, participation, recognition, capability and responsibility. We focus on the following questions: **1. How is the public interest defined and shaped in the institutional response?** Is there a set of hegemonic justifications in the planning institutional discourse? How does government perceive its responsibility to serve the public interest? What types of third-party rights or development prospects are often highlighted? **2. What variations are evidenced in the patterns of planning justification?** Are there variations according to the geographic area or to the socio- spatial status of the objectors? Can we identify patterns of closeness and openness towards particular social groups or demands? **3. What can we learn about the level of discursive communicability in planning institutions?** Do the planners present governmental positions or their own disciplinary frames?

**Key words: Public interest, planning justification, urban citizenship, institutional planners, objections**

## Introduction

In the last years planning proposals have increasingly raised public debates in Israeli cities, over social and environmental justice, identity politics and democratic decision-making, among others. Although of wider public significance, and despite recurrent claims on the need to democratize planning, most debates have been effectively channeled through the institutional procedure of objections' hearings. In this framework, the Israeli Planning Law mandates all planning committee professionals to justify their decisions following the

[1] Talia Margalit, David Azrieli School of Architecture, Tel Aviv University, taliamar@post.tau.ac.il
2 Adriana Kemp, Department of Sociology and Anthropology, Tel Aviv University, akemp@post.tau.ac.il

hearings, with a detailed written explanation to each objectors' claims. The proceedings of the Committees are now all available to public scrutiny on the web, thus offering a unique opportunity for the empirical examination of current planning ethics and power-knowledge relations in the Israeli planning field.

In researching this data we focus on identifying what constitutes the public interest in Israeli institutional planning practice today, and critically analyze how planning choices and decisions correlate with the varying socio-spatial positions of the projects and actors at stake, and how the committee members perceive their own social role in serving different publics in Israel. We argue that adding a sociological dimension, that takes into account how ethics in planning interlink with socio-spatial inequalities, is crucial for engaging with the larger debates on urban citizenship animating current social struggles.

The growing academic interest in urban citizenship reflect increasing social unrest and mobilization addressing urban issues and increased demand for democratization and deliberative planning practices (Held, 2006; Healy, 1996; Inns and Bohr, 2004). Notions of urban citizenship, we believe, are especially relevant regarding the ethics of institutional planners whose role is to both promote the public interest, and advance growth and real estate activity simultaneously. In this capacity, their conceptions and decisions inevitably impact many spatial, social, cultural and environmental aspects. Questio responsibility, pluralism, fairness, social justice and equality connect their daily decision making to grand social narratives at the heart of urban citizenship (Campbell & Marshall, 2000). We thus suggest that planning justifications in objection hearings offer a prolific arena for examining institutional views of urban citizenship in action, as they define who is considered a citizen, on what grounds rights

and obligations should be accorded, and how distributive and redistributive justice are to be attained promoted.

**Urban citizenship and the "Public Interest" justification**

As research on urban social movements shows, claims on the right to the wide variety of demands such as the right to affordable housing and environmental justice, as well as the right to participate in planning the city, and ultimately, the right to be in and make use of urban space itself (Clarke and Gaile 1998; Holston and Caldeira 2008; Mayer 1994). Such contestations touch upon basic issues of urban citizenship, reflecting deep-seated conflicts between local communities and residents and the political and economic interests driving urban development (Ellis, 2004; Kemp, 1990; Lake, 1993; Burgess et al, 1988; Burningham and Thrush, 2001). In this manner, planning institutions are compelled to explain and justify their choices in ways that resonate with the wider issues mobilized by urban contest.

In this context, the idiom of the "public interest" serves as key concepts for justifying planning decisions. Critical scholars have documented how planners choices and justifications frequently conceal the unfair distribution of rights and obligations and reflect narrow understandings of what consists the public interest (Fl PlÖger, 2001; Richardson, 1996; Alfasi, 2003; Yiftachel and Huxley, 2000). Yet since the 1960s, "public interest" has been defined in relation to procedural democracy and distributive justice norms (Innes et. al., 2004), and planning institutions articulate specific notions of it in their quest for professional and institutional legitimation (Alexander, 2002; Campbell & Marshall, 1999). In fact, conceptions of the public interest are tied to the very validation of planning as public institution. The institutional history of planning points to hard-won debates from which the profession drew its legitimacy to become an inextricable part of state bureaucracy and a form of scientific expertise at the service of the public

benefit (Klosterman, 1985; Friedman, 1987). The institutionalization of planning was indeed due to welfare states' conceptions of a normative and shared "public interest" (Campbell and Marshall, 2002), perceived as an "objective of duly authorized governments carrying out activities necessary to the welfare of the community" (Grant, 2005, page 48). Thus, the legitimacy of planning as an institution and a form of rational knowledge was re-opened with the decline of rational- welfarist frameworks since the 1970's (Klosterman, 1985), while substantive and procedural questioning regarding the nature of "good planning" aligned with the demise in planner's legitimation as professionals "healing" society (Friedman, 1987). The current credibility crisis relates first and foremost to planning criteria and to planning institutions. In the urban field, scholars showed how intensified neo- liberal strategies, privatization and divestment of many government responsibilities brought up growing procedural and ethical concerns (Harvey, 1989; Heally, 1992; Tasan- Kok, 2008; Fainstein, 1991, 1994; 2013; Sagalyn, 2007; Teitz and Chapple 2013; Krumholz 2013; Brlow, 1995; Rydin, 1999; Brenner, 2003; Hasson, 1997). As "a collective goal is not a sufficient justification" for according or denying individuals rights (Dworkin, 1984, p, xi), increase of objections by local NGO'S, neighborhood committees and third- right parties was evidenced. These agents tackled not only specific planning issues, but also the institutional accountability of planners in serving the public (Ellis, 2004; Lake, 1993). At a deeper level, by objecting planning decisions they questioned the legitimation of the planning institution as a fair or just arbiter of conflicts operating in the name of [hared citizens' right or public interest.

These legitimation crises provides the context for our analysis of planning justification in Israeli cities. Yet our preliminary tracing of current planning hearings in Israel shows that the notion of "public interest" still underlies much of the discourse produced by planning authorities when explaining their decisions. The terminology has

been also traced in other recent studies of planning debates in Israel, showing the supremacy of legitimating arguments adducing the common interest over self-interest or special interest (Alfasi, 2004; Carmon, 2007). It is n planning. According to Ernest Alexander, "for planners and the planning profession, the public interest has always remained relevant as a legitimating principle and a norm for practice, even while philosophers and political theorists debated its existence" (Alexander, 2002: 227). Despite the growing uncertainties in regard to its meaning, the idea is still vital in legitimating planning as state activity (ibid; Campbell and Marshall, 2002), as a norm for professional institutions and planning practice (Campbell and Marshall, 2000) and as a criterion for evaluating policies, projects and plans (Alexander, 2002).

With "the public interest" thus currently conceived as a "flexible construct for the articulation of disparate views (Grant, 1994, p. 73) we claim that tracing the p ethical schemas planners draw to legitimate their decisions when invoking public interests is crucial for unraveling wider notions of urban citizenship and related debates. In line with current understanding that urban space itself has become the subject for claims to citizenship' rights (Jessop, 1997; Brenner, 1997; Kearns, 2000), we thus examine how the notion of public is currently defined, how planners claim it is to be served and on grounds; what lines of urban development are to be pursued, etc.

**Research questions**

The paper presents preliminary findings of our study of the justificatory logics underlying the institutional world of planning and how they link to different socio-spatial correlates. Planning objections in Israel have been the subject of earlier empirical research. In their study of planning objections hearings for the years 1999-2001 Carmon (2007) and Carmon and Alterman (2011) compared the legal procedure in Israel, England and the Netherlands, and focused the procedural aspect of planning hearings and the degree of

democratization in the Israeli system. Others have carried out substantive discourse analysis of specific planning debates that pays attention to the content of planning rhetoric and its dynamics (Alfasi, 2004; Portugali and Alfasi, 2008; Fenster and Yacobi, 2005). We looked at the national scale. Our analysis traces both substantive and procedural contents of planning hearings, explanations and decisions and aims at grasping hegemonic notions as well as varying framing of planning justifications.

Drawing on an empirical analysis of more than 2500 justification claims handed by institutional planners in five central and peripheral planning committees and regarding eight Israeli cities between the years 2010- 2013, we ask two main sets of questions:

1- How do planning institutions define what the public interest is? What is the frequent balance between their aesthetic, historic, economic, legal and environmental values? Is there a set of hegemonic justifications? How do institutional planners perceive their professional expertise, their commitment and attachments?
2- What variations are evidenced in the patterns of planning justification? Is there a correlation between the ethical frames justifying planning decisions and the socio-spatial position of the cities and neighborhoods where planning projects are taking place, the type of actors submitting the objection (public-private), and the timing of the decision (before/after social justice mass protests)?

Given the changes taking place in the Israeli public discourse in the last years regarding socio-spatial debates and urban protest, we also hypothesized that planning justifications discourse might reflect a move towards different notions of democratic and substantive aspects of urban citizenship. In this manner, we also compare socio- spatial affiliations associated with its variations (for example, in central vs. peripheral areas) and see how the justification frames and framing were used to impact substantial planning conflicts.

**Methodology**

The selected committees cover most of the national area and a majority of its urban sites, and the selected cities were sampled due to comparatively intensive planning activity and building activity in recent years, and to represent a variety of sizes, centrality and marginality, locations, ethnic and socio- economic arenas.

| | Population* | | Socio-economic ratio\ | marginality ratio ratio** | Number of schemes issued 2010-2013 | Regional planning committee |
|---|---|---|---|---|---|---|
| | residents | Ethnicity | | | | |
| Tel Aviv- Jaffa | 418,590 | Mixed | 8 | 10 | 244 | Tel Aviv |
| Petach Tikva | 219,303 | Jewish | 6 | 9 | 209 | Center |
| Beer Sheeva | 199,334 | Mixed | 5 | 5 | 112 | South |
| Holon | 186,399 | Jewish | 5 | 9 | 59 | Tel Aviv |
| Ashkelon | 123,478 | Jewish | 5 | 6 | 59 | South |
| Lod | 71,642 | Mixed | 4 | 8 | 57 | Center |
| Kiryat motzkin | 39,228 | Jewish | 7 | 6 | 25 | Haifa |
| She'faram | 38,717 | Arab | 3 | 5 | 103 | North |

* according to the Israeli central Census, 2013 **accessibility & distance from Tel Aviv.

*Table 1: selected cities and planning committees*

We believe that this sample covers the various notions of Israeli urban citizenship, and enable a thorough outline of the hegemonic legitimating features as well as the social meaning of their variations. We used quantitative and qualitative tools:

1. We identified all planning schemes that had registered objections in the 8 cities under study in the relevant years
2. For each scheme, we traced the following independent variables: the planning components (size, height, relation to the urban context, land use), the location of the project according to the marginality ratio and socio-economic ratio of the city and of the project within the city; ethno-national affiliation of the objectors.
3. We identified the ethical frames underlying each justification handed by the institutional architects and planners to explain their decisions. The ethical frames were identified in two-stages: first, we conducted a pilot analysis and inductively singled out the main ways in which the committees justified their decisions. Second, we built a list of 9 main

substantive or ethic frames.

**Justification frames**

Analyzing the justification claims we found the following main substantive or ethic frames:

**1. Aesthetic Justification:** refers directly to Architectural features, urban typology and urban beauty.

**2. Historic Justification:** refers to preservations and local legacy

**3. Environmental justification:** sustainability, traffic and other infrastructure needs.

**4. Social justification:** refers to distribution of housing, public buildings and public spaces, to residential density, community, neighborhoods' socio- spatial standards, to social unity, regeneration and encouragement etc.

**5. Property Rights Justification:** refers to such rights of the projects developers and the assets owners involved.

**6. Economic Justification:** refers to economic goals, leverage and accountability in the project, to developers' exactions, finances and economic public benefits.

In addition, we realized that many of the planners claims do not provide concrete substantive justification of the type listed above, but rather emphasize the planners' disciplinary' knowledge, education and institutional framework. We thus defined three "expertise" frames:

7. **Substantive expertise:** focus the supremacy of the inner disciplinary knowledge, for example: `The committee feels that the influence of the plan, once real minimal. , Neither this nor that cause an invasion of privacy excessi in any case exists in the dense development of a metropolitan urban c` committee was thorough in its analyze and consulted several experts".

8. **Procedural expertise:** focus the institutional planning practice and terms.
9. **Standards and codes:** relates to existing plans, laws and codes.

**In the analysis we will re-code the PSE (Procedural and Substantive Expertise) and SD (Standards and Codes) as an overall frame called: Institutional self-justification.**

**Preliminary Empirical Findings**

We classified each one of the justificatory claims in each one of the projects according to this list of framings, and according to each one of the socio-spatial independent variables above mentioned, and counted their frequencies.

1. *Number of justifications per city:*

We computed the number of schemes objected, the number of objections, and the number of justifications handed down in each city.

The number of schemes are mostly related to the size of the cities. As for the number of objections: we found that it does not always correlate with the number of schemes. For example: Holon, a small city in the Tel Aviv metropolitan first ring, has almost the same number of objections as Tel Aviv while it has a 1/6 of Tel Aviv s schemes. Interestingly, in Arab towns and areas we surveyed, the ratio between number of schemes and of schemes with objections was substantially lower.

| | Population* | | Socio-economic ratio\ marginality ratio ratio** | Total number of schemes issued 2010-2013 | Number of schemes objected (% of total scheme) | Number of Objections handed (relative to objected scheme) | Number of Justification claims (relative to objected scheme) | Regional committee |
|---|---|---|---|---|---|---|---|---|
| | residents | Ethnicity | | | | | | |
| Tel Aviv- Jaffa | 418,590 | mixed | **8\10** | 244 | **46 (18.8%)** | 115 (X 2.5) | **1550 (X 33.7)** | Tel Aviv |
| Holon | 186,399 | Jewish | **5\9** | 59 | **8 (13.5%)** | **104 (X 13)** | **527 (X 65.8)** | Tel Aviv |
| Petach Tikva | 219,303 | Jewish | **6\9** | 209 | 13 (6.2%) | 57 (X 4.4) | **454 (X 35)** | Center |
| Lod | 71,642 | mixed | 4\8 | 57 | 7 (12.2%) | 27 (X 3.8) | **150 (X 21.4)** | Center |
| Kiryat Motzkin | 39,228 | Jewish | **7\6** | 25 | **5 (20%)** | 6 (X 1.2) | 48 (X 9.6) | Haifa |
| Ashkelon | 123,478 | Jewish | 5\6 | 59 | 6 (10.1%) | 8 (X 1.3) | 14 (X 2.3) | South |
| Beer Sheeva | 199,334 | mixed | 5\5 | 112 | 12 (10.7%) | 13 (X 1.1) | 27 (X 2.2) | South |
| She'faram | 38,717 | Arab | 3\5 | 103 | 13 (0.12%)* | 43 (X3.3) | 45 (X 3.5) | North |

*Table 2. Schemes, objections and justification claims per city*

*Several reasons can be hypothesized on this regard such as the lack of trust of members of an ethno-national minority on institutional authority and/or their fairness, especially regarding highly volatile issues such as land use and planning; or that members of disadvantaged minorities will tend to refrain from

objecting to projects developed by their co-ethnics in their areas of residence.

Regarding the number of justification claims we get another interesting picture: The committee in dealing with the central area (Tel Aviv) raised many more justification claims then other committees. We can fairly see correlation between the affluence and centrality of a city- and the effort put by the committee's to justify their planning decisions.

2. *Justification frames in general and per city*

In general, the most frequent concrete justification frame is the environmental. Yet, when we combine the PSE and SC, we get twice as many as the environmental frame and half of the entire sample.

Justifying by social, property, aesthetic historic or financial claims is less common. The latter three are the last in number, but indeed the main components around which neo-liberal planning in Israel revolves nowadays. This means that planners are highly invested in urban beautification, preservation and financial partnerships they justify their doing by "wider" public interests.

When we break justifications by city, we didn t find a consistent correl

of frame and the location of the city. But the distribution of frames frequencies according to the location of the project in the socio-economic index nation-wide, we found that the PSE and SC frames are more common in justification regarding the lower ranks of the SES.

3. *Justifications by land use (type of project)*

In each one of the categories of land use, we find as expected justifications taken from the substantive area of the project (environmental, historic, etc).

Yet, in regard to land uses that are controversial but not part of local daily life (like: tourism, historic preservation and industry), the appeal to institutional power is less

frequent. The same goes for large projects that incur a major change in the urban context. We interpret this finding as reflecting planners' awareness of the need to give considerable substantive justification regarding projects that are likely to be more contentious.

4. *Type of justification per year*

As already mentioned, our study spans the years 2010-2013. We now pay special attention to the patterns of social justificatory frame and whether its use changed after the so called social justice protests that took place during summer 2011. During this time, unprecedented social protests took hold of the streets and the social media, starting in Tel Aviv with tent camps and then virally expanding nation-wide. The tent camps came to symbolize one of the main issues contended in the Israeli public sphere, namely the lack of affordable housing for the younger generation of the middle class and the lack of public housing for low class, all of which were attributed to rampant neo-liberal policies and politics taking place in Israel since the early 1980s.

We found the following: first, the most significant shift was the drop in the use of the financial and property frames in general and the rise of the social, historic and aesthetic frames. When we compare between cities, we find that in the large cities there was a drop in the institutional expertise self-justification, clear drop in the use of the property and finance frames but this did not happen in smaller cities, regardless of their location in the SES and the marginality ratio index. This longitudinal dynamics regarding the social frame is most clear in TLV where we find a dramatic increase in its use in 2013 when compared to 2010 alongside the dramatic reduction in economic laden frames. We assume that the justificatory framing of the planners are in clear disconnect from their actual deeds meanwhile as the expensive and large size projects continue to be the forefront of urban development in TLV.

**Concluding discussion**

Our preliminary conclusions raise some interesting insights regarding common arguments raised in critical scholarship on planning.

First, unlike arguments regarding the ongoing democratization of planning institutions as a form of institutional and professional adaptation to current critiques and social changes, we find that institutional planners still use considerable institutional symbolic power when it comes to justifying their choices. At the same time, the use of power is not done in a uniform fashion as it has clear correlation to socio-economic variables. In this context, we found that the degree of marginality of the city and the location of the project in the socio-economic map are correlated to the number of justification given by planners and to their type. Meaning that in less affluent areas the city planners are less likely to expand their justifications and they are more likely to use their institutional power as we come closer to the lower ranks of the socio-economic map.

Second, we found a clear gap between what planners say to the public in committees and the plans they make and approve "on the ground". This comes out very strongly in cities like Tel Aviv that in daily life lead clear and outspoken entrepreneurial development policies based on the triangle of urban beautification, historic preservation and PPP, but in planning committees refrain from talking about them.

Finally, we found that the rhetoric in planning institutions is tuned to shifts in public discourse. This is especially visible in large cities such as Tel Aviv where we found a clear shift towards the use of social talk following the so called in Summer 2011, despite minor actual socially-driven planning actions.

# NEW DEVELOPMENT AREAS (NDAs) IN RURAL HONG KONG: WHOSE SPATIAL JUSTICE AND WHOSE RIGHT TO THE CITY?

Mee Kam NG
Department of Geography and Resource Management, The Chinese University of Hong Kong,
meekng@cuhk.edu.hk

Keywords (maximum 3): spatial justice, the right to the city, Hong Kong

**Abstract**

Justice is a prerequisite for civil order (Rasmussen, 1999). To many Hong Kongers, the return to Chinese rule since 1997 has seen the further bias of the Government s policies towards t recent controversial plan that has triggered multiple protesting acts is to bull-doze farms and non-indigenous farmers in rural New Development Areas (NDAs) to make way for housing produ ultra-expensive commodity fuelled by growing demand from local residents and Chinese investors. If justice means giving people what they deserve (Sandel, 2009, p.7), then the ca thought. Legally, justice is done when non-indigenous farmers who are also squatters, are cleared to make way for housing construction. Socio-economically, the move is to liberate the land value and provide homes for hundreds of thousands of urbanites. However, from a geographical equity point of view, these multi-generation farmers have played a significant role in securing local farm produces to the city. So whose right to the city should be protected: Farmers rights to their farming pr rights to be displaced? Or the claim rights of many urbanites to reasonable housing? Detailed examination of the evolution of the NDA plans reveals the importance of the right to voice out differences to prevent the complete transformation of spaces saturated with use values to exchange values. Nevertheless, the NDA plans can still be seen as a smokescreen to fatten the pockets of big developers who have accumulated huge land banks in the NDAs.

## 1. Introduction

Lefebvre argues that the production of space has nothing incidental about it; it is a matter of life death (1991, p.417). To Lefevbre (1991), plans made by the experts are often abstractions that cause destruction and so it is very important for the users in lived space to voice out their concerns and propose counter-plans to realise their rights to difference. This paper examines the recent planning and controversies surrounding rural new development areas in Hong Kong, a post-British colony best known for its capitalist mode of development under the One Country Two Systems its return to Chinese rule. On the surface, the problems are related to the removal of multi-generation squatter-farmers and their rented farmland for housing development, the shortage of which has created much social debates and discussions. However, a deeper question that is not directly addressed by the Government but widely reported in the mass media is the accumulation of land banks by big and small developers who are keen to have a share in the NDAs. This paper traces the planning process and outcomes of the NDAs. It is interesting to note that the voices of the squatter-farmers were not heard until towards the end of the Study on the NDAs and the problem of land hoarding (and the displacement of farmers and fallowing of fertile farmland) by big developers in the NDAs was not directly addressed in any of the planning documents.

The following section discusses what spatial justice is and how it is related to the right to the city. Then the origin and evolution of the NDA plans are discussed, focusing on the key changes that could be identified in the process. Section four tries to argue that social activism has been an important factor leading to key changes in the NDA plans though the plan remains a tool to privilege big developers who have accumulated land banks in the area. Section five concludes the paper by highlighting the lessons to be learned in this case.

## 2. What is Spatial Justice and What is the Right to the City?

What is justice? According to Aristotle, justice is to give people what they morally deserve. This can be discerned in several of his quotes[1]:

> Man perfected by society is the best of all animals; he is the most terrib
> without law, and without justice; All virtue is summed up in dealing justly; Men acquire a particular quality by constantly acting a particular way... you become just by performing just actions, temperate by performing temperate actions, brave by performing bra

There are several dimensions embedded in these quotes that define justice. First justice cannot be done by oneself, it has to be a collective societal endeavour and the aim is to perf collective. Second, it seems that the perfecting of members of this collective is through a process of dealing things justly so that virtue will emerge, hinting on the importance of procedural j meaning of the last sentence is clear: justice cannot be rhetorical. Justice is done through actions. We cannot be just unless we carry out just actions. If we take Aristotle s quotes t the reason to define justice as giving people what they morally deserve is because only then, can each member of the collective be perfected , virtuous and just and this can only be done group of people willing to adopt procedural justice in their interactions and when they act, they act justly to not just perfect themselves but to bring out the best potentials of their fellow human beings. This definition is very different from the liberal definition by frequently cited author such as Rawls *A Theory of Justice* (1971) who defines justice as distributional justice and based on primarily material terms. To imagine the possibility of justice in a hugely polarized world, he asks us to imagine a position of ignorance, that is no one knows his place in society so that we can agree a providing equal basic liberties for all citizens and that social and economic inequalities should not be permitted unless they work to the advantage of the lease well off members of society. Unlike Aristotle, Rawls does not engage in the conception of perfecting human beings or developing a virtuous society it is about the distribution of things, tangible and intangible.

In Aristotle s quotes, there is a hint for procedural justice which according to Blade refers not only to the formal procedures of decision making and the quality of treatment as stipulated in the rules and regulations but also how they are treated by the authorities and the qualities of the decisions made by these authorities. This brings us back to the issue of HOW we can collectively live out justice in our everyday life. After all, perhaps as Sandel (2009, p.259) arg about the right way to distribute things. It is about the right way to value things .

Values are extremely important when it comes to the organization of space because all spatial locations are unique. Also [a]ll spaces embody power relations of some sort (Amin, Mas Thrift, 2000, p.12) and spatial organization depends on who decides on what land uses will be allowed in space. Hence spatial justice is intertwined with the discussion of the right to the city: who has what right to the city, its planning, design and development? To Lefebvre (1991, pp.336-7), the problem with capitalism is that land must first be wrenched away from the traditional the stability of patrimonial inheritance the entirety of space must be endowed w However, use value constitutes the only real wealth (op cit., 1991, p.341). Tab differences between exchange and use values.

Table 1. Exchange Value vs. Use Value

| | Exchange value | Use value |
|---|---|---|
| Philosophy | Normative and rationalistic | Empirical and humanistic |
| Framework | Positivism | Emancipatory and post-structural pluralistic possibilities |
| Premise | Planning as reaction to socio-political-environmental contexts | Planning as intrinsic understanding of places and creative placemaking |

[1] Quote extracted from http://www.quotationspage.com/quotes/Aristotle/, accessed on 8 Feb. 2015.

| | Exchange value | Use value |
|---|---|---|
| Methodology | Imposition of orthodox modern design principles | Design recommendations based on resident experience and direct naturalistic observation |
| Boundaries | Exclusive and profession-based | Inclusive and people-oriented |
| Knowledge | Professional or expert knowledge | Situated knowledge expert knowledge merged with local knowledge |

Lefebvre s (1991) triadic spatial framework is instrumental in highlighting the importance of representational space (lived space) vis-a-vis representations of space (conceived space) and spatial practice (Figure 1). According to Lefebvre (1991, pp.38-39), *spatial practice* (perceived space) embodies a close association between daily reality (daily routine) and urban reality (the routes and networks which link up the places set aside from work, private life and leisure) *space* (conceived space) is the the space of scientists, planners, urbanists, tech and social engineers all of whom identify what is lived and what is perceived with what is conceived. This is the dominant space in any society (or mode of production); representational space is directly lived the space of inhabitant and users This is the dominated her experienced space which the imagination seeks to change and appropriate . To Lefebv [r]epresentational space is alive; it speaks. It embraces the loci of passion, situation, and thus immediately implies time (op cit., 1991, p.41). Predominant social relation reproduced through spatial practice and the representation of space, that is, plans made by planners and technocrats are often tied by technical knowledge and power and hence will have little room for representational space (op cit., 1991, p.50). Hence, the whole project for Lefebvre is to call for the reconstruction of spatial codes (p.64) through recognition of time , the most esse lived experience, the greatest good of all goods (p.95). Hidden in any spatial order is a social order, determining who can benefit and who are excluded from it (op cit., 1991, p.289). This usually would not be revealed until spatial contradictions appear and this can only be overcome if those who lived in space struggle to fight for their right to difference, their right to the city (op cit., 1991, p.391).
